Methods: We used adult male Wistar rats (~ 420 g, N=9). All procedures were approved by the Animal Ethics Committee. Each rat was anesthetized with 2% isoflurane in 100% O2 and two lesions with 2 X 2 cm separated by 1 cm of distance were carried out in the skin of the rat's back. The lesions were covered with Integra® or rayon bandage (control) and the edges of both coverings were sutured in the rat skin with 3.0 mm nylon suture. Veterinary Pentabiotic (2000 U/mL, i.m., single dose) was used as prophylactic measure and tramadol (10 mg/kg i.m., every 12 h) was injected for 2 days after surgery for analgesia. At 7, 14 or 21 days after performing the surgery, rats (N=3/group) were euthanized with sodium thiopental (100 mg/kg, i.p.) and the lesion sites were sampled and stored in 10% formalin solution for histological preparation. The tissues were embedded in paraffin and sliced in microtome (20 m thickness/slice). Histological sections of the wound were stained using Hematoxylin-Eosin or PicroSirius red and analysed in microscope (Nikon®).

Results and Conclusions: The tissue samples covered with Integra® presented as good cicatrization as rayon bandage at 7 and 14 days, with migration of fibroblasts and collagen type 1 and 3 formation. The great migration of fibroblasts was observed at 21 days, in which the healing was completed.

Conclusion: The data suggest that Integra® act as a great dermal substitute helping for fast skin healing.

Open treatment of the recalcitrant lateral epicondylitis: Clinical outcome and postoperative ultrasonographic change of the ECRB tendon status

List of authors:
Sang-Eun Park*, Eung-Sic Kim
1 Daejeon St. Mary's Hospital, The Catholic University of Korea (Daejeon)

Objectives / Interrogation: To report on the clinical outcome of the open treatment of the recalcitrant lateral epicondylitis and the postoperative change of the ECRB tendon status using ultrasonography

Methods: Included in this study were 38 patients (10 male, 28 female; mean age, 51.8 years) who underwent the open excision of the degenerative portion of the ECRB for their recalcitrant lateral epicondylitis. Preoperative ultrasonography was performed in all patients. Postoperative ultrasonography was performed at 4 to 6 months (31 patients) and one year (20 patients). The mean follow-up duration was 12.4 (range, 4-40) months. On ultrasonography, preoperative tendon status was classified into three types according to the pattern of the fibrillar disruption (diffuse intrasubstance tear, deep focal defect, large intrasubstance defect). Postoperative ultrasonographic change was recorded according to the degree of restoration of the fibrillar pattern (minimal, moderate, complete). Tendon thickness was also recorded at each time of the ultrasonography and the change was compared.

For a functional evaluation, Visual Analogue Scale (VAS) pain score, The Disabilities of the Arm, Shoulder and Hand (DASH) score, Patient-Rated Elbow Evaluation (PREE) score were recorded and compared with the preoperative data.

Results and Conclusions: At final follow up, VAS improved from a preoperative mean of 4.2 (at rest), 5.7 (at daily living activities) and 8.9 (at sports or occupational activities) to a postoperative mean of 0.3, 1.3 and 2.3, respectively (P < .001). DASH and PREE also improved significantly from a preoperative mean of 59, 130 to a postoperative mean of 4, 29 respectively (P < .001). Preoperative ultrasonography revealed hypoechoic area and swelling and the disruption of the fibrillar pattern of the ECRB origin in all patients (diffuse intrasubstance tear 17; deep focal defect 12; large intrasubstance defect 9). Preoperative mean of the tendon thickness was 6.2 mm at long axis and 5.6 mm at short axis. At postoperative 4 to 6 months, tendon thickness increased to 7 mm and 6.7 mm but decreased to 6.2 mm and 5.9 mm at postoperative one year. Of 20 patients with ultrasonography at one year, the degree of restoration of the fibrillar pattern was minimal 0, moderate 8 and complete 12. Conclusively, open treatment of the recalcitrant lateral epicondylitis yielded satisfactory clinical improvement. Postoperative follow-up ultrasonography showed restoration of the fibrillar pattern and the change of the ECRB tendon thickness.

A new entity of carpal instability non dissociative after wrist fractures

List of authors:
margaret fok*, Diego Fernandez
1 Department of O & T, 5/F, Professorial Block, Queen Mary Hospital (Hong kong)
2 University of Bern (Bern)

Objectives / Interrogation: Adaptive carpal instability following mal-united extra-articular Colles' fracture is a well-recognized condition. Yet carpal instability non-dissociative (CIND) after intra-articular distal radius fractures or radiocarpal dislocation has not been reported. This study aims to report this new entity.

Methods: 12 patients with an average age of 32 years old were identified with CIND, 9 after intra-articular fractures and 3 after radiocarpal fracture-dislocations between 2013 and 2018. Ten patients exhibited CIND- volar intercalated segmental instability (VISI) radiographically at different post-operative periods, while 2 patients exhibited CIND- dorsal intercalated segmental instability (DISI) already present at initial post-operative x rays.

In cadaveric dissections, CIND-VISI displacement could be reproduced by applying an axial loading and dorsal shearing force on a wrist with sectioned short radiolunate ligament and dorsal radiotriquetral ligament. For the intra-articular fractures with CIND-DISI malalignment the cause is most likely a result of a volar radiocarpal extrinsic ligament injury combined with intra-articular incongruity of the scaphoid fossa.

Results and Conclusions: Eight out of 12 patients with severe wrist pain underwent additional surgery. Three patients with reducible CIND-VISI had open capsular repair and temporary radiocarpal trans-fixation while 5 patients with fixed non-reducible malalignment were treated with radioscapholunate arthrodesis. At an average follow up of 2.3 years, pain relieved was noted, together with an improvement in the grip strength and a functional range of movement of the wrist. Radiographically the wrist alignment was corrected and maintained in the 8 patients. No surgical complications were observed.

This article describes a new CIND entity that may present after acute wrist injuries. Most of the patients are young and are involved in high energy trauma. High index of suspicion is warranted in patients presented with stiffness at the sub-acute period. Early detection of the malalignment can preserve the joint mobility by capsular repair. In cases with fixed deformity, a limited radiocarpal fusion is recommended for treatment.

Evaluation of the use of collagen membrane in the repair of joint cartilage lesion in an animal model.

List of authors:
Rafael Saleme alves¹, Edson Kenji Nakano¹, Marcelo Navarro¹, barbara do vale¹, bernardo barreto correà³, Nuha Ahmed Dsouki¹, Juliana Mora veridiano¹, monica akemi sato¹
¹FMABC (São Paulo)

Objectives / Interrogation: Joint cartilage injury can occur due to joint diseases, especially osteoarthritis, genetic or metabolic conditions, or as a result of trauma. The articular cartilage is a specialized tissue, formed by hyaline matrix and does not present vascularization, innervation or lymphatic network, thereby, when it is injured due to trauma or degenerative process, it presents little capacity for intrinsic regeneration. Studies related to cartilage regeneration are extremely important in the search for possible interventions that accelerate regeneration or minimize the degeneration of articular cartilage.

Objective: To evaluate the use of the equine collagen membrane in the repair of lesions in the articular cartilage of rats by histological analysis.

Methods: Six adult male Wistar rats (~420 g) were used. All procedures were approved by the Animal Ethics Committee. The animals were randomly divided into 2 groups with 3 animals each. Each group corresponds to the postoperative time of 21 days after the accomplishment of the chondral lesion of 2 mm width in the femoral intercondylar region. All rats were submitted to a chondral lesion only in one knee, and rats were submitted to the placement of the equine collagen membrane (Biocollagen®), or sterile plastic for protection. Veterinary Pentabiotic (2000 U/mL, i.m., single dose) was used as prophylactic measure and tramadol (10 mg/kg i.m., every 12 h) was injected for 3 days after surgery for analgesia. Rats from each group were euthanized with sodium thiopental (100 mg/kg i.p.) and the knees were collected for evaluation of the lesion site for histological analysis. If any tissue was observed in the lesion site the one was embedded in paraffin and sliced in microtome (20 m thickness/slice). Histological sections of the tissue were stained using Hematoxylin-Eosin and analysed in microscope (Nikon®).

Results and Conclusions: The tissue formed in the knees submitted to the placement of the equine collagen membrane (Biocollagen®) presented hyaline cartilage with typical mature chondrocytes and chondroblasts. No tissue was found in the knees of the rats in which sterile plastic was placed in the chondral lesion.

Conclusion: The equine collagen membrane (Biocollagen®) showed to be an inducer cartilage repair.

Outcomes of release of the entire A4 and partial A2 pulleys for distal zone 2 primary flexor tendon repair in 27 fingers

List of authors:
Xiang Zhou¹, Jun Qin³, Jing Chen²
¹ People's Hospital of Jiangyin (Wuxi)
² Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: We report the outcomes of using 6-strand M-Tang repair method in 27 flexor digitorum profundus (FDP) tendons in distal zone 2 of 23 patients followed by postoperative early active motion.

Methods: We used the 6-strand repair in repairing 27 FDP tendons of 23 patients in the past 4 years. The patients aged 17 to 63 years old, average 34 years. There are 18 men and 5 women. Twelve tendons were in zone 2A, fifteen in zone 2B. All patients were repaired primarily in the day of injury or within the first or second days after injury. The FDP tendon was repaired with a 6-strand M-Tang repair using 4-0 looped suture and sparsely placed simple running peripheral suture with 6-0 or 5-0 nylon. The C1, C2, A3, A4 pulley was completely released and A2 pulley was partial released in all fingers. After surgery, the fingers were immobilized for 3-4 days and active motion was initiated after that. The patient was encouraged to move the fingers interphalangeal joints and metacarpophalangeal joint to about ½ of the total motion range in the first 1-3 weeks after repair. Then the patient proceeded to full range of active motion around the end of week 3. The active motion was performed mostly out of splint and splint was used at the intervals not performing any motion exercise and during night.

Results and Conclusions: We tested the gliding of the repaired tendon during surgery through passive full extension and flexion of the repaired fingers immediately after repair and all repairs passed the test. There was no repair rupture in this case series. The functional outcomes were evaluated with Strickland criteria. The mean total active motion of fingers was 158° at 5 to 27 months of follow-up. The recovery of function was excellent in 17 (63%), good in 8 (30%), fair in 0 (0%) and poor in 2 (7%) fingers. No bowstringing was found in the fingers after venting of partial A2 pulley and entire A4 pulley during follow-up.

Conclusions: Releasing of entire A4 pulley and partial A2 pulley does not cause tendon bowstringing and achieve high excellent and good rate. We conclude that a strong repair method, such as the method used in this report, should be used and pulley should be vented properly to allow smooth tendon gliding, and early out-of-splint active motion is safe.

CHRONIC DISLOCATION/INSTABILITY OF THE BASE OF THE FIFTH METACARPAL - MULTILIGAMENTARY RECONSTRUCTION TECHNIQUE

List of authors:
DIEGO FERNANDO RINCON*, JULIAN ENRIQUE CADENA, PAULA ANDREA RINCON, JORGE CLIFTON, ALVARO ANTONIO KAFURY, JHON FREDY CASTAÑEDA
1 UNIVERSIDAD INDUSTRIAL DE SANTANDER (FLORIDABLANCA)
2 CLINICA RIVIERA (FLORIDABLANCA)
3 CLINICA MIELINA (FLORIDABLANCA)
4 CENTRO MEDICO IMBANACO (FLORIDABLANCA)
5 UNIVERSIDAD NACIONAL DE COLOMBIA (BOGOTA)

Objectives / Interrogation: The chronic dislocation without fracture is very rare, acute event is less than 1% of hand injuries, and literature does not report cases of chronic dislocation or instability with the cartilage intact. We described two cases and proposed a surgical technique with clinically evaluation.

Methods: A retrospective series of cases study who underwent a ligament reconstruction with the proposed technique. We evaluated pain (VAS), passive and active movement with goniometer, injured and contralateral hand strength with dynamometer, and surgical procedure satisfaction.

Surgical Technique: Dorsal curvilinear incision is made over the fifth carpometacarpal joint. Release interposed fibrosis, then fix the fifth metacarpal to the hamatal, and the forth metacarpal with kirschner wires. The radial hemi tendon of the ECU is taken, with a drill perform a tunnel in the fourth metacarpal between the metaphysis and the shaft, the tendon is directed from ulnar to dorsal, then placed below the insertion of the ECU, and sutured with periosteum or anchored suture over the hamatal.

Results and Conclusions: RESULTS
Two male patients, with 31.5 years of average age, 5.5 months evolution prior surgery, VAS pain 10. One year of POP follow up. Wrist: Flexion: 40 ° and extension 45 °. Pinch straight 8 kg and grasp force 19 kg; 82.5% and 73.3% comparative grip and pinch force. Averaged pain at rest 0 and 1.5 with activity. All patients were satisfied, and no complications reported.

CONCLUSION
There is no treatment in the literature for the chronic injury with undamaged cartilage. The ligament reconstruction tries to restore the anatomy and also maintains the alignment of the joint allowing stability in this mobile joint, does not restrict movement, does not alter the function of the ECU, have good comparative hand function and does not rule out the use of other surgical procedures in patients in whom the described technique fails.

Non-Tuberculous Mycobacterial tenosynovitis of the hand

List of authors:
Dong Hee Kim*, Jin Sung Park, Sang Hyun Lee, Sung Wook Yaung
1 Samsung Changwon Hospital, Sungkyunkwan University School of Medicine (Changwon)
2 Gyungsan National University Hospital (Jinju)
3 Pusan National University Hospital (Pusan)
4 Samsung Changwon Hospital, Sungkyunkwan University School of Medicine (Changwon)

Objectives / Interrogation: The incidence of the hand among musculoskeletal infections caused by Non-tuberculous mycobacterium (NTM) is very rare. Especially, Only a small number of cases have been reported in NTM tenosynovitis of the hand, there has been controversy about appropriate treatment including antibiotic therapy, surgical debridement, and time of drug administration. We report outcomes from two Korean hospitals responding to chronic tenosynovitis of hand caused by NTM treated with surgical debridement and drug administration.

Methods: From January 2010 to December 2017, twenty patients who had a NTM tenosynovitis of the hand were treated at two center. There were 8 male and 12 female patients. The average age was 63.65 years. Symptom were present for 1–24 months (average 9.3 months). A history of trauma or operation was reported in 11 cases. The history of steroid injection before diagnosis was average 1.15 times. Most common species is Mycobacterium intracellulare (11 cases), second is Mycobacterium marinum/ulcerance co-infection (3 cases). Mycobacterium chelonae, Mycobacterium abscessus, Mycobacterium Szulgai, Mycobacterium gordonae, Mycobacterium kansasi, Non-classified were each a case. All patients have been treated by combination therapy - extensive tenosynovectomy and antibiotics. The average period of antibiotic administration was 9.13 months and the mean times of surgical debridement were 2.75 times. Depending on the site of tendon involvement, surgery was required more frequently in cases of extensor tendon (average 3.86 times) than in cases of flexor tendon (average 2.0 times). (p=0.012)

Results and Conclusions: NTM tenosynovitis of the hand is rare and difficult to diagnosis and treatment. In this study, it was found that the species of mycobacterium were different from those of previously published papers, and this might be due to occupational and regional differences. And there is difference in the number of operations between the extensor tendon and flexor tendon. Because that most extensor tendons lack an extensive retinacular system, so well-localized infection of extensor tendons is rare. Since diagnosis is often difficult, clinical suspicion is the most important step of treatment for NTM infection. It takes at least 3 months for response to combination treatment of NTM infection. Therefore, physician should explain to patient sufficient explanation of the progress of diseases.

Internal brace augmentation of the scapholunate interosseous ligament repair: A biomechanical study

List of authors:
IL JUNG PARK*, Mauro Maniglio2, Steven S. Shin3, In Jun Koh1, Nilay A. Patel4, Charles C. Lin4, Victor Truong5, Michelle H. McGarry5, Thay Q Lee4
1 Orthopaedic Biomechanics Laboratory, VA Medical Center, Department of Orthopedic Surgery, The Catholic Univ of Korea (Long Beach)
2 Orthopaedic Biomechanics Laboratory, VA Medical Center, Department of Orthopedics and Traumatology, Inselspital Bern (Long Beach)
3 Kerlan Jobe Orthopaedic Clinic (Los Angeles)
4 Orthopaedic Biomechanics Laboratory, VA Medical Center, Department of Orthopedic Surgery, Univ of California, Irvine (Long Beach)
5 Orthopaedic Biomechanics Laboratory, VA Medical Center (Long Beach)

Objectives / Interrogation: Acute, complete tears of the scapholunate interosseous ligament (SLIL) are best treated by open reduction and direct repair. However, direct repair of this ligament is often unreliable. It is not easy to repair securely, and therefore requires a long period of pin fixation and postoperative cast immobilization. Internal bracing (IB) is a new augmentation method using Fiber tape that has been applied to an orthopedic applications. However, there is no published paper about the SLIL injury treated by this augmentation. This study aimed to compare the biomechanical strength of SLIL repair only and repair augmented with IB.

Methods: Fourteen fresh frozen cadaveric specimens (7 matched pairs) were used in this study. From each matched pair of specimens, one limb was randomly assigned to underwent repair only and the contralateral limb was underwent repair augmented with IB. In the repair only group, dorsal, palmar, and proximal parts of the SLIL were sharply dissected off its scaphoid attachment site and the dorsal part was repaired using 2 single-loaded suture anchors. In the repair with IB augmentation group, the augmentation using Fiber tape (Internal Brace, Arthrex) was performed using SwiveLock suture anchors after the repair. Each specimen was mounted on the Instron machine. Specimens were preloaded to 3 N and then cyclically loaded in tension from 3 to 25N for 30 cycles. After cyclic testing, specimens were tested in tension to failure at a rate of 20 mm/min. Load to failure, extension, and stiffness were calculated, and the mode of failure was noted.

Results and Conclusions: In cyclic tensile testing, the pattern of repair with IB augmentation is much similar to the intact dorsal SLIL model than that of repair only. In other words, under the load of 3 to 25 N, IB augmentation made a condition very similar to the intact ligament. In the repair with IB augmentation group, the maximum extension and the hysteresis were significantly lower than in the repair only group in each cycle. In load to failure testing, the repair with IB augmentation group demonstrated a significantly higher the ultimate load (37.7N vs 98.5N) and load at clinical failure (4mm; 33.4N vs 84.1N) compared with the repair only group. The SLIL repair with IB augmentation demonstrated significantly higher strength compared with the repair only. However, additional testing of the orientation, location, and number of IB should be followed to effectively address flexion of the scaphoid.

ONE STAGE FLEXOR TENDON RECONSTRUCTION USING A SILASTIC ACTIVE TENDON IMPLANT. TEN YEARS OF EXPERIENCE.

List of authors:
JHON FREDY CASTAÑEDA*, GERMAN HERNANDEZ1, RICARDO GALAN2
1 UNIVERSIDAD NACIONAL DE COLOMBIA (BOGOTA)
2 UNIVERSIDAD MILITAR NUEVA GRANADA (BOGOTA)

Objectives / Interrogation: INTRODUCTION: The idea of reconstruction in only one stage arose when the extraction of the implant was declined by one patient with good results. This study is the first Case-Series with this treatment

OBJECTIVES: 1. Evaluate clinical and functional results after the management with a single-stage procedure in flexor tendon after chronic injuries using a Silastic active tendon implant. 2. Analyze the biomechanical behavior of the Silastic tendon implant

Methods: Case Series Study. Biomechanical tests of the silastic tendon were performed in the mechatronic engineering laboratory to determine the long-term viability of the implant. Thirty-eight (patients were included, four of them presented situations that led to the removal of the implant and a second time with the conventional technique. 34 patients preserved the active silastic tendon. The longest follow-up is 14 years. 63.2% (24/38 patients) had >10 year follow-up period, with an average of 10.8 years. Two personal assessments (May 2010 - June 2017) of the clinical status were made. The DASH score was used

Results and Conclusions: RESULTS: In the biomechanical tests we found a critical point of failure due to a tear of the tendon fibers in the metallic-elastomeric anchor interface at a breaking load of 400N. This value shows that there will be NO alteration in the functionality of the silastic tendon in the long term because the loads during daily activities (35N) are lower than those of rupture. 100% of the patients improved the previous function and range of motion with an average recovery of 105 degrees for the thumbs and 157 degrees for the long fingers. Complications were few, a non-infectious local reaction and a rupture of the proximal suture. We did not find the presence of complications such as loosening of the implant, infection, rupture or migration, functional loss or joint stiffness. Two patients presented mild mechanical discomfort in the distal phalanx with the pressure at the distal anchor site. Final evaluation with the DASH scale showed a general average of 3.4 (range of 1 to 8)

CONCLUSIONS: The functional and biomechanically results are excellent and the tendon does not alter its function in the long term, which allows its use as a definitive management in the treatment of chronic lesions of the flexor tendons. This technique is a valid and safe option with few complications for the management of these injuries since, regardless of the result of the same, conventional management in two stages will always be available

Tips under the Skin: a Simple but Great Modification of Extension Block Pinning for Mallet Fractures

List of authors:
Seung-Han Shin*, Yong-Suk Lee2, Jin-Woo Kang2, Wonwoo Kang2, Yang-Guk Chung1
1 Department of Orthopedic Surgery, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea (Seoul)
2 Department of Orthopedic Surgery, The Catholic University of Korea (Seoul)

Objectives / Interrogation: The pins exposed out of the skin keep the patients from washing their hands after the surgery for mallet fractures. The aim of this study was to report the feasibility of placing pin tips under the skin in extension block surgery for mallet fractures.

Methods: We buried tips of all pins under the skin while performing extension block pinning for mallet fractures. 14 mallet fracture patients treated with such a modified procedure were reviewed. To prevent subsidence, the pins for extension block and distal interphalangeal (DIP) joint transfixation were inserted until it just penetrated the volar cortex and to the subchondral bone of the middle phalangeal base, respectively. Then the pins were cut shortly enough to place the tips under the skin. Postoperatively a bulky dressing was applied with or without an aluminum finger splint. The patients were allowed to wash their hands 4-5 days after the surgery, without any dressing or splinting. The pins were removed mean 8 weeks after the surgery.

Results and Conclusions: Solid union was achieved in all 14 fractures. No pull-out or subsidence of the pin was observed. No patient developed infection or other pin-related complications. Mean extension lag at final follow-up was 4° and mean DIP flexion was 75°. Placing pin tips under the skin appears to be a feasible modification in extension block surgery for mallet fractures. Our modification allows patients to wash their hands and keep their bread-an-butter jobs soon after the surgery.

Effectiveness of median nerve decompression in carpal tunnel syndrome in the early postoperative period

List of authors:
Andrey Baytinger*1
1 Institute of microsurgery (Tomsk)

Objectives / Interrogation: Carpal tunnel syndrome (CTS) is a compression of the median nerve in carpal canal. The aim of our research was to compare the results of treatment with an open and an endoscopic method.

Methods: In order to achieve the aim we needed to assess the functions of hand before and after surgery from the patient's point of view according to the DASH questionnaire and cross section area (cm²) of the median nerve by using ultrasound investigation. 40 patients were selected and divided into two groups group 1 (n = 20) - patients who had open median nerve decompression; group 2 (n = 20) - patients who had endoscopic median nerve decompression. There

Results and Conclusions: There were no statistically significant differences between assessed parameters in groups 1 and 2 (p > 0.05). Conclusion: in the early postoperative period, endoscopic decompression is as effective as the open decompression.

THE SAFETY USE OF ONE-PER-MIL TUMESCENT INFILTRATION INTO VIABLE SKIN TISSUES THAT ONCE SUFFERED FROM AN ISCHEMIC INSULTS

List of authors:
eliza nindita*, Theddeus OH Prasetyono
1 Plastic Reconstructive Surgery, Universitas Indonesia (jakarta)

Objectives / Interrogation: OBJECTIVES: In the field of hand surgery, the 'wide-awake' anaesthetic technique using one-permil-tumescent has been shown to allow the possibility of safely and successfully performing on unimpaired vascularity tissues. This study is aimed to establish fact that the methods could also be used safely on viable skin flaps, in which the tissues once suffered from an ischemic condition.

Methods: METHODS: 40 groin flaps from 20 healthy Wistar strained-Rattus novergicus weighing 220-270 grams were conditioned to acute ischemia by clamping the pedicle for 15 minutes. Merely totally survived and viable flaps on the seventh postoperative day were randomly divided into: One-per-mil tumescent infiltration group(A), normal saline infiltration group(B), and control group(C). Before and after the infiltration, transcutaneous oxygen tension (TcPO2) measurement was performed, and the changes values were calculated by statistical analysis using ANOVA and Paired T-Test. Viability of flaps was assessed clinically and by using Analyzing Digital Images® 7 days later.

Results and Conclusions: RESULTS: TcPO2 readings yielded a decreasing value significantly (p<0.001) following both One-per-mil tumescent and normal saline infiltration. All groin flaps had successfully survived with no signs of tissue necrosis.

CONCLUSION: The effect of One-per-mil tumescent injection on viable skin flaps was found safe. This result may bring out a consideration of using one-per-mil tumescent injection as local anaesthesia for assisting the future secondary reconstructive procedures such as flap revision or furthermore, reconstructive procedures after finger replantation.

Keywords: ischemia, skin flap, one-permil-tumescent
Comparison between with or without axillary nerve neurotization for the management of upper brachial plexus palsy.

List of authors:
KRISHNA PRIYA DAS
1 BSMMU (DHAKA)

Objectives / Interrogation: Restoration of elbow flexion & shoulder abduction is the aim in the treatment of upper brachial plexus injury. Intraplexus surgery is the mainstay of treatment but most of the time is not possible. Our objective is to assess the result of neurotization for the management of upper brachial plexus palsy.

Methods: From January 2014 to June 2018, we have operated 48 cases of upper brachial plexus palsy cases, duration >3 months with C5, C6 ± C7 root avulsion or disruption close to the foramina. Age <60 years old. SAN to SSN transfer and double fascicular neurotization of MCN was done in all cases. Axillary nerve neurotization was done in 16 cases out of 48 patients.

Results and Conclusions: Among 48 patient, 45(93.75%) was male & 3(6.25%) was female, with the mean age of 24.8 years, mean time from injury was 4.8 month & mean follow-up was 18 months (range 6 to 48 months). With double fascicular neurotization of MCN(Oberlim-II), Grade M4 elbow flexion was restored in 45(93.75%) cases remaining 3(6.25%) patient elbow flexion power was M3 and age of those patient was >45 years. We achieved mean shoulder abduction 900 (range 500 to 1100) in those patients who are treated only SAN to SSN neurotization procedure but neurotization of SSN and axillary nerve case mean shoulder abduction was 1100(900-1700). Average strength of elbow flexion was also improves in both SSN & axillary nerve neurotization cases that was 4.5 kg in comparison with only SSN neurotization cases, 3.8kg elbow flexion we achieved. Grip strength decreased by a mean 3kg in the first week postoperatively, then gradually increased on average of 18.2 kg pre-operatively to 24.3kg at the end point follow-up at 1 year.

Our results of neurotization technique for upper brachial plexus injury cases reveal a high percentage of success with excellent results in elbow flexion strength. In cases of shoulder abduction, neurotization of both SSN & axillary nerve reveals excellent result but only SSN neurotization cases, shown limited shoulder abduction.

The Critical Ligamentous Stabilizers of the Intercalated Segment. A Cadaveric Study

List of authors:
Alfonso Perez*, Rishabh Jethanandani2, Emil Vutescu2, Kathleen Meyers2, Steve Lee3, Scott Wolfe3

1 Hospital del Trabajador (Santiago)
2 Hospital for Special Surgery (New York)
3 Hospital for Special Surgery, Weill Cornell Medical College (New York)

Objectives / Interrogation: Isolated injuries of the scapholunate interosseous ligament (SLIL) are insufficient to cause changes in scaphoid or lunate posture on static radiographs. Complete injuries of the SLIL may not produce lunate extension or increases in scapholunate gap (SLG) and scapholunate angle (SLA) acutely. Disruption of secondary ligamentous stabilizers are critical. The aim of this study was to evaluate the role in carpal posture of the long radiolunate (LRL), scaphotrapeziotrapezoid (STT) and dorsal intercarpal (DIC) ligaments in a cadaveric SL instability model.

Methods: 30 fresh-frozen forearm specimens were randomized to 5 ligament section sequences, studying SLIL, LRL, STT and DIC. The DIC-lunate insertion (DIC_L) and scaphoid insertions (proximal pole and waist, DIC_S) were studied separately, DIC insertions on the trapezium and triquetrum were left intact. Loaded posteroanterior and lateral standardized radiographs were taken at baseline and repeated after each ligament was sectioned. After each step in the sequence, wrists were subject to cyclic loading (71 N load). Radiolunate angle (RLA), scapholunate angle (SLA) and dorsal Scaphoid Translation (DST) were measured in lateral radiographs with load, scapholunate gap (SLG) was measured in loaded PA views. Statistical analysis was conducted using ANOVA for repeated measures with Bonferroni poshoc analysis.

Results and Conclusions: Complete sectioning of the SLIL did not increase RLA, SLA or SLG. Section of SLIL and LRL (p=0.002), STT (p=0.011) or DIC_L (p=0.02) significantly increased RLA. Dorsal intercalate segment instability (DISI) was recreated with SLIL + STT or SLIL + DIC_L + DIC_S disruption. SLA significantly increased when in addition to SLIL, the STT (p=0.0008) or DIC_L (p <0.03) were cut. SLG increased when SLIL, DIC_L, DIC_S, and STT were cut in Group 1, all ligaments sectioned (Groups 2, 3 and 5) or SLIL, LRL, STT and DIC_L in group 4.

Conclusions
In addition to SLIL, division of at least one major secondary ligament stabilizer of the scaphoid or lunate (STT, DIC_L or LRL) produced significant changes in lunate extension.
SLA increase was recreated when SLIL and scaphoid (STT) or lunate (DIC_L) ligamentous attachments were sectioned.
There is a spectrum of radiographic manifestations of Scapholunate dissociation, depending on the secondary stabilizers injured.

Keywords:
scapholunate injury, scapholunate dissociation, dorsal intercalated segment instability, DISI, secondary ligament stabilizers, wrist, ligament, carpal, carpal instability
Immobilization Versus Early Active Mobilization After Surgical Repair of Injured Extensor Tendon of Hand and Forearm.

List of authors:
KRISHNA PRIYA DAS*
1 BSMMU (DHAKA)

Objectives / Interrogation: Extensor tendon injuries are very common injuries in hand & forearm, which inappropriately treated can cause severe lasting impairment of hand function of the patient. After the extensor tendons repair whether to immobilization or to early active mobilization is debatable. Compare the two common protocols, immobilization vs. early active mobilization by using a simple static splint after surgical repair of extensor tendon

Methods: This prospective randomized study was conducted in the Department of Orthopaedic Surgery, BSMMU, Dhaka for duration of January 2014 to December 2017. Forty (40) patients of extensor tendon injuries in zone V-VIII were selected. The patients were divided into two groups by sealed envelope technique, Group A-immobilization group & Group B-early active mobilization group. Extensor tendon was repaired by Doyle proposed technique. Mayo Wrist Score and Dargan criteria were used for evaluation of final result at 12th months.

Results and Conclusions: Mayo Wrist Score and Dargan criteria were used for evaluation of final result at 12th months. Results: Most of the patients were in 3rd decade. Male and right hand injury were predominant in both groups. More than one third, (35.0%) patients were factory worker in immobilization group and 8(40.0%) in EAM group. Majority 17(85%) patients had glass cut injury in both groups. Nine (45.0%) patients had Zone VI injury in immobilization group and 10(50.0%) in EAM group. In immobilization group out of 72 tendon injury EDC injury was 37(51.38%) and in EAM group out of 69 tendon injury EDC injury was 37(53.62%). Complications developed 6(30.0%) in immobilization group and 4(20.0%) in EAM group. Satisfactory outcome was 85% in immobilization group and 95% in EAM group at 12th months. Assessment at 12th weeks and 6th months were statistically significant (p<0.05) but not at 12th months between two groups.

EAM by using simple static splint following extensor tendon repair shown faster recovery, gain complete range of motion and improved grip strength at early post operative period.

Significance of tissue savage and sensory recovery in avulsed finger replantation

List of authors:
Bin Sun*, Wenhai Sun1, Bin Wang1
1 Shanghai Ninth People's Hospital (Shanghai)

Objectives / Interrogation: To achieve satisfactory results in replantation of complete finger avulsion injury remains to be a great challenge. The aim of this study was to assess the outcomes of a series of procedure including microscopic debridement, nerve and vein graft, and tendon transposition in replantation of complete finger avulsion.

Methods: A total of 32 cases with complete avulsed fingers injuries in the past 15 years were included. The mean follow-up period was 5.1 years. Microscopic debridement was performed in all cases. Tendon transposition was performed when the tendon lacerated from muscle belly. Arterial defect was bridged by vein graft from foot. Nerve laceration was trimmed to expose normal nerve papilla and bridged by autologous cutaneous nerve graft. The total active range of motion, sensation, pain, cold intolerance, and percussion tenderness of the digits was assessed. Patient satisfaction with the aesthetic outcome was assess by using the Michigan Hand Outcomes Questionnaire.

Results and Conclusions: The complete survival rate of replantation was 87.5%. Partial necrosis occurred in the left 3 cases, which was repaired by secondary flap transfer. The replanted digits had a mean static 2-point discrimination of 7.8 mm (6 -14 mm), a mean total active range of motion of 185°, and a mean grip strength of 27.4 kg. A total of 53% digits had mild cold intolerance. Only 3 patients reported mild percussion tenderness. A total of 90.6% of the patients were satisfied with the appearance of the reconstructed fingertips.

In conclusion, microscopic debridement was essential to check the tissue status after complete avulsion injury and create the condition for anastomosing. Primary nerve and vein graft, as well as tendon transposition, was advocated to achieve high survival rate and functional outcomes.

Keywords: complete finger avulsion, replantation
Scaphoidectomy with four-corner fusion using dorsal locking plates: a retrospective study with mid-term follow-up

List of authors:
SOPHIE SABAU*, ATHLANI LIONEL, DAP FRANCOIS, DAUTEL GILLES
1 CHRU Nancy (NANCY)
2 CHRU NANCY (NANCY)

Objectives / Interrogation: Scaphoidectomy, combined with four-corner fusion, is commonly used to treat scapholunate and scaphoid nonunion advanced collapse (SLAC; SNAC) wrists. We evaluated the effectiveness of this technique using the Medartis Aptus 4CF locking plate in a retrospective study followed up for at least two years.

Methods: We included all patients with SNAC or SLAC wrists grade 2 or 3 who underwent scaphoid excision with four-corner fusion using the Aptus 4CF dorsal locking plate (Medartis® Four-corner fusion dorsal locking plate, Medartis AG, Basel, Switzerland) between January 2010 and February 2015. A total of 50 patients (42 men, 8 women) were included and were followed up for at least two years.

All operations were performed in our department by the same surgical team, and all patients underwent clinical and radiologic assessments by an independent observer.

Results and Conclusions: Fifty patients (median age 58 years; range 23-80 years) underwent surgery. Median pain scores decreased from 9 (range 6-10) to 3 (range 0-8). Postoperative wrist motion was statistically significantly improved, both in flexion and extension (medians, 30° vs. 60° in flexion; 20° vs. 40° in extension). Similarly, ulnar and radial deviation improved from 20° to 30° and from 10° to 30°, respectively. Median grip strength improved significantly after surgery (80% vs. 57% of contralateral grip strength at last follow-up). Nonunion occurred in 7/51 (13.7%) wrists, and conversion to total wrist fusion was necessary in 5/51 (9.8%) wrists. We achieved successful fusion in 44/51 (86.3%) cases. Scaphoidectomy with four-corner fusion using the Aptus 4CF locking plate resulted in successful joint fusion in 86.3% of wrists and led to statistically significant reduction of pain and ROM as well as statistically significant improvement of grip strength. However, we believe that regardless of the type of material used, it is crucial for successful joint fusion to respect all surgical steps, namely complete removal of the cartilage and subchondral bone, proper positioning of the implant, use of a healthy bone grafts from the distal radius, and compliance with a an immobilization period of 4 to 6 weeks.

A new strategy with locked-wire type external fixator (the Ichi-Fixator) for hand fractures

List of authors:
Satoshi Ichihara*, Akira Hara¹, Masao Suzuki¹, Yuka Igeta², Yuichiro Maruyama³
¹ Hand Surgery Center, Juntendo University (Chiba)
² Department of Orthopedic Surgery, Juntendo University (Tokyo)
³ Department of Orthopedic Surgery, Juntendo University (Chiba)

Objectives / Interrogation: Recently, there are plenty of commercial external fixators for hand fractures. However, they are difficult to adjust after application. The ideal external fixator in hand is low profile and adequately rigid for early mobilization, and easy to apply and modify. We developed adjustable linking wire type of external fixator that enable to use all type of fractures and possess several unique features, including exclusive use in hand fractures and on-site, on-demand construction. The aim of this study is to demonstrate its ease of application, low profile, and simple design as well as the possibility to apply it as a static as well as a dynamic fixator.

Methods: The Ichi-Fixator (Neomedical, Saitama, Japan) set includes three different size metal clamps and wires (1.2, 1.5, 1.8mm diameter, two type of each in smooth needle and partial thread screw). For the use of distraction type of external fixator, the basic construct of the Ichi-fixator is made of two wires bent into a wire frame and secured together with two special adjustable metal clamps fixation with small two screws. Because of the adjustable function of small screws inside of fixator, the Ichi-Fixator enable to modulate under fluoroscopic inspection such as a static or distraction fixator for simple or comminuted diaphysis fractures of all phalanges and all metacarpal, and all interphalangeal joints and the thumb metacarpal joint as well as a dynamic fixator.

Results and Conclusions: Twenty-two patients in a variety of fracture patterns were treated with Ichi-Fixator. The fixator was rigid and maintained reduction in all fractures. The procedure lasted 20 to 45 minutes. Ichi-Fixator were removed in a mean period of 6 weeks, and follow-up was 6 to 15 months. Averaged the QDASH score was decreased from 78.69 to 12.35 and the VAS score was decreased from 6.75 to 1.44. The grip strength and total active motion were 84.9% and 76.7%, respectively, compared with the contralateral side. There was no wire site infection and no non-unions. There were no pain and returned to all their previous activities without discomfort. The findings of this case series demonstrated that Ichi-Fixator can be considered for all hand fractures requiring surgical treatment, and especially for comminuted fractures. Ichi-fixator enables enhanced security of fixation, facilitates postoperative mobilization, and may allow an immediate return to work.

Causes of procedural failures of closed reductions using an extension-block pin for bony mallet finger

List of authors:
Taku Suzuki*, Takuji Iwamoto¹, Noboru Matsumura¹, Shigeki Nagura¹, Ruriko Iigaya¹, Kazuki Sato¹
¹Department of Orthopaedic Surgery, Keio University School of Medicine (Tokyo)

Objectives / Interrogation: This retrospective study evaluated procedural failures of closed reductions using an extension-block Kirschner-wire (K-wire) for bony mallet finger.

Methods: A total of 132 patients who underwent a closed reduction for bony mallet finger in a procedure using an extension-block K-wire technique were radiographically assessed. Radiographs were used to evaluate: (1) postoperative displacement of the reduction before or after K-wire removal and (2) inaccurate reduction of the fragment immediately after surgery. The causes of procedural failure and bone union were evaluated using plain anteroposterior and lateral radiographs and medical records of the intraoperative findings.

Results and Conclusions: Out of 132 patients, 17 patients of mean age 48 (range, 17 to 71) years with procedural failure were enrolled in this study. Displacement of the reduction before and after K-wire removal occurred in 7 and 6 cases, respectively. Inaccurate reduction immediately after surgery occurred in 4 cases. The most common cause of procedural failure was inaccurate insertion of the K-wire to fix the distal interphalangeal (DIP) joint (8 cases) followed by inaccurate insertion of the extension-block pin (5 cases). Two patients underwent a second operation. All patients who underwent a single operation had bone union regardless of the displacement of the reduction or inaccurate reduction of the fragment. Caution should be exercised during the reduction and fixation when an extension-block K-wire is used for a closed reduction procedure.

Arthroscopic assisted reduction versus fluoroscopic reduction in treatment for AO type C intra-articular distal radius fracture. A review of functional and radiological outcome between two methods.

**List of authors:**
Siu Cheong Jeffrey Justin Koo¹, Kam Yiu Adrian Leung², Pak Cheong Ho³
¹ Department of Orthopedics and Traumatology, Alice Ho Miu Ling Nethersole Hospital (Hong Kong SAR)
² Department of Occupational therapy, Alice Ho Miu Ling Nethersole Hospital (Hong Kong SAR)
³ Department of Orthopedics and Traumatology, Princes of Wales Hospital (Hong Kong SAR)

**Objectives / Interrogation:** Arthroscopic assisted reduction versus fluoroscopic reduction in treatment for AO type C intra-articular distal radius fracture. A review of functional and radiological outcome between two methods.

**Methods:** Between April 2016 and March 2018, 24 patients (15 males, 9 females, average age 57.3, follow-up time 12.5 months) were recruited into 2 groups and retrospectively reviewed. In Arthroscopic group, articular fragments are reduced and stabilised with K-wire arthroscopically. All patients in 2 groups had fractures fixed with volar distal radius locking plate. Active range of motion, grip strength, Modified Mayo Wrist (MMWS) score and Quick Disabilities of the Arm, Shoulder, and Hand (DASH), radiological assessment in distal radius parameters were assessed.

**Results and Conclusions:** Arthroscopic group had statistically better restoration in articular stepping and gapping as well as volar tilt and ulnar variance. Wrist extension and flexion, forearm pronation and supination as well as grip strength also have statistically improvement when compared with conventional fluoroscopic method.

Concomitant intra-articular soft tissue injuries were detected in arthroscopic group (5 TFCC tear, 3 Scapho-lunate interosseous ligament tear and 1 Luno-triquetral interosseous ligament tear) and treated accordingly.

Arthroscopic group had 2 excellent, 2 good and 8 satisfactory results whereas fluoroscopic group had 1 good, 8 satisfactory and 3 poor results with better mean MMWS score (P=0.02). However, Quick DASH score failed to show any difference.

Our study showed arthroscopic assisted technique precisely restore the distal radius radiological parameters with good functional outcome. Also, missing intra-articular soft tissue injury can be avoided and treated simultaneously.

Operative Treatment Options For Treating Pediatric Hand Fractures and Presentation of Results

List of authors:
Gergo Jozsa¹, Zoltan Kispai², Peter Vajda³
¹ University of Pécs Department of Paediatrics, Surgery (Pécs)
² LKH.Univ Klinikum Graz (Graz)
³ University of Pécs Department of Paediatrics (Pécs)

Objectives / Interrogation: Fractures in the bones of the hand are a common injury both in children and adolescents. Hand fractures which are unstable, oblique, or have a rotational deformity, or are pathologic or open are an indication for surgery.

Methods: The authors evaluated in a retrospective study the therapeutic options and results of operatively treated paediatric hand fractures of patients treated between 1st January 2016 and 1st January 2018. Gender distribution, age specifics, fracture mechanism, operative treatment method, and final results after metal removal were inspected. In the above period altogether 42 patients were treated because of the fracture of one or more long finger phalanx (33/42) or fracture of the metacarpus (9).

Results and Conclusions: In the case of the phalangeal injuries (33/42), 21 patients were male and 12 were female. All patients with the metacarpal fractures were male. Most injuries occurred both in the phalanx (25/33) as well as in the metacarpus group (9/9) above the age of 10. The most common mechanism of injury was direct trauma caused by a ball. Among the patients with phalangeal fractures an identical function to the contralateral side was found in 28/33 patients, whereas in 5/33 patients good functional results were found. In the metacarpal injury group identical functional results to the contralateral side were found in 7/9 patients, good function was seen in 1/9 and bad function was found in 1/9. In most phalanx injured patients the external retention (aluminum splint, plaster, orthesis) was removed at the 3rd week, whereas the K wires were removed on the 5th-6th week. In the case of patients treated with elastic nails because of a metacarpal fracture (7/9), the involved finger was taped to the neighbouring intact finger. Following a week in a cast, functional therapy was started with a physical therapist. The elastic nail was removed after complete remodelling of the fracture. In the cases of angle stable plate osteosynthesis (2/9) we used external fixation till the healing of the soft tissue. In these cases there was no metal removal.

Conclusion: In the case of hand injuries requiring operative treatment, one should always strive for an accurate reduction. In the case of minimally invasive methods, the most stable and simple fixation should be used. By choosing the above operation types in most cases outstanding results can be achieved in childhood and adolescence.

Unplanned excisions of soft tissue sarcomas of the upper extremity

List of authors:
VASILEIOS KONTOGEORGAKOS*, IOANNIS ANTONIOU, SOKRATIS VARITIMIDIS, DIONYSIOS PAPACHRISTOU, MARIANNA VLYCHOU, ZOE DAILIANA, KONSTANTINOS MALIZOS
1 ATTIKON UNIVERSITY HOSPITAL (XAIDARI, ATHENS)
2 UNIVERSITY HOSPITAL OF THESSALY (LARISSA)
3 ANATOMY PATHOLOGY LAB, UNIVERSITY OF PATRAS (PATRA)

Objectives / Interrogation: Unplanned excisions of soft tissue sarcomas is a surgical challenge and overall treatment should be individualized. The aim of the study is to investigate the outcome of repeated surgical treatment of these patients.

Methods: A retrospective study of 18 patients with non-metastatic upper extremity STS referred for further treatment after unplanned excision. Patients with STS at the fingers were excluded. All patients had initial tumor resection in pieces or histologically microscopic or gross positive resection margins. Tumor resection under local anesthesia was performed in 8/18, while no pre-op imaging was performed in 6/18 of the patients. In 6 patients, a palpable mass was present for 3 to 4 years before resection.

Results and Conclusions: An amputation was performed in 3 patients, while 15 patients underwent re-excision of the surgical field. Negative margins were obtained in 16/18 patients. Flap reconstruction of skin graft was used in 6 patients. Adjuvant radiation therapy were offered in 11/15 of the patients within 5-8 weeks after re-excision. No chemotherapy was administered. Local recurrence and metastatic disease occurred in 1 and 3 patients respectively. Follow-up ranged from 12 to 50 months. A long standing mass does not preclude malignancy. The combination of surgical bed re-excision combined with local radiation therapy offers a low local recurrence rate. Extensive neurovascular and tendon infiltration by the tumor will result in amputation.

The Clinical Outcome of The Novel Hand Therapy Protocol That Based on Staged Outcome Assessment for Zone 1 and 2 Flexor Tendon Injuries -a preliminary study-

List of authors:
Hideyuki Ota*, Yoshiyuki Inagaki1, Kentaro Watanabe1
1 Department of Orthopaedic Surgery, Nagoya Ekisaikai Hospital (Nagoy)
2 Department of Rehabilitation, Nagoya Ekisaikai Hospital (Nagoya)

Objectives / Interrogation: We treated by modified Kleinert regimens (mKR) combined with 4 or 6 strands core suture for flexor tendon injuries in Zones 1 and 2 to 2015. Watanabe reported the novel core suture technique that named 8-strand core suture cross-locked cruciate procedure (Watanabe procedure: WP) in 2016. The purpose of developing WP is for establishing the standardized EAM protocol that is not depend on experience of hand therapist. We assessed the cases who treated by mKR and compared the outcome between excellent, good outcome cases and fair, poor cases. Thus, we calculated the cutoff value to set target value up. After that, we invent the novel EAM protocol that based on the target value. The purpose of this study, one is to point the evidence of novel EAM protocol out, another is to indicate the clinical outcome of the patients who treated by the novel EAM protocol.

Methods: We reviewed the outcome of the patients who treated by mKR (34 patients 40 fingers) in our institution between 2008 and 2015. We assessed the ROM of the PIP, the DIP joints, and the outcome of original Strickland's criteria. We define them as A group (35 patients 29 fingers) were Excellent and Good in the outcome of original Strickland's criteria, and B group (5 patients 5 fingers) were Fair and Poor in the outcome of original Strickland's criteria. Thus, we calculated the cutoff value by receiver operating characteristic curve (ROC) after the operation 4, 6, 8 weeks. And we reviewed the the clinical outcome of the novel EAM protocol combined with WP (EAMWP) of 7 fingers 7 patients between 2016 and 2017. We assessed the ROM, the outcome of original Strickland's criteria at final visit.

Results and Conclusions: The mean ROMs in group A and B at 2, 4, 6, 8 weeks are shown in Table 1. Thus, the cutoff value at 4, 6, 8 weeks from the ROC are shown Table 2. We set the target value up, PIP flexion 75°/80°/90°/100°, PIP extension -30°/-20°/-10°/0 °, DIP flexion 40°/40°/50°/60°, DIP extension -10°/-5°/0°/0° at 2, 4, 6, 8 weeks respectively. We established the target value of EAMWP at 2 weeks that based on the result. The original Strickland's criteria of all patients who treated treated with EAMWP was excellent. The mean ROMs are PIP flexion 100±4°, PIP extension -3±7°, DIP flexion 71±10°, DIP extension -3±4° at final visit. There was no complication in 7 cases.

Endoscopic anatomy in carpal tunnel surgery.

List of authors: Amirouche DAHMAM*, Jean-Luc ROUX1, Gero MEYER ZU RECKENDORF1
1 Institut Montpelliérain de la Main (Montpellier)

Objectives / Interrogation: Endoscopic release of the median nerve according to Agee's original technique is limited to section of the flexor retinaculum without endocanalar exploration. We present a video of the modified Agee technique the purpose of which is to explore the carpal tunnel, including its contents and walls.

Methods: The procedure is performed under locoregional anesthesia with a tourniquet at the root of the arm. As soon as the endoscope is introduced into the carpal tunnel, the median nerve is located and section of the retinaculum is only performed afterwards. Once the retinaculum has been divided, exploration becomes easier. By longitudinal rotational movements of the endoscope we may visualize the following anatomical elements: the retinaculum margins confirming its complete section, the median nerve and its motor branch on the radial side, the long flexor of the thumb in its sheath outside, the flexor tendons of the 4th and 5th fingers with their lumbrical muscles on the ulnar side, the uncus of the hamatum and finally, behind the flexor tendons, the anterior capsulo-ligamentous parts of the carpus.

Results and Conclusions: On a continuous series of 100 carpal tunnels, the median nerve was always visualized before section of the retinaculum and the motor branch was visualized 82 times. Release of the motor branch was performed under endoscopy in 27 cases who presented thenar atrophy or a compressive anatomical element. In most of these cases, endocanalar vision associated with passive flexion/extension movements of the first metacarpal, revealed shearing of the motor branch due to fibrous reinforcement of the flexor fascia, this arch was sectioned. The long flexor of the thumb was individualized 87 times, the flexors of the 4th and 5th fingers with the lumbrical muscles 68 times. In 18 cases we found degenerative tendon lesions with a rough hamate. The anterior part of the carpus was visualized by passing the endoscope under the flexor tendons. A synovial cyst was found in one case.

This film shows that the endoscopic technique offers endocanalar anatomical vision with better quality than the classical open technique. It proves that complementary procedures, such as neurolysis of the median nerve and its motor branch, associated with section of the retinaculum are possible by endoscopy. This experience has led us to believe that, just as with wrist arthroscopy for the carpus, endoscopy will become a standard means of exploring the carpal tunnel.

Keywords: carpal tunnel, endoscopy, neurolysis
Does a vascularized proximal interphalangeal emi-joint transfer worth the efforts?

List of authors:
Stefano Lucchina*1, Cesare Fusetti2, Marco Guidi2
1 Hand Unit EOC Locarno's Regional Hospital, Locarno Hand Center (Locarno)
2 Hand Unit EOC Locarno's Regional Hospital, Hand Unit EOC, Bellinzona's Hospital (Locarno)

Objectives / Interrogation: Open intra-articular fractures of digital interphalangeal (DIP) joints occasionally destroy major amounts of joint cartilage and supporting bone with functional limitations. Previous reports described the use of vascularized total joint transfers or not vascularized partial toe joint osteochondral autografts as unique alternatives to salvage proximal interphalangeal (PIP) joints with loss of one condyle when open reduction and internal fixation is not feasible.

Methods: A 22 yo carpenter sustained an open fracture of the non-dominant left index finger middle phalanx (P2) with ulnar condylar loss. A homolateral vascularized 2nd toe proximal phalanx (P1) unicondylar transfer to the left index finger P2 head was undertaken. The defect was templated and a corresponding osteochondral graft was harvested from the head of the 2nd toe P1. The defect was measured intra-operatively and then a slightly larger graft than required was harvested, allowing for in situ adjustment. The osteochondral graft and medial collateral ligament, partial extensor tendon, the ipsilateral artery, vein and digital nerve were harvested and joined at the recipient site with microsurgical technique. The osteochondral graft was secured to the P1 head with 2 transverse 1,0 mm K-wires. All other composite tissues were sutured to the recipient site.

Results and Conclusions: The patient was splinted post-operatively and discharged on the 7th day. An early mobilization protocol of the injured finger was started with hand therapists. At 8 weeks post-operatively the two K-wires were removed. At 6-months follow-up, a pain-free active PIP joint range of motion (ROM) of 10-85° and DIP ROM of 10-50° were obtained, with a grip strength of 42 lbs. No donor site complications were found, and post-op. X-rays at 4 months and MRI at 6 months respectively revealed a good bone union, a normal vascular patency and bone viability of the unicondylar graft.

This report represents an example of vascularized toe unicondylar bone grafting as an alternative tool in the management of significant PIP injuries. In spite of technical demand, this procedure is a feasible and represents an ideal alternative surgical therapy in adults with > 5 mm bone loss and asking for a functional interphalangeal joint.

An increasing burden of bureaucracy due to health insurances in Swiss hand surgery practice: a comparative study over 5 years

List of authors:
Stefano Lucchina*, Cesare Fusetti1, Marco Guidi2
1 Hand Unit EOC Locarno’s Regional Hospital, Locarno Hand Center (Locarno)
2 Hand Unit EOC Locarno’s Regional Hospital, Hand Unit EOC, Bellinzona’s Hospital (Locarno)

Objectives / Interrogation: Previous international surveys report an increasing dissatisfaction among doctors with several aspects of practice, including income, workload and time consumed by administrative tasks being writing certificates and denied insurance claims among the most tedious. Purpose of the study was to assess the number of certificates for health insurances in a private practice, the prevalence and type of claim denials in hand surgery sent to the major health provider in Southern Switzerland.

Methods: An observational study was made, which retrospectively collected data from the claims and denial reports for ‘surgical’ outpatients in hand surgery, including the number of certificates requested and completed for health insurances during the period 2013 to 2017. The denials were classified into “administrative” (AD) and “clinical” (CD). For each case the cause of denial, the time required to reply to insurances’ requests, end result and time for bills to be paid were recorded. The certificates were divided into 3 categories: accidents, detailed reports for any reason and loss of income.

Results and Conclusions: The overall frequency of denials was 294, equivalent to 5.4% of the total number of invoices issued. The frequency of AD was 82.6%, whereas that of CD was 19.4%. Any CD required an average time of 107.8 minutes of work compared to 6 minutes for AD. In 81% of cases the denial was not justified and led to a final payment of the original bill. The number of CD that required the surgeon’s contribution for the invoice to be paid doubled from 2014 to 2016. The total number of certificates increased from 371 to 525 (+41%) being detailed reports the most noticeable. Our data confirm previous surveys that health insurances and bureaucracy rob patients of doctor’s time with a continuous increasing trend over time. Compared to the U.S. literature the overall prevalence of denials in the studied sample was low but the limit of this study is that denials in private offices and for inpatients were not considered. Administrative denials were the most prevalent but the costs of surgeon’s contribution to insurances’ request should be considered and represented the only way for the reimbursement to happen. An easier coding system and a continuous education of all actors of the health system are mandatory to reduce the burden on surgeons and the billing offices of physician organizations.

Usefulness of preoperative MRI in pediatric Monteggia fractures

List of authors:
Koji Suzuki*, Mitsuru Horiki1, Shunsuke Nishimoto1, Reiko Nakagawa1
1 Dept. of Orthop. Surg., Kansai Rosai Hospital (Amagasaki)

Objectives / Interrogation: To clarify whether the preoperative MRI for pediatric Monteggia fracture predicts the cases of irreducible or easily re-dislocated radial head dislocations.

Methods: We retrospectively evaluated 6 patients (3 male, 3 female) below the age of 15 years who underwent preoperative MRI and surgical treatment for Monteggia fractures from 2012 to 2018. The average patient age at the operation was 8.7 years (range, 4-14 y). We initially treated the ulnar fractures including acute plastic bowing deformities by closed or open reduction followed by tried to reduce radial head dislocations by closed means. When the radial head dislocations were irreducible or easily re-dislocated, we performed open reduction. On MRI, we obtained the T2-weighted fat-saturated sagittal images of the injured elbow, and checked whether the annular ligament was entrapped between the radial head and the capitellum. Further, to evaluate an extent of interposed annular ligament quantitatively, we measured the length of entrapped anterior band of annular ligament (d mm) below the posterior side of radial head, and the diameter of radial head (D mm) in both open and closed reduction groups. We calculated and evaluated the d/D ratio in each group.

Results and Conclusions: Out of 6 cases, 3 cases (1 irreducible and 2 easily re-dislocated cases) were underwent open reduction of the radial head. On the basis of preoperative MRI, the annular ligament entrapment was detected in 2 cases (67%) with open reduction of radial head and 2 cases (67%) with closed reduction. Furthermore, in the 4 cases which detected annular ligament entrapment, the value of d/D ratio in open reduction group (0.50 and 0.75) was higher than the ratio in the closed reduction group (0.23 and 0.25). On the other hand, in only one case, open reduction of radial head was needed even though the annular ligament was not interposed in the radiocapitellar joint on the preoperative MRI. In this case, we confirmed intra-operatively subluxation of radial head because of partially injured and slightly elongated annular ligament. These results indicated the possibility of the relevance between the extent of interposed annular ligament and the necessity of radial head open reduction. Meanwhile, in case the annular ligament was partially or fully ruptured, we might not be able to detect interposition on MRI. In the present study, we conclude that preoperative MRI may help predict irreducible or easily re-dislocated patients of pediatric Monteggia fracture.

Maximum utility and certain safety for WALANT Technique in Hand Surgery

List of authors:
oxana-madalina grosu*, Sorinel Lunca, Mihaela Pertea
1 University of Medicine and Pharmacy “Gr. T. Popa” Iasi, “Sf. Spiridon” Emergency Hospital Iasi (Iasi)
2 University of Medicine and Pharmacy “Gr. T. Popa” Iasi, Institute of Oncology Iasi (Iasi)

Objectives / Interrogation: The aim of this study is to confirm the utility, safety and benefits of using WALANT technique and to encourage its use in Romania and all over the world for as many different hand and wrist surgeries as possible.

Methods: The study was conducted in a group of 75 patients admitted to our institution starting with January 2017. We included in the study 40 men and 35 women (M/F ratio = 1.14) aged 24 to 76 years. They accounted for 25% of the group of patients with carpal tunnel syndrome (CTS) and 35.71% of the group of patients diagnosed with Dupuytren Disease (DD). The anesthetic used in all cases was a solution of lidocaine 1% with 1:100,000 epinephrine without buffering it with 8.4% sodium bicarbonate. The amount of anesthetic solution used did not exceed 20 mL for CTS and 15 mL for each digital ray affected by DD. Onset of anesthesia took 6 to 15 minutes, being checked by subjective testing of the patient and by monitoring for skin color change at the injection site.

Results and Conclusions: Results
No changes in digital vasculature were found in any of these cases. Hospital stay was of at least 6 hours (due to the lack of infrastructure and a legal system for short-term hospitalization). Only one patient stayed in hospital for 48 hours, the patient being diagnosed with neglected high values essential hypertension and oscillations. The correlation coefficient between the amount of anesthetic and number of digital rays affected by DD is 0.63, for p = 0.0002 (Significance F <0.001), showing a positive, direct and high correlation. Therefore, the significant statistical results can be extrapolated to larger groups. Regression (ANOVA) shows a positive, moderate and direct correlation between the duration of hospitalization and the amount of the anesthetic used in CTS patients, with a correlation coefficient of 0.52, statistically significant with p<0.01 (Significance F=0.002).
Applying regression in ANOVA, correlating the amount of anesthetic used to the entire group with the anesthesia onset time we get a correlation coefficient of 0.43, showing a moderate correlation, but high statistically significant, for p<<0.00001.

Conclusions
The use of WALANT technique in hand surgery is safe and efficient, has many advantages for both the patient and the surgeon and is cost-saving. Complications such as digital necrosis are excluded when 1% lidocaine with 1:100,000 epinephrine anesthetic solution not exceeding the safe zone of 7mg/kg is used.

Biomechanical Analysis of Thumb Ulnar Collateral Ligament Tear Kinematics

List of authors:
Steven Shin*, Charles Lin, Nilay Patel, Yasuo Itami, Michelle McGarry, Thay Lee
1 Cedars-Sinai Kerlan-Jobe Institute (Los Angeles, CA)
2 Orthopaedic Biomechanics Laboratory, Long Beach VA Healthcare System (Long Beach, CA)

Objectives / Interrogation: Although thumb ulnar collateral ligament (UCL) injuries are common, the kinematics of thumb UCL injuries have not been extensively described. The purpose of this study was to assess the kinematic changes of the thumb MCP joint with progressive UCL injury.

Methods: Eleven cadaveric specimens were utilized for this study. Thumbs were dissected of soft tissue while taking care to leave the UCL, volar plate and dorsal capsule intact along with the EPL, EPB and FPL tendons. Each specimen was potted in plaster of Paris and placed in a custom jig for kinematic testing of the thumb. Each thumb underwent kinematic testing in four conditions: intact, partial tear (50%) of the proper UCL, full tear of the proper UCL and complete tear of both the proper and accessory UCL. Kinematic testing parameters included varus / valgus stress, pronation / supination and volar / dorsal translation. Each testing parameter was assessed at -10, 0, 15, 30° of MCP flexion.

Results and Conclusions: Partial tear of the proper UCL did not result in any significant increase in varus / valgus angulation, pronation / supination or volar / dorsal translation (Figure 4) at any degree of flexion. Full tear of the proper UCL resulted in a significant increase in valgus angulation (intact: 11.5 ± 1.5 degrees vs. full tear: 18.8 ± 1.7 degrees; p = 0.024) and pronation at 30 degrees of flexion relative to intact (intact: 12.6 ± 2.3 degrees vs. full tear: 15.4 ± 2.5 degrees; p = 0.034). Complete tear of the proper and accessory UCLs resulted in increased valgus angulation compared to intact at all degrees of flexion (p < 0.001). It also resulted in a significant increase in total pronation / supination relative to intact at all degrees of flexion (p < 0.004). Furthermore, complete tear resulted in significant volar translation at 0, 15 and 30 degrees of flexion (p < 0.016).

Sequential tearing of the thumb UCL leads to progressive instability of the MCP. Partial tear of the proper UCL does not significantly affect the stability of the joint, but full tear of the proper UCL increases valgus instability at 30 degrees of flexion. Complete tear of the UCL is necessary for increased varus / valgus instability at all degrees of flexion and also results in significant increases in pronation/supination and volar translation.

Essex Lopresti Fracture-Dislocation

List of authors:
Daniela Pereira¹, Vítor Rodrigues¹, Luís Machado¹, Carlos Ferreira¹, Carlos Pina¹, António Sá¹
¹Centro Hospitalar de Leiria (Leiria)

Objectives / Interrogation: Essex-Lopresti injury is a rare entity that consists of a fracture of the radial head, rupture of the interosseous membrane and disruption of the distal radioulnar joint (DRUJ).

Methods: Case report.

Results and Conclusions: We report a case of a 34 year-old male that fell onto an outstretched right hand. He presented to the emergency department with elbow and wrist pain. Clinical examination revealed elbow swelling with tenderness and wrist and forearm pain with DRUJ compression test. Plain radiographs revealed a comminuted radial head fracture and dorsal subluxation of the distal ulna. Intraoperative wrist examination was compatible with wrist instability and elbow approach revealed a lateral collateral ligament (LCL) injury. He underwent LCL repair, open reduction and internal fixation of the radial head with plate and screws. The DRUJ was reduced spontaneously and it was stable in all positions.
A long arm splint was applied in full supination and 90° of elbow flexion for 4 weeks and 2 weeks with munster - type elbow cast. The patient returned to work 2 months after the surgery. At 6 months follow up he presented without pain. Clinical examination revealed full arc of pronosupination, full flexion and a deficit of 10° in extension. This clinical report aims to highlight the importance of a careful examination of the wrist in all patients with displaced radial head fractures as the diagnosis can be often missed. Prompt diagnosis is mandatory for optimal outcome.

Tumors of the palm - clinical and imagistic diagnosis

List of authors:
oxana-madalina grosu*¹, Alina Stan¹, Petru Ciobanu³, Mihaela Pertea³
¹ University of Medicine and Pharmacy"Gr. T. Popa" Iasi, "Sf. Spiridon" Emergency Hospital Iasi (Iasi)

Objectives / interrogation: The purpose of this study is to highlight the possible existence of rare tumors in hand. Clinical diagnosis can be difficult in these cases and only paraclinical examinations, such as IRM and histopathology, can orient and establish the diagnosis. Therefore, these rare tumors must be considered, even when they are present in hand.

Methods: This study included 14 patients, diagnosed and treated over a period of 9 years. In 7 cases, the tumor was a lipoma. Their localization was the thenar eminence in 6 cases and mid-palm region in 1 case. All tumors were over 5 cm (giant), the sizes of the mid-palm one being 9.5/5/3.5 cm, with a weight of 137 grams. The IRM exam oriented us to the diagnosis of cystic formation, but it did not give other details. Also, in the other 7 cases, the IRM exam was very helpful, with oriented-detailed descriptions for liposarcoma in 1 case, epidermal inclusion cyst in 1 case and rice-bodies tenosynovitis in 5 cases. In the liposarcoma case, the image on MRI was of a heterogenous, poorly encapsulated tumor, with thick fibrous septa and nodules on T1-weighted sequences and hypertenseptae on fat-suppressed T2-weighted. The IRM exam with contrast agent for the epidermal inclusion cyst revealed the presence of a cystic-polyloculated tumor (hypersignal T2, hyposignal T1) with a moderate contrast medium uptake in the wall and septa, located on the palmar face of the right hand, with significant deformations of the region and sizes of approximately 21/22/53mm. For the rice-bodies tenosynovitis, MRI exam showed millimetric and nodular images in flexor group tendon sheath in T2-weighted sequences, thickening of the synovial membrane with increased vascularization, fluid within the tendon sheath, reactive inflammation around the tendon and swelling of the tendon. In all cases, the treatment consisted in surgery with complete excision of the lesions and the histopathological examination established the diagnosis.

Results and Conclusions:

Results
In all cases, the ablation of tumors was performed with good results, without relapse at distance. Socio-professional reintegration was complete and fast, functional and aesthetic results were very good. The patients rated the results with "good" and "very good" in one interview.

Conclusions
Although the clinical examination is sometimes uncertain, the symptoms being similar for different tumors, the imagistic exams, like MRI, can orient us for the best. Of course, the histopathological examination offered the diagnostic certainty.

lipoma, epidermal cyst, rice-bodies tenosynovitis.
Biomechanical Analysis of Thumb Ulnar Collateral Ligament Repair with Suture Tape Augmentation

List of authors:
Steven Shin¹, Nilay Patel², Charles Lin², Yasuo Itami², Michelle McGarry², Thay Lee²
¹ Cedars-Sinai Kerlan-Jobe Institute (Los Angeles, CA)
² Orthopaedic Biomechanics Laboratory, Long Beach VA Healthcare System (Long Beach, CA)

Objectives / Interrogation: To assess the kinematics and angular stiffness of the thumb ulnar collateral ligament (UCL) repair with and without suture tape augmentation.

Methods: 8 cadaveric thumbs were tested in a custom hand testing system. Varus/valgus kinematics was measured at -10°, 0°, 15°, and 30° degrees of thumb MCP flexion in the following conditions: (1) intact thumb UCL, (2) complete UCL tear (proper and accessory ligaments), (3) UCL repair, and (4) UCL repair with suture tape augmentation. Angular stiffness was measured after application of sequentially increasing valgus torque in the intact, UCL repair, and UCL repair with suture tape augmentation conditions. UCL repair alone was performed by passing 3-0 FiberWire suture (Arthrex, Naples, FL) in horizontal mattress fashion through the distal UCL from a 3.5 mm DX SwiveLock (Arthrex) at the volar ulnar base of the proximal phalanx. Suture tape augmentation was performed with two tails of 1.3 mm SutureTape (Arthrex) and brought proximally over the repaired ligament and loaded into a 3.5-mm SwiveLock anchor at the proximal origin of the UCL.

Results and Conclusions: Complete UCL tear increased varus/valgus angulation at 0°, 15°, and 30° degrees of thumb MCP flexion (p < 0.02). Thumb UCL repair alone and repair with suture tape augmentation decreased varus/valgus angulation relative to complete UCL tear at all flexion angles (p < 0.002). Total varus/valgus angulation was not significantly different from intact for either the repair alone or the repair with suture tape augmentation at all flexion angles (p > 0.19). Repair with suture tape augmentation had significantly higher valgus angular stiffness compared to repair alone (p = 0.040).

Thumb UCL repair with suture tape augmentation is able to restore varus/valgus kinematics after complete UCL tear. In addition, the higher angular stiffness afforded by the suture tape augmentation may allow for earlier rehabilitation after surgery.

Suppression of finger tremor using dynamic vibration absorbers

List of authors:
Masashi Matsuta*1, Kaoru Tada1, Tadahiro Nakajima3, Mika Nakada1, Hiroyuki Tsuchiya1
1 Department of Orthopaedic Surgery, Kanazawa University (Ishikawa Kanzazwa Takaramachi)

Objectives / Interrogation: A major impediment to precise microscope operation is finger tremor. We evaluated tremor and investigated tremor suppression using dynamic vibration absorbers.

Methods: Postural tremor
We evaluated postural tremor in 10 healthy men (average age: 22.7 years). Piezoelectric elements were attached to the dorsal and radial sides of the index fingers. The palmar bases of the fingers were attached to supports, and the fingers were held in extension. We processed acceleration with an amplifier and analyzer and evaluated the time base waveform and frequency characteristics of biaxial tremors.

Intention tremor suppression
We evaluated intention tremor in 10 healthy men (average age: 22.7 years). Subjects gripped a 30-G needle with a needle holder for microsurgery and held the needle tip in the lumen of an 18-G needle under the microscope. We evaluated tremor perpendicular to the nail surface. A passive type dynamic vibration absorber with a weight that induced 10-Hz natural frequency was prepared. Dynamic vibration absorbers were attached perpendicular to the nail surface, and tremor with or without attachments was evaluated. An active type dynamic vibration absorber with active damping force produced by external energy was prepared. Tremor was evaluated in 8 orthopedic surgeons (average age: 33.6 years) in the same manner as for the passive dynamic vibration absorbers.

Results and Conclusions: Postural tremor
The root-mean-square of the time base waveform was calculated, and postural tremor perpendicular to the nail surface was greater than that parallel to the surface. Peak postural tremor frequency was approximately 10 Hz.

Intention tremor suppression
The root-mean-square of the time axis waveform was 0.50 ± 0.09 (V) when a passive type dynamic vibration absorber was not used and 0.46 ± 0.05 (V) when a vibration absorber was used. However, no significant difference was observed. In some cases, the intention tremor showed a peak frequency of approximately 10 Hz. The peak decreased with the use of a passive type dynamic vibration absorber, but in some cases the peak was not clear and in others the decrease in the peak with use of the passive type dynamic vibration absorber was also not clear.

The root-mean-square of the time axis waveform was significantly suppressed to 19.9 ± 3.4 (mV) when an active type dynamic vibration absorber was not used and 18.1 ± 3.5 (mV) when a vibration absorber was used (p = 0.002).

This study investigated an active type dynamic vibration absorber may be effective.

Use of ultrasonography in carpal tunnel syndrome diagnosis

List of authors:
Mihaela Pertea¹, Sergiu Ursu², oxana-madalina grosu¹
¹ University of Medicine and Pharmacy”Gr. T. Popa” Iasi, "Sf. Spiridon” Emergency Hospital Iasi (Iasi)
² University of Medicine and Pharmacy “N. Testemitanu” , Orthopaedic and Traumatology Clinic, Chisinau (Chisinau)

Objectives / Interrogation: The aim of the paper was to analyze the effectiveness of ultrasonography in diagnosing carpal tunnel syndrome (CTS), to propose the use of sonographic index of median nerve in carpal tunnel (SIMNCT), and developing a diagnostic algorithm.

Methods: We study a group of 344 patients with SCC symptoms were examined with ultrasonography. The size of the cross-sectional area of the median nerve was measured at carpal tunnel inlet and outlet, nerve morphology at passage through carpal tunnel and the analysis of the neighboring structures, with the purpose of possibly determining the disease etiology. In all patients, we examined, in the affected hand, the vertical thickness of median nerve (MN) as entering into the carpal tunnel (CT) - G1, the lowest vertical thickness in the CT or leaving the CT - G2, the thickness of the MN in the transverse plane, as entering in the CT - L. Normal values were considered the similar measurements in healthy contralateral hand. We proposed the SIMNCT calculation after the formula: SIMNCT = 100% (1-G2 / G1). We have established normal value in the healthy hand as SIMNCT = 16%.

Results and Conclusions: Results
We demonstrated a statistically significant sensitivity of median nerve sonographic index at carpal tunnel level (p <0.0001) compared with cross-sectional area (CSA) and flattening ratio in the diagnosis of CTS. By analyzing the SIMNCT, developed by us, with a higher value than 16%, we demonstrated a sensitivity of 94.81% and a specificity of 99.66% in establishing the diagnosis of CTS. Thus, we proposed a classification of the severity of CTS according to the SIMNCT: normal = 16%, mild = 16-19%, moderate = 19-28%, severe = 28-50%, very severe over 50%.

Conclusions
Ultrasound is an effective method of studying the morphology of the tunnel and compressed nerve at various CTS stages and of determining the cause of compression in patients this disease. The median nerve sonographic index at the level of the carpal tunnel is a valuable and practical indicator and it can be used in the diagnosis of CTS and, also, it may be helpful in determining the severity of lesion. Is has a more valuable significance than the flattening ratio (sensitivity 4.49%, specificity 97.95%) and the cross-sectional area (sensitivity 88.76%, specificity 32.08%).

Soft Tissue Reconstruction and Microsurgery

---

**Tamai zone I and II replantation functional and cosmetical results versus conservative treatment: retrospective analysis**

**List of authors:**
Pierfrancesco Pugliese*, Pier Paolo Pangrazi1, Andrea Campodonico1, Andrea Marchesini1, Francesco De Francesco1, Letizia Senesi1, Michele Riccio1

1 AAOOU Ospedali Riuniti di Ancona, DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)

**Objectives / Interrogation:** There are only relative indications for distal digital replantation in zones 1 and 2 according to Tamai. Replantation is a complex procedure that requires skills in supermicrosurgical techniques, a longer hospital stay and the longer time off from work. On the opposite side a conservative treatment with local flap, in order to avoid further finger shortening, offer to the patient an easier course of treatment and healing. The aim of the present retrospective study is to make a comparison in terms of final functional and cosmetical result between reconstructed and replanted finger tip.

**Methods:** The study included 20 patients who underwent replantations distal to the distal interphalangeal joint or conservative reconstruction meaning direct closure with local flap. Lesion involved zone 1 and 2 according to Tamai classification. In case of replantation arterial anastomosis was accomplished after bone fixation, and venous anastomosis and nerve repair were performed whenever possible. When venous anastomosis was not possible, venous decompression was performed with heparinized gauze placed on the bleeding nail matrix. In case of conservative treatment patients were treated with local finger flaps in order to maintain bone length on distal phalanx. Functional and cosmetical results were evaluate at least after one year with test Semmens Weinstein monofilament, Weber Disk Criminator, total range of motion and quickDASH. Data were statistical analysed with t-Student test.

**Results and Conclusions:** All patient healed with no necessity of further operation on long time. All of them went to post-operative rehabilitation protocol. Functional, cosmetical outcome and sensibility result are presented and compared in respect of objective and subjective patient's daily need and quality of life.

Distal digital replantation is complex and technically challenging, the treatment is more demanding both for surgeon and patient if compared to a local flap. A correct analysis of patient need and an exhaustive explanation of all the potential risk and complication of two different approach is fundamental. Even if one could think that a missing finger tip is not so invalidating, long time results, the high patient gratification and the greater functional limitations of a local flap, justify the replantation attempt.

Using Abdominal Fasciocutaneous Flap to Salvage the Compromised Replantation

List of authors:
Chi-Ying Hsieh*1, Ke-Chung Chang1, Yo-Shen Chen1
1 Far Eastern Memorial Hospital, Department of plastic and reconstructive esthetic surgery (New Taipei City)

Objectives / Interrogation: The successful rate of replantation depends on a variety of factors including the mechanism of injury, surgical skills and patient conditions, etc. Sometimes, the failure of replantation is upset and frustrating. We provide a case report that the crushing amputated thumb was salvaged by a abdominal fasciocutaneous flap.

Methods: We present a 29-year-old healthy man who sustained a crushing injury on left thumb. Traumatic amputation was seen at the level of base of proximal phalanx (Fig 1). First attempt of replantation was performed but turned into vascular compromise (Fig 2). Abdominal fasciocutaneous flap was created to salvage the compromised stump on the post injury day 3 (Fig 3). After three weeks, the abdominal flap was divided from the abdomen.

Results and Conclusions: The amputated thumb was preserved successfully on the length and is functioning well in two months (Fig 4-6).
It is not necessary to amputate the stump if replantation fails. Abdominal fasciocutaneous flap can be used as a salvage for replantation when vascular compromise occurs

Keywords:
salvage; Abdominal fasciocutaneous flap; replantation; vascular compromise
Outcomes of Supplemental Bridge Plate Fixation of Highly Comminuted Distal Radius Fractures Treated by Open Reduction Internal Fixation

List of authors:
Libby Anderson*, Karen Smith
1 Hand Unit, Middlemore Hospital, Counties Manukau Health (Auckland)

Objectives / Interrogation: Dorsal bridge plating has been used in complex comminuted intra-articular distal radius fractures (AO 23-C) as a means of supplemental fixation of poorly supported fracture fragments. This allows a fracture to be held out to length with a prolonged period of wrist immobilisation in order to allow healing and prevent collapse. The evidence regarding the use of dorsal bridge plating is limited to retrospective case series in the literature. Most of these cases have utilised dorsal bridge plating as the primary means of fixation, ie as a distraction technique, without attempt at anatomical reduction and fixation of individual fragments. The aim of this study was to define the outcomes of patients with distal radius fractures treated with ORIF plus a supplemental dorsal bridge plate.

Methods: Two hundred and eighty-three distal radius ORIFs were performed by five senior hand surgeons in a single unit from 1 January 2016 to 31 December 2017. Of these, ten patients were identified as having an ORIF + dorsal plate placed as a neutralisation device. All of these fractures were type AO 23-C3. Average follow-up was 16.4 months post removal of the dorsal bridge plate. Intra-operative and most recent radiology was evaluated for radial inclination, volar tilt and ulnar variance. Objective measurements of forearm, wrist and digit range of motion and grip strength were recorded at last follow-up. Patients' subjective outcome measures were reported. This cohort of ten patients was compared to an age and gender matched group of ten patients treated by the same surgeons with ORIF only and 12 months follow-up (1 AO 23-C1, 3 AO 23-C2, 5 AO 23-C3).

Results and Conclusions: Mean radial inclination was 21 degrees with no difference at last follow-up. Volar tilt was lost in two patients (mean difference 1 degree). Ulnar variance was lost in four patients (mean difference -1 degree). ROM outcomes showed a statistically significant difference in flexion, extension and ulnar deviation when compared to uninjured wrist but no statistically significant measures when compared to the control group of patients. Mean active tip to distal palmar crease was 0.5cm. PRWHE was 22 ± 7 and QuickDASH was 18 ± 6 at final follow-up.

This is the first study that reports on outcomes of neutralisation bridge plating as a supplement to truly anatomical fixation with otherwise "standard" distal radius fixation techniques, and compares a bridge plate series to a case matched control group.

Keywords:

What PROMs measure in Dupuytren's disease: unrecognised issues unmasked by combining PROMs with the Aachen item banking protocol

Objectives / Interrogation: A key assumption of a patient-reported outcome measure (PROM) that delivers a summary score is that the items it comprises all measure the same underlying entity, or construct, i.e. that the PROM is unidimensional.

Two of the most popular PROMs for the study of Dupuytren's disease (DASH and URAM) have been examined previously. The URAM has been found to be unidimensional, whereas the DASH has not.

One issue with such studies is that the analysis has to extract the underlying entities and can only do so if enough of the PROM items relate to each underlying factor.

This study hypothesised that the URAM is not truly unidimensional, but that its multidimensionality would only be unmasked when extra information from DASH answers was added to a relevant model. Such analyses form part of "item banking" where items from multiple PROMs are combined.

Methods: This study involved the secondary analysis of cross-sectional data from 1 and 5-year follow ups of aponeurotomy, fasciectomy and dermofasciectomy procedures performed at 5 UK hospitals. Steps from the Aachen Protocol for item banking were employed, using common person equating, as each patient had completed both the DASH and URAM questionnaires.

Factor analyses were performed using principal axis factoring and promax rotation, and with the number of factors extracted in each analysis based on standard heuristics (scree plots, parallel analysis and Eigenvalue>1).

Separate analyses were run for URAM items and DASH items, and then all items from both were analysed together in a single model.

Results and Conclusions: 433 patients completed DASH and 252 patients completed URAM as well. As in previously published results, the URAM appeared unidimensional when studied in isolation, and the DASH did not - the “symptom” items loaded separately from the “task” items.

However, in the combined model the URAM was no longer unidimensional with questions “can you hold a bottle?” and “can you pick up small objects with your thumb and index finger?” loading alongside DASH items, and not with the rest of the URAM items.

This suggests that these two URAM questions might measure a different construct from the others, but because only two questions are affected, this may not be detected when the URAM items are studied alone.

Conclusions

This study suggests that the URAM may be less valid than previously thought. Consideration should be paid to the design of analyses of PROM validity to ensure that issues affecting small numbers of items are still identified.

The reliability of tomosynthesis for Heberden's node

List of authors:
Masashi Matsuta*, Kaoru Tada1, Tadahiro Nakajima1, Mika Nakada1, Hiroyuki Tsuchiya1
1 Department of Orthopaedic Surgery, Kanazawa University (Ishikawa Kanazazwa Takaramachi)

Objectives / Interrogation: Radiography is widely used for the diagnosis of Heberden's node, however, few studies have reported the accuracy of this technique. The purpose of this study was to report the intra- and inter-examiner errors in the diagnosis of Heberden’s nodes using radiography and tomosynthesis.

Methods: Our study included 136 fingers (17 persons; 6 men and 11 women; average age, 56.7 years) from individuals who underwent radiography and tomography at our hospital. Three examiners evaluated osteoarthritis using the Kellgren/Lawrence classification, from index to little fingers, of each DIP joint. The inter-examiner error was calculated from the data, which were collected twice in total, by the same orthopedic non-specialist at a one-week interval. Intra-examiner error was calculated from the data of three individuals, of whom two were orthopedic non-specialists (examiners 1 and 2) and one was an orthopedic specialist (examiner 3). For the statistical method, we used Cohen’s kappa and Pearson’s (r) correlation coefficients.

Results and Conclusions: The kappa coefficient for inter-examiner error related to radiographic examination showed a moderate match (examiner 1: kappa = 0.497), and the kappa coefficient for intra-examiner error related to radiographic examination showed a mild-to-moderate match (kappa 12 = 0.571, kappa 13 = 0.404, kappa 23 = 0.343). The kappa coefficient for intra-examiner error related to tomographic examination also showed a moderate match (examiner 1: kappa = 0.571), but the kappa coefficient for the inter-examiner measurement error showed very slight-to-moderate agreement (kappa12 = 0.522, kappa 13 = 0.201, kappa 23 = 0.189). The simple radiography and tomography examination methods showed a very strong correlation, with r = 0.683.

For determining the Heberden’s node grade, the Kellgren/Lawrence classification based on radiographic examination is commonly used. The inter-examiner errors were moderate in radiography and tomography for Heberden’s node diagnoses, but the measurement accuracy of tomography was lower than that of radiography. The correlation between radiography and tomography was considerably strong; therefore, it is unnecessary to perform tomography when diagnosing Heberden’s nodes.

Prospective study of Stage III Thumb Carpometacarpal Joint Osteoarthritis Treated with Arthroscopic Arthrodesis

List of authors:
Esther Ching San Chow*^1
^1 United Christian Hospital (Kwun Tong)

Objectives / Interrogation: The thumb carpometacarpal joint (CMCJ) osteoarthritis (OA) is a common pathology with controversial treatment options. Arthroscopic thumb CMCJ arthrodesis for CMCJ OA had never been reported. The aim of our study is to prospectively evaluate the effectiveness of arthroscopic arthrodesis for the treatment of Eaton stage III thumb CMCJ OA.

Methods: This study prospectively recruited all cases with Eaton III thumb CMCJ OA treated with arthroscopic arthrodesis from January 2015 to June 2017. The patients were evaluated objectively with grip strength, pinch strength, range of motion and Kapandji score. Subjective evaluation include Disabilities of the Arm, Shoulder, and Hand (DASH) questionnaire and the visual analog scores (VAS) for pain. All cases were assessed before the surgery and at 3 months, 6 months and 12 months after surgery. Radiographs were reviewed.

Results and Conclusions: There were total 11 cases. The average age was 62.2 with M:F = 2:9. The average follow-up time was 26.3 months. The pre-treatment pain score (VAS) was average 6.4. There was improvement of pain score at post-op 3 months (VAS 3.1, p<0.001), 6 months (VAS 1.2, p<0.001) and 12 months (VAS 0.2, p<0.001). There was improvement of grip strength and pinch strength at 12 months (p<0.001). The Dash score improved at 6 months (p=0.003) and 12 months (p<0.001). There was no significant change in the range of motion of the thumb and the Kapandji score. There was no major complication. There was one case of pseudoarthrosis.

In conclusion, this prospective study is the very first report of thumb CMCJ arthroscopic arthrodesis for stage III thumb CMCJ OA. Arthroscopic arthrodesis is a feasible treatment option and provides excellent pain relief, restore thumb strength and stability, retain thumb mobility, and hence improvement in hand function.

Advantages include: 1) allow clear assessment of joint; 2) Small scar and minimal disturbances of joint capsule and soft tissue; 3) Avoid tendon adhesions and 4) better preservation of blood supply resulting in better union rate.

Future study is needed for long-term result.

The incidence of distal ulna fractures by classification

List of authors:
Maria Moloney1, Simon Farnebo2, Lars Adolfsson3
1 Department of Plastic Surgery, Hand Surgery and Burns (Linköping)
2 Department of Plastic Surgery, Hand Surgery and Burns, Department of Clinical and Experimental Medicine (Linköping)
3 Department of Orthopaedics, Department of Clinical and Experimental Medicine (Linköping)

Objectives / Interrogation: Distal ulna fractures can occur isolated, but often accompany a distal radius fracture. The aims of this study were to investigate the incidence of distal ulna fractures and by classification examine if any fracture types are more common than others. Further to investigate methods of treatment used.

Methods: Data were collected from all patients aged 18 years or older, treated for a fracture of the distal ulna in our region during 2010-2012. Patients were identified in the national registry of diagnose codes using the ICD 10 system, followed by screening of radiographs. The fractures were classified according to the AO comprehensive classification of fractures with a Q-modifier.

Results and Conclusions: The incidence of distal ulna fractures was 0.00074 per year based on the prevalence during 2010-2012. The most common fracture type was a fracture of the ulnar styloid (79 % Q1), followed by fractures of the ulnar neck (11 % Q2). The rarest fracture type was ulna head fractures (1 % Q4). Patients aged 65 years or older more commonly had a Q2 fracture (14%) or a Q3 fracture (6%). Younger patients, aged 18-34 years, were not found to have fractures of class Q3 or Q4 and only one patient had a Q5 fracture. The mean age at the time of injury was 63 years (SD 18), and 76 % of the patients were women. 92 % also had a fracture of the radius. A fall from standing height on an extended wrist was the cause of trauma in 79 % of the patients. 30 % of all the patients with Q2-Q6-fractures were treated operatively with internal fixation of the ulna fracture. We found the incidence of the distal ulna fractures in adults to be 74/100,000 person-years. In comparison, the incidence of distal radius fractures has been reported to be more than three times higher. Most common is fractures of the ulnar styloid, followed by fractures of the ulnar neck. Fractures of class Q2-Q6 were most common in the population over 65 years, probably due to better bone quality in the younger and middle aged population. We found distal ulna fractures to be more common in females, and a high average age. This indicates that, just like distal radius fractures, distal ulna fractures can also at least partially be explained by the higher incidence of osteoporosis in postmenopausal women. Only a third of the ulna fractures were operated, indicating that most were considered either stable without internal fixation or stable after a concomitant radius fracture was internally fixed.

EVALUATION OF SCAPHO TRAPEZIUM TRAPEZOID JOINT AFTER THE IMPLANTATION OF A TRAPEZIUM METACARPAL PROSTHESIS.

List of authors:
Juan Carlos Sanchez Hernandez¹, Sergio Fernandez Roldan², Roque Emilio Perez Exposito², Fernandeo Aranda Romero², Cecilia Del Rey Ortega²
¹ Ramon y Cajal Hospital, San Francisco de Asis Hospital (Madrid)
² Ramon y Cajal Hospital (Madrid)

Objectives / Interrogation: OBJECTIVE: The aim of this study was to analyze the long term impact on the Scaphotrapezium Trapezoid (STT) joint after the implantation of a Trapezium Metacarpal Prosthesis (CMC).

INTRODUCTION: The STT joint is the second most common site in the wrist affected by degenerative arthritis, usually associated with CMC osteoarthritis. Besides, the function of the STT in the biomechanics of the wrist and thumb is not well known. We evaluated the repercussion of the CMC over time on the STT joint.

Methods: MATERIALS AND METHODS: An observational descriptive retrospective study with 100 patients with CMC osteoarthritis grade III of Eaton who had undergone non cemented “ball & socket” total CMC prosthesis, (an average follow-up of 5.9 years -range 4 to 9 years-), was iniciated to evaluate the clinic, radiological and functional changes over STT joint.

In order to avoid the bias of the effect the prosthesis, we decided to evaluate the patient 6 months after the surgery and nowadays. Results were compared by DASH and VAS scales, articular range of motion and clamp force with Jamar dynamometer.

The STT radiological changes on RX and scanner images were classified according to Crosby et al JHandSurg 1978.

Results and Conclusions: RESULTS: Through this study we found out that 95.2% of the patients were satisfied with EVA scale under 3.5 DASH scale parameters changed from an average of 16.5 to 20.1.

Thumb mobility and clamp force slightly modified from the obtained at 6 months.

Radiologic study showed that in most cases (97%) the osteoarthritic degeneration of STT was not modified by the previous surgery compared with contralateral hand.

CONCLUSIONS:
Osteoarthritic degeneration of STT after the implantation of a CMC prosthesis did not change significantly way compared with its standard evolution.

More studies in patients treated by other techniques or non treated would help its evaluation.

Ulnar Nerve Entrapment At The Cubital Tunnel. To Transpose Widely Or Not To Transpose At All?

List of authors:
Daniela Pereira*, Sérgio Figueiredo, Vítor Rodrigues, Carlos Ferreira, António Sá
1 Centro Hospitalar de Leiria (Leiria)

Objectives / Interrogation: Ulnar nerve entrapment at the cubital tunnel is the second most common peripheral neuropathy, right after carpal tunnel syndrome. Surgical approaches differ, from the standard treatment of care, ulnar nerve release followed by anterior transposition, to novel minimally invasive approaches performed in outpatient surgery. The objective was to compare outcomes achieved after either minimally invasive neurolysis or ulnar nerve transposition when treating ulnar nerve entrapment at the cubital tunnel.

Methods: We performed a retrospective cohort study with all 19 patients suffering from ulnar nerve entrapment at the cubital tunnel who were submitted to surgery, for 5 years, in our institution. Minimally invasive neurolysis was performed in 5 patients, while complete ulnar nerve transposition was performed in 14. The observed ratio between ulnar nerve entrapment at the cubital tunnel versus carpal tunnel syndrome was 1:78. Pre and post-operative nerve conduction study/electromyography data was collected and compared for outcome. Non-parametric tests were performed, assuming statistical significance whenever p<0.05.

Results and Conclusions: Minimally invasive neurolysis offered a better outcome on nerve conduction study/electromyography data, nearly achieving statistical significance (p=0.065). None of the ipsilateral upper limb neurocompressive complaints (9 patients, 2 for minimally invasive neurolysis, 7 for ulnar nerve transposition), obesity (7 patients, 1 and 6, respectively) or Diabetes Mellitus (3 patients, all submitted to ulnar nerve transposition) were related with a worse outcome (p=0.134; p=0.978; p=0.459).

Minimally invasive neurolysis offered a better outcome on nerve conduction study/electromyography data, nearly achieving statistical significance (p=0.065). Computer-assisted preoperative planning of corrective osteotomy for extra-articular distal radius malunions: Surgical technique and a case series of 10 patients

List of authors:
Lionel ATHLANI, Romain DETAMMAECKER, Juliette LOMBARD, François DAP, Gilles DAUTEL
1 nancy university hospital (Nancy)

Objectives / Interrogation: Corrective osteotomies of the distal radius for symptomatic malunion are time-tested procedures that rely on accurate corrections. The positioning of the radius osteotomy line and the creation of a suitable cortico-cancellous bone graft are the two delicate elements during the procedure. In order to facilitate and obtain more precision for these two steps, we propose an approach consisting of a computer-assisted planning and realization. On the preoperative, CT-scans of the pathological and the healthy wrists are made. On these two exams, radial inclination, ulnar variance and palmar tilt are calculated. On the pathological wrist, it is also specified the height and orientation of the old fracture line. Comparing the data and superpostion procedure will make it possible to obtain the better correction. Using specific software and a 3D printer, Newclip Technics lab will provide a specific osteotomy guide, a perfect graft template and an anatomic locking plate. The length of the screws will also be simulated.

Methods: The approach is anterior according to Henry. Elevation of the pronator quadratus muscle, visualization of the distal radius and the original fracture callus. The osteotomy guide is positioned and stabilized by pins. One of them comes to be placed in line with the future osteotomy. A first scopic control is performed to confirm, the correct position of the osteotomy. The radius osteotomy is then performed with the oscillating saw. Using the same guide, the holes of the epiphyseal screws are made. The guide is then removed. The second step is the realization of a cortico-cancellous iliac graft using the model printed in 3D. Then, we performed the distraction of the osteotomy site and the introduction of the bone graft. The third step is the osteosynthesis using the anatomic plate. The epiphyseal screws are first positioned at the level of pre-holes and the metaphyseal screws thereafter. The final scopic control confirms the good correction of the malunion with restitution of a physiological distal radius anatomy. It is also verified the correct positioning of the osteosynthesis material and the bone graft. Skin closure with drainage completed the procedure. An immobilization during the consolidation will be carried out.

Results and Conclusions: We reported results of the first ten cases operated at the same facility. we noted a significant improvement of the pain and mobilities, a restoration of prono-supination and a systematic consolidation with the stability of the reduction.

The Digital Artery Perforator Flaps and Dorsal Metacarpal Artery Perforator Flaps for Treatment of a Soft Tissue Defect of the Finger: Versatile Coverage Options to Avoid the Use of a Skin Graft.

List of authors:
Kiyohito TAKAMATSU¹, Akira Kawabata², Yuusuke Sogabe², Yukiko Morimoto², Ema Onode³
¹ Yodogawa Christian Hospital Dept. of Orthop. Surg. (Osaka)
² Yodogawa Christian Hospital (Osaka)
³ Osaka City Univ Dept of Orthop. Surg. (Osaka)

Objectives / Interrogation:
Introduction
The digital artery perforator (DAP) flap, which was first reported by Koshima, is useful in the reconstruction of a soft tissue defect of the finger. Recently, many studies using the DAP flap have been published. However, to adequately close the donor site, Koshima recommended that the DAP flap should be no more than 10 mm wide. If the width of the flap exceeds 10 mm, full-thickness skin graft may be required at the donor site. This type of graft is associated with some complications, and the need of a second donor site to harvest a skin graft is inevitable. Therefore, to avoid the use of a skin graft, the dorsal metacarpal artery perforator (DMAP) flap is used in cases of large soft tissue defects.

Purpose
The aim of this study was to describe the therapeutic strategy for and clinical experience while treating soft tissue defects of fingers using the DAP and DMAP flaps to avoid the use of a skin graft for donor site closure.

Methods: Patients
The included patients (n = 14, all males; average age: 41.7 years, range: 24-84 years) were diagnosed with soft tissue defect of the fingers. The soft tissue defects of the patients included 10 cases of trauma and 4 of scar contracture. The follow-up period averaged 9.6 months.

Methods
The size of the actual skin defect was measured during surgery; the DAP flap was used for reconstruction of the defects with widths of 10 mm or less, and DMAP flap was used when the widths exceeded 10 mm. This study retrospectively investigated the type of perforator flap, size of the flap, and complications.

Results and Conclusions:
Results
All DAP and DMAP flaps survived completely. For the soft tissue defects due to trauma, there were seven cases of DAP flaps and three of DMAP flaps. For the four cases of scar contracture, the DAP flap was used for all. Notably, all donor sites could be closed. The average size of all flaps was 10.3 × 27.4 mm². The average size of the DAP flap was 8.9 × 21.2 mm² and of the DMAP flap was 15.7 × 50 mm². The complication of delayed wound healing in the distal part of the flap occurred in one DMAP flap. Congestion was observed in another DMAP flap, and a leech was used. In all cases, there was no infection, hematoma, and additional surgery.

Conclusion
Use of skin graft to donor site was avoided in all cases, and all donor sites could be successfully closed. Following careful consideration, DAP and DMAP flaps were useful for reconstruction of soft tissue defects of the fingers.

Innervated Reverse Digital Artery Island Flap through Bilateral Neurorrhaphy using Direct Small Branches of the Proper Digital Nerve

List of authors:
Yo Han Lee*, Young Ho Lee¹, Jihyeung Kim¹, Yeun Soo Kim¹, Che Ho Lee¹, Young Ju Chae¹, Qingyuan Li¹, Goo Hyun Baek¹
¹Seoul National University College of Medicine (Seoul)

Objectives / Interrogation: The reverse digital artery flap uses the radial or ulnar surface of the proximal phalanx of the involved digit and has been applied to sensate flaps using the superficial sensory nerve branch and the dorsal branch of the proper digital nerve. As these nerve branches innervate the dorsal surface of the finger, however, hypesthesia of the dorsal side of the middle phalanx is inevitable.
In the present study, we successfully used the innervated reverse digital artery island flap through bilateral neurorrhaphy by using the direct small branches of the proper digital nerve. In a previous cadaveric study, the anatomical constancy of the direct small branches of the proper digital nerve was verified, and these branches have been used in the innervated lateral middle phalangeal finger flap.

Methods: Thirty fingers of 25 patients who had the innervated reverse digital artery flap using direct small branches of the proper digital nerve were included in this study. The minimum follow-up duration was 24 months, and the average defect size was 2.8 cm².
First, the proper digital nerve and its direct small branches were dissected and preserved. Two or three branches that projected toward the donor flap were cut at the branching points from the proper digital nerve, preserving the proper digital nerve and dorsal branch of the nerve. The flap was then elevated and placed on top of the injured finger. Bilateral neurorrhaphy was performed, under a microscope using 10-0 nylon microsutures, between one or two direct small branches and the ulnar digital nerve stump, and between the branches and the radial digital nerve stump.

Results and Conclusions: In all cases, the pulp defects were successfully reconstructed with this flap. The average size of the donor flap was 3.9 cm². At 6 months after surgery, the average static two-point discrimination value was 5.9 mm, the average moving two-point discrimination value was 5.0 mm, and the average Semmes-Weinstein monofilament score was 3.79. At 1 year postoperatively, the average Cold Intolerance Severity Score was 20. The percentage total active motion was measured at 99 percent 2 years after surgery.
Because this flap does not sacrifice the proper digital nerve or dorsal branch of the nerve, the sensibility of the dorsal aspect of the proximal and middle phalanx can be preserved. This flap is cosmetically excellent, as it uses a donor flap similar to the injured fingertip and the donor scar can be hidden by adjacent fingers.

High Velocity Distal Radius Fractures - a cohort study

List of authors:
Alphonsus Chong*, Amaris Lim
1 National University of Singapore, National University Hospital (Singapore)
2 Department of Hand and Reconstructive Microsurgery, National University Hospital (Singapore)

Objectives / Interrogation: Distal radius fractures are common, potentially disabling injuries. Much of the research done has concentrated on low energy injuries in older patients. In contrast, less has been studied about this injury in young adults, or due to high energy injuries alone. For the latter, work has largely focused on the surgical management of these injuries.

In our practice, we perceived differences between the typical older patient with low energy distal radius fractures, and the less common high energy trauma fractures. These differences included patient and injury characteristics, as well as treatment choices. We performed this study to determine if such differences really existed. If so, the findings would have implications for injury prevention, diagnosis, treatment, and eventual outcome.

Methods: Patients with distal radius fractures who were treated at our institution, were obtained from our database. This included demographic data, injury mechanism, fracture classification (using the AO classification), associated injuries, work-related injury, and associated distal ulna fractures, treatment types, complications and outcomes.

Results and Conclusions: The high velocity distal radius fracture (HVDRF) patient was on average 20 years younger (95% CI 17.1 to 22.9 years), and likely male (77.8% vs 27.3% in the low velocity group, p < 0.05). These group of patients were also more likely to have sustained work related injuries.

Falls, sporting injuries and motor vehicular accidents were the most common causes of high velocity injuries. From falls, 17/41 (41%) were due to a fall from height greater than 2m.

There were also significant differences in the fracture patterns and associated injuries in these patients. All the bilateral fractures came from the high velocity injury group (p < 0.05). Based on the AO classification, the HV group had a much high incidence of AO B type fractures compared to the LV group, were more likely to have associated injuries, including an concomitant ipsilateral arm injury.

The high velocity injuries represent a substantial patient group that has different patient and injury profiles compared to the better-studied osteoporotic fractures. The result of these contrasting profiles is a different treatment profile between the two groups. In order to better understand, treat, and prevent them, HVDRF injuries deserves to be considered a distinct entity, much as paediatric distal radius fractures are now considered separately from osteoporotic adult fractures.

Arthroscopic-assisted reduction and internal fixation with pin-plate construct for distal radius volar rim fracture

List of authors:
Yun-Liang Chang*

1 National Taiwan University Hospital (Taipei)

Objectives / Interrogation: Fixation of volar rim in distal radius fracture remains challenging. Small fragment of volar rim fracture may not be easily fixed with conventional implants. Currently, the fixation methods for volar rim fracture includes volar rim plates, fragment-specific devices and pin-plate construct. Volar rim plates can cover more volar rim area compared to regular volar plates, but they also cause more tendon irritation and volar radiocarpal impingement. As a result, volar rim plates usually need to be removed after fracture union. Fragment-specific devices includes small hook plates or various buttress pin implants. They can effectively fix small volar fragments without causing much soft tissue irritation or impingement. However, this kind of implants may not be available in many countries or facilities. Pin-plate construct was also proposed for volar rim fracture, using the common volar plates and Kirschner wires which are available for most facilities. Compare to volar rim plates, pin-plate construct may also cause lesser hardware irritation since the plate is not placed distal to watershed line. Combined with wrist arthroscopy, accurate reduction of volar fragment can be achieved.

Methods: In this article, we demonstrate our cases using arthroscopic-assisted reduction and internal fixation of volar rim fracture with pin-plate construct. Three patients with volar rim distal radius fracture were treated with this method. Bony union were achieved in all three patients without further displacement. No volar tendon irritation or impingement were noted. One patient with poor compliance of physical therapy results in limited wrist flexion and extension, which need for further implant removal and arthroscopic release after one year. Another patient developed extensor pollicis longus tendon rupture about 5 months after operation, which tendon transfer was done.

Results and Conclusions: Arthroscopic-assisted reduction and internal fixation with pin-plate construct can effectively fix volar rim fracture of distal radius. Advantage of this method includes accurate reduction, reliable volar rim fixation with lesser volar tendon irritation. However, proper pin length and adequate post-operative rehabilitation can be crucial for avoidance of complications and achieving better outcomes.

Is it worth operating severe, old carpal tunnel syndrome? Which technique?

List of authors:
Amina Shammat*, Vladislav Gyebrnar, Mihaela Mastacaneanu, Izabela Popa, Veronica Romanescu
1 University Emergency County Clinical Hospital "Pius Brinzeu" (Timisoara)
2 CHU Martinique, SOS Main, Hopital Pierre Zobda Quitman (Fort-de-France)
3 Office of Neurology "Dr Izabela Popa" (Timisoara)

Objectives / Interrogation: Nerve conduction studies (NCS) in carpal tunnel syndrome (CTS) stage 4 show sensory nerve action potential absent but motor response preserved, distal motor latency to abductor pollicis brevis 4.5 ms to 6.5 ms. After several years of disease evolution, median nerve fibrosis is always present. We presume that median nerve epineurolysis (MNE) improves the result of the carpal tunnel release (CTR) in all cases of long lasting, stage 4 CTS (prospective study).

Methods: Inclusion criteria: stage 4 CTS (NCS), at least two years of evolution, nocturnal pain interfering with sleep, neurologist's recommendation for MNE. All patients were operated by the same surgeon, using mini-invasive CTR. In all cases, the epineurium of the median nerve was visibly fibrosed and MNE was performed. Postoperatively: 5 days of AINS, 10 days compressive dressing, follow-up at 12-14 days. All patients completed a questionnaire one day before and one year after surgery. Patient-reported outcomes regarded nocturnal pain and awakening, numbness resolution (measured on visual analogue scale VAS) and overall satisfaction. The NCS were performed by the same neurologist, 1-2 months preoperatively and one year after surgery, using the same device and technique.

Results and Conclusions: We included 208 patients (331 hands), 73 male, mean age 56,5 years. Twenty-two patients had more than 3 months of sick leave in the past year prior to surgery and 16 had to change their workplace. Simple CTR led to median nerve hyperemia. Intraoperative fibrosis was assessed visually and tactiley. Following MNE, the nerve increased in volume. The pain resolution was immediate (7.9 preoperatively to 1.4 VAS postoperatively). Numbness remission was noticed at 2-3 months (7.2 preoperatively to 2.3 VAS postoperatively). All patients were very satisfied with the results. Electrophysiological findings: the distal latencies diminished by a mean of 0.5 ms and the compound muscle action potentials CMAP increased with around 1,5 mV.

No matter how old is a severe CTS, there was a definite improvement in all operated cases, mainly regarding the disparition of pain. All patients with long-lasting evolution of CTS must undergo NCS to evaluate the severity of the disease and median nerve fibrosis (standard of care). In stage 4 CTS surgical intervention is still indicated, but mini-invasive carpal tunnel release needs to be completed by epineurolysis. Intraoperative NCS might be the next step in predicting the need for MNE.

Objectives / Interrogation: Axial loading of a wrist with deficient scapholunate ligament (SLL) induces scaphoid flexion and pronation, the radioscaphoid peak pressure displacing dorsoradially.

This study was designed to document the alignment of the scaphoid and the lunate under axial traction as opposed as what we know for axial compression.

Methods: The changes in the alignment of both, scaphoid and the tandem lunate-triquetrum, were assessed in 5 fresh normal cadaver wrists, axially loaded first and then axially tractioned, using an electromagnetic motion tracking device. The experiment was subsequently repeated after complete scapholunate ligament (SLL) sectioning and the results assessed using ANOVA with repeated measures. Significance was set at p<0.05.

*<0.05 relative to SLL intact
Wrist traction substantially modifies the scaphoid misalignment typically found in the axially loaded SLL deficient wrists.

Consequently, it is mandatory to completely release the arthroscopic traction in three circumstances:
(1) when testing the scapholunate gap from the midcarpal joint,
(2) when checking the dorsoradial radioscaphoid impingement in the radiocarpal joint
and (3) when fixing percutaneously the scaphoid flexion-pronation misalignment, to avoid an incomplete scaphoid supination restoration.

Prospective study of needle fasciotomy for Dupuytren's contracture with four years follow-up

List of authors:
Sinolichka Djambazova*, Dusanka Grujoska1, Vejsel Salmani1
1Hospital for Orthopedic Diseases University (Skopje)

Objectives / Interrogation: The advantage of needle fasciotomy is a very short recovery combined with high cost effectiveness compared to open surgery. The purpose of this study is to report results, reduction of contracture, complications and early recurrence after four years.

Methods: The indication was contractures of the MCP joint in stages I, II, III and IV with well defined fibrosis. The contracted Dupuytren's tissue is divided longitudinally along multiple points so that the finger can stretch out straight again. The procedure is performed with a needle through the skin and the sharp, small bevel of the needle is used to cut the Dupuytren's tissue beneath the skin. We also administer a corticosteroid injection to the treatment area at the time of the procedure. Stretching, exercises and extension splinting during the recovery phase are important to gain maximum benefit from the procedure. The patients were evaluated preoperatively and per-operatively at one, eight, twenty-four weeks, after one, two, three, four years. 117 patients with 129 fingers were operated. Median age was 59 (44-74) with 114 man and 3 women.

Results and Conclusions: No cases of flexor tendons lesions, hematomas or infections were registered. The patients were allowed to use the hand directly after the procedure. Needle aponeurotomy does not involve incisions to the skin of the hand, so there is less tissue damage, less swelling, less pain, less down time and quicker healing. Needle fasciotomy is a good alternative in cases with well defined fibrosis because of these preliminary good results and low morbidity.

Percutaneous neutralisation screw fixation with scaphoid arthroscopic bone grafting

List of authors:
Nicholas Smith*
1 4/410, Edgecliff Road, Woollahra (Sydney)

Objectives / Interrogation: Arthroscopic cancellous bone grafting of the scaphoid is a technique with many potential advantages - high union rates, minimally invasive and less deep scarring. The associated fixation is generally buried Kirschner wire fixation, as described by PC Ho. The fixation must remain in situ until union is confirmed, and generally mobilisation must be minimal while the wires remain, due to the risk of migration and soft tissue irritation.

Since cancellous bone grafting is performed, which will not resist compression, headless compression screws are not preferred, since they may lead to deformity, in the presence of a defect. We have designed a non-compressive neutralisation screw, which will hold the scaphoid in its corrected position before the cancellous graft is inserted.

Methods: Study Material
The rationale for the implant design is discussed, and the surgical considerations which have been considered in fine tuning the technique.

Finite element analysis of the implant versus 3 K-wires is presented.

The surgical technique and some cases are presented.

Operative method
Dry arthroscopy is the presenter's preferred option. My preference is for 3 midcarpal ports, the most ulna is the radial midcarpal. The non-union is debrided to cancellous bone.

The wrist is then removed from traction. If there is deformity, a temporary Linscheid wire may be used to stabilise the lunate to the radius. The wrist is then extended over a bump and a retrograde K-wire inserted with image intensification. The correction and wire position are assessed with fluoroscopy. The wire is over-drilled, then the screw inserted. Traction is re-applied and the joint and fixation assessed arthroscopically. Cancellous bone graft is then inserted and sealed with fibrin glue.

Results and Conclusions: Results
The interference screw fixation is markedly more stable than 3 K-wire fixation, as assessed by finite element analysis. Some cases where passive motion has begun prior to bony union are presented.

Discussion
This screw design has the potential advantages of increased stability, which may allow the surgeon to hold correction of deformity without the use of a post-operative Linscheid type wire. It also allows earlier motion, which in conjunction with arthroscopic surgery, may lead to improved range of motion. It also avoids associated K-wire complications and the need for K-wire removal.

Conclusion
The role of intereference, non-compressive screw fixation with arthroscopic scaphoid bone grafting is presented.

Trapeciectomy versus joint replacement in basal thumb osteoarthritis. Prospective study.

List of authors:
Pilar Aparicio*, Òscar Izquierdo, Enric Domínguez, José Torres, Juan Castellanos
1 Parc Sanitari Sant Joan de Déu (Barcelona)
2 Consorci Mar Parc de Salut (Barcelona)

Objectives / Interrogation: Osteoarthritis of the base of the thumb is one of the most prevalent sites of osteoarthritis in the upper limb leading to pain and disability of the hand.

None of the available surgical treatments have proved to be superior to another.

We designed a prospective study in which we compared the clinical outcomes after performing two surgical techniques: joint replacement (Maïa prosthesis, MP) and trapeciectomy with ligament reconstruction and tendon interposition (following Burton-Pellegrini technique, BP).

Methods: Sixty-eight patients with first carpometacarpal joint osteoarthritis grade III of Eaton-Littler were included in this prospective one-year follow-up study comparing joint replacement (MP), n = 43, with trapeciectomy with ligament reconstruction and tendon interposition (BP), n=25.

Pain (using AVS), opposition (using Kapandji index), terminolateral pinch strength and grip strength (using dynamometer) disability and quality of life (using DASH and SF36 questionnaires), were assessed preoperatively and during the follow-up at 4 and 12 months.

The role of nerve conduction studies in diagnosing and staging of the carpal tunnel syndrome

List of authors:
Amina Shammat*¹, Vladislav Gyebrnar¹, Mihaela Mastacaneanu², Izabela Popa³, Veronica Romanescu³
¹ University Emergency County Clinical Hospital "Pius Brinzeu" (Timisoara)
² CHU Martinique, SOS Main, Hopital Pierre Zobda Quitman (Fort-de-France)
³ Office of Neurology "Dr Izabela Popa" (Timisoara)

Objectives / Interrogation: Carpal tunnel syndrome (CTS) diagnostic is based on clinical symptoms and physical examination, usually confirmed by electrodiagnostic methods. We wanted to assess the diagnostic value of nerve conduction studies (NCS) and if it can be correlated with intraoperative findings (retrospective study).

Methods: Between 2009-2017, 353 patients presented with symptoms of CTS. All patients underwent NCS by the same neurologist 1-3 months before surgery, resulting in CTS staging and indication for median nerve neurolysis (MNE) in selected cases. Surgery performed by the same surgeon - mini-invasive CTR +/- MNE. The operated patients have completed a questionnaire before the procedure and one year postoperatively. NCS was repeated one year after surgery.

We studied the correlation clinical symptoms / NCS result; recommendation to perform MNE based on NCS / intraoperative aspect of the median nerve; the obtained results (patient-reported outcome and postoperative NCS).

Results and Conclusions: NCS did not confirm CTS in 16 patients; other neuropathies with symptoms of median nerve entrapment were diagnosed.

We included 275 patients (446 hands). Cf. Bland (2000) electrophysiologic classification, there were 15 hands (3.36%) grade 2, 93 hands (20.85%) grade 3, 311 hands (69.73%) grade 4 and 27 hands (6.06%) grade 5. No patients with grade 1 or 6 were diagnosed during the study.

Based on NCS, the indication for MNE was recommended for 342 hands (76.68%). In all these cases, median nerve fibrosis was noted intraoperatively and MNE was done. In 8 hands we did MNE without neurologist's recommendation.

Clinical relief was noted in all cases. On visual analogue scale, the pain decreased from 6.2 preoperatively to 0.8 postoperatively, and paresthesia from 5.7 preoperatively to 0.5 postoperatively. All patients were satisfied or very satisfied with the outcome. The electrophysiologic parameters improved: distal latencies diminished with about 0.5 ms, even to normal values, nerve conduction velocities either increased or became normal. The recovery of sensory and motor function varied from good to excellent. In situations with severe axonopathy the degree of denervation in EMG was reduced.

NCS is the standard of care for the positive and differential diagnosis of CTS and for staging the disease. Postoperative NCS help in controversial cases (simulations, litigations, recurrences).

The recommendation for MNE based on NCS correlates excellently with intraoperative findings.

Intraoperative NCS is expected in the future.

"Stepwise" method of arthroscopic reduction and plate fixation of intra-articular distal radius fractures - an evolution of technique and instrumentation

List of authors:
Nicholas Smith*1
1 4/410, Edgecliff Road, Woollahra (Sydney)

Objectives / Interrogation: Arthroscopic visualisation of articular fractures of the distal radius can allow accurate reconstruction of the articular surface whilst minimising disruption of the dorsal capsular structures. In minimising the iatrogenic injury, this may lead to improved outcomes, though this remains unproven.

Technically, one of the most challenging problems is how to hold the reduction while definitive fixation is employed. Where a volar locking plate is used, typically the plate is applied with proximal fixation, prior to the arthroscopy and articular manipulation. Two technical difficulties often ensue. Firstly maintaining accurate reduction of volar fragments after applying traction. Secondly, inserting distal locking fixation whilst holding the articular reduction under arthroscopic visualisation with the wrist in traction. It is difficult to simultaneously maintain traction for arthroscopy, and retraction to allow safe introduction of the drill and screws.

Methods: The stepwise technique and the newly evolved fixation are presented.
A trans FCR approach is used. The volar cortex is reduced under direct vision. The plate is fixed proximally with screws. Interference K-wire sleeves are then applied to the distal locking screw holes. K-wires are then introduced only as far as the volar fragments, using II. The dorsal fragments remain free.
Traction is applied, dry arthroscopy performed using 1/2, 3/4 and 6R ports.
The articular surface is reduced by the surgeon and provisionally fixed by advancing the wires. Traction is removed, correct wire length assessed with II. Using the cannulated system, peg length is calculated, the sleeve removed, the wire overdrilled, and cannulated locking pegs inserted over the wires.

Results and Conclusions: Results
Some cases will be briefly presented to illustrate the technique.

Discussion
The technique may bring this technically challenging method into the repertoire of most capable wrist arthroscopists. As each step of the surgery is completed, the articular surface is brought closer to anatomical alignment, with increasing stability. The chance of a backwards step is minimised, decreasing frustration and optimising the result.

Conclusion
An evolution of surgical technique and instrumentation for arthroscopic reduction and stable fixation of exploded articular fractures of the distal radius is presented.

Osami Suzuki*, Takaya Mizuseki1, Tetso Masuda1
1 Hiroshima Prefectural Rehabilitation Center (Higashi-hiroshima)

Objectives / Interrogation: We treated two patients with old digital nerve injury complaining persistant pain in fingers by dissection of the injured part and artificial nerve graft. The artificial nerve is consisted of atelocollagen gel core and polylactic acid (PLLA) shell. In both patients, the same postoperative course were recognized and reported in this article although they are short-term results.

Methods: Case 1, 52-yea-old woman. She got a small cut wound on the radial side of the medial segment of the left index finger while cutting a tin plate. Although the wound was sutured at nearby clinic, persintant pain and numbness remained more than 6 months. Surgery was performed 8 months after injury. The injured part of the radial digital nerve was covered with scar tissue. When the part was dissected, it became a nerve deficit of 10 mm. The defect was reconstructed with a 10cm length, 1.5 mm diameter artificial bridge nerve graft.

Case 2, 65-year-old man. He cut the palmar side of the right index finger at the PIP joint level with a kitchen knife. Persistant pain and numbness remained in the ulnar side of the finger. Surgery was performed 9 months after injury. The injured ulnar digital nerve was completely torn and there was formation of a stump neuroma on the proximal side. The neuroma was dissected and the defect was reconstructed with 20 mm length, 1.5 mm diameter artificial nerve graft.

Postoperative immobilization with a cast was performed for 2 weeks followed by an automatic exercise in both patients.

Results and Conclusions: In case 1, pain and numbness of the left index finger completely disappeared immediately after the operation. However, numbness appeared again at 3 weeks after surgery and Tinel sign was recognized at distal level of the grafted artificial nerve. Nine months after surgery, she was satisfied with the result of no pain but had weak numbness that was gradually improving. The touch sensation by Semmes-Weinstein (S-W) test was normal.

In case 2, pain and numbness of the right index finger also disappeared immediately after surgery. However, numbness and Tinel sign was recognized 5 weeks after surgery. Eight months after the operation, he was satisfied with no pain although slight numbness still remained. The result of S-W test was diminished light touch.

We concluded artificial nerve graft is effective for pain relief for the patients of old digital nerve injury. However slight numbness will remain in a short-term.

Usefulness of Eppikajutsuto for lymphatic malformation

List of authors:
Shigeko Ushio*1
1 Sendai plastic surgery clinic (Sendai)

Objectives / Interrogation: There are macrocystic pattern and microcystic pattern in lymphatic malformations, and sclerotherapy using various curing agents is very effective in the former case, but in the latter case, treatment is often difficult. We were able to control by using the traditional Chinese medicine Eppikajutsuto for the case of recurrence after extirpation of the lesion and the diffuse case difficult to treat. We will examine its use experience and report on the usefulness of Eppikajutsuto for this disease.

Methods: From 2016 to March 2018, image findings and clinical course were examined for recurrent cases and pervasive cases after surgical operation.

Results and Conclusions: In all cases, side effects of Eppikajutsuto were not recognized, and oral administration continued. Although no significant reduction was observed, certain effects such as suppressing increase and decreasing the frequency of infection were observed. It is a disadvantage that the amount of internal use of the day is large and the taste is bitter, but it was possible to cope with children by devising such as enclosing it in chocolate. Eppikajutsuto is a traditional Chinese herbal medicine used for nephritis, nephrosis, rheumatoid arthritis, dermatitis, etc. In 2011, Ogawa et al reported on the usefulness of lymphatic malformations, and gradually the use cases have gradually increased since then. Our case administered Eppikajutsuto acted effectively in all cases and it seemed to be very useful for lymphatic malformations which had been difficult to treat until now. However, it is sometimes necessary to carefully use such as a person with a weak constitution, a person with a bad gastrointestinal condition, a person with a lot of perspiration, etc. Therefore, it is necessary to grasp the state of the patient in detail and use it.

Bone tumors of the upper extremities. A case series.

List of authors:
KONSTANTINOS TOLIS*, Emmanouil Fandridis¹, Filippos Giannoulis¹, Christos Eftychiadis¹, Sarantis Spyridonos¹
¹ GENERAL HOSPITAL KAT (ATHENS)

Objectives / Interrogation: The presence of benign and malignant bone tumors that arising in the upper extremities are rare in comparison to other anatomical locations. Even rare are large epidemiological series presenting those lesions in literature.

Methods: We retrospectively reviewed the medical archives of the Microsurgery, Hand and Upper extremity Department, considering patients who were operated for bone tumor and tumor like lesions between 1995 and 2015. Patients were reviewed for demographic data, type of tumor and affected area.

Results and Conclusions: Results: From a total of 1102 patients who were operated for any tumor during a period of 20 years, 143 patients (13%) were found suffering from a bone tumor. 65 patients (45%) were male with a mean age of 38,41 years, while females (78 patients/55%) had a mean age of 38,74 years. Histopathological studies revealed 12 cases (8,4%) of malignant tumors affecting 9 women(6,3%) and 3 men (2,1%), 5 (3,5% of total) of whom were considered primary.

79 patients (55,25%) had a bone tumor on their right extremity, 44 of whom where women. Considering the anatomical area, the hand (104 patients, 72,7%) was most affected, followed by the humerus (13 patients, 9%), the radius and ulna (12 patients, 8,4%), the carpal bones (6 patients, 4,2%), while 8 patients (5,6%) affected at the elbow, clavicle and the scapula. Enchondroma is the most common neoplasma (59 patients, 41,3%), followed by osteochondroma (18 patients, 12,6%), osteoid osteoma (12 patients, 8,4%) and GCT of the bones (7 patients, 4,9%). Other types of bone tumors cover the 32,2% of cases.

Conclusion: Our series confirms the fact that malignant bone tumors are extremely rare in the upper extremity, as well as that the hand is the most affected area considering a variety of bone tumors. Enchondromas cover the majority of cases. Since our department is considered a reference center for upper extremity and hand surgery, this study can be a useful tool when dealing with bone lesions at the referred anatomical areas in the Greek population.

Evaluation using the preoperative three-dimensional computed tomography and clinical results for surgical treatment of mallet fractures

List of authors:
Shunsuke Nishimoto
1 Kansai Rosai Hospital (Amagasaki, Hyogo)

Objectives / Interrogation: Many authors have reported the good results of the extension block technique described by Ishiguro et al. for the treatment of mallet fractures. However, there are several cases that postoperative extension lag and incongruity of joint surface remain. We aimed to evaluate the clinical results using preoperative three-dimensional computed tomography (3D-CT).

Methods: Between 2012 and 2017, 23 patients (11 men and 12 women; mean age, 35.4 years; range, 12-70 years) with mallet fractures were treated using the extension block pinning by Ishiguro method. Konishiike et al. classified the mallet fractures into 4 types: type 1, avulsion; type 2, rotate avulsion; type 3, split avulsion; and type 4, split compression. According to this classification, there were 3 cases of type 1, 5 cases of type 2, 7 case of type 3, 8 case of type 4. Evaluation of preoperative 3D-CT was classified as center (non-deviation group) and ulnar or radial side (deviation group) in the deviation direction of the bone fragment. Patient outcomes were assessed with DIP range of motion measurement, radiographic examination, range-of-motion measurements, and Crawford classification.

Results and Conclusions: This mean follow-up period was 4.2 months (range, 2-12 months). In preoperative 3D-CT, the non-deviation group were 15, and the deviation group were 8. In Konishiike classification, type 4 was the most frequent in the no-deviation group and type2 was the most frequent in the deviation group. At the final follow-up, the mean extension angle in the non-deviation group was -8.6°, which was significantly different from that of the deviation group (mean, -16.8°). The step-off was seen in the deviation group significantly compared with the no-deviation group in the X-ray. Crawford classification was no significant difference between the non-deviation and the deviation group. It is considered restoring the joint surface with accurate reduction to be important to prevent secondary osteoarthritis, and loss of movement. In the evaluation of bone fragment for mallet fractures, it may be difficult to assess the displace of it in the X-ray. In the preoperative 3D-CT evaluation, the clinical results were poor in the deviation group compared with the no-deviation group. Therefore, 3D-CT examination is a useful, and it is suggested that it will help to determine the surgical technique for mallet fractures.

HISS SCORE AND MODIFIED VASCULAR HISS SCORE CORRELATION WITH SHORT AND LONG-TERM OUTCOMES IN COMPLEX HAND INJURIES: A RETROSPECTIVE PRELIMINARY STUDY.

List of authors:
Letizia Senesi*, Francesco De Francesco2, Antonio Gigante3, Michele Riccio2
1 Clinical Orthopeadics, DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)
2 DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)
3 Clinical Orthopeadics (Ancona)

Objectives / Interrogation: Complex hand traumas (CHT) are critical injuries that involve three different structures in the same digital ray at least or one structure in two digital rays at least. These lesions are very difficult to approach and even if they are subject to immediate and correct surgery, outcomes are scarce due to the complexity of injury. The aim of the present study is to verify the incidence of CHT and to investigate the hand injury severity score (HISS) correlation with short and long terms outcomes in these patients.

Methods: From 2012 to 2016, we treated 227 CHT patients arrived in our department. Patients were classified by age, sex, traumatic mechanism, involved digital rays and type of surgical treatment. For each class of traumatic mechanism, we verified HISS score and its correlation with qDASH score recorded at follow-up. We also verified if HISS score might be a short-term prognostic factor.

Results and Conclusions: Among all 227 CHT patients, we counted 201 males and 26 females. The average age when trauma occurred was 49 for males and 47 for females. The most common mechanism of trauma was crushing (125 occurrences). Trauma were mostly pluri-digital (52%). Specifically, we focused on avulsion as mechanism of trauma which concerned 33 patients, accounting for 48 fingers in total (2 were excluded because they were ring finger avulsions). Amputation was performed immediately in 11 patients and in 4 cases at the second look. Eighteen where did not receive this treatment. Patients were classified retrospectively according to HISS score. Residual disability was evaluated with qDASH score at average time of 22 months after trauma. Statistical analysis was performed with Spearman's test and it shows a positive correlation between HISS score and qDASH (p=0.85, p=0.001). We also propose a modified HISS score (modified vascular HISS score, mV-HISS) with additional parameters for vessels examination, and we investigated its possible usefulness as short-term prognostic factor. In conclusion, CHT are serious injuries with significant economic and social consequences for patients and represent a great challenge for hand surgeons. For avulsion as mechanism of injury, HISS score had a statistically significant prognostic factor in long terms outcomes for patients. mV-HISS score might be a valuable prognostic tool in understanding short terms outcomes in CHT.

Minimal endoscopic release procedure of ulnar nerve in the cubital tunnel

List of authors:
Dawid Mrozik*, Agnieszka Jackiewicz
1HANDPROJECT Clinic, SWISSMED Private Hospital (Gdansk)

Objectives / Interrogation: Compression of the ulnar nerve in the cubital tunnel is the second most frequent entrapment neuropathy of the upper extremity after carpal tunnel syndrome. None of the described techniques have proved to be superior in randomized prospective trials. We therefore present our series of endoscopically decompression of the ulnar nerve at the elbow to determine the effectiveness of this procedure.

Methods: It was prospective, non-randomize two-center clinical study. In 45 patients: 25 men and 20 women (age's range 28-77) with clinical McGowan grade I (6 patients), II (29 patients), and III (10 patients) and electrophysiological signs of cubital tunnel syndrome, 21-cm of the ulnar nerve was released through a 2-cm long skin incision. Diagnosis was based on history, clinical examination (i.e. pain over medial epicondyle, sensory loss, positive Tinel's sign, weakness or atrophy of the muscles innervated by the ulnar nerve, and positive elbow flexion test) and confirmed by neurophysiological studies (nerve conduction velocity and electromyography). A 4-mm, 30° standard endoscope and Wolf retractor were used during the procedure, and the mean postoperative follow-up examination was 12 months.

Results and Conclusions: Results: There were no visible nerves and vessels injured during the procedure. The main postoperative complication was hematoma in 4 patients that resolved after conservative management. There was no elbow extension deficit after surgery and surgical wounds all healed within a week. Grip strength showed a highly significant increase after surgery. Outcomes were excellent in 27 of 45 cases and good in 13 of 25 cases. Grip strength showed a highly significant increase after surgery compared to the non-operated hand (p<0.005). The mean DASH score was decreased significantly about 65% (from 74,8 before operation to 26,3 after procedure) (p<0,005). 88% patients were satisfied with the procedure.

Conclusion: Endoscopic technique for treating cubital tunnel syndrome is a safe and reliable procedure, characterized by a short incision, minimal soft tissue manipulation, less scar sensitivity and early postoperative mobilization. It demonstrates promising benefits against conventional approaches (complete release and good visualization), and reduced complication profile (painful scarring and elbow contracture). Endoscopy is a widely imaging study for assessing nerves providing useful information on the severity and stage of nerve pathology.

Basilar thumb arthritis: early mobilization versus splinting after trapeziectomy with ligament reconstruction and tendon interposition

List of authors:
Daniela Pereira¹, Sérgio Figueiredo¹, Vítor Rodrigues¹, Luís Machado¹, Carlos Ferreira¹, Carlos Pina¹
¹ Centro Hospitalar de Leiria (Leiria)

Objectives / Interrogation: The aim of this study was to evaluate the clinical, functional and radiographic benefits of the postoperative immobilization after trapeziectomy with ligament reconstruction and tendon interposition according to Burton-Pellegrini technique.

Methods: A randomized prospective 2:1 study comprised of a sample population of 15 individuals was performed, excluding those who had previous surgeries of this joint and those who do not present the adequate follow-up. Post-operative splinting for a length of 4-6 weeks was performed in 5 patients and not in the remaining 10. The gender, age, laterality and the hand dominance were ascertained. The following parameters were evaluated preoperatively, in the period of 4 to 6 weeks and at 3 and 6 months: Visual Analog Scale (VAS) for pain, QuickDASH, grip strength, palmar and lateral pinch strength. The Dorsal Subluxation of the first metacarpal and the scaphometacarpal distance were measured. The comparison of evolutionary pattern between groups was made by a Repeated Measures Analysis of Variance (rANOVA), assuming Greenhouse-Geiser correction due to an absence of sphericity. Statistically significant value was considered for p <0.050.

Results and Conclusions: All subjects were female, with a median age of 60.5 years (interquartile range of 10.0 years), with no statistically significant differences between groups (p = 0.662). Follow-up for both groups revealed a favorable evolution for all the considered variables (p<0.050). When comparing groups, considering age, dominant hand involvement and Eaton's classification as confounders, only the VAS measured at rest and lateral pinch strength revealed statistically significant measureable differences (p=0.011 and p=0.013), both favoring early motion. The surgical technique according to Burton-Pellegrini's original description includes a 4-week immobilization period with subsequent onset of active motion, with additional protective splinting ranging from 2 to 4 weeks. In this study, up to 6 months after surgery, immobilization between 4 and 6 weeks did not prove to be superior to immediate motion, in regards of pain management, functional development, grip, palmar and lateral pinch strength. Also with regard to imaging parameters, there was no benefit in the use of splint. Although this result may question the true usefulness of splinting in the postoperative surgical treatment of basal thumb arthritis, it will be necessary to include more patients, as well as a longer follow-up to confirm the results obtained.

Supplemental Method for Reduction of Irreducible Mallet Finger Fractures by the Two Extension Block Technique: The Dorsal Counterforce Technique

List of authors:
Young Ho Lee*, Seung Hoo Lee¹, Yo Han Lee¹, Yeun Soo Kim¹, Che Ho Lee¹, Young Ju Chae¹, Qingyuan Li¹, Goo Hyun Baek¹
¹Seoul National University College of Medicine (Seoul)

Objectives / Interrogation: Extension block pinning consists of a dorsal extension block K-wire and a second volar K-wire to hold the DIJ in extension. This technique has been modified by several authors to improve the accuracy of reduction and stability of fixation. However, dorsal fragments that are large, markedly displaced, or rotated are not easily controlled with a single extension block K-wire. In many cases, this is due to rotation of the dorsal fragment in the axial plane. To address these limitations, we previously proposed a modified procedure, the two extension block K-wire technique. An anatomic reduction is more easily obtained with two extension block K-wires. Together, the wires create a broader stabilizing force that prevents rotation of the dorsal fragment in the axial plane when a reduction force is applied. The parallel and lower angled wires contact a wide area of the fragment, and the fragment is strongly compressed when the distal phalanx is extended. However, there are limitations to this technique in certain circumstances. While two extension block wires can prevent the dorsal fragment from migrating proximally and rotating in the axial plane, they cannot exert sufficient compressive force against the distal part of the dorsal fragment. This results in dorsal rotation of the dorsal fragment in the sagittal plane. The goal of the study was to describe the results of a supplemental method to achieve anatomical reduction in cases that are insufficiently treated by the two extension block K-wire technique.

Methods: Of 95 displaced mallet finger fractures treated using a modified two extension block Kirschner-wire (K-wire) technique, 18 (19%) were found to have an irreducible dorsal fragment and distal interphalangeal joint (DIJ) incongruence, due to rotation of the dorsal fragment in the sagittal plane. In these cases, we additionally employed a dorsal counterforce technique to supplement the two extension block technique. An additional K-wire was used to apply counterforce against the distal part of the dorsal fragment and control rotation in sagittal plane.

Results and Conclusions: All 18 fractures united. Congruent joint surfaces and anatomical reduction were seen in all cases. The mean active flexion of the DIJs was 83.8° (range, 79-88°) and the mean extension loss was 0.4° (range, 0-4°). We believe that the dorsal counterforce technique effectively supplements the two-extension block K-wire technique and aids control of dorsal fragment rotation in the sagittal plane.

Web creep control with a novel orthosis

List of authors:
Qinyuan Yu*, Bin Wang, Tong Zhang, Guodong Huang, Zhe Li, Taoli Wang
1 Shanghai Yangzhi rehabilitation hospital (Shanghai)
2 Shanghai Ninth Peoples Hospital (Shanghai)
3 Shanghai Normal University TIANHUA College (Shanghai)
4 Shanghai University of Medicine&Health Sciences (Shanghai)

Objectives / Interrogation: Web creep is the most common complication after syndactyly separation. We developed a novel orthosis which can exert consistent pressure on web and incision scar postoperatively. The orthosis is applied with silicone sheet simultaneously. The study was to evaluate the aesthetic and functional outcomes using this novel orthosis to control web creep.

Methods: A total of 71 patients underwent syndactyly separation in past 10 years were included in the study. Among these patients, 40 patients used the novel orthosis, while 31 cases used traditional splinting and scar massage postoperatively. We assessed the height and width of the webs according to the criterion of D'Arcangelo, and total active digital motion compared with the normal side. Scar formation was measured by the Vancouver Scar Scale score. We also administered a parent-based satisfactory questionnaire.

Results and Conclusions: The mean follow-up period was 4.5 years. The height and width of 36 webs were good, 3 webs were fair, and 1 web was poor in the group using the novel orthosis, while 13 webs were good, 10 webs were fair, and 8 webs were poor in the group using the traditional method. Mean total active motion of the index, middle, ring, and little fingers of the affected side was 160, 158, 153, and 150 in orthosis group, respectively, which was significantly greater than those in traditional group. Mean Vancouver Scar Scale score was 1.4 in orthosis group, which was better than that in traditional group with the score of 3.1. All parents were satisfied with the appearance and function of the fingers in orthosis group. In conclusion, applying the novel orthosis was a reliable method to control web creep and restore hand function for patients with syndactyly separation.

DISTAL PHALANX Fractures MANAGEMENT WITH 23 GAUGE PERCUTANEOUS NEEDLES VS KIRSCHNER WIRES.

List of authors:
Francesco De Francesco*¹, Letizia Senesi², Andrea Marchesini¹, Pier Paolo Pangrazi³, Michele Riccio¹
¹ DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)
² Clinical Orthopedics, DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)

Objectives / Interrogation: The most common fractured bone in the hand is the distal phalanx (DP). These fractures are often managed conservatively but the presence of high comminution or articular fractures with injuries of nail beds sometimes require a surgical approach. In literature, different techniques of internal fixation were described. The aim of the present retrospective study is to make a comparison between Kirschner wires vs 23 Gauge percutaneous needles in treatment of these fractures, evaluating functional outcomes and time to union.

Methods: We performed a retrospective study in patients who had DP fractures and were treated from 2013 to 2015. Collected clinical data include patient demographic data, mechanism of injury, type of treatment, follow-up, range of motion (ROM), and complications. Patients were divided into 2 groups based on methods of fixation (Group A: K-wire; Group B: 23-G needles) and we compared their baseline demographics and final outcomes accordingly. Statistical analysis was done using t-test for paired samples in case of variables normally distributed or Wilcoxon signed-rank test in case of not-normally distributions. Statistical significance was measured at p <0.01.

Results and Conclusions: A total of 60 patients with surgical DP fractures were treated. 12 of these were excluded from the study because of diabetes mellitus type II or because they are smokers. On remaining 48 patients, 14 were female and 34 were male. 23 patients (52%) had k-wire fixation (Group A) and 25 patients (48%) had 23-G crossed needle fixation (Group B). Time to union was 51 days for group A and 39 days for Group B. The difference was statistically significant (p<0.001). At the final follow-up (six months after surgery), the average DIP joint ROM was 45° for Group A and 60° for Group B. This difference was statistically significant (p<0.001). Side effects were 1 non-union in group B and 4 non-union in group A, which required surgery. In conclusion, the present study shows that DP fractures treated with 23 G percutaneous needles heal faster with a higher ROM, if compared to K wires. The present technique might be a valuable alternative, safe and cheaper if compared to other techniques for these fractures. However, nail bed repair and nail presence are fundamental elements to provide best clinical outcomes in patients.

distal phalanx fracture, DP treatment, percutaneous needles
CMC OSTEOARTHRITIS ARTHROSCOPICALLY TREATED BY HEMITRAPECECTOMY AND MINI TIGHT ROPE SUSPENSION

List of authors:
JOAQUIM CASANAS*, PAu Lopez Osornio¹, Cristobal Martinez Andrade¹, Silvia Lopez Marne²
¹ traumaunit. Centro Medico Teknon (SANT CUGAT DEL VALLES)
² Hospital de Bellvitge (Hospitalet de Llobregat)

Objectives / Interrogation:
We introduce our results of treating CMC osteoarthritis by distal hemitrapecectomy and mini tight rope suspension system performed with a minimally invasive technique and no implant device.

Methods: From 2014 to 2017, 41 patients have been surgically treat by arthroscopic CMC arthroplasty. Volar and dorsal CMC portals have been used, age ranges from 51 to 76 yo, 5 males and 36 females. Thumb traction was done in all cases, and no tissue or tendon interposition is done. All cases have type IV condral lesions in the trapezium and hemitrapecectomy was done by completely excised. When arthroscopic resection is completed under fluoroscope, a mini tight rope suspension system is implanted paying special attention that thumb abduction and retroversion range of motion must be complete. Clinical control is done with the Kaplan score, abduction and grip test; X-Ray controls are also done. Three cases with severe MTC-P hyperextension were treated with sesamoid metacarpal fusion.

Results and Conclusions: Patients mean follow up is 2.2 years. Pinch strength was restored between 100 to 80% compared to the contralateral hand at 4 months postop in 90% of cases, K10 in 87%. The mini tight rope had to be removed in 21% of cases because of disorders caused by metal plate or knot wire. Secondary surgery for trigger finger in the thumb happened in 12% of patients. No revision surgery was done neither to converse it into an arthroplasty or any other surgery on CMC. X-Ray haven't revealed to be a useful tool to evaluate results. Incomplete edge trapezium resection or narrowing arthroplasty have the same functional results to those cases with more 3 mm gap between bases of metacarpal and trapezium resection.

CONCLUSIONS
a very attractive method for patients. Functional outcomes are satisfactory despite we consider it can only be performed by highly skilled surgeons and there still is a high rate of suspension system removes. X-Ray is not a useful technique to get prospective results.

carpo metacarpal, arthroscopy arthroplasty, osteoarthritis
Recovery of Infracavicular Brachial Plexus Injury after Anterior Shoulder Dislocation

List of authors:
Feiran Wu*, Jagwant Singh, Chye Yew Ng
1 Wrightington Hospital (Wigan)

Objectives / Interrogation: We report the patterns of infracavicular brachial plexus injuries (BPI) after anterior shoulder dislocation and their functional recovery rates.

Methods: This was a retrospective review of a prospectively-maintained database of patients who presented with infracavicular BPI following anterior shoulder dislocation. Each patient was examined by the senior author. All underwent EMG and MRI of the affected shoulder. Patients were followed up until functional recovery was achieved.

Results and Conclusions: Between 2014-18, 42 patients (23 male:19 female) with a mean age of 61 years (range 15-87) presented with these injuries. There were 15 pure shoulder dislocations and 27 fracture-dislocations. Twelve had concomitant rotator cuff tears. Four patterns of nerve injuries were observed: a) Isolated axillary nerve (n=20), b) 3-cord plexopathy (5), c) 2-cord injury (axillary & medial - 2, medial & posterior - 4, posterior & lateral - 1), d) Single cord injury (medial - 6, posterior - 3, lateral - 1).

The mean follow-up duration was 15 months (SD 11). Overall, 45% had full spontaneous recovery, 29% had partial recovery and 26% had no recovery at the time of their latest review. All lateral cord palsies recovered spontaneously to M4/5 elbow flexion (either in isolation or in combination with other cords). Amongst 13 posterior cord palsies, 11 recovered to M4/5 elbow extension and 2 did not show recovery at the 7-month review. Of the 17 medial cord palsies, 6 regained M4/5 intrinsic power, 5 recovered to grade M1-3, and 6 did not show any recovery at a mean of 13 months post injury. For those with isolated axillary nerve palsy, 11 recovered to M4/5 deltoid power, one had M3 activity, one did not show recovery at 7-months, and 7 underwent radial-to-axillary nerve transfer at a mean duration of 9 months post injury.

Nerve injury following anterior shoulder dislocation is not necessarily a benign condition. Isolated axillary nerve palsy is the commonest associated nerve injury with 60% spontaneous recovery rate. Lateral and posterior cord injuries have the best spontaneous recovery potential. The presence of medial cord palsy signifies a more severe nerve injury and recovery of hand function is often poor. All nerve palsies should be monitored closely and early referral to a specialist nerve service is recommended.

THE ROLE OF NEW REHABILITATION PROTOCOL IN DUPUYTREN'S DISEASE

List of authors:
Francesco De Francesco*, Letizia Senesi, Oletta Serpilli, Elisa Romani, Pierfrancesco Pugliese, Michele Riccio
1 DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)
2 Clinical Orthopeadics, DPT of Reconstructive Plastic Surgery - Hand Surgery Unit. (Ancona)
3 Clinical Neurorehabilitation (Ancona)

Objectives / Interrogation: Dupuytren's disease (DD) is a benign fibroproliferative disorder characterized by the progressive development of a scar-like, collagen-rich cord within the palmar fascia of the hand which typically results in a permanent finger contracture. Recurrences are high in DD and its causes are almost unknown actually. In our opinion the adherence of an appropriate post-operative rehabilitation protocol is fundamental. In literature, there are not studies that assess the correct post-operative management in DD. The aim of the present study is evaluating the outcomes of a new post-operative rehabilitation protocol.

Methods: From February 2016 to February 2018, 78 patients were treated in our department. Collected clinical data included patient demographic data, post-operative side effects, type of treatment, protocol accession, rate of recurring events at follow-up time. The Anova one-way test was performed to evaluate the statistical significance of recurrences (p<0.05) in both groups: patients who adhere to rehabilitation protocol and who not adhere.

Results and Conclusions: We excluded 7 patients treated for recurrences. A total of 71 patients were submitted to the first surgery and in 44 cases (62%) the disease involved a single digital ray. In 34 cases (48%), we performed enzymatic cordotomy (Xiapex), in 37 cases (52%) was performed open surgery (aponeurectomy, cordectomy, dermoaponeurectomy). Post-operative side effects included wound dehiscence (5 cases in enzymatic cordotomy, 3 cases in open group). Statistical analysis does not reveal any correlation between adherence to protocol and rate of recurring events in both groups, according to literature. In conclusion, DD represents a mysterious pathology and currently the causes of recurrences are unknown. Rehabilitation protocol may be useful to regain an early complete function of the hand, but it does not influence the rate of recurrences. However further and multicenter studies will be necessary to understand the role of rehabilitation in this disease.

Keywords: dupuytren's disease, rehabilitation protocol, recurrences
Interpretation of Ulnocarpal Stress Test in Different Forearm Rotation

List of authors: Taehyeon Kim*, Hanvit Kang¹, Hyunseok Seo¹, Joo-Yup Lee¹
¹ St. Paul's Hospital, Orthopedic Surgery (Seoul)

Objectives / Interrogation: Ulnocarpal stress test is an essential physical examination for differential diagnosis of ulnar-sided wrist pain. However, there were some debates on the interpretation of the results of ulnocarpal stress test according to different forearm rotation position. Aim of this study was to analyze the correlation of positive results of ulnocarpal stress test in different forearm rotation with specific tender point of the wrist joint.

Methods: From March 2015 to February 2017, 54 patients who were diagnosed as ulnar impaction syndrome or ulnar styloid impingement syndrome by MRI or arthroscopy were included. We performed ulnocarpal stress test in forearm supination and pronation position and checked tenderness on dorsal lunate and ulnar head area (point A) and ulnar aspect of triquetrum and ulnar styloid area (point B). We analyzed odds ratio and statistical significance between positive physical examination and sites of tenderness using Fisher’s exact test.

Results and Conclusions: 46 patients had tenderness on the point A and finally diagnosed as ulnar impaction syndrome through consistent radiologic findings; Subchondral sclerosis, subchondral cysts, and "kissing" lesions of the lunate, triquetrum, and ulnar head. Among them, 40 of 46 patients had positive ulnocarpal stress test in forearm supination position. Odds ratio of positive ulnocarpal stress test in forearm supination and tenderness of point A was 8.25 and it was statistically significant. 8 patients had tenderness at point B and were diagnosed as ulnar styloid impingement syndrome with radiographic chondromalacia between proximal triquetrum and the ulnar styloid. 6 of 8 ulnar styloid impaction syndrome patients had positive ulnocarpal stress test in forearm pronation position. There were 12 patients who were diagnosed as ulnar impaction syndrome had positive ulnocarpal stress test in both supination and pronation position. In conclusion, patients who had positive ulnocarpal stress test in forearm supination tend to have a tenderness on the luno-triquetral joint area and be diagnosed as ulnar impaction syndrome, and who had positive ulnocarpal stress test in forearm pronation tend to have a tenderness on the ulnar aspect of the triquetrum and ulnar styloid area and be diagnosed as ulnar styloid impingement syndrome.

Short-term results of Revision Cubital Tunnel Release Treated With Neurolysis and Procine Submucosa Extracellular Matrix

List of authors:
RaviKanth Mallina¹, Pieter Jordaan¹, Tahseen Chaudhry¹, Dominic Power¹
¹ Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Epineural scarring following decompression of a peripheral nerve results in significant morbidity. We report a single institution experience of using procine submucosa extracellular matrix (AxoGuard® AxoGen Inc., Alachua FL) in revision Cubital tunnel release.

Methods: Twenty-four patients with recurrent ulnar nerve compression neuropathy at the elbow were treated with revision cubital tunnel release, neurolysis and AxoGuard® nerve wrapping. Idiopathic cubital tunnel syndrome was the primary operation in 16 cases and 9 had primary ulnar decompression following elbow trauma. Patient demographics, pre-and post-operative pain scores, sensory function, Tinel's sign and patient satisfaction were recorded in each case.

Results and Conclusions: Results
All patients were followed up to an average of 6 months (range 3-40), mean age of patients 50 was years (range 27-75). Post-operative pain levels improved from 7 to 3 (p<0.05) and sensation improved from a mean of 4 to 8. Following revision surgery absence of Tinel's sign was noted in 18 patients. One case had early re-exploration due to a wound haematoma. There were no complications associated with the use of the porcine submucosa extracellular matrix as a nerve wrap.

Conclusions
In this series of revision cubital tunnel decompression and neurolysis the addition of an AxoGuard® demonstrated good clinical results with no complications.

Nerve Wrap, Cubital tunnel, Neurolysis
**Objective / Interrogation:** Many wounds of extremity were intractable despite of adequate debridement and wound closure which it formed dead space or infectious focus. We tried to treat these intractable wound effectively with strong negative pressure suction using 50cc disposable syringe. We report the method and result of this treatment.

**Methods:** From Sep 2007 to Aug 2015, 150 wounds of 121 patients were treated with NPST. Average age was 49 years with 87 men. Location of wounds were 98 cases of hand, 27 forearm and arm, 11 foot, 10 thigh and leg and 4 trunk. After through debridement of dead or infected tissue, suction tube using connecting tube for IV fluid or butterfly needle was insertion into the wound with multiple hole. Wound was closed with airtight and 50cc disposable syringe was connected to the tube. Negative pressure suction was applied with drawback of piston of syringe to 50mm marking line. Negative pressure was adequately controlled remaining 0~5cc air into the syringe. Syringe was emptied out more than 10 cc of drainage and maintained from 3 to 14 days.

**Results and Conclusions:** 134 of 150 wounds were treated with this method despite of infectious or dirty wound. 110 of 121 patients were treated by 1st try of NPST, 7 patients were 2nd try, 3 patients were 3rd try, and one patient was 4th try of NPST. NPST with 50cc disposable syringe was useful method for the treatment of intractable wound due to through removal of hematoma and infection exudate, obliteration of dead space, and tight contact of separated wound with strong negative pressure into the wound. NPST had the great advantage than can be easy done without any special equipment.

Negative pressure suction treatment, disposable syringe, closable wound.
Ray amputation for the treatment of foot macrodactyly in children

List of authors:
Bin Wang*
1 Shanghai 9th People's Hospital, Shanghai Jiaotong University (Shanghai)

Objectives / Interrogation: To investigate the results of surgery on foot macrodactyly who underwent ray amputation.

Methods: 16 feet of 15 patients were included in the study. We radiologically measured the intermetatarsal width and forefoot area pre-operatively and at six weeks and two years after surgery. Clinical results were recorded using the Oxford Ankle Foot Questionnaire for children (OxAFQ-C) and the Questionnaire for Foot Macrodactyly.

Results and Conclusions: Mean follow-up was 49 months. The intermetatarsal width and forefoot area ratios were significantly decreased after surgery. The mean OxAFQ-C score was 35 (16 to 60) pre-operatively, improving to 48 (5 to 60) at two years post-operatively (p<0.05). The mean questionnaire for foot macrodactyly score two years after surgery was 8 (6 to 10). In conclusion, reduction in foot size with excellent functional results were achieved using ray amputation. For patients with metatarsal involvement, a motionless toe, or involvement of multiple digits, ray amputation is a clinically effective option.

"Less than ten" - Amputation injuries among surgeons

List of authors:
Lars H. Evers*, Richard Bodor1
1 University of California (San Diego)

Objectives / Interrogation: Amputation injuries and their microsurgical treatment are part of a daily routine of a Hand-Trauma-Center. In the majority of these cases, the patients are technical skilled workers appointed in agriculture and industry. Little is known about amputation injuries of surgical colleagues. To best of our knowledge, data about type, numbers, results, long term follow-up, rehabilitation and the psychological impact after amputation injuries among surgeons are very rare.

Methods: Here we present an interesting case of a vascular surgeon, who sustained a three finger amputation in a circle saw accident in private settings. The immediate operative care as well as the follow-up and the rehabilitation is presented. Special attention is paid to the high motivation of this colleague. Furthermore a comprehensive literature review was undertaken.

Results and Conclusions: In the case of the vascular surgeon colleague, due to the devastating injury pattern with multiple trauma locations in all affected digits, only the ringfinger could be successfully replanted. However due to his extraordinary high motivation, he was able to return full-time to his surgical profession even with only 3 fingers in his one hand.

Amputation injuries are an extremely devastating accident for the life of the patients. However our example of an highly motivated surgeon colleague, who is still working as an active surgeon emphasize the impact of the psychological strength and self motivation.

Keywords:
Median Nerve Motor Branch Transfer for Treatment of Severe Cubital Tunnel Syndrome

List of authors:
Li Wang*, Xinzhong Shao¹, Zhemin Zhang¹, Li Lv¹, Wenxu Duan¹, Fengyu Wang¹
¹ Third Hospital of Hebei Medical University (Shijiazhuang)

Objectives / Interrogation: This study aimed to present a modified method for treatment of severe cubital tunnel syndrome (CuTS), using ulnar nerve anterior subfascial transposition and an additional median nerve motor branch transfer to ulnar nerve.

Methods: From May 2013 to October 2016, 41 patients with grade III CuTS based on McGowan's classification were enrolled. All patients were treated with the same procedure: 1. ulnar nerve neurolysis and anterior subfascial transposition at the elbow, 2. median nerve motor branch of pronator quadratus transfer to motor branch of ulnar nerve at the forearm. Patients were followed at 3, 6, 9, 12 months postoperatively. All patients underwent preoperative and final follow-up assessments of Disabilities of the Arm, Shoulder, and Hand (DASH) score, nerve conduction velocity (NCV), 2-point discrimination, and pinch and grip strength. The mean follow-up time was 33 months using the Modified Bishop scores system.

Results and Conclusions: RESULTS: At the final follow-up, the average DASH score, NCV, 2-point discrimination, and grip and pinch strengths improved in all patients. At least a 1-McGowan grade improvement was achieved in 37 patients (90.2%). According to the modified Bishop scores, 34 patients (82.9%) achieved good or excellent outcomes, 5 patients achieved fair outcomes (12.3%) and 2 patients (4.8%) had poor outcomes.

CONCLUSIONS: The modified method using ulnar nerve anterior subfascial transposition and an additional median nerve motor branch transfer to ulnar nerve, is a reliable and safe treatment option for treatment of patients with McGowan grade III severe CuTS, with satisfactory mid-to-long term functional and patient-rated outcomes.

Factors Associated with Surgeon Recommendation For Additional Cast Immobilization of a Nondisplaced Scaphoid Waist Fracture

List of authors:
Anne Eva Bulstra1, Tom Crijns2, Stein Janssen3, Geert Buijze4, Ruurd Jaarsma5, David Ring6, Miryam Obdeijn7, Job Doornberg5
1 Flinders Medical Centre, Flinders University, University of Amsterdam (Bedford Park)
2 VU Medical Centre, Dell Medical School, The University of Texas at Austin (Amsterdam)
3 Amphia Hospital, Academic Medical Centre (Amsterdam) (Breda)
4 Academic Medical Centr (Amsterdam)
5 Flinders Medical Centre (Bedford Park)
6 Dell Medical School, University of Texas at Austin (Austin)
7 Academic Medical Centre (Amsterdam)

Objectives / Interrogation: Recent evidence suggests that a shorter period (4-6 weeks) of cast immobilisation is adequate for the treatment of nondisplaced scaphoid waist fractures. This study was set out to investigate patient and surgeon factors associated with surgeon recommendation for prolonged cast immobilisation (>8-12 weeks) of a nondisplaced scaphoid waist fracture.

Methods: 218 orthopedic and upper-extremity surgeons participated in an international online survey study. Participants were presented with 16 case scenarios of patients with nondisplaced scaphoid waist fractures treated with cast immobilisation. They were asked whether they would continue or stop cast immobilisation. Patient variables included sex, age, gender, radiographic fracture consolidation, presence of fracture tenderness and duration of completed cast wear (8 or 12 weeks). Multivariable linear regression analysis was used to identify which characteristics were associated with surgeon recommendation for continued cast wear.

Results and Conclusions: Results:
Up to 84% and 49% of the surgeons recommended additional immobilization after 8 and 12 weeks, respectively. Unclear fracture healing on radiographs increased the likelihood of prolonged cast duration (>8-12 weeks) with an odds ratio (OR) of 35.0 (95% confidence-interval(CI): 4.6-262, p=0.001). The presence of fracture tenderness was associated with an OR of 9.6 (95%CI 2.1 to 36, p=0.001) for continued cast wear compared to no fracture tenderness. Female surgeons (OR 3.0, 95%CI 1.3-6.8, p=0.011) and those not specialized in trauma or upper-extremity surgery (OR 2.6, 95%CI 1.3-5.3, p=0.007) were more likely to recommend continued cast wear, while surgeons practicing in Europe were less likely to recommend additional immobilization (OR 0.15, 95%CI 0.051-0.46, p=0.001).

Conclusion:
In this online survey study, cast duration was dictated by radiographic fracture appearance and the presence of fracture tenderness. This runs counter to good evidence that radiographs are unreliable in assessing scaphoid union. The role of fracture tenderness in assessing fracture healing merits further investigation. Considering the high union rates of this type of fracture following cast immobilisation (>90%), the use of CT may not always be justified to assess union. A clinical prediction rule to determine scaphoid fracture healing may contribute to reducing immobilisation time, or help identify patients who require a CT-scan for follow up.

Surgical Dislocation and Cancellous Bone Graft is Alternative Operative Treatment in Capitellar and Trochlea Fracture with Elbow Instability

List of authors:
Young Ho Lee*, Min Ho Lee¹, Yo Han Lee¹, Yeun Soo Kim¹, Che Ho Lee¹, Young Ju Chae¹, Qingyuan Li¹, Goo Hyun Baek¹
¹Seoul National University College of Medicine (Seoul)

Objectives / Interrogation: Recently, AO classification using fracture location, degree of articular involvement and type of fracture in distal humerus fracture is widely used and is helping to standardize the treatment results, and determine the treatment method and prognosis. However, fractures involving the capitellum and trochlea are rare and often not consistent with the AO classification or the previously reported classification. In addition, the treatment is still very controversial. Therefore, in this study, we propose a surgical treatment method for elbow instability with capitellum and trochlea fracture.

Methods: Fifteen patients with elbow instability with capitellum and trochlea fracture were treated surgically between 2003 and 2014. The lateral approach was used, and fracture site of the capitellum and trochlea was completely exposed by the medial dislocation of the elbow. The articular bony fragment was anatomically reduced and fixed with absorbable pins and screws. Iliac bone graft was applied to the bony defect. The mean age at operation was 53 years (range, 16 to 76 years), and the mean follow-up period was 24 months (range, 18 to 71 months). Postoperatively, ROM (range of motion) was measured, and Mayo Elbow Performance Index (MEPI) and Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire was assessed.

Results and Conclusions: The range of motion of the elbow at final follow-up was 142.5 degrees (SD = 7.9) in flexion/extension and 162.5 degrees (SD = 8.8) in supination/pronation. The mean MEPI was 90.5 (SD = 7.6), and MEPI stability score was 9.5 out of 10 (SD = 1.5). The mean DASH score was 11.2 (SD = 11.9). One patient had evidence of osteonecrosis, but she had no complaints of pain and adequate ROM at last follow-up.

In elbow instability patients with capitellum and trochlea fracture, we were able to effectively expose the fractured site by lateral approach using medial dislocation of the elbow, without the olecranon osteotomy. In addition, anatomical reduction and stable internal fixation were achieved by disimpaction, autologous iliac bone graft, absorbable pin and screw fixation, and results were good. Therefore, the method proposed in this study may be a good alternative for the surgical treatment of elbow instability patients with capitellum and trochlea fracture.

Wrist proprioception and forearm muscles biomechanical parameters dependency in DISI cases

List of authors:
Marta Jokiel¹, Pawel Surdziel¹, Piotr Czarnecki¹, Leszek Romanowski¹
¹ Hand Surgery Department Poznan (Poznan)

Objectives / Interrogation: Dorsal intercalated segment instability (DISI) is problematic, complicated wrist disorder which cause great disturbances in patients everyday living, work and sports activities. Because of pain patients often diminish wrist ROM and function which indicates even more imbalance. In ligamentous DISI cases proper operative or non-operative treatment is crucial for patients recovery. Despite the fact that the medicine know more and more about proprioception and its influence to the wrist stability it is still a great challenge to objectively assess its activation in wrist motion and stability.

Methods: 18 patients with ligamentous DISI (age: 32 y.o) and 20 volunteers as a control group underwent wrist isotonic examination on Biodex System 4 Pro and joint position sense examination on Three Dimensional Upper Limb Movement Zebris System HAF. The examination was concerned with the basic wrist movements: flexion and extension, adduction, abduction and with retrieving the "0" position (the one line with the forearm). For the research the method of assisted presentation and active reproduction was taken.

Results and Conclusions: There was significant difference (p<0.05) between DISI wrist flexors and extensors biomechanical parameters in comparison to the healthy wrist and control group. Wrist and fingers extensors average peak velocity was 308,2 deg/sec and wrist and fingers flexors average peak velocity was 405,7 deg/sec. The agonist antagonist ratio in DISI wrist was 72%, healthy wrist 58% and control group 57%. There were no significant difference in EARJP (error of active reproduction of joint position sense) between DISI group and control group. EARJP for wrist extension was 3,7 ± 1,9 deg in DISI wrist and in control group 3,1 ± 2,4 deg.

Conclusions: Disabled ligamentous stabilization is supported by higher forearm muscles activation. Decreased level of forearm muscles biomechanical parameters is responsible for increased error of active reproduction.

Changes in Ulnar Variance after a Triangular Fibrocartilage Complex Tear

List of authors:
Hyunseok Seo*, Hanvit Kang¹, Taehyeon Kim¹, Joo-Yup Lee¹
¹ St. Paul's Hospital, Orthopedic Surgery (Seoul)

Objectives / Interrogation: The relationship between triangular fibrocartilage complex (TFCC) tear and ulnar impaction syndrome has not been fully understood. We hypothesized that a TFCC tear could change the ulnar variance, which may be the cause of ulnar impaction syndrome.

Methods: A total of 72 patients who underwent TFCC foveal repair between January 2011 and June 2016 were included in this retrospective study. Among them, 44 patients diagnosed with TFCC foveal tear with distal radioulnar joint instability and no ulnar impaction syndrome underwent TFCC foveal repair only (group A) and 28 patients diagnosed with TFCC foveal tear with ulnar impaction syndrome underwent TFCC foveal repair and ulnar shortening osteotomy simultaneously (group B). We measured their ulnar variances in preoperative, postoperative, and last followup plain radiography. We also compared them with the ulnar variance of the contralateral (uninjured) wrist. Postoperative clinical outcomes, such as range of motions of the wrist, the visual analog scale (VAS) for pain, grip strength, and Quick Disabilities of the Arm, Shoulder, and Hand (QuickDASH) score, were assessed.

Results and Conclusions: Ulnar variance increased after TFCC tears compared with that on the uninjured side in both groups (group A: 0.98 vs. 0.52 mm; group B: 2.71 vs. 2.13 mm). Once the TFCC was repaired, ulnar variance decreased (group A: 0.98 to 0.01 mm; group B: 2.71 to 0.64 mm). However, it was increased on the last follow-up radiograph (group A: 0.01 to 0.81 mm; group B: 0.64 to 1.05 mm). There were no significant improvement of range of motion, except for pronation-supination motion. Mean grip strength increased from 56.8 to 70.8% of the contralateral unaffected hand at the last assessment. Mean VAS for pain decreased from 7.4 preoperatively to 2.7 postoperatively. The QuickDASH score significantly improved from 45 to 9. In conclusion, ulnar variance may be changed after a TFCC tear. In our study, it decreased after TFCC foveal repair. However, as time went on, the ulnar variance increased again, which could be one of the causes of ulnar impaction syndrome and ulnar-sided wrist pain.

Use of Kirschner Wires With Eyelets for Tension Band Wiring of Olecranon Fractures

List of authors:
Jung Eun Lee¹, Young Ho Lee², Jihyeung Kim², Yeun Soo Kim², Che Ho Lee², Young Ju Chae², Qingyuan Li², Goo Hyun Baek²
¹ Gil Medical Center, Gachon University School of Medicine (Incheon)
² Seoul National University College of Medicine (Seoul)

Objectives / Interrogation: Tension band wiring is a widely accepted fixation technique for displaced olecranon fractures. It has a well-established biomechanical basis and has been reported to provide good outcomes in several long-term studies. However, the technique may be insufficient in the presence of comminution, instability, or substantial extension into the coronoid process. Despite the efficacy of this technique, prominence of the Kirschner wire at the insertion site is a commonly reported problem. In the majority of cases, this prominence is caused by proximal pin migration and can result in pain, skin breakdown before pin removal, secondary displacement, or subsequent malunion or nonunion. Although an alternative technique involving running the distal ends of Kirschner wires through the anterior ulnar cortex has been proposed to reduce the incidence of pin migration, other complications such as restrictions of forearm rotation and anterior interosseous nerve injury have been reported regarding this modification. Therefore, we proposed that a more effective approach was required to prevent pin migration and other complications such as restriction of forearm rotation or neurovascular injury. Accordingly, we have used a modified Kirschner wire, which features an eyelet near the trailing end to prevent pin migration.

Methods: The authors retrospectively reviewed 44 patients treated for an isolated, displaced olecranon fracture and checked range of motion, postoperative pain, complications, and incidence of hardware removal. The mean follow-up period was 41 months (range, 26-73 mo).

Results and Conclusions: All fractures united, and anatomical reduction was achieved in all cases at final follow-up. Mean elbow flexion was 135° (range, 115° to 140°), and mean elbow extension was 4° (range, 0° to 15°). No pin migration, restriction of forearm rotation, or neurovascular injury occurred. Hardware removal was performed in 8 cases (18%). Compared to previous results with conventional Kirschner wires, no meaningful improvement in postoperative pain level or in the rate of hardware removal was observed.

Tension band wiring using the pin studied produced excellent clinical and radiologic outcomes for the treatment of isolated, displaced Mayo type IIA and some type IIB olecranon fractures. The pin was effective in preventing the backing out of Kirschner wires and avoiding the complications associated with anterior cortical engagement of Kirschner wires, such as neurovascular injury or restriction of forearm rotation.

Pianists most common hand and wrist disorders as effect of forearm muscle overload

List of authors:
Marta Jokiel*, Piotr Zuchowski¹, Piotr Czarnecki¹, Leszek Romanowski¹
¹Hand Surgery Department Poznan (Poznan)

Objectives / Interrogation: Professional musicians are often compared to professional sportsman but the diversity of muscle work and its implications to patients health vast difference. Musicians maintain one improper position for long time which indicates great level of muscle overload in time. Most of the problems are caused not by high energy injury but because of microtrauma and muscle fatigue which leads to muscle imbalance and proprioception disorders. Treating musicians hand is a great challenge for surgeon as well as for therapists because very often patients admit about the problem and pain because of being afraid of playing break and losing their abilities.

Aim of the study was to asses most common hand and wrist disorders according to muscle overload while playing in professional pianist group.

Methods: 17 professional pianists (average age: 31 y.o.) with time of play min 15 years underwent clinical examination, DASH questionnaire and electromyography Noraxon Telemyo examination while playing. All participants were measured at the same instrument and with the same program - sitting position, 3min all board repetitive octave, different rest positions and pace instrumentals. To assess flexors strength global grip strength was measured.

Results and Conclusions: Clinical examination reveled most common problems with wrist pain and painful palpation. 56% of group had positive results of Thomsons, Cozens and chair test. 39% of group claimed ulnar or median neuropathy symptoms. 64% of group present incorrect posture with neck and shoulder protraction. 53% of participants had present skin laxity symptoms. The superficial electromyography reveled significant difference (p<0,05) between resting position and playing. Average amplitude during play of ECU was 72,4 uV, ECRB 55,6 uV while FCR 62,3 uV and FCU 42,3 uV and FCR 47,9 uV. Global grip strength was 29,8 kg for right hand and 28,1 for left hand.

Conclusions: Superficial electromyography indicates high overload of wrist extensors and flexors muscles which are responsible for wrist pain and disorders. Wrist laxity, poor posture and lack of proper warm up may paly important role for wrist disorders.

Informed Consent for trigger finger release - our experience with video consent for trigger finger release.

List of authors:
Ian Dhanaraj*, Thommen Kuruvilla¹, Amir Adham², Hannah Ng³, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: Informed consent has become mandatory in the current environment for safe surgical procedures. There are specific legal requirements for what has to be disclosed to patients and the accompanying documentation.

Methods: This is a quasi-experimental pilot study on the use of video consenting for informed consent taking for trigger finger release. Prior to obtaining consent for trigger finger release, a validated consent taking video of the procedure that provide the patient with information about the nature of the surgery, the expected benefits, material risks and adverse effects, alternate treatments and the consequences of not having the surgery was shown to the experimental group of 5 patients undergoing the trigger finger release. Material risks included risks common to all surgery and risks specific for the proposed surgery including the very rare. The control group consisted of five patients undergoing trigger finger release who were consented using the standard oral consent form with information provided by the surgeon in the clinic. Following the surgery, the experimental group were then provided with similar information to the control group for trigger finger release and then subjected to a survey about the suitability and utility of the video consent procedure using the System Usability Scale (SUS) score. The control group were then shown the video consent information and then provided with the similar validated suitability and utility survey form.

Results and Conclusions: In general, the patients preferred the video consenting process for trigger finger release. The SUS scores were high for the video consenting process.

Even though video consenting as a process for informed consent has its utility in trigger finger release practice. However, the preliminary results showed that there is a challenge in the acceptance and relevance of informed consent generally in the local context. Further quality studies need to be conducted to see the relevance and acceptance of informed consent in local patients for common hand conditions in Singapore.

Keywords: Informed consent, Trigger Finger
Biomechanical evaluation of wrist flexors and extensors function after arthroscopic treatment of triangular fibrocartilage lesions

List of authors:
Marta Jokiel*, Kacper Judka¹, Robert Saplowski², Piotr Czarnecki³, Leszek Romanowski¹
¹ Hand Surgery Department Poznan (Poznan)
² Rehasport Clinic (Poznan)

Objectives / Interrogation: TFCC injuries significantly affect patients quality of life. Most of patients complains are concerned with high developed pain which unable performing the everyday living activities. Most recommended treatment is the arthroscopic treatment of the lesion. The aim of the study was to asses patients wrist flexors and extensors biomechanical parameters after TFCC operative treatment.

Methods: 28 patients (9 male and 19 female) with mean age 36 years were biomechanically tested on Biodex System 4 Pro device with isotonic protocol. Mean time of follow up was 5 years after the surgery. There were 15 patients after arthroscopic repair of TFCC Palmer 1B tear, 2 patients after TFCC Palmer 1A tear, 2 patients after TFCC Palmer 1D tear and 1 patient with TFCC Palmer 1A and 1B tears. Wrist flexors and extensors were tested in 3 trials (0,5Nm/1Nm/0,5Nm) in which the patients performed sequentially 4 movements of wrist flexion and extension. Grip strength was measured with electronic dynamometer.

Results and Conclusions: There were no significant differences between wrist extensors and flexors biomechanical parameters in operated and healthy limb. The average functional ROM for the operated wrist was 117.58 degrees and 123.64 degrees for the healthy one. The average velocity of the wrist extensors was 225.96 deg/sec for the operated wrist and 221.14 deg/sec for the healthy one. The average velocity of the wrist flexors was 343.74 deg/sec for the operated wrist and 368.79 deg/sec for healthy one. Grip strength value was 32.07 kg for operated wrist and 33.58 kg for healthy one. Over 75% of patients were extremely satisfied with the operative results and only 2 patients had no improvement.

Conclusions: TFCC arthroscopic treatment enables almost full recovery of the injured hand and allows to achieve high values of wrist flexors and extensors muscles biomechanical parameters. Biomechanical evaluation of wrist function after surgery significantly expands our knowledge of the results of arthroscopic treatment of TFCC lesions.

Proximally based pedicled first dorsal interosseous muscle flap for index finger pollicisation in children: an anatomical study of the vascular and innervation patterns and surgical technique.

List of authors:
Yoan-Kim de Almeida*, Lionel Athlani¹, Marine Krebs², Marc Braun², François Dap¹, Gilles Dautel¹
¹ Centre Chirurgical Emile Galle (NANCY)
² Laboratoire d’Anatomie Faculté de Médecine (Vandoeuvre les Nancy)

Objectives / Interrogation: Pollicisation of the index finger is the gold standard treatment for severe hypoplasia or aplasia of the thumb in radial longitudinal deficiency in children. Thumb opposition deficit is a common complication and may require abductor digitii quinti muscle or ring finger superficialis tendon transfer. We hypothesized that failure of the first dorsal interosseous muscle (FDIM) could partially explain these results. We report an original technique of FDIM pedicled flap transfer to recreate the lateral thenar muscle. Before elevating the flap, we investigated the vascular and innervation patterns of the FDIM.

Methods: An anatomical study was carried out. Fourteen fresh upper limbs were dissected to determine the vascular and innervation patterns of the FDIM. Three upper limbs were used for the description of the transfer technique.

Results and Conclusions: The point of penetration of the deep branch of the ulnar nerve (DBUN) in the FDIM was located at 41% (28-48%) from the base of the second metacarpal. Four arteries vascularize the FDIM: the direct dorsal interosseous branch, the first palmar metacarpal artery, the first dorsal metacarpal artery and the dorso-ulnar artery of the thumb. The direct dorsal interosseous branch originating from the radial artery is the major pedicle. The FDIM pedicled flap was moved backward and ulnarly-ward and, then, fixed to the anterior retinacular ligament.

The DBUN is vulnerable during the dissection of the first dorsal and the first palmar interosseous muscle in the index finger pollicization. The DBUN must be seen and protected in order to avoid its iatrogenic section. We demonstrated the feasibility of FDIM pedicled flap transfer in adult cadaver. Moving backward and ulnarly-ward the proximal insertion of the FDIM, hence recreating the lateral thenar muscle, should theoretically improve the opposition capacity of the new thumb.

Study of the anatomical vascular pattern of the hand in children with radial longitudinal deficiency must be performed. Clinical application is the next step toward confirming the reliability and efficiency of FDIM pedicled flap transfer.

Endoscopic Cubital Tunnel Decompression - A True "Keyhole Technique" Using the Tulip ® Endoscope System.

List of authors:
Sami Hassan*, Nakhul Kain1, Lionel Bainbridge1
1 Pulvertaft Hand Centre (Derby)

Objectives / Interrogation: A number of endoscopic techniques have been described utilising a traditional mini-open incision with a steep learning curve. We describe our experience of a suprafascial technique to decompress the ulnar nerve at the elbow using a custom-made Tulip® Endoscope System, and present the results from this novel technique. The Tulip ® Endoscope allows both blunt and sharp dissection, as well as excellent visualisation and access to all structures essential for nerve decompression.

Methods: The majority of patients had regional block anaesthesia with less than 10 opting for WALANT. The patient is positioned laterally, with the shoulder abducted and elbow flexed over a support. A 2 cm endoscopic portal in the proximal forearm allows identification of the flexor carpi ulnaris (FCU) fascia. The Tulip ® instrument is introduced and a channel over the fascia, identifying Osborne's fascia and medial epicondyle. A small constant perforating vessel helps identify the site of incision of Osborne's fascia. The remainder of the fascia and more proximal structures are divided with scissors under direct visualisation. Reversing the direction of the scope allows proximal to distal dissection deep to FCU, allowing for the division of all fascial bands down to distal third of the forearm.

Subsequently a retrospective single surgeon series involving 255 consecutive patients undergoing endoscopic cubital tunnel decompression (ECuTD) over a 9 year period (2008 to 2017) was conducted. The demographics, reoccurrence, and complications were recorded.

Results and Conclusions: RESULTS: From our cohort, there were 57 percent males (N=146) and 43 percent females (n=109). The mean age of our patients were 55 years (range 13 - 90).

2 cases (0.78 Percent) were converted to open procedures, one due to significant scar tissue, and the other for excessive patient movement. One patient (0.39 percent) had a post-operative haematoma. There were no instances of reoccurrence - defined as return of symptoms after a 3 months being symptom-free, However 4 (1.56 percent) patients underwent further open exploration for failure of relief of symptoms. 1 patient ( 0.39 Percent) was found to have a subluxating nerve and underwent anterior transposition. No injury to the medial cutaneous nerve of the forearm was observed.

CONCLUSIONS: Our results demonstrates that the Tulip ® Endoscope provides a safe and reproducible means to decompress the ulnar nerve at the elbow with very low complication, recurrence and re-operation rates.

Stage III basal joint arthritis of the thumb: Clinical and radiological outcome after total trapeziectomy and ligament reconstruction and tendon interposition (LRTI) with partial Flexor carpi radialis (FCR) tendon

List of authors:
Sang-Eun Park*, Eung-Sic Kim
1 Daejeon St. Mary's Hospital, The Catholic University of Korea (Daejeon)

Objectives / Interrogation: Thumb basal joint arthritis is common. Total trapeziectomy and ligament reconstruction and tendon interposition (LRTI) is commonly used surgical option for the stage III, IV basal joint arthritis of the thumb. We reported the clinical and radiological outcome after total trapeziectomy and LRTI with partial FCR tendon for the stage III basal joint arthritis of the thumb.

Methods: A retrospective review was performed for the patients treated with total trapeziectomy and LRTI for their stage III basal joint arthritis of the thumb. Functional outcome was evaluated with a DASH questionnaire and visual analog scale (VAS) pain score. Clinical evaluation examined grip strength and lateral key pinch in kilograms-force. For the radiologic evaluation, stressed and unstressed radiographs assessed metacarpal proximal migration. To evaluate proximal migration, an anteroposterior (AP) wrist view (with true thumb lateral position) was used. The degree of proximal migration was compared with contralateral wrist X-ray and expressed with percentile ratio both at rest and maximal-effort tip pinch.

Results and Conclusions: This study included 18 patients (male 1, female 17) who underwent total trapeziectomy and LRTI for their stage III basal joint arthritis of the thumb. The average age was 62 years (range 57-77 years). The mean follow-up period was 18 months (range, 12 to 27 months). 10 of the affected hands were non-dominant hand.

VAS improved from a preoperative mean of 5.7(at daily living activities) and 7.9(at sports or occupational activities) to a postoperative mean of 1.3 and 2.3, respectively (P < .01). DASH also improved significantly from a preoperative mean of 73(range, 54 to 92) to a postoperative mean of 23 (range, 16 to 43) (P< .05). Grip strength and lateral key pinch improved from a preoperative mean of 13.2kg (range, 5 to 18) to 22.4kg (range 16 to 26) and 3.4kg (range, 1.3 to 4.5) to 5.4kg (range, 4.5 to 7.2) (P< .05). The mean proximal migration was 27% (range, 11 to 43) at rest and 53% (range, 43 to 68) at maximal tip pinch.

Conclusively, this study suggest that total trapeziectomy and LRTI with partial FCR tendon is an effective surgical treatment for the stage III basal joint arthritis of the thumb and provides stable, painless thumb.

Simultaneous Multiple Long Sural Nerve Cable Graft with Saphenous Vein Graft and Staged Tendon Transfer for Brachial Plexus Injury with Ischemic Injury

List of authors:
Che Ho Lee*, Young Ho Lee¹, Hyun Sik Seok¹, Jihyeung Kim², Yo Han Lee³, Yeun Soo Kim³, Young Ju Chae³, Goo Hyun Baek³
¹ Seoul National University College of Medicine (Seoul)

Objectives / Interrogation: Many surgical treatments of brachial plexus injury (BPI) such as nerve repair, nerve graft, and nerve transfer have been introduced over the times, but simultaneous neurovascular reconstruction for traumatic BPI with long neurovascular defects has rarely been reported. The purpose of this study was to analyze the outcome of neurovascular reconstruction associated with multiple long sural nerve cable graft, saphenous vein graft and staged tendon transfer in a patient with whole-type paralysis of BPI accompanied by ischemic injury.

Methods: A 43-year-old man who had been injured in the left axillary area by rotating drill machine visited an emergency room. His left upper extremity was completely absent in neurologic function and seemed to be pale. In surgical exploration, complete rupture in axillary nerve, musculocutaneous nerve, median nerve, ulnar nerve, and radial nerve accompanied by complete brachial artery rupture were found. Defect of axillary nerve, musculocutaneous nerve, median nerve, ulnar nerve and radial nerve was 4cm, 4cm, 5cm, 6cm, and 5cm. So he received neurovascular reconstruction using multiple autogenous long sural nerve cable graft with autogenous great saphenous vein graft. 4cm axillary nerve defect was reconstructed by using 2 strands of 6 cm sural nerve graft. 4cm musculocutaneous nerve defect was reconstructed by using 3 strands of 6cm sural nerve graft. 6cm ulnar nerve defect was reconstructed by using 3 strands of 8cm sural nerve graft. 5cm median nerve defect was reconstructed by using 4 strands of 7 cm sural nerve graft, and 5cm radial nerve defect was reconstructed by using 3 strands of 7 cm sural nerve graft. 2 years after surgery, he received opponensplasty and correction of the intrinsic-minus hand using ECRL tendon transfer were performed.

Results and Conclusions: Immediately after the 1st surgery, the ischemic limb was fully recovered, and 2 years after 1st surgery, shoulder, elbow, wrist joint and extrinsic hand muscles were completely recovered. At the last follow-up, opposition and intrinsic function of hand were improved. Simultaneous multiple long sural nerve cable graft with vascular reconstruction in a patient with whole-type paralysis of BPI accompanied with ischemic injury is thought to be a method to restore the function of the shoulder, elbow, wrist joint and extrinsic muscle of hand. And staged tendon transfer such as opponensplasty, correction of intrinsic minus hand may be required for function restoration of intrinsic muscles of hand.

Early result of Pyrodisc interposition arthroplasty for advanced thumb CMC joint osteoarthritis

List of authors:
Yang-Guk Chung*1, Seung Han Shin1, Yong-Suk Lee1
1 Seoul St. Mary's Hospital, The Catholic University of Korea (Seoul)

Objectives / Interrogation: The osteoarthritis of the thumb CMC joint is one of the common medical problems in middle years of life. Management of advanced thumb CMC osteoarthritis is challenging. Resection arthroplasty and arthrodesis have been used traditionally and implant arthroplasty are gaining popularity recently. Since Sep 2013, we performed Pyrodisc interposition arthroplsties for advanced Eaton-Littler stage III thumb CMC joint osteoarthritis and analysed early result of them.

Methods: We analyzed 13 patients who had undergone Pyrodisc interposition arthroplsty for thumb basal joint arthritis in our hospital from September 2013 to March 2017 and had a minimum 6 month follow-up. All patients were women and the mean age at diagnosis was 64.4 (range: 54-75) years. All 14 joints in 13 patients revealed Eaton stage III osteoarthritis. The symptomatic improvement, the position and survivalship of implant and the stability of reconstructed joints, and any secondary procedure performed were evaluated. The mean follow up period was 28.3 (6-56) months.

Results and Conclusions: The Pain was completely relieved in 7 joints and improved in remaining 7 joints. The positions of implants were good in 9 and fair in 3 and poor in two joints. One of joint with poor position revealed a progressive medial subluxation with accompanied swan neck deformity, which required revision of CMC arthroplasty and MP joint fusion. The other joint with poor position showed dislodgement of Pyrodisc which might be associated with rupture of FCR tendon sling and repositioning and stabilization with tendon allograft was performed. All Pyrodics implanted were surviving at last follow up. The stability of reconstructed joints was maintained in 12 joints. Two patient complained hypesthesia on thenar area. The average Quick DASH score in 10 joints was 17.1(5-39).

Conclusion: The Pyrodisc interposition arthroplsties was one of the reliable options in advanced thumb CMC joint osteoarthritis. To obtain good functional result, a proper surgical technique is mandatory.

Unusual Case of Persistent Choreiform Movements of the Upper Limb after Elbow Injury

List of authors:
Rares-Adrian Giurgiu*, Mircea Bogdan Maciuceanu-Zarnescu, Floricel Cristea, Sorin Ghiea, Matei Iordache, Sandra Iordache,
Cristian Vladimir Vancea

1 Clinical Emergency Hospital Bucharest (Bucharest)
2 Spitalul Monza (Bucharest)

Objectives / Interrogation: There are very atypical cases in the upper limb pathology and the neurological pathology in particular, can have polymorphous manifestations. This was also the case of a healthy young man without any medical history that presented with choreoathetosis of the right upper limb, which started a few hours after an injury of the ipsilateral elbow. Despite the advanced investigations, the patient could not benefit from a diagnosis or effective treatment for four months. Our aim was to find similar cases in the literature and any possible physiopathological mechanism for this situation.

Methods: We present the diagnostic route before, during and after the admission to our hospital, of a healthy young man without any medical history that presented with persistent choreiform movements of the right upper limb, which started after an injury of the elbow. We also studied the available literature, in order to identify the mechanisms that could trigger this situation. About six hours after two consecutive injuries of the right elbow, the patient started to have intense pain and fixed extension of the right forearm that developed, during the next days, into pain and paresthesia of the whole upper limb, the inability to control the limb, progressive choreiform movements and temporary paralysis. The etiology of the disorder was unclear and in spite of the several inconclusive investigations, multidisciplinary approach, aggressive neuroleptic treatment, the patient remained undiagnosed and without any effective treatment. Eventually, exploratory elbow surgery was decided, where we found a small intramuscular haematoma that was compressing the ulnary nerve right at its entrance in the cubital tunnel. We performed external neurolysis of the ulnary nerve and all the symptoms subsided immediately.

In our literature review we found no similar case and very few reports of localized choreiform movements of one single limb.

Results and Conclusions: As a result of the decompression surgery performed, the patient is now free of symptoms. The reports that we found in the literature regarding choreiform movements localized in one extremity were scarce and resumed in situations like autoimmune diseases, paraneoplastic syndrome, stroke or injury of the brachial plexus. It is unclear to us how the choreiform movements were triggered by a peripheral nerve compression and together with the lack of data available on this topic we were encouraged to draw the attention to this case.

Worse outcome (DASH) at 12 months in 128 patients with combined radius-ulna metaphyseal fracture than radius fracture alone. A register study of 3666 patients. Need for Evidence Based Treatment Guidelines?

List of authors:
Linnea Arvidsson*, Elin Österhed†, Marcus Landgren*, Antonio Abramo‡, Magnus Tägil‡

1 Department of Orthopedics, Clinical Sciences, Lund University, Skåne University Hospital (Lund)
2 Dept. of Orthopedics/Hand Surgery, Clinical Sciences, Lund University, Skåne University Hospital (Lund)

Objectives / Interrogation: Up to six percent of the distal radius fractures (DRFs) have a concomitant distal ulna metaphyseal fracture (DUF), treatment algorithms are widely used for DRFs, but are missing for a concomitant DUF. In the present study we used our prospective register to describe and analyze patients with combined DRF and DUF.

Methods: Since 2002, all DRFs in patients 18 years and older at our hospital are prospectively registered and patient-reported outcome (DASH) recorded at one year. Between 2003 and 2012, 3666 patients (2833 women) were included in the register (mean age 62 (18-98) years). All patients with a DRF and a concomitant DUF were identified. The radiographs were evaluated and distal ulnar styloid fractures without metaphyseal extension were excluded. 128 patients (111 women) were classified according to AO:s Q Modifier for ulnar fractures, and the Biyani classification. Patient characteristics, type of treatment and 1-year DASH were extracted from the register. Medical records were reviewed for current drug use and comorbidity according to the Charlson index.. Statistical testing was made using the Mann-Whitney U test.

Results and Conclusions: The subjective outcome at one year was worse (DASH 23) in patients with DRF+DUF compared to the whole DRF cohort (DASH 9; p<0.001). 67/128 patients (52%) were treated conservatively in plaster, time in plaster varied between 4 and 8 weeks. 61/128 patients (48%) were operated for the DRF, of these 34 also had internal fixation of the DUF. Six different methods of internal fixation were used. The subjective outcome in the surgically and non-surgically treated DRF+DUF patients were similar (DASH 25 vs 26, ns).

The patients operated for both DRF and DUF were younger (mean 66 years) than the patients treated non-surgically for the DUF (mean 76 years, p<0.001). A high degree of comorbidity was found in the DRF+DUF cohort. 59% had a Charlson score for comorbidity of 1 or higher, 63% were using at least one drug and 29% met criteria for polypharmacy (an intake of 5 or more drugs regularly).

The patient group with both DRF and DUF had a substantially worse subjective outcome one year after the injury compared to patients with DRF alone. A majority of the patients were elderly with multiple health issues. We could not see that the choice of DUF treatment was done systematically. Additional studies are needed to determine how to best treat this subgroup of patients in the future.

Study of independent extension of little finger after reconstruction of extensor tendon rupture of ring and little fingers in rheumatoid arthritis

List of authors:
Tetsuo Masuda*, Takaya Mizuseki¹, Osami Suzuki¹
¹Hiroshima Prefectural Rehabilitation Center (Higashi-hiroshima)

Objectives / Interrogation: The extensor tendon subcutaneous rupture caused by rheumatoid arthritis (RA) is the most commonly observed in the ring and little finger, and we frequently use the extensor indicis proprius (EIP) transfer in its reconstruction. According to the method, the independence movement of the ring and little finger is theoretically impossible. On the other hand, as the number of RA patients returning to society increases, it is expected that more patients need to develop independent fingers such as typing and piano performances. This may make piano playing or typing difficult. In this study, we followed up the cases of surgical reconstruction for subcutaneous extensor rupture of the ring and little fingers and examined the independent function of the little finger.

Methods: Since 1992, there were 32 patients who received reconstructive surgery for extensor tendon ruptures of the ring and little finger. 32 cases were reconstructed with EIP transfer and 6 were reconstructed with end-to-side suture (suture to middle EDC) were targeted. The postoperative function was evaluated by the range of motion of the little finger MP joint, EDM test, the presence / absence of troubles in daily life activity, and deterioration of functions due to exacerbation of RA.

Results and Conclusions: Three cases developed joint deformity due to exacerbation of RA, and two cases developed re-rupture. In the other cases, the averaged the range of motion of the little finger MP joint improved from -48 degrees to -8.8 degrees in the EIP transfer group, while in the end-to-side suture group from -42 degrees to -6.4 degrees. In postoperative EDM test, 20 cases were negative and 12 cases were positive in EIP transition group, 3 cases were negative and 3 cases were positive in end-to-side suture group. As for the troubles in daily life activity, one case (3.1%) in the EIP group and two cases (33.3%) in the end-to-side suture group answered that there was a problem; all of them had positive postoperative EDM test. Although independent extension disturbance of the little finger was anticipated after grouped reconstruction of the ring and little fingers, only limited patients exhibited impairment of independent little finger extension and very few patients complained of ADL disturbance.

Outcome in radial polydactyly at the interphalangeal and metacarpophalangeal level: An international multicenter study

List of authors:
Robert Dijkman*, Ruud Selles¹, Wiebke Hülsemann², Max Mann², Rolf Habenicht², Steven Hovius³, Christianne van Nieuwenhoven¹
¹Erasmus MC (Rotterdam)
²Catholic Children's Hospital Wilhelmstift (Hamburg)

Objectives / Interrogation: The aim of this international multicenter study was to investigate how patient characteristics and surgical technique influence outcome in radial polydactyly.

Methods: Patients with radial polydactyly types II, IV and IV with triphalangism ('IV-Tph') were evaluated using the validated Rotterdam outcome assessment system. Multiple determinants of outcome were studied, including polydactyly type, number of surgeries, age at operation, nail presentation, clinical deviation, tendon anomalies, surgical technique and surgeon experience.

Results and Conclusions: Of the 114 cases in this study, 94 (82%) were evaluated after single surgery with a mean follow-up of 7.8 years, and 20 (18%) cases were evaluated after multiple surgeries with a mean follow-up of 11.5 years. There were no significant differences in overall outcome between the specific types of radial polydactyly. Within the single surgery group, functional domain outcome was worse for type IV (1.3 points; p=0.005) compared to types II and IV-Tph. The multiple surgeries group had worse overall outcome (4.2 points; p<0.001), functional outcome (1.4 points; p=0.010), pain (1.1 points; p<0.001) and satisfaction (0.7 points; p=0.012) compared to the single surgery group. Tendon anomalies were more frequently treated in the worst outcomes. Overall outcome was better in patients primarily treated by dedicated congenital hand surgeons (2.7 points; p=0.014) compared to less specialized consultants.

The most common types of radial polydactyly have similar overall outcome. However, a number of item- and domain-specific outcomes of type IV are worse. This indicates treatment of type IV remains challenging, especially in cases with tendon abnormalities, which are likely to influence outcome in a negative way. Our results suggest treatment of radial polydactyly by dedicated congenital hand surgeons is associated with better outcomes.

Early pin removal for pediatric radial neck fracture treated by percutaneous pin fixation

List of authors:
Wan-Sun Choi*, Kwang-Hyun Lee2, Joo-Hak Kim3, Chang-Hun Lee4, Sung-Jae Kim5, Jae-Ho Cho1
1 Ajou University School of Medicine (Suwon-si)
2 Hanyang University College of Medicine (Seoul)
3 Myongji Hospital (Goyang)
4 Eulji University College of Medicine (Seoul)
5 Hallym University College of Medicine (Hwaseong)

Objectives / Interrogation: To compare the outcomes of percutaneous pinning and early pin removal (less than 3 weeks) for pediatric radial neck fractures with those of percutaneous pinning and late pin removal (after 3 weeks)

Methods: Forty-one pediatric radial neck fractures treated with percutaneous pinning in a single institute from 2003 to 2015 were divided into the following two groups: the early pin removal group (below 3 weeks, n=21) and the late pin removal group (>3 weeks, n=20). A Steinmann pin (S-pin) was inserted at the fracture site and the fracture was reduced using the leverage technique. The S-pin was then removed to release the soft tissue kinked in the process of fracture reduction and to minimize the potential for posterior interosseous nerve damage. During pin removal, the fracture site was supported by the thumb and a final supporting S-pin was inserted to secure the fracture site. The radiological results were graded based on the Metaizeau classification. The clinical results were evaluated by the range of motion and Mayo elbow performance score (MEPS). Statistical tests, including the Mann-Whitney U and Chi-square tests, were performed to compare the demographic factors and outcomes of the two groups.

Results and Conclusions: There were no significant differences in the demographic factors and other predisposing factors affecting the outcomes between the two groups. There were also no significant differences in the Metaizeau classification and MEPS between the two groups. In view of dressing care and additional oral antibiotics usage, early pin removal is more beneficial. Removal of the pin within 3 weeks after percutaneous pinning in pediatric radial neck fractures showed good outcomes that were comparable to those of late removal.

⁴ ICATME; Hospital Quirón-Dexeus, Universitat Autònoma Barcelona (UAB) (Barcelona)
⁵ Hospital Sant Joan de Deu (Barcelona)

Objectives / Interrogation: Vascularized periosteal flaps (VPF) have been reported as very effective for treating complex bone non-union in pediatric patients with excellent results due to their osteogenic potential. The objective of this study is to present a detailed anatomical description of the periosteal vascularization of the radius and the ulna and the design of vascularized periosteal flaps. In addition, we report here the clinical utility of the VPF in complex cases of forearm nonunion in children.

Methods: Ten latex-colored upper limbs from fresh human cadavers were used. Branches were dissected under 3x loupe magnification, noting the periosteal, muscular, and cutaneous branches arising from the radial (RA), ulnar (UA), anterior (AIA) and posterior interosseous (PIA) arteries for the radius and ulna. The size of the pre and post-dissection flaps and vascular pedicles length were measured.

Three patients under age 18 years with forearm nonunion, who underwent a VPF procedure without bone grafting, were included for this study at a mean follow-up of 26 months.

Results and Conclusions: The AIA Vascular Axis was used to rise the Volar-Radial VPF. An average of 16.2 periosteal branches were obtained, with an average distance of 6.6 mm between them being the average size of the VPF was 41.3 cm² before the dissection and 32.4 cm² after dissection. Average pedicle length of 16.1 cm.

The RA Vascular Axis was used to rise the Radial VPF. The mean of periosteal branches was 20.8 branches with a mean VPF pre-dissection size of 54.8 cm² and 39.3 cm² post-dissection. Average pedicle length of 20.2 cm.

IPA Vascular Axis was used to rise the Dorso-Ulnar VPF. An average of 12.8 periosteal branches were obtained, with the mean CVP size being 26.2 cm² pre-dissection and 20.4 cm² post-dissection with an average pedicle length of 12.6 cm.

The UA Vascular Axis was used to rise the Ulnar VPF. The mean was 10.2 periosteal branches with an average size of the pre-dissection CVP of 37.5 cm² and 28.2 cm² post-dissection and a pedicle of 14.8 cm.

There were two radius nonunions and a ulna nonunion. The mean bone defect was 18 mm. Successful consolidation was achieved in all cases.

Conclusions: we have described 4 new VPF. The most useful and versatile VPF were the Dorso-Ulnar VPF based on the PIA and the Volar-Radial VPF based on the AIA. The main advantages of these flaps comparing to microsurgery techniques, are the simplicity and short time of the technique, its elasticity and adaptability to the surgical site.

A multinomial logistic regression analysis on characteristics of hand and wrist tumours: A multi-ethnic study

List of authors:
Pamela Chong Qin Yi¹, Alyssa Toh LiYu², Sze Ryn Chung¹, Andrew Chin Yuan Hui¹, Muntasir Mannan Choudhury¹, Duncan Angus McGrouther¹
¹ Singapore General Hospital Department of Hand Surgery (Singapore)
² Singapore General Hospital Biomechanics Laboratory (Singapore)

Objectives / Interrogation: Hand tumours are frequently encountered in clinical practice, however, large-scale epidemiological data is infrequently published. The existing literature is not homogeneous with differing accounts of the commonest tumours. Epidemiological data can provide diagnostic cues to guide the workup and management of hand tumours. Assessing significant independent demographic factors and tumour characteristics associated with incidence of hand tumours are essential in the planning and delivery of healthcare services.

Methods: A retrospective review of all patients between 2004 and 2015, who underwent excision of hand tumours in a tertiary hospital in Singapore, was conducted. The following data were collected: age, gender, ethnicity, histological diagnosis, malignancy and location of tumour. A multinomial logistic regression analysis was then performed.

Results and Conclusions: A total of 4476 tumours from 4226 patients were identified with a mean age of 51.3 (8-101 years), male to female ratio of 1:1.15. Majority of the patients were Chinese (75%), followed by Malays (9%), Indians (8%) and others (8%). The most common hand tumours excised were ganglions (43%), with the majority located in the wrist. The next most common were giant cell tumours (9%), which were most commonly found in the digits. The majority of soft tissue tumours were benign (97%), with only 3% malignant cases. Interestingly, a multinomial logistic regression analysis showed that the risk of malignant tumours originating from the skin was 22 times higher than from soft tissue, and 7.6 times higher than from bone for patients of the same age, ethnicity and sex. Also, the relative probability of tumours occurring at the metacarpals rather than fingers was about 1.32 times higher for males than for females and close to 2 times higher for patients with malignant tumours than those with benign tumours.

The overwhelming majority of soft tissue tumours of the hand and wrist are benign and this can guide workup as well as counselling of patients prior to operation. Malignant tumours, while the minority, have the potential for significant morbidity and mortality if not appropriately evaluated or treated. The application of a multinomial logistic regression analysis model observed that tissue origin from skin and tumour location over the metacarpals were significant predictors for malignant hand tumours.

Objectives / Interrogation: A bite from the King Cobra is often fatal due to its potent venom. This case report describes a man who survived a king cobra bite to his index finger and the subsequent disease process and management of snake envenomation.

Methods: The patient's case notes were reviewed and details regarding admission and treatment was recorded. A literature review of snake bites and envenomation by king cobras was performed to inform the case recommendations.

Results and Conclusions: A 32 year old professional snake carer working in a zoo sustained a king cobra bite to his index finger when trialling a snake handling glove he had invented. He was acutely admitted to an intensive care unit. His finger progressively swelled around his puncture wound with development of finger compartment syndrome and the entire digit became necrotic over the course of a few days. He was managed with serial debridement and ultimately required an amputation of the finger, however he did survive the potentially fatal envenomation.

In this rare case we discuss the management principles of snake bites and envenomation, the physiological and pathological properties of snake venom, the indication for antivenom and the potentially digit saving procedure of early compartment release and finger fasciotomy.

Conclusion
Prompt management is essential in rare venomous snake bites including antivenom and early washout and decompression of compartments at risk. These early interventions have the potential to be digit, limb and lifesaving.

Price of a finger

List of authors:
Martin Van*, Francesca Ghini¹, Ravi Mallina¹, Rajive Jose¹
¹ Plastic Surgery and Hand unit, Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Traumatic loss of an index finger is offered twice the amount of compensation as compared to a loss of little finger. However, the little finger plays a pivotal role in power grip thus is underestimated in its importance. Our aim was to test our hypothesis that loss of the little finger will result in greater loss of grip strength compared to loss of the index finger.

Methods: Grip strength in the power grip position was measured in 12 healthy volunteers using a JAMAR hand dynamometer. Grip strength of their dominant hand was recorded as a mean kg force of three attempts in three grip configurations 1) using all fingers 2) excluding the index finger and 3) excluding the little finger. Grip strength percentage compared to the full hand was calculated and statistical significance was investigated with a two-tailed T-test

Results and Conclusions: Participants' age varied from 19-64 years, with 4 males and 8 females. Mean full hand grip strength was 28.3 kg force; grip strength with index finger excluded was 65.8% and with little finger excluded was 66.2%. There was no significant difference in grip strength percentage between index or little finger exclusion (p=0.92). Conclusion We did not find a difference in power grip using a simulated model of index or little finger loss in a healthy volunteer cohort. Limitations of the study and future study designs are discussed.

Keywords: compensation; traumatic loss of finger; jamar; grip strength assessment
Determination of correct length in total trapeziometacarpal arthroplasty

List of authors:
Bram Van Hove¹, Amber Bruijnes¹, Pieter Caekebeke¹, Kristoff Corten¹, Ilse Degreef², Joris Duerinckx¹
¹ Ziekenhuis Oost-Limburg, VUB (Genk)
² KUL (Leuven)

Objectives / Interrogation: The goal of this study is to examine the effect of increasing neck length on range of motion and stability of trapeziometacarpal total joint (TMC) arthroplasty. We want to determine the ideal neck length for optimal stability and motion.

Methods: This study is based on the analysis of 7 fresh-frozen human cadaveric forearms with no signs of TMC osteoarthritis. Thumb length and range of motion were measured using a three-dimensional electromagnetic motion tracking device (Patriot system®, Polhemus). Sensor 1 was fixed on the head of the first metacarpal (MC) and sensor 2 on the distal phalanx of the thumb. Raw data was captured with PiMgr GUI and exported to MathLab. All the tendons were individually loaded with a hanging weight of 1N (100g) to simulate muscle tone. Active movement was obtained by additionally loading muscles. Positional data of both sensors was captured. This was first performed for the native TMC joint. Next, an Arpe TMC prosthesis (Zimmer Biomet) was implanted. Assessments were made for progressively longer necks: 0, +2, +4 and +6mm. We repeated each measurement 5 times for every excursion, and the mean of the five tests was used for analysis.

Data processing
1. From the position of the head of the first MC(sensor 1), the center of motion (COM) of the TMC joint could be determined.
2. The range of motion of the TMC joint in the planes flexion-extension and abduction-adduction was expressed as the angle formed by the line connecting the head of the first MC (sensor 1) and the COM.
3. The range of motion of the distal phalanx was determined in the same way, but by using data of sensor 2.
4. The distance between the COM and the first metacarpal head was calculated.

Statistics
The data was analyzed by repeated measures analysis of variance with post hoc Bonferroni analysis. The differences between different neck lengths were compared using the paired t-test.

Results and Conclusions: Thumb length was adequately reconstructed after implantation of a total joint implant with neutral neck length. With increasing neck length, range of motion of the trapeziometacarpal joint and the distal phalanx of the thumb decreased. Longitudinal stability of the TMC joint increased with increasing neck length. By increasing prosthetic neck length, thumb range of motion decreased, while increasing the stability of the construct, as is intuitively assumable. We were able to determine a "sweet-spot" of optimal stability and range of motion. This information can guide the surgeon intra-operatively.

Improving management of NORSE hand referrals by introducing one-click digital advice template: A study of 100 cases in a tertiary hand trauma unit

List of authors:
Martin Van*, Lt Col Mark Foster¹
¹ Plastic Surgery and Hand unit, Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: NORSE is an electronic referral system where all our external hand trauma referrals are received. The referrals are then acted upon by the on-call hand team. The aim of this study was to establish the variation in management plan and advice given through NORSE in order to identify areas of improvement and address these by improving the electronic referral system.

Methods: We conducted a retrospective study of 100 referrals between July and September 2018 on the NORSE system. The diagnosis code for the referrals, information provided by the referees, advice given by our unit and management plan was collected. We then introduced an one-click electronic advice template for each diagnosis referral category and re-audited our results in another 100 patients.

Results and Conclusions: The largest number of referrals consisted of closed metacarpal fractures (24%) followed by single flexor tendon injuries (14%) and single extensor injuries (8%). Forty-seven percent of referrals were open injuries. Our primary study showed that we missed out on requesting antibiotics (19%), tetanus status (19%), washout of wound (7%) and x-ray to be taken (3%) respectively in cases where this was indicated. Upon re-audit these rates showed a significant improvement and decreased time of management plan formulation.

Conclusions
By introducing an editable advice template function in the NORSE system for each diagnosis category we were able to achieve more efficient formulation of patient management plans and standardise the treatment. We showed that incorporating assistive technology in a digital referral management system can simplify the workload for our physicians and reduce variability in essential acute management of hand injuries.

Keywords:
A review of 1000 upper limb infections and their management in a tertiary hand unit

List of authors:
Martin Van*, Katie Dickson¹, Tom Challoner¹, Deborah Mortiboy², Lt Col Mark Foster¹
¹ Plastic Surgery and Hand unit, Queen Elizabeth Hospital (Birmingham)
² Microbiology and Virology, University Hospitals Birmingham (Birmingham)

Objectives / Interrogation: Infections of the upper limb constitute a common presentation with significant morbidity and in rare cases mortality. In a majority of cases, upper limb infections are caused by Staphylococcus and Streptococcus species however patients with a higher risk of infection such as diabetics and immunocompromised patients often have cultures positive for polymicrobial growth, fungi and even mycobacteria. Recurrent and 'difficult to treat' infection in the upper limb pose a challenge for the hand surgeon and our aim was to review the incidence of upper limb infection, the microbiological implications and management in our unit.

Methods: We performed a retrospective study of 1000 consecutive patients presenting to our unit with upper limb infections during 2016-2018. From our digital databases we recorded demographic data, co-morbidities, length of hospital stay, antibiotics used, organisms grown, number of surgical debridements required, amputations and number of recurrent admissions. Statistical tests were performed with SPSS.

Results and Conclusions: Out of 1000 patients, a majority of infections were caused by animal bites, most predominantly dog bites. In our cohort, the patients were treated with intravenous antibiotics and the majority had surgical debridement and washout. The recurrent and persistent infections were more commonly seen in patients with impaired vascular perfusion, diabetes and other immunocompromising conditions. We have reviewed current and future technologies in reducing microbiological load in the treatment of complicated hand infections.

Conclusion
Prompt treatment of upper limb infections with tailored antibiotics and surgical debridement if required is essential. Special notice is also given to the difficult to treat upper limb infections and we suggest a treatment protocol of upper limb infections based on the results in our unit.

**Hand surgery in a clinic setting using ultrasound percutaneous procedures : a review of 1100 procedures**

**List of authors:**
Pierre Croutzet*, Iskander Djerbi¹, Regis Guinand¹
¹ Institut Toulousain Membre Supérieur (Toulouse)

**Objectives / Interrogation:** With local anesthesia and ultrasound-guided percutaneous procedures, it is now more often possible to perform hand surgery in minimal settings. Indeed, the authors have reported morbidities in a continuous series of 1167 ultrasound-assisted hand procedures performed under local anesthesia in a clinic setting.

**Methods:** Over a period of 4 years, 1167 in-office procedures (787 patients) were performed using specific ultrasound-guided techniques (previously published) under local anesthesia. We included 372 trigger fingers, 516 carpal tunnel releases, 29 de Quervain releases and 243 Dupuytren contractures, 7 epicondylitis.

Exclusion criteria for office surgery were:
- ASA (American Society of Anesthesiologists) grade 3 or higher
- allergic history (latex, lidocaine)
- age over 85

Asepsis was achieved with a preoperative iodine shower and a 5-step antiseptic skin preparation. Fasting was forbidden and disease-modifying treatments, including anticoagulants, taken as usual. The WALANT technique was used for local anesthesia.

All procedures were performed percutaneously under ultrasound guidance. Surgical blades were proscribed, only a 18 gauge needle was used for skin incision. All the instruments were thinner than 1.5 mm, non-disposable and cost less than 50. Bandages were removed by the patient the day after surgery.

Morbidities were reported systematically:
- before surgery, during local anesthesia (vagal faintness, panic attack)
- during surgery (pain, excessive bleeding, faintness, mild heart attack)
- after surgery (infection, Sudeck's disease, hematoma, scarring problem)

Individual procedure efficacy was assessed in previous studies and not included in this series.

**Results and Conclusions:** Preoperative:
- 21 vagal faintness, including 7 syncopes with spontaneous resolution; 5 faintness with 3 syncopes in the last 1000 patients
- no panic attack

Operative:
- no pain felt
- no excessive bleeding, no specific hemostasis procedure needed

Postoperative:
- 1 infection in a trigger finger requiring re-operation
- 15 Sudeck's disease
- 9 mild hematoma after carpal tunnel release with spontaneous resolution

The combination of the WALANT technique and ultrasound-assisted procedures provides an original approach that can be used in a clinic setting. The morbidities reported were at least equivalent to those published in standard operating theatre procedures; only one patient was re-operated (case of infection).

Hand surgery can be performed in good conditions as in-office surgery using local anesthesia and ultrasound guidance

**Keywords:**
ultrasound surgery, office surgery, mini-invasive surgery
Factors influencing the results of flexor tendon repair

List of authors:
Anna Kiseleva*, Dmitry Nakonechny
1 Russian S.R.I of T.O named after R.R. Vreden (Saint Petersburg)

Objectives / Interrogation: Today, flexor tendon injury is a relevant issue. At the end of the 20th century, a variety of different types of suture tendons and corresponding protocols of postoperative management were introduced, which were subject to a repeated comparison among themselves. However, periodical literature did not address the issue of the effect of the organizational factors on the outcome of the treatment.

The aim of the study was to evaluate the medium-term results of the treatment while providing specialized care to patients with injuries flexor tendons of the fingers. To determine the factors which have a significant impact on the clinical outcomes of this category of patients.

Methods: Materials of the case histories of the patients who received emergency medical care at the hospital RNIITO named after R.R. Vreden during the years 2013-2015 were analysed in the course of the study. The patients were interviewed by phone or summoned for a follow-up examination, while the quickDASH questionnaire was filled in, the amplitude of the finger joint movements was clinically evaluated and the findings were characterized according to the Strickland and Kleinert scales. Statistical treatment of the dependence of the treatment results on organizational factors, clinical factors, features of the surgical team was carried out.

Results and Conclusions: In the course of the analysis, it was found that damage to the tendons of the finger flexors occurs most often among men (77%) of working age (M±SD 35.18 ± 12.3 years). Damage to the flexor tendons on one finger predominates (81%), combined with damage to the finger nerve (32%). The treatment results for the timeframe from 1 to 3 years had been evaluated according to the Strickland and Kleinert scales, and were excellent in slightly more than half of the cases. A significant influence on the result of the treatment was provided by the presence of alcohol intoxication of the patients at the moment of their arrival. The statistically significant dependence of the treatment results on the time of the operation and the presence of a narrow specialization of the surgeon, and, to a greater extent, the timing of the beginning of rehabilitation and the conditions for its undergoing were revealed.

Characteristics of hand and wrist benign fatty tumours. A study of 32 cases and literature review.

List of authors:
Guillaume Bacle*, Emilie Marteau2, Gonzague De Pinieux2, Jacky Laulan2
1 CHRU de Tours, Hôpital Trousseau, Inserm U1253 (Tours)
2 CHRU de Tours (Tours)

Objectives / Interrogation: Background
Lipomatous tumours are common and represent 1 to 4% of benign tumors of the hand. Diagnosis and treatment managements could be sometimes non obvious. Very few studies on large series of patients have been published.

Objectives and interrogation
The goal of the present study was to analyze the specific characteristics of fat-like tumors located at the distal end of the upper limb and managed in our adult orthopedic surgery unit.

Methods: Methods
Among all the soft tissue tumors of the hand and wrist treated in the department over a period of 26 years, 28 tissue tumors of lipomatous nature with histological evidence were identified in 28 patients. The characteristics of the symptoms, their duration, the location and the size of the tumor, the therapeutic management and the results of the treatment with a possible recurrence were analyzed with an average follow-up of 5.4 years.

Results and Conclusions: For all 28 cases, there was a palpable tissue mass. This mass was troublesome or disabling in 20 cases and was associated with distal paresthesia in 5 cases: four cases were due to compression of the ulnar nerve in the Guyon canal and the remaining case was due to compression of the median nerve in the canal carpal. Seven tumor lesions were located on the wrist, 11 by hand and 10 with finger chains. The average length of the largest axis of the lesions was: 4.1 cm on the wrist, 3.4 cm on the hand and 2.6 cm on the fingers. In 19 cases, the tumor masses were deep and were often present for several years. Additional investigations have not been systematic. An MRI was performed in 17 cases, an ultrasound in 14 cases, an X-ray in 13 cases and an electromyogram in five cases. All tumor lesions were resected. A previous biopsy was performed in 4 cases. Routine pathological analysis confirmed the benign nature of all lesions. There was no case of liposarcoma. No recurrence was observed.

Conclusions
Patients often consulted late because of good initial tumor tolerance. The use of MRI had made it possible to diagnose localized lesions in the palm and had helped with the decision whether or not to perform the biopsy. Early surgery is preferable because of the risk of developing neurological compression.

Utilization of a Dermal Substitute (Hyalomatrix) in Pediatric Upper Extremity Procedures

List of authors:
Joshua Abzug*, Rebecca N. Freed2, Alexandria Case1, Danielle Hogarth1
1 University of Maryland School of Medicine, Department of Orthopaedics (Baltimore)
2 University of Maryland School of Medicine (Baltimore)

Objectives / Interrogation: Hyalomatrix is a skin graft substitute that may be able to be utilized as an alternative to partial or full thickness skin grafts in a variety of procedures involving the pediatric upper extremity. Composed of an esterified Hyaluronic Acid layer and a silicone layer, Hyalomatrix provides a matrix for dermal induction while protecting the wound from the external environment. The use of this skin graft substitute can potentially decrease the overall operative time associated with a procedure since there is no need to harvest skin graft. The purpose of this study was to assess the outcomes and complications of procedures incorporating Hyalomatrix during pediatric upper extremity procedures.

Methods: Patients were identified utilizing a search of Current Procedural Terminology (CPT) codes to identify patients that had a dermal substitute (Hyalomatrix) utilized. Each identified patient's chart was reviewed retrospectively to assess for functionality (ability to return to daily activities), recovery time (time taken to return to daily activities), and complications associated with the use of Hyalomatrix. Basic statistical analysis was performed.

Results and Conclusions: Hyalomatrix was utilized in 12 procedures, performed on 10 unique individuals, and was applied to 25 total wound sites. Indications for use of Hyalomatrix included syndactyly release procedures, areas lacking coverage following contracture releases, and substantial road rash wounds. The average length of follow-up associated with the Hyalomatrix application was 11.18 (10.97) weeks. Successful healing was achieved in 90% of patients. One patient required a return to the operating room due to recurrent syndactyly, at which time Hyalomatrix was again utilized. Minor complications were noted, including the development of a pyogenic granuloma (n=1), serosanguinous drainage (n=2), and mild scar hypertrophy (n=1). One patient experienced a keloid formation at the operative site (n=1), although it is important to note that this patient had a history of prior keloid formation. No infections were observed in these patients.

Hyalomatrix is a viable dermal substitute for a variety of pediatric upper extremity conditions. The use of Hylomatrix dermal substitute may reduce operative time by negating the need to obtain skin graft while decreasing potential morbidity to the patient. Further prospective investigations into the use of this skin graft substitute are warranted.

Reparing small soft tissue defect in the hand with various free micro-skin flaps

List of authors:
Gaofeng Liang¹, Yunsheng Teng¹, Yongming Guo¹, Junwen Dong¹, Junwen Dong¹, Zonghai Jia¹, Xiaobo Quan¹
¹ Weapons Industrial Health Institute (521 Hospital) (Xi an)

Objectives / Interrogation: Objective: To investigate and summarize various free micro-skin flaps repairing small soft tissue defect in the hand.

Methods: Methods: From March 2014 to May 2015, 15 patients with soft tissue defect in the hand, including 12 males and 3 females, of which were repaired with various free micro-skin flaps, such as the free lateral metatarsal flap, the free medial plantar flap, the free perforator flap of the lateral iliac artery, the free perforator flap of the radial artery and the free wrist transverse flap. During the operation, avoiding to injury the perforating vascular pedicle for ensuring the blood supply of the flap. The wound was directly sutured except for the medial side of the plantar and the lateral donor site, which were repaired with skin grafting.

Results and Conclusions: Results: All the free flaps survived and all the wounds healed in one stage. The patients were followed up during 6 months, with the average of 4 months. The color and texture of the flap is good.
Conclusion: According to the different situation of the injury, it is an efficient and quick method to design corresponding free micro-skin flap for repairing small soft tissue defect in the hand.

Validation of digital tourniquet pressures: T-Ring compared with conventional surgical glove

List of authors:
Byung Jun Kim*, Hyunwoo Kim¹, Tae Un Kim¹, Hyokyung Yoo¹, Na Hee Yu¹, Julong Hu¹, Sung Tack Kwon¹
¹Seoul National University Hospital (Seoul)

Objectives / Interrogation: Digital tourniquets are used for undemanding hand surgeries due to its simplicity and efficacy. However, the pressure exerted by digital tourniquet has not precisely validated yet. In the present study, we investigated the digital pressures exerted by T-Ring and conventional surgical gloves.

Methods: Thirty volunteers were enrolled in the study. The digital pressures were measured on the dorsal and volar side of the 1st, 2nd, and 5th fingers. Artificial finger model was manufactured using 3-dimensional printer, which was used to measure the serial pressure change over 24 hours.

Results and Conclusions: The pressure exerted by T-Ring was 154.3 ± 54.9 mmHg on the volar side, compared with 224.7 ± 57.7 mmHg on the dorsal side (p<0.05). Similarly, the pressure exerted by the surgical glove was 162.6 ± 61.0 mmHg on the volar side and 228.8 ± 66.0 mmHg on the dorsal side (p< 0.05). There was no difference between T-Ring and surgical gloves (p >0.05). Also, the pressure was not influenced by the finger circumference.
There was no significant decrease in the pressure over 24-hour measurement. The digital pressure exerted by finger tourniquet was significantly lower on the volar side compared with the dorsal side, regardless of the tourniquet materials or finger circumferences. Tourniquet pressure was maintained for 24 hours.

Arthroscopic surgery for recurrence after wrist ganglion excision, a series of 12 procedures

List of authors: Pierre Croutzet*, Iskander Djerbi1, Regis Guinand1
1 Institut Toulousain Membre Supérieur (Toulouse)

Objectives / Interrogation: Recurrences after a wrist ganglion excision are a common problem. It occurs either after arthroscopic or open surgery, various series have reported a recurrence rate around 10% whatever the procedure. We wanted to evaluate the efficiency of the arthroscopic surgery after recurrence of a wrist ganglion excision. We report our outcomes concerning 12 consecutive cases.

Methods: Over a period of 5 years, 12 ganglion cysts recurrences were operated on. In these 12 cases, 7 recurrences occur in the first year after excision, 4 between 2-5 years, 1 after 10 years, it was a second recurrence in one case. The first excision was performed open in 11 cases and arthroscopic in 1 case.
To cure these 12 recurrences, all procedures were performed with arthroscopy using two midcarpal portals: an optical ulnar midcarpal portal and an instrumental radial midcarpal portal, portals were switched during the surgery.
Articular diagnosis was performed first then the transverse midcarpal ligament was incised longitudinally. An extra-articular excision of the cyst was performed between the capsule and the extensor then between the extensor and the extensor retinaculum.
A single layer adhesive dressing with a splint was kept for a week.
Clinical examination and Quick-Dash were performed before and after surgery.

Results and Conclusions: The mean follow up was 30 months (12-61).
The pre-op clinical examination reported a ROM of 110°in F/E° and a mean QuickDASH score of 11 (6-24); the post-op examination reported a ROM of 130° (at 3 months) and a phone interview QuickDASH score (at follow-up) of 6 (0-9).
The time of surgery was 28 minutes (22-45), articular abnormalities were reported in 8 cases.
1 recurrence occurs after 6 months.

Although the recurrence after wrist ganglion excision is a frequent issue, this study is the first dedicated specifically to this complication.
This series suggests the recurrence rate would be equivalent after a first or a second excision.

Arthroscopic surgery is reliable to cure recurrences after wrist ganglion excisions.

Keywords: wrist ganglion cyst, arthroscopy, recurrence
Pyrocarbon Interposition Arthroplasty for The Thumb Carpo-Metacarpal Joint Osteoarthritis - mid to long term outcome analysis

List of authors:
Sonja Cerovac*1
1 St George’s Hospital, Hand Unit (London)

Objectives / Interrogation: This talk presents a mid to long-term result and operative technique on use of a pyrocarbon, non-anatomical implant for arthrosis of the first carpo-metacarpal joint (CMCJ) arthritis.

Methods: Data was collected prospectively for 25 patients (average age 56) with radiological stage I - III arthroses who failed conservative management and underwent interposition arthroplasty over the last 8+ years. Patient satisfaction was high. At the mean follow up of 43 months, pain decreased in all patients from 7.4 to 2.2 and DASH score from 57 to 19 (p < 0.01) whereas pinch and grip strength showed less dramatic improvement from 2.9 to 3.9 kg and 15-19kg (p > 0.05), respectively. Thumb mobility was restored to that of the contralateral thumb at average 7 months post surgery. Two patients had implant dislocations. Both were found to be due to suboptimal technique at the time of primary surgery. One of these patients underwent successful trapeziectomy and another one a revision surgery with larger prostesis. No joint instability or periprosthetic lucency has been observed at this interim period. Results of this single surgeon cohort will be compared against the published literature.

Results and Conclusions: Midterm results appear encouraging, but critical analysis of this technique and data collection on long term outcomes and implant survival continues.

thumb, basal joint, arthritis, interposition arthroplasty, pyrocarbon
The lumbrical plus disease: a review of our experience

List of authors:
antonia russomando¹, Antonio Landi²
¹ Villa Verde (Reggio Emilia)
² Villa Laura (Bologna)

Objectives / Interrogation: The lumbrical plus disease is also described as Park's Syndrome or Paradoxical extension. The lumbrical muscle's proximal origin is from the tendon of flexor digitorum profundus in the palm, while the distal insertion is dorsal on the radial bundle of extensor tendon on the back of proximal phalanx.
If for several reasons the proximal origin of lumbrical muscle shifts proximally or becomes contracted, the increased tension will be applied through the radial bundle on the dorsum of the finger causing paradoxical extension of the PIP joint while attempting to flex the fingers.
Possible causes of this mechanism may be: avulsion of FDP, partial severance of FDP, amputation through the middle phalanx, over long flexor tendon graft, adhesions between muscle and tendon sheath.
The paucity of published material on this condition testifies to its rarity or the condition still going un-recognised after many years since its initial description.

Methods: We reviewed the cases of lumbrical plus observed in our experience, following tendon graft, tendon transfers, amputation and other cases of adhesion between lumbrical muscle and tendon sheath.
On 22 tendon graft who underwent to complete follow up, we found 2 cases of paradoxical extension; only one of 16 Paneva-Holevich procedures; one case after amputation of middle finger at distal inter-phalangeal joint;2 cases following tendon transfer of FS of ring finger pro FP; 4 cases following hand's fractures and 2 cases after tendon suture;
All lumbrical plus diseases were treated with lumbrical release at the proximal origin on the tendon of Flexor digitorum profundus, with successful results.
We had only one case of recurrence.

Results and Conclusions: From 1973 to 2016 we observed a total of 12 cases of lumbrical plus.
The digits more frequently involved were middle finger(5 patients), ring finger (2 patients), little finger(5 patients), little finger was also the finger more frequently injured. Middle finger is the most commonly involved as Park described. We found a relationship with surgeon experience in tendons reconstructive surgery (more frequent in older graft performed).
Our experience confirms that is an un-frequent disease and often diagnosis is missed or delayed.
We recommend Importance of clinical tests and to consider the diagnosis when we have a patient who seems un-cooperative during rehabilitation.

lumbrical plus, parodoxical extension, lumbrical release
Analysis of Large Cohort of Spastic Arm Paralysis Patients after Contralateral Seventh Cervical Nerve Transfer: A Retrospective Study

List of authors:
Wendong XU*, Yudong GU
1 Department of Hand Surgery, Huashan Hospital, The National Clinical Research Center for Aging and Medicine, Dept of Hand and Upper Extremity Surgery, Jingan DC Hospital (Shanghai)

Objectives / Interrogation: The application of contralateral C7 transfer in treating central hemiplegia has achieved favorable results in our previous report. The aim of this study was to introduce the authors' experience with contralateral C7 transfer in patients with spastic arm paralysis in a larger number and to analyze the functional outcomes after over 1-year follow-up.

Methods: From 2008 to 2018, a retrospective study of upper limb function in patients with spastic arm paralysis caused by central nervous system injury with a follow-up of more than one year post-operatively were carried out in the hand surgery department of our center. Evaluation methods include Fugl-Meyer upper-extremity scale, Modified Ashworth Scale and active range of motion, which were compared before and consecutively throughout 1-year after operation. Through subgroup analysis, the etiology or factors which might affect postoperative functional recovery and the spasm degree such as gender, age, and affected side were analyzed.

Results and Conclusions: Results: Since 2008, over 200 spastic arm paralysis patients received contralateral C7 nerve transfer surgery in our center. In retrospective analysis, we found that there was a significant increase in the mean Fugl-Meyer score from the baseline to 1-year postoperatively. In the grouped analysis stratified by age, there was an obvious tendency that younger patients acquired higher scores. In the etiological analysis, cerebral palsy patients acquired the largest increase in total Fugl-Meyer score comparing to other groups. There was no significant difference in the functional recovery between paralysis side and gender. Spasticity from baseline to 1-year as measured on the Modified Ashworth Scale showed a decrease in all joints. Conclusions: In a large cohort retrospective study, functional improvement in patients were noted with different etiology, age, gender and paralyzed side. Generally, cerebral palsy and younger patients were expected to have better functional improvement comparing to other subgroups.

Keywords: contralateral C7 transfer, retrospective study, spastic arm paralysis
Patient characteristics in cubital tunnel syndrome at a referral centre and predictive factors for outcome of simple decompression versus subcutaneous transposition of the ulnar nerve

List of authors:
Erika Nyman*, Alice Giöstad1
1 Dept of Clin and Exp med, Linköping University, Division of Hand Surg and Plastic Surg, Linköping University (Linköping)

Objectives / Interrogation: The objectives were to study characteristics of patients with cubital tunnel syndrome at a referral centre and to analyse predictive factors for outcome of simple decompression versus ulnar nerve transposition.

Methods: A retrospective observational study was performed on patients with cubital tunnel syndrome operated 2011 - 2014. Data were obtained from patient charts from, a specially designed form, and a DASH (Disabilities of the Arm, Shoulder and Hand) questionnaire. Patient characteristics and predictive factors for surgical outcome were analysed in 202 cases (173 patients; each arm evaluated as a separate entity).

Results and Conclusions: The mean age was 51 years, 61% of the cases were females, 31% were smokers, and mean BMI was 27. Fifty-four percent suffered from another nerve compression lesion in the same arm, 35% from another nerve compression lesion in the opposite arm, 23% had neck problems, 17% had shoulder problems and 12% had diabetes. Fifty-six percent (n=114) of the cases had simple decompression, 28% (n=56) had primary, and 16% (n=32) had secondary subcutaneous transposition. Patients with secondary transposition were significantly younger than patients treated with simple decompression.

Overall, 55% of the patients were satisfied with the surgical result (56% after simple decompression, 48% after primary and 64% after secondary transposition), but only 8% stated that they would not go through the surgery again. The mean DASH score was 31 (SD 25) with no significant difference in DASH scores between surgical groups, or between patients with positive or negative electrophysiological tests; nor was there any association between results from the tests and type of surgery. There was a significantly increased risk of complications, following primary and secondary transposition compared to simple decompression, and the complication rate was doubled in smokers.

We conclude that surgically treated cases with cubital tunnel syndrome at a referral centre constitute a heterogeneous group with great comorbidity and often other nerve compression lesions with a wide variation in symptoms and surgical outcome. We recommend simple decompression as surgical procedure of first choice. Anterior transposition should only be used in selected cases or when simple decompression fails. All patients should be strongly recommended to stop smoking considering the remarkably increased risk for complications among smokers.

Frozen Amputated fingers - Replantation and Other treatments

List of authors:
Zdenek Dvorak*, Tomas Kubek1, Pavel Novak2, Igor Stupka2, Jiri Vesely1
1 Department of Plastic and Aesthetic Surgery St.Anna’s UH, Faculty of Medicine, Masaryk University Brno (Brno)
2 Department of Plastic and Aesthetic Surgery St.Anna’s UH (Brno)

Objectives / Interrogation: Treatment outcomes presentation of patients with upper limb amputation injuries, whose amputated fingers were inadequately treated during transportation to the replantation center and suffered from cold injury.

Methods: A set of 21 patients (19 men, 2 women) operated at Department of Plastic and Aesthetic Surgery in Brno from 1 January 2007 to 31 December 2017. Following is an overview of malpractices used to treat the amputates: 8 times the amputate was packed in gauze with dry ice, 4 times amputates were frozen in ice cube, 3 times frozen in crushed ice, 1 hand was lined with frozen saline solution, 2 amputates were transported in package of frozen vegetables. There were cases when the amputate was first frozen by ice, then dipped in saline solution and then dried in the ambulance or another case, when the amputate was primarily heavily burned with fire, then it was cooled in the snow for 45 minutes and, then it was wrapped in gauze and brought in a snowball.

Results and Conclusions: Results: Primary amputation was performed in 8 patients (reasons: 3 times - mechanical destruction of amputate, 3 times - thermal damage, 1 - a patient’s wish and 1 - indication of comorbidity). Two patients were treated with the composite graft method, both grafts were successfully healed. Replantation was performed in 11 patients and in one case the hand was completely replanted. Perioperative complications were frequent, repeated arterial thrombosis in 2 patients, necessity of micro anastomosis of both vessels, use of venous graft, 3 patients had repeated venous anastomosis for repeated venous thrombosis, 2 patients had rapid development of burn changes on replanted fingers - skin whitening, then livid color and formation of blisters. In 2 patients, the blood flow was very slow and blood supply was established with a time delay in ICU. Revision operations were performed in 6 patients, the reasons were arterial thrombosis, graft thrombosis, 3 times venous thrombosis, once bleeding, and twice finger amputation for necrosis. 11 fingers and one hand were healed on the sample of 8 patients. Thermal damage was unmasked after the replantation. Replants failure occurred in 3 fingers in 3 patients. The overall success rate of replantation of frozen fingers was 73%. Conclusion: Even inadequately treated and thermally damaged amputates can be replanted with a relatively high success rate but more frequent perioperative and postoperative complications have to be considered.

Spasticity surgery/What we learned in three years of practicing it.

List of authors:
Constantinos Kritiotis¹, Anuj Mishra¹
¹ Manchester Hand Centre (Manchester)

Objectives / Interrogation: We present our experience with 7 spasticity patients. We present where we were successful, where we failed and what we have to recommend in the management of this challenging and increasing population.

Methods: We have operated on 7 spasticity patients from 2015 to date. Causes of spasticity were CVA (thromboembolic or haemorrhagic) and traumatic brain injury. Patients were evaluated preoperatively using the Ashworth and House scale. Video evaluations were used as well and two of the patients received Botulinum Toxin injections.

The aim of surgery was primarily to reduce spasticity and if possible, improve the functional outcome as well.

Post-operatively, the patients were referred for physiotherapy and occupational therapy to obtain the best possible outcome.

**14th IFSSH Congress**

**Abstract no.: IFSSH19-1300**

FDS 4 to APL, BR to EDC, release of PT and thenar muscles, tenotomy of FCU |

Had long assessment period | did not help with finger opening

4. PA 58 Ischaemic CVA |

17/6/17 1. Had preoperativ e nerve blocks to assess, was able to open fingers with extreme wrist flexion |

Functional outcome was not expected, general posture of upper limb improved except from fingers/now in clenched fist/will need superficialis to profundus transfer
Results and Conclusions: All seven patients had a reduction of spasticity. Two patients had an improved functional outcome which allowed them to use their hands again for basic functions. Thromboembolic CVA patients despite having reduced spasticity, did not have any functional gains. One of the patients unmasked intrinsic spasticity after the procedure. Patients with traumatic brain injuries and haemorrhagic CVAs (and no other concomittant injuries) were more prone to developing spasticity of the intrinsics (3 in our series) than patients that suffered a thromboembolic CVA.

Conclusions: Patients with spasticity need to be evaluated meticulously and for a significant amount of time prior to surgical intervention. We believe that there is a link between haemorrhagic brain injuries (of traumatic aetiology or CVA) and intrinsic spasticity but further research needs to be done to solidify this argument. Tendon transfers to augment finger extension have no place in spasticity surgery. Neurectomies tend to produce very good results regarding the elimination of spasticity. Patients need to be informed that spasticity surgery is about reducing spasticity and not about improving the functional outcome, although there are cases that they some functional improvement could be expected(especially in patients following traumatic brain injury)

**Objectives / Interrogation:** Spasticity in the upper limb has a significant impact on the patient's function. Management of patients inflicted with this condition demands care from across multiple disciplines. There is however little collaborative work process established for adult patients. We aim to develop a comprehensive management for skeletally mature patients who developed upper limb spasticity in a coordinated multi-disciplinary team. Our treatment objectives are to improve patient's well-being through pain reduction, function optimisation, limb posturing reduction, and to prevent complications through early intervention.

**Methods:** An outpatient clinical care pathway involving the neurologist, hand surgeon, advance practitioner nurse, hand occupational therapist, medical social worker, pharmacist and dietician has been developed. Eligible patients are referred to the clinic following diagnosis and stabilization of inciting causes including cerebrovascular accidents, brain or spinal cord injuries and neurodegenerative disorders. Joint assessment by the different disciplines is performed in the same clinic session. Domains of evaluation included patient's general cognitive ability, condition specific pattern of neurological deficits, limb specific degree of spasticity and classification of limb function. A proposed algorithm based on contemporary evidence, techniques and available expertise is used by the team to suggest treatment options for patients and align management objectives with patients' expectations.

**Results and Conclusions:** Six patients have been reviewed under the proposed clinical pathway. There were 4 males and 2 females with mean of 62.9 years of age during the time of review. They were reviewed on average 279 days from the episode of inciting condition. The median number of activities of daily living (ADL) the patients could perform independently was 1.5 out of 6 prior to any treatment. Other patient outcomes and satisfaction will be collected before and after treatment.

We propose an outpatient clinical care pathway for adult patients suffering from spasticity of upper limbs. In view of the complexity of management in these patients, a treatment algorithm will lay out options available for patients, therapists and physicians to provide optimal care in line with current practices and patients' expectations.

Early Amputation vs Limb Salvage: Characterization of Procedural Management for Limb Threatening Upper Extremity Injuries in Hospital Days 1 to 30

List of authors:
RF Westenberg\textsuperscript{1}, Chris Langhammer\textsuperscript{1}, Femke Nawijn\textsuperscript{1}, K Eberlin\textsuperscript{1}, NC Chen\textsuperscript{1}
\textsuperscript{1}Massachusetts General hospital (Boston)

Objectives / Interrogation: There is little quantitative data regarding the acute care burden for patients with upper-extremity threatening injuries. This study characterizes procedural care provided for a cohort of patients with acutely limb-threatening traumatic upper-extremity injuries at an urban level-1 trauma referral center based on the decision to perform early amputation versus limb salvage.

Methods: Retrospective chart review of an institutional database from 2010 - 2017 was performed, identifying patients who were diagnosed with upper-extremity amputation or treated with extremity replant at a level proximal to the MCP joints. Patients were excluded for atraumatic mechanism of injury or for incomplete records. Patient and injury demographics as well as the sequence of procedural management were extracted through chart review.

Results and Conclusions: 22 patients met inclusion criteria; 6 underwent early amputation (EA cohort), 16 attempted limb salvage (LS cohort). There was a 63% limb salvage rate. The EA cohort was more severely injured (average ISS: EA = 54, LS = 33; p = .02), and had more proximal injuries (Table 1). Differences in the average length of ICU admission (EA = 11d vs. LS = 9d), inpatient admission (EA = 19d vs. LS = 23d), or number of upper-extremity procedures during the first 30 days (EA = 3.0 vs. LS = 4.3), did not reach statistical significance. In the EA cohort, only 4 procedure types (I&D, amputation, wound closure, and local flaps) accounted for 75% of upper extremity interventions. In the LS cohort, 6 additional procedure types (ORIF, external fixation, tendon repair, fasciotomies, skin graft, and vessel anastomosis) were needed to account for 75% of upper extremity interventions. Free tissue transfer was ultimately performed in 4 of 22 patients (18%) (Figure 1).

Conclusions
This study demonstrates that LS cohort patients had less extreme global injuries. However, the frequency of their procedural interventions and length of ICU and inpatient admissions did not significantly differ from the EA cohort. Additionally, attempted limb salvage required inclusion of orthopaedic and microsurgical skills not required for early amputation. This information may be used to instruct institutional decision making regarding team composition, training, and resource allocation required to maintain limb salvage programs.

Investigation of RARg Signaling in Human Growth-Plate Chondrocytes

List of authors:
Joshua Abzug*, Masatake Matsuoka¹, Motomi Enomoto-Iwamoto¹, Masahiro Iwamoto¹
¹ University of Maryland School of Medicine, Department of Orthopaedics (Baltimore)

Objectives / Interrogation: Pediatric fractures involving the growth-plate (GP) require careful follow-up, as these fractures can lead to inhibition of bone growth resulting in progressive growth imbalance, deformity and/or painful conditions. Currently, surgical intervention is the only means to correct substantial imbalance and deformity due to a physeal injury. However, these procedures are invasive and cause substantial burden to the child and their family. Previous studies show that retinoic acid receptor (RAR) isoform RAR gamma (RARg) is a critical regulator of bone growth. RARg is dominantly expressed in GP chondrocytes, regulates matrix synthesis and turnover, and transition of cartilage to bone. Pharmacological activation of RARg causes early closure of the GP and inhibits further bone growth while inactivation delays maturation of GP chondrocytes. RARg agonists/antagonists may have therapeutic potential for the treatment of abnormal endochondral ossification and bone growth. The purpose of this study was to investigate the role of RARg signaling in human GP.

Methods: Expression of RARg and its signaling-related molecules in damaged or normal GPs collected at the time of epiphyseodesis surgery were analyzed via immunohistochemistry. Surgical specimens were immediately fixed in 4% PFA, decalcified and sectioned.

Results and Conclusions: RARg and Aldh1a2, a rate-limiting enzyme of retinoic acid synthesis were detected in pre-and hypertrophic chondrocytes in the intact growth-plate. In damaged GP, the typical pattern of columnar GP was completely gone. There was no sign of progression of active endochondral ossification as the remnant of cartilage (resting or arrested cartilage) is completely sealed by bone tissue. In a subsequent experiment, the response to RARg agonist in human and mouse chondrocytes were compared. Human GP-chondrocytes were isolated from the GP of polydactyly samples and mouse chondrocytes were isolated from new bone mouse epiphysis. Cells were maintained in culture until confluent and then treated with 100nM of selective RARg agonist for 47h. Total RNA was purified and subjected to Clariom Gene Array. In ether cells, pharmacological activation of RARg down-regulated cartilage-matrix genes and up-regulated expression of genes related to MMPs, angiogenesis and osteoclastogenesis.

These findings indicate that RARg signaling is present and functioning in human cartilage, and selective RARg agonists might be an effective therapeutic drug utilized for growth restriction/epiphyseodesis.

Outcomes of Repeated Treatment in Dupuytren's Disease; a Comparison with Initial Treatment

List of authors:
Nienke Mendelaar\textsuperscript{1}, Ralph Poelstra\textsuperscript{1}, Christianne van Nieuwenhoven\textsuperscript{2}, Harm Slijper\textsuperscript{2}, Reinier Feitz\textsuperscript{3}, Steven Hovius\textsuperscript{2}, Ruud Selles\textsuperscript{2}

\textsuperscript{1} Erasmus Medisch Centrum, Room Ee15.89, Postbus 2040 (Rotterdam)
\textsuperscript{2} Erasmus Medisch Centrum, Postbus 2040 (Rotterdam)
\textsuperscript{3} Xpert Clinic (Eindhoven)

Objectives / Interrogation: There are multiple studies about effectiveness of primary treatment in Dupuytren's disease. This is however not the case concerning treatment effectiveness of recurrent disease. Therefore, the primary aim of this study is to compare treatment effectiveness of initial and repeated surgery in patients with Dupuytren's disease.

Methods: Patients who underwent both initial and repeated treatment were selected from a prospectively maintained database consisted of finger goniometry and the Michigan Hand Outcomes Questionnaire (MHQ) prior to treatment and 3 months afterwards. Treatment effectiveness was measured as improvement in extension deficit and patient-reported hand function. In addition, measurements at intake of both treatments were compared. Subgroup analysis was done to evaluate influence of type of surgery of initial treatment on outcomes of repeated treatment. Finally, complications were scored after both treatments.

Results and Conclusions: 114 Patients were included in the final analyses. In the majority of the patients, the initial treatment was needle fasciotomy (49\%) or limited fasciectomy (40\%), whereas most patients (79\%) underwent a limited fasciectomy for their recurrent contracture. Improvement in extension deficit and MHQ outcomes was equal for initial and repeated treatments. Extension deficit and MHQ were significant worse at intake of repeated treatment compared to these outcomes at intake of initial treatment. In addition, patients who initially underwent needle fasciotomy achieved a better contracture reduction after repeated treatment compared to those who underwent limited fasciectomy as initial treatment. A total of 23 complications were observed. The largest groups of complications were alterations in sensation (e.g. pain or numbness), 10 out of 23, and problems with scar tissue (e.g. adhesions or scar tissue contraction), 6 out of 23. The majority of complications, 14, were seen after a limited fasciectomy for recurrent disease.

This study demonstrates that treatment of recurrent Dupuytren's disease is as effective as initial treatment in reducing contracture and improving patient-reported hand function, despite larger extension deficit and worse self-assessed hand function before undergoing repeated treatment. Furthermore, needle fasciotomy for initial treatment results in better outcomes of repeated treatment. These findings can be used for a more evidence-based preoperative counseling with patients with recurrent Dupuytren's disease.

Keywords: Dupuytren's contracture, treatment outcome, recurrent disease, PROM, finger goniometry
Objectives / Interrogation: The metacarpal fractures are common, and to many of this fractures are treated without surgical, but some of the are unstable, the need fixation. There are different types of fixation, like wires, plates, but in fractures near to the articular surface when the metaphysis is fracture and has comminuted, we prefer use codilar plates, because this give angular stability to the fracture. This research wants to review the use of the codilar plates in this type of fractures.

Methods: We review 80 fractures in all we used the condilar plates, all patients was examined by a different surgeon no the same who performed the surgery. All the condilar plates was from the same company (Mondeal). We used the same instruments to measure the results, we use a goniometer and dynamometer

Results and Conclusions: The results was find union at 6 weeks (4 - 9 weeks), range of movement was flexion 80 degrees (62 - 95), grip strength 12 mmHg (8 - 17) pain 3 (2 - 5), return to work at 20 days (15 - 52), All patient was check at 2 week, 6 week and 6 montes post surgical. Our results are compared with other methods of fixation, but we think the condilar plates has advantage because gives angular stability to the fracture

Does the Use of a Parent’s Cell Phone Reduce Anxiety During Cast Removal?

List of authors:
Joshua Abzug*1, Serge Tzeuton2, Danielle Hogarth1, Alexandria Case1, Nathan O’Hara1
1 University of Maryland School of Medicine, Department of Orthopaedics (Baltimore)
2 University of Maryland School of Medicine (Baltimore)

Objectives / Interrogation: Cast immobilization of pediatric and adolescent fractures is the mainstay of treatment for the vast majority of fractures. However, cast removal may cause the child to be anxious making the removal difficult and potentially leading to an adverse complication during the removal. Previous studies have demonstrated reduced anxiety utilizing art and music therapy, however this requires substantial resources and may not be possible in the outpatient setting. The purpose of this study was to prospectively determine the effectiveness of visual stimulation utilizing a parent’s cell phone or hand-held device to determine if this “no cost” alternative can reduce anxiety during cast removal.

Methods: A prospective study was performed to enroll all pediatric patients that presented in the outpatient setting for cast removal. Blood pressure and heart rate were recorded using an automated sphygmomanometer and the child’s Faces score was assessed. Measurements of these proxies for anxiety were performed in the waiting area prior to cast removal, in the cast room during cast removal, and in the cast room 5 minutes following cast removal. Patients were randomized to utilize their parent’s mobile device or not. Repeated measures mixed effect models were used to determine the effect of the mobile device to reduce the patient’s heart rate and blood pressure compared to the control group. A student t-test was used to determine the effect of the intervention of the Faces score.

Results and Conclusions: Fifty patients were randomly assigned to either the experimental group (n=21) or the control group (n=29) via REDCap survey. Despite adequate power, no statistically significant difference was present in the heart rate (p=0.82), systolic blood pressure (p=0.45), and Faces score (p=0.06) between the groups.

Using a parent’s mobile device to distract a child during cast removal did not reduce anxiety. Alternative methods such as music and art therapy may be better suited to reduce anxiety during cast removal, but these methods require substantial resources. Future studies are needed to identify a low cost alternative to reduce anxiety during cast removal. Mobile cell phones and personal electronic devices are not effective at reducing anxiety during cast removal and therefore we cannot recommend them as an alternative low-cost distractor.

cast removal; anxiety; pediatrics
'WALANT Carpal Tunnel Release: Technical Considerations and Pain Outcomes

List of authors:
Julia Ruston*, Dariush Nikkhah1, Robert Pearl1, James Blair1
1 Queen Victoria Hospital, Hand Surgery Department (East Grinstead)

Objectives / Interrogation: Carpal tunnel release (CTR) is often performed under local anaesthetic (LA), as a day case. Streamlining the operation to better utilise healthcare resources, and improve the patient experience, led us to compare the use of wide awake local anaesthesia no tourniquet (WALANT) with 'standard' LA and tourniquet (LAT).

Methods: We retrospectively identified and analysed the data of patients who underwent CTR; consulting electronic records, operation notes, self-reported Visual Analogue Scale (VAS) pain scores, and satisfaction reports. WALANT technique involved subcutaneous infiltration of 4.4ml 2% lignocaine with 1:80,000 adrenaline; 15-20 minutes pre-operatively. LAT technique employed plain Lignocaine and Levobupivicaine (injected in the same manner) with the addition of an upper arm tourniquet for the operative dissection.

Results and Conclusions: 46 patients underwent CTR; 22 had WALANT, 24 had LAT. Mean VAS pain scores (0-10 point Likert scale; 10 being most painful) were 0.73 and 1.88 respectively. With the exception of 1 outlier the WALANT cohort all reported pain scores of 3 or less; whereas 5 LAT were recorded at 5 or over. That this descriptive trend was not found to be significant (Mann-Whitney U test p<0.05) inferentially, is likely to represent a type 2 error, as extending to a p=0.08 results in significance. Reasons for discomfort in the WALANT group were deep nerve pain (n=4) and retractor discomfort (n=1). Patients in the other group noted deep nerve pain (n=6) and tourniquet pain (n=5). 93% were extremely satisfied and all would recommend this technique.

Our infiltration volume is smaller than original WALANT descriptions and this may account for intraoperative pain in some patients. In larger hands we recommend increasing volumes, and waiting longer than 20 minutes.

In summary, both methods were acceptable in terms of pain, efficacy and satisfaction. This supports the literature that WALANT is at least as good as the standard LA/tourniquet method for most cases, and would transfer readily to an outpatient procedure room setting if this became a necessity.

median nerve, carpal tunnel, wide awake surgery
Does an Associated Elbow Dislocation Lead to Worse Outcomes in Medial Epicondyle Fractures?

List of authors:
Joshua Abzug*, Sarah Toner¹, Alexandria Case¹, Danielle Hogarth¹
¹ University of Maryland School of Medicine, Department of Orthopaedics (Baltimore)

Objectives / Interrogation: 50% of all medial epicondyle fractures are associated with an elbow dislocation. The purpose of this study was to assess differences in outcomes and complications between patients with isolated medial epicondyle fractures and those with a concurrent elbow dislocation.

Methods: A retrospective review was performed over a seven-year period. Patients were identified utilizing CPT and ICD-9/10 codes for medial epicondyle fracture and elbow dislocation. Data obtained included demographics, mechanism of injury, concurrent injuries, treatment modality (immobilization alone vs. operative intervention), post-operative range of motion, and complications. Statistical analysis was performed utilizing Student's t-tests to assess differences between the samples. A power analysis concluded that the use of at least 9 patients with complete data yielded a 90.55% power to detect a 5 degree difference.

Results and Conclusions: Forty-eight patients (22 females, 26 males) with an average age of 10.49 years (range: 4-17) were identified with medial epicondyle fractures over the study period, of which 17 had a concurrent elbow dislocation. The most common mechanisms of injury were falls onto outstretched hands (n=22) and falls from heights (n=16). The medial epicondyle fractures with concurrent elbow dislocations more frequently had additional concurrent injuries (8/17 vs 3/31; p=<0.01), which included ulnar nerve injuries (2/17 vs 1/31), anterior interosseous nerve injuries (2/17 vs 0/31), UCL tears (2/17 vs. 0/31), and other fractures (2/17 vs 2/31). Furthermore, the group with concurrent elbow dislocations was more frequently treated operatively (12/17 vs 8/31; p<0.01). However, final range of motion, as compared to the contralateral side, was not statistically different between the groups (p=0.25). There was no difference in the rate of complications between the groups (3/17 vs 8/31; p=0.57), percentage of therapy referrals (6/17 vs 7/31; p=0.35), or length of follow up (p=0.77).

The outcomes and complications of pediatric and adolescent medial epicondyle fractures with a concurrent elbow dislocation are not different than those of isolated medial epicondyle fractures. Further investigation into other influencing factors of medial epicondyle fractures that lead to various outcomes and complications is warranted to better guide treatment planning and counseling to these patients and their families.

HAND HOT CLINIC -WHAT do Patients think ?

**List of authors:**
Cheyenne Kate Rebosura*, Mohan Shanmugam¹, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

**Objectives / Interrogation:** Emergency departments are constantly experiencing high patient load, and their physicians under high pressure for proper disposition of their patients. We noticed that a significant proportion of admissions to the inpatient ward may be avoided, when the definitive management by the relevant specialty could be carried out in the outpatient setting, and in a timely fashion. This has positive effects on delivery of patient care and on healthcare cost.

Hand Hot clinic has been introduced in our institution to provide quick access to speciality service, improve Hand emergency care, and to reduce burden on the emergency department.

Our objective is to find out patients' experience, to evaluate and improve delivery of Hand Hot Clinic care.

**Methods:** Hand Hot clinic is intended to reduce the admissions of patients with acute hand problems. Patients will be assessed by the hand surgery team, who will institute initial management and draw up a definitive plan.

A questionnaire was specifically designed to explore patients perspectives and experience. All the patients were triaged by the nurse on arrival, followed by review and management by the Hand team doctor on duty.

Patients were then asked to fill in the questionnaire before leaving the clinic. All data were anonymised and no patient identifiable data was used in the study.

**Results and Conclusions:** The initial results are encouraging. Patients as well as the Emergency Department physicians are happy that their immediate concerns get addressed promptly. Deeper analysis will be presented.

**Keywords:**
Hot clinic
Secondary Traumatic Stress and Depression in Obstetrical Providers After Shoulder Dystocia and Brachial Plexus Birth Palsy Deliveries

List of authors:
Joshua Abzug*, Keisha Robinson², Danielle Hogarth¹, Nathan O'Hara¹
¹ University of Maryland School of Medicine, Department of Orthopaedics (Baltimore)
² University of Maryland School of Medicine (Baltimore)

Objectives / Interrogation: Traumatic deliveries occur at a rate of 29 per 1000 births in the United States. Shoulder dystocia delivery, specifically, is seen, in 0.2 to 3.0% of all vaginal births posing a risk for brachial plexus birth palsy to the child. Frequent exposure to traumatic birth events that have high rates of secondary complications is suggested to correlate with secondary traumatic stress or depression symptoms. Parents have been found to exhibit secondary traumatic stress symptoms, however, it is unknown whether obstetrical providers are just as, if not more, susceptible to such diagnoses. The purpose of this study is to determine if shoulder dystocia deliveries potentiates secondary traumatic stress syndrome and depression in obstetrical providers following a shoulder dystocia delivery.

Methods: A thirty-eight question survey was distributed to obstetrical providers in three health systems in the metropolitan Baltimore region. Secondary traumatic stress was measured via the Secondary Traumatic Stress Scale while depressive symptoms were evaluated using the PHQ-9 questionnaire included in the survey. Simple statistics were performed to analyze the data.

Results and Conclusions: Eighty-five obstetrical providers including residents, attendings, nurse-midwives, and medical students participated in this study. A significant relationship between exposure to a shoulder dystocia delivery and prevalence of secondary traumatic stress syndrome and depression could not be established. Secondary Traumatic Stress scale scores (range: 34.5-39.2) indicated that moderate or severe (STS scores > 49) levels of secondary traumatic stress was not exhibited. Similarly, the PHQ-9 scores (4.9-6.6) did not demonstrate a moderate to severe (PHQ-9 scores > 10) level of depression. Despite 44.7% of the sample regularly attending shoulder dystocia deliveries, only 28.2% of participants believed they had adequate training for shoulder dystocia deliveries.

Obstetrical providers do not experience secondary traumatic stress and depression following shoulder dystocia deliveries. It is possible that providers have outlets and/or training following to know how to cope with these deliveries. Unlike parents of brachial plexus birth palsy patients, obstetrical providers do not experience secondary stress syndrome and depression following shoulder dystocia deliveries.

Keywords: obstetrics; shoulder dystocia; providers; secondary traumatic stress; depression; post-traumatic stress disorder; brachial plexus birth palsy
A new pattern of extremely distal articular fragments in distal radius fractures

List of authors:
Virginia Crafuni*1, Pedro Bronenberg Victorica1, Gerardo Gallucci1, Agustin Donndorff1, Jorge Boretto1, Pablo De Carli1

Hospital Italiano de Buenos Aires (Capital Federal)

Objectives / Interrogation: Fractures of the distal Radius are very common, and they frequently are intra-articular. In most of these cases surgical treatment is required and an adequate fixation is achieved with the current implants. Nevertheless there is an unusual pattern, determined by the presence of extremely distal fragments, where traditional osteosynthesis could not be useful.
The goal of this study is to analyze this distal radius fracture pattern that has some distinctive specific fragments and might be treated in a different way from the standard distal radius articular lesions.

Methods: X-rays and CT scans were used to retrospectively study 1019 distal radius fractures operated in our Hospital between January 2012 and December 2017.
Our inclusion criteria were:
- Radial Styloid fracture
- Avulsion of the ventral and/or dorsal rims of the distal radius
- A very distal articular fragment of the lunate and/or scaphoid fossa of the radius, including a shell of subchondral bone not more than 3 mm thick.
We excluded:
- Patients younger than 18 years-old
- Patients with radiocarpal dislocation
The resulting preoperative X-rays and CT scans were compared looking for a common fracture pattern.
Postoperative studies were evaluated to review the type of fixation used.

Results and Conclusions: Ten patients among 1019 distal radius fractures met the inclusion criteria (1%).
All patients but one were male. Mean age was 39 years old.
In all the cases the 3D CT scans clearly defined the fracture fragments, seldom identified with only plain X-rays. All the patients that met inclusion criteria had an associated fragment of the lunate and/or scaphoid fossa and its subchondral bone, not thicker than 3 mm.
Both Radial Styloid fractures and dorsal or volar avulsion solid fragments were fixed with cannulated headless 2.3 screws. Smaller avulsion or comminuted avulsion fragments were fixed with bone sutures or bone anchors. Dorsal comminution was buttressed with 2.0 or smaller plates. None of the fractures was feasible for standard volar locking plating.
We describe a pattern of distal radius avulsion fracture without dislocation, which is associated with subchondral distal fracture of the lunate and/or scaphoid fossa.
This pattern of fracture affected more frequently young males with high energy injuries.
It is probably necessary to develop new types of osteosynthesis materials to efficiently fix these very distal small fragments, since it is difficult to achieve this with the existing osteosynthesis.

distal radius, avulsion fractures, subchondral bone
Short term results of the adapted Mennen technique of pollicization (no detachment of intrinsic musculature)

List of authors:
Andrea Jester\(^*\), Kerstin Oestreich\(^1\), Sami Alani\(^1\), Carla Baldrighi\(^1\)
\(^1\) Birmingham Women's and Children's Institute (Birmingham)

Objectives / Interrogation: Standard practise during pollicization is to detach and re-attach intrinsic musculature from the MCP region into the PIP region. Most surgeons are reluctant to change their technique once they feel safe with their chosen approach. We have adapted our technique from detachment and re-insertion of intrinsic musculature (Kozin, 2012), to leaving dorsal interossei and extrinsic muscles attached as described by Ulrich Mennen (personal communication). The aim was to demonstrate that the modified technique leads to a decrease in operating time, shorter rehabilitation and good postoperative results.

Methods: In 2017/8, 11 patients with Blauth 3b to 5, including one patient with an underlying Bayne 4 radial hemimelia, underwent surgery according to the Mennen modification. The rest of the technique was as described by Kozin in 2012, except two sutures were used to stabilize the new CMC joint at the base instead of K-wire. All patients were immobilized for 4 weeks in a bulky dressing and then started to move freely.

Results and Conclusions: No intra or postoperative problems were encountered in any of the patients. Despite leaving the intrinsic muscles in place good access to the metacarpal 1 was achieved. Operating time was decreased. Patient used the newly pollicised thumb sooner than with our previous method. Interfering with the intricate anatomy of the MCP capsule including the insertion of the dorsal interossei appears to be unnecessary. Short-term results with regards to speed of recovery and early functionality are promising. Long-term results obviously need to be awaited regarding CMC movement.

Keywords: pollicization, intrinsic musculature,
The Results of Surgical Treatment for Osteoarthritis of the Thumb Trapeziometacarpal Joint: The Correlation With Trapezial Space Height

List of authors:
Hirofumi Imai*, Masatoshi Takahara2, Daichi Ota2, Mikiro Kondo2
1 International Center for Lymphedema, Hiroshima University (Hiroshima)
2 Izumi Orthopedics Hospital (Sendai)

Objectives / Interrogation: It is not well known whether the degree of shortening of the Trapezial Space Height (TSH) after trapeziectomy for osteoarthritis of thumb trapeziometacarpal joint has any effects on the results. The aims of this study were to assess the pre/postoperative changes of the TSH and the results and investigate the relationship between them.

Methods: This retrospective study was composed of 33 patients (37 hands) who underwent surgical treatment for osteoarthritis of thumb trapeziometacarpal joint, 5 patients (6 hands) of men and 28 patients (31 hands) of women with ages 63 (45 – 84). All patients were treated with trapeziectomy and Ligament Reconstruction without Tendon Interposition (LR without TI). The K-wires were inserted to stabilize the thumb for 4 weeks after surgery. We assessed the TSH on the X-ray preoperatively and postoperatively at 2 weeks, after removal of the K-wires, 3 months, 6 months and 12 months. We also assessed pain visual analog scale (VAS) preoperatively and postoperatively at 6 months and 12 months. We investigated the relationship between the TSH and pain VAS.

Results and Conclusions: Results: The preoperative mean TSH was 12.4 mm and the postoperative mean TSH was 8.9 mm at 2 weeks, 6.7mm after removal of the K-wires, 6.7 mm at 3 months, 6.3 mm at 6 months and 6.1 mm at 12 months. The mean degree of TSH shortening from preoperatively to 2 weeks postoperatively was 3.4mm, from preoperatively to 3 months postoperatively was 5.7mm and from preoperatively to 12 months postoperatively was 6.3mm. The preoperative mean pain VAS was 6.2 and the postoperative mean pain VAS was 3.2 at 3 months, 2.1 at 6 months and 1.2 at 12 months. Analysis of the correlation between the TSH and the 12 months postoperative VAS did not show any significant correlation (Pearson correlation coefficient was < .20). Similarly, analysis of the correlation between the degree of shortening of the TSH and the 12 months postoperative pain VAS did not show any significant correlation (Pearson correlation coefficient was < .20).

Conclusion: We concluded that LR without TI not only successfully maintained the Trapezial Space Height without significant shortening after removal of K-wires but also yielded the excellent results. There was no correlation between the pre/postoperative changes of TSH and the results. We expected the cause that we performed ligament reconstruction without any compression or traction to the thumb. Because of these results we prefer the "in site" ligament reconstruction.

Wrist Arthrodesis in Patients with Cerebral Palsy

List of authors:
Marvin Dingle*1, Derek Ipsen1, Jefferson Jex1
1 Walter Reed National Military Medical Center (Bethesda)

Objectives / Interrogation: Management of patients with cerebral palsy (CP) with upper extremity involvement is complex. One known deformity in this population is the development of contracture about the wrist. The role of wrist arthrodesis for patients with CP has become much more common. This option was previously used only when the patient has little or no function in fear that wrist arthrodesis will have a negative effect on grip strength by means of altering the tenodesis effect of the finger tendons. To our knowledge, treatment of this complex issue has not been reported among patients in the military health care system. The goal of this study was to examine the outcomes and clinical course of wrist arthrodesis in this population.

Methods: Study design was a prospective case series. Computer-based review of operative codes and a subsequent chart review identified 5 children who had wrist arthrodesis performed between 2014-2018. All patients were diagnosed with cerebral palsy of various severity. 2 patients had hemiplegia, the other 3 patients had spastic quadriplegia. All patients had moderate to severe cognitive impairment and were dependent on their parents and caregivers. Age range at the time of surgery was 13-35 years of age. Mean follow-up was 3 years (range, 0.5-4.3 years). All children are enrolled within the military medical insurance program, TRICARE. Their surgical procedure and post-operative care were all within the military health system.

Results and Conclusions: Prior to surgery, 4 patients were given a trial of casting. This was meant to simulate neutral wrist position obtained by wrist fusion. The parents and the patients observed improved function with casting and subsequently underwent wrist arthrodesis.

In 4 cases, wrist arthrodesis was performed with a proximal row carpectomy. In those cases, the removed carpal bones were used as autograft to aide in fusion. Plate fixation with the Acumed wrist fusion plate or with a Synthes small fragment LCP 3.5 mm plate.

Post-operatively, all patients were casted for 6-12 weeks and enrolled in formal occupational therapy. All patients had improved function and cosmesis after the procedure by patient and parent report. This was true for patients with low and high GMFCS classification. None of these patients required further surgery after the index procedure.

With careful patient selection, surgical intervention for the upper extremity in patients with wrist contracture related to CP may be indicated to improve function, cosmesis, and hygiene.

Histological examination of osteochondritis dissecans of the elbow

List of authors:
Masatoshi Takahara*, Mikio Harada, Masahiro Maruyama, Tomohiro Uno, Mikiro Kondo, Hiroshi Satake, Michiaki Takagi
1 Izumi Orthopaedic Hospital (Sendai)
2 Izumi Orthopaedic Hospital, Yamagata University (Sendai)
3 Yamagata University (Yamagata)

Objectives / Interrogation: Osteochondritis dissecans (OCD) of the elbow is a localized injury of the articular cartilage and subchondral bone that is commonly seen in the young athlete. Mechanical factors seem to play an important role. The etiology of OCD lesions remains unclear. The aim was to address the course of pathologic progression.

Methods: The subjects were twelve elbows in 12 patients (average age, 13 years) with osteochondritis dissecans of the humeral capitellum. During osteochondral autograft, cylinder osteochondral plugs were taken from the center of the osteochondritis dissecans lesion and examined with light microscopy.

Results and Conclusions: The specimens were grossly divided into 3 parts: Articular fragment, intermittent part and basal bone. The intermittent part including a partial cleft consisted of fibrocartilage and connected the articular fragment with the basal bone. In the basal bone, there were no findings of osteonecrosis and active bone formation was found. The superficial area of the articular fragment consisted of articular cartilage and the deep area consisted of three components: (1) calcified cartilage, (2) viable bone, and (3) necrotic bone. The deep area of articular fragment consisted of calcified cartilage without bone in eight patients (average age, 12.8 years), although it had viable subchondral bone in two (average age, 12.5 years) and necrotic bone in two (average age, 15 years).

Discussion: Fibrocartilage in the intermittent part seemed to be reparative tissue to connect the articular fragment to basal bone. Basal bone was normal, suggesting that primary separation occurred just beneath the articular fragment. The radiographic images OCD showed delayed calcification and bone formation in the affected subchondral bone. These delayed ossification was observed in the articular fragment: cartilage calcification in eight, viable bone in two and necrotic bone in two. These findings suggest the following course of pathologic progression of OCD: (1) primary separation occurs horizontally under the deep cartilage and is followed by fibrocartilaginous repair, (2) Calcification occurs horizontally in the deep cartilage to be replaced by bone, however repetitive microtrauma causes bone replacement difficult, (3) Subchondral bone is formed by enchondral ossification, (4) Osteonecrosis occurs due to additional injury.

Conservative Therapy of the Proximal Phalangeal Fracture: Adaptation and Limitation

List of authors:
Kazuma Wada*, Ryosuke Sato, Naohito Hibino, Koichi Sairyo
1 Takamatsu Municipal Hospital (Takamatsu, Kagawa)
2 Tokushima Municipal Hospital (Tokushima)
3 Tokushima Prefecture Naruto Hospital (Naruto, Tokushima)
4 Tokushima University Graduate School (Tokushima)

Objectives / Interrogation: The purpose of the study was to assess the adaptation and limitation of the conservative treatment with dorsal block functional cast or surgery for proximal phalangeal shaft and base fractures.

Methods: We retrospectively reviewed the medical records and radiographs of patients from January 2015 to January 2017 with a diagnosis of proximal phalangeal fractures. Outcome was analysed in terms of the alignment of the proximal phalangeal bones and %total active motion(%TAM) at the time of injury and 4 months later after treatment.

Results and Conclusions: Ultimately, 46 fractures in 44 patients (mean age 35.8 years(range=7-76 years), female/male 9/35) were enrolled. Fractures affected index finger (n=7), middle finger (n=1), ring finer (n=7) and little finger (n=31). The type of fractures were condylar fractures (n=16), shaft fractures (n=7) and base fractures (n=23). Surgical treatment was performed for 20 fractures of the condylar fractures, the long oblique fractures with gap and the base fractures with intra-articular fracture. 26 fractures with the conservative treatment were retained good alignment. The alignment at the time of injury and the 4 month later after treatment were volar-dorsal angulation:21.0,2.5°, lateral angulation: 11.6,1.8°, lateral dislocation: 0.9,0.2mm and shortening: 0.5,0.4mm. The mean %TAM after the conservative treatment was 92.1%.

All fractures were bone union without overlapping. The proximal phalangeal fractures could be treated conservatively were good outcomes.

However, surgical treatment were needed for the condylar and intra-articular fractures needing anatomical reduction or the long unstable oblique fractures.

Comparison of the efficiency between the extrinsic and intrinsic extensor muscles for extension of the proximal interphalangeal joint of the finger

List of authors:
Sung-Jae Kim*1, Kwang-Hyun Lee2, Joo-Hak Kim3, Chang-Hun Lee4, Wan-sun Choi5
1 Hallym University Hospital (Hwaseong-si)
2 Hanyang University hospital (Seoul)
3 Myongji hospital (Goyang-si)
4 Eulji University hospital (Seoul)
5 Ajoo University hospital (Suwon-si)

Objectives / Interrogation: Extension of the proximal interphalangeal (PIP) joint of the finger is consisted of both the extrinsic and intrinsic muscle function. We aimed to analyze combined role of both functions in extension of the PIP joint of the finger with fresh cadaver specimen.

Methods: Seven fingers of fresh cadaver were used in current study. One tendon of the extensor digitorum communis (EDC) and two tendons of the intrinsic tendon were dissected and the Krackow suture was done for each tendon. Each finger is mounted with Kirschner wires on the custom-made experiment system. One tendon of the EDC was connected to one pneumatic actuator, and two tendons of the intrinsic muscles were connected to the other pneumatic actuator. One pendulum of 120g was connected to the flexor digitorum profundus to give continuous flexion load on the PIP joint. Extension force was loaded on each tendon and the load was gradually increased from 0 to 900g with control of the computer software. Angle of the PIP joint was measured with the sensor connected to the K-wire inserted at the distal portion of middle phalanx. Previous literature noted that physiologic cross sectional area (pCSA) of the EDC and the interosseous muscle are 1.53cm² and 0.86cm², respectively. We assumed that the maximal contraction force of the each muscle system was proportional to pCSA of the each muscle.

Results and Conclusions: With MP joint of 20 degree of flexion, efficiency of the EDC for extension of the PIP joint was 26% greater than the intrinsic muscles. With MP joint of 60 degree of flexion, efficiency of the EDC for extension of the PIP joint was 41% greater than the intrinsic muscles. Proportion of the roles in extension of the PIP joint of the EDC and the intrinsic muscle are, 69.2:30.8%, respectively with MP joint of 20 degree of flexion. Proportion of the roles in extension of the PIP joint of the EDC and the intrinsic muscle are, 71.5:28.5%, respectively with MP joint of 60 degree of flexion. Intrinsic muscles showed trends of decreasing efficiency of the PIP joint extension with MP joint flexion.

The EDC muscle has more role in extension of the PIP joint than the intrinsic muscle. With MP joint flexion, role of the intrinsic muscle for extension of the PIP joint declines.

The reserve option for the thumb abduction

List of authors:
Dmitry Nakonechny*¹, Alexander Kochish¹, Anna Kiseleva¹, Evgeny Veber¹, Maria Sudyakova¹
¹ Russian Institute of Traumatology & Orthopedics n.a. Vreden (St. Petersburg)

Objectives / Interrogation: The management of the spastic hand remains a surgical challenge, especially for the cases with severe shortening of the flexor and a marked lack of transferrable muscle-tendon units. In order to achieve a significant elongation of the finger flexors and simultaneously provide enough thumb abduction, a modified flexors harvest technique can be used, where the flexor digitorum superficialis is transferred to the flexor digitorum profundus tendon. Initially introduced by R.Brown, this technique in Russian tradition is strongly associated with G.Epstein and V.Rosov, who described this surgical procedure with minor differences.

Methods: We suggest the use of a modified technique in this surgery: the tendons of the flexor digitorum superficialis are cut at the proximal falanx level, and then their distal ends are used for the PIP tenodesis. The proximal ends are sutured with the distal ends of the FDP, that are cut near the carpal ligament. And finally, the proximal parts of the FDP can be used as a motor unit for the transfer. If we may need additional strength in the thumb abduction after its contracture release, we can suture the ends of the FDP to the EPL or the EPB, or anchor the FDP to the 1st metacarpal bone. Two patients, one male and one female, both showing some after-effects of a brain injury with spastic hemiparesis, underwent the procedure.

Results and Conclusions: In the first case, enough finger extension to satisfactorily release the grip and perform thumb adduction was achieved. As per the second case, thumb abduction was attained only due to the tenodesis effect of the FDP attached to the 1st metacarpal bone. In the cases where a lack of transferrable muscle-tendon units is pronounced, this technique can be considered as a good treatment option.

**Aesthetic reconstruction of palmar soft tissue defects with medial plantar artery perforator flap**

**List of authors:**
Shengbo Zhou*, Wenhai Sun, Bin Wang

1 Department of Plastic and Reconstructive Surgery, Shanghai Ninth People's Hospital, Shanghai Jiaotong University School of Medicine (Shanghai)

**Objectives / Interrogation:** Reconstruction of glabrous skin of palm and fingers is a great challenge for hand surgeons. The purpose of this study is to present our experience on using medial plantar artery perforator flaps to repair palmar soft tissue defects.

**Methods:** From 2005 to 2017, 21 patients received free medial plantar artery perforator (MPAP) flap to recover the soft tissue defects in palm or fingers. The causes of the defects included congenital hand malformation, tumor, scar contracture and trauma. A comparison has been made pre- and postoperatively about total active motion, flap survival rates, skin color and texture, static 2-point discrimination, range of motion (ROM) of the hands.

**Results and Conclusions:** The flap size ranged from 25mm x 15mm to 80mm x 40mm. All flaps survived in the mean follow-up period of 50 (36-120) months. The donor sites healed uneventfully in 20 cases, and mild wound dehiscence occurred in one case. At patients' last visits, the mean ROM was 245°. The mean s-2PD was 8.5mm. The mean Vancouver Scar Scale Score of the recipient sites and donor sites were 1.8 and 2.6, respectively. The donor foot functioned well. All the patients were satisfied with the results. In conclusion, medial plantar artery perforator flap is an ideal flap for aesthetic reconstruction of palmar soft tissue defects.

**Keywords:** medial plantar artery perforator flap, aesthetic reconstruction
Tendo-arthrolysis is more Effective than Splinting in the Management of the Stiff Proximal Interphalangeal Joint - A Systematic Review

List of authors:
Parviz Sorooshian*, Camilla Stewart¹, Toby Smith², Caroline Hing³, Sonja Cerovac¹
¹ Department of Plastic Surgery, St George's University Hospital (London)
² Nuffield Orthopaedic Centre, University of Oxford (Oxford)
³ Department of Trauma and Orthopaedic Surgery, St George's University Hospital (London)

Objectives / Interrogation: 1) To review the functional outcomes of surgical (tenolysis, arthrolysis and teno-arthrolysis) and non-surgical (mobilisation and splinting) interventions that are used to treat the stiff proximal interphalangeal joint (PIPJ) following flexor tendon surgery.

2) To evaluate the complication rates of each of these surgical and non-surgical interventions.

Methods: A PRISMA compliant search of databases registering published and unpublished literature prior to May 2018 was conducted. This included Cochrane, Medline, Embase, CINAHL, BioMed Central, Zetoc and PEDro. All studies that evaluated the change in function of the PIPJ following flexor tendon surgery were included. Animal and cadaveric studies were excluded. Methodological quality was assessed using the Downs & Black Protocol.

Results and Conclusions: A total of 1102 studies were identified in the preliminary search. Twelve studies assessing 685 digits met the inclusion and exclusion criteria. The mean age of participants was 35 (5-79) years old. While initial flexor tendon injury was the primary aetiology of PIPJ stiffness in all studies (accounting for 42.5% of all analysed digits), other aetiologies of PIPJ stiffness were included in the analysis of 11 studies. All interventions lead to an overall improvement in active and passive PIPJ motion. Surgical interventions led to a greater improvement in passive motion of the PIPJ compared to splinting (26º vs 18º), with teno-arthrolysis yielding the greatest gain in active and passive motion of the PIPJ. Of the studies reporting post-surgical complications, tenolysis yielded a higher rupture rate (7.78% N=249 vs 0% N=50; p=0.21) and infection rate (2.5% N=152 vs 0% N=50; p=0.42) compared to teno-arthrolysis. Skin dehiscence or necrosis was reported more frequently following teno-arthrolysis compared to tenolysis (6.25% N=67 vs 3.55% N=123; p=0.72). No cases of pulley rupture were noted in either group. There was significant heterogeneity in terms of surgical approach, mean follow-up (6-406 weeks) and timing of the intervention after initial injury (13-234 weeks). Furthermore, 83% of studies were considered to be of poor quality.

Whilst teno-arthrolysis appears superior to other surgical interventions or splinting, further high-quality research is warranted to identify and compare the true value of surgical and non-surgical interventions for managing the stiff PIPJ.

Survival of Aptis Distal Radioulnar Joint (DRUJ) Implant Arthroplasty.

List of authors:
Hans Tromborg* 1
1 Odense University Hospital (Odense C)

Objectives / Interrogation: The purpose of this study was to report survival of the Aptis Distal Radioulnar Joint Implant Arthroplasty (Aptis).

Methods: We performed a retrospective review of patients who had at least 1 year follow up after Aptis arthroplasty from 2013 to 2017. Mean follow up was 3 years (1-5 years). Of 102 consecutive patients 1 was lost to follow up and was excluded. In our database we had one year follow up of functional outcome (DASH). Fifty six patients were treated with the Aptis as primary indication (instability and pain without prior surgery to the DRUJ) and 46 patients with the Aptis as rescue indication (pain after earlier ulnar resection, Sauve-Karpandi, other arthroplasties a.o.)

Results and Conclusions: DASH score improved from 58(14) to 30(15) after one year (n=102), (p<<0.01). Grip strength improved from 10(8)kg to 25(7)kg (p<<0.01).
Seventeen percent needed minor surgery (surgery to relieve pain due to synovitis of extensor tendons in 1st, 5th and 6th Compartment.
Five patients (5%) needed Removal of the Aptis, of these two Aptis were removed and treated with One-bone forearms and 3 had a revision arthroplasty due to infection with a functional Aptis at follow up.
All but two patients (98%) had a functional Aptis at follow up

CONCLUSION: We have had good results with the Aptis Distal Radioulunar Joint Implants with significant improvement of grip strengths, DASH score and a 95% survival after 3 years (1-5 years).

DRUJ, arthroplasty, aptis, wrist
Functional outcome after a surgical reconstruction of a chronic extensor pollicis longus tendon rupture - a case report

List of authors:
Eduardo Ramalho Silva¹, Gonçalo Lavareda³, Sofia Carvalho³, Filipe Machado¹, Francisco Gonçalves³, Catarina Bispo¹, João Neves¹

¹ Hospital Ortopédico Sant’Iago do Outão (Setúbal)

Objectives / Interrogation: The aim of this work is to determine/evaluate the functional outcome of an extensor indicis proprius (EIP) tendon transposition after an extensor pollicis longus (EPL) chronic rupture based on a clinical case.

Methods: The authors report a case of an individual, female, 50 years old, factory worker, that had an EPL chronic rupture on the TV zone with nearby 6 months and complete lost of the thumb extension. The surgery performed was a transposition of the ipsilateral EIP tendon and the tenodesis was done using the pulvertaft technique. Study-specific outcome measures were used to assess function in activities of daily living, pain, and patient satisfaction: grip strength, pinch strength, range of motion, kapandji score and DASH score. The current follow-up was 5 months.

Results and Conclusions: The patient maintained a cast immobilization during the first four weeks of surgery and then it was changed to an orthosis and the patient started to do physiotherapy. After 15 weeks of surgery the kapandji score was 10. After 20 weeks of surgery the kapandji score was still 10, the pinch strength was 2.5 kg (5 kg on the contralateral side), the grip strength was 18 kg (22 kg on the contralateral side), the range of motion was 90° (100° on the contralateral side) and the Quick DASH score of 11.4.

Besides the EIP tendon has been the used tendon on the case reported, the extensor digitorum profundus communis II is also a valid option and the pulvertaft technique was used because of the unequal size of the tendons. The authors concluded that the transposition of the EIP for the EPL chronic rupture is a safe and effective procedure, with good functional outcomes. The success of this surgery depends on a rigorous technique and an appropriate program of functional rehabilitation so that further clinical and biomechanical investigations may give additional informations about the postoperative management, in order to maximize the surgical outcomes.

extensor pollicis longus chronic rupture, extensor indicis proprius
The management of thumb base osteoarthritis - A multicentre service evaluation project

List of authors:
Simon Parker*, 1 Oxford Upper Limb Collaborative 2
1 Oxford University Hospitals NHS Foundation Trust, John Radcliffe Hospital (Oxford)
2 Oxford University Hospitals NHS Foundation Trust, Nuffield Orthopaedic Centre (Oxford)

Objectives / Interrogation: Thumb base (trapeziometacarpal) osteoarthritis is a common problem, with 15% radiographic prevalence across the entire adult population and as much as 91% of those over the age of 80 years. Resultant pain and loss of function can severely affect quality of life. The British Society of Hand Surgery (BSSH) advises surgery be reserved as a last resort option, for those with symptoms refractory to non-operative treatments. We aimed to assess current UK practice in the management of thumb base OA in secondary care, with specific regard to; the nature and duration of non-operative treatments and the surgical procedures performed.

Methods: 10 consecutive patients undergoing surgery for thumb base OA from 12 UK centres were prospectively identified. Patient demographics, symptom duration, radiographic Eaton-Littler grade, non-operative management strategies and the operation performed were recorded.

Results and Conclusions: Data was gathered for 120 patients from 12 centres over a 12 month period. The mean age was 64 years, comprising of 26 males and 94 females. The mean symptom duration pre-surgery was 32 months, and the median radiological grade was 3.

40% of patients had physiotherapy pre-surgery and 50% used a splint. 80% of patients received at least one injection, with a median of two injections pre-surgery. 100% of injections were a corticosteroid derivative. 74% were image guided (61% fluoroscopic and 13% ultrasound) and 26% were landmark guided. Simple trapeziectomy was carried out in 43% of cases, compared to surgery involving ligament reconstruction and/or interposition arthroplasty in 56%. Two patients had alternative operations, including one arthroplasty and one arthrodesis.

There is considerable variation in practice of both non-operative and operative management of thumb base OA in the UK. It is interesting that image guidance is the most common means of injection delivery. These findings likely relate to a lack of high quality evidence from which to guide practice and demonstrate the need for future research in this area.

Predictive factors for severe post-operative chronic pain after surgery for cubital tunnel syndrome

List of authors:
Erika Nyman*, Alice Giöstad1, Ronja Räntfors1, Torbjörn Nyman2
1 Dept of Clin and Exp med, Linköping University, Division of Hand Surg and Plastic Surg, Linköping University (Linköping)
2 Dept of Clin and Exp med, Linköping University, Rehabilitation Medicine, Linköping University (Linköping)

Objectives / Interrogation: There is a wide variation in outcome after surgery for cubital tunnel syndrome. Chronic pain is a well known and relatively common complication with severe consequences for the individual patient. In this study, we aimed to evaluate possible predictive factors for severe post-operative chronic pain after surgery for ulnar nerve entrapment at the elbow.

Methods: A retrospective observational study was performed on patients with ulnar nerve entrapment at the elbow operated at a referral centre 2011 - 2014, using data from medical charts and a post surgical survey. In total 173 patients were included. A subgroup of 28 patients, postoperatively referred to a Pain Centre due to chronic neuropathic pain, was identified and further categorized with questionnaires for: 1) health status (EQ-5D), 2) life satisfaction (Li-Sat 11), 3) fear of movement related to pain (The Tampa Scale of Kinesiophobia), and 4) levels of anxiety and depression (Hospital Anxiety and Depression Scale). Logistic regression was used to evaluate predictive factors for referral to the Pain Centre regarding age, gender, BMI, smoking, civil status, interpreting requirements, comorbidity, and surgical method (simple decompression or subcutaneous ulnar nerve transposition). To compare the EQ-5D values with values for the national population, one sample t-test was done.

Results and Conclusions: Emerged postoperative neurogenic pain was seen in 8% of the whole population (n=173) and 2% developed CRPS (complex regional pain syndrome). Of the patients referred to a Pain Centre (n=28), 12/28 (43%) had previously been in contact with the Pain Centre and 20/28 (71%) suffered from earlier pain problems. A significant association was found between referral and interpreting requirements, depression, other nerve compression lesions in the same arm, and surgery with ulnar nerve transposition instead of simple decompression. The mean value of EQ-5D was significantly lower than for the national population.

We conclude that earlier pain problems, interpreting requirements, depression and other nerve compression lesions are readily identifiable risk factors for developing postoperative severe chronic pain following surgery for cubital tunnel syndrome. Such patients have a low health-related wellbeing and need particular pre- and postoperative care. It should be carefully evaluated whether surgery should be performed or not. Simple decompression is the first choice of surgery.

Factors affecting union rate when treating scaphoid nonunion using non-vascularized bone grafting with internal fixation: preliminary report

List of authors:
Jin Young Kim*, Sang lim Lee
1 Dongguk University Ilsan Hospital (Goyang)
2 Sanggye Baek Hospital (Seoul)

Objectives / Interrogation: We attempted to investigate whether the union rate changed according to different techniques of non-vascularized bone grafting and internal fixation, when treating unstable scaphoid nonunion at waist.

Methods: 39 patients with unstable scaphoid nonunion at waist were involved. We divided the patients into three groups, according to bone grafting and fixation methods: Cancellous bone grafting with K-wire fixation, cortico-cancellous bone grafting with K-wire fixation and cortico-cancellous bone grafting with headless screw fixation. We longitudinally observed how many patients in each group had bony union. Time to surgery, type of nonunion, time to union and number of union failure were also checked for comparison between the groups. The failure cases were presented for analysis.

Results and Conclusions: There were 37 men and 2 women with mean age 28.7 years (range, 18-56). Mean follow-up period is 26.3 (range 24- 53) months. 13 patients were treated by cancellous bone grafting with K-wire fixation, 12 patients by cortico-cancellous bone grafting with K-wire fixation and 13 patients by cortico-cancellous bone grafting with headless screw. Overall union rate was 86.8% (33/38). Union rate was 100% in cancellous bone grafting with K-wire fixation group, 83% in cortico-cancellous bone grafting with K-wire fixation group and 77% in cortico-cancellous bone grafting with headless screw group. There was no difference in time to surgery, type of nonunion, type to union and number of union failure between the groups. All the failure cases were sclerotic scaphoid nonunion and had DISI deformity.

Cancellous bone grafting seems to be more helpful to achieve union of unstable scaphoid nonunion at waist than cortico-cancellous bone grafting, regardless of the type of unstable scaphoid nonunion. The method of internal fixation seems to have had little impact on union rate of bone grafting for scaphoid nonunion. However, the failure of union was most commonly encountered when sclerotic nonunion with DISI deformity was treated by cortico-cancellous bone grafting + headless screw fixation. Based on this study, further studies regarding the advantages and disadvantages of each bone grafting and internal fixation methods should be performed in a larger number of patients.

Keywords: scaphoid, scaphoid nonunion, bone grafting
Stener Lesion: A Comparison Between Two Methods Of Primary Repair

List of authors:
Eduardo Ramalho Silva¹, Gonçalo Lavareda³, Sofia Carvalho³, Filipe Machado³, Francisco Gonçalves³, Catarina Bispo³, João Neves³

¹ Hospital Ortopédico Sant’Iago do Outão (Setúbal)

Objectives / Interrogation: The aim of this work is to compare the results achieved with two different techniques on the primary repair of Stener lesion.

Methods: The patients (N = 16) with stener lesion were divided in two groups according to the surgical procedure: Group 1 (n = 7) - reattach with miniature intra-osseus suture anchor and Group 2 (n = 9) reattach with pre-fashioned steel wire, the Barb-wire of Jennings (Tendofil®). The clinical assessment included a physical examination and functional testing (QuickDash score, range of motion, grip strength, pinch strength, instability and pain).

Results and Conclusions: The sample average age was 47.8 years (25 to 69 years) with an average follow-up of 57 months (24 to 101 months). The QuickDash score on group 1 was on average 16,5 and on group 2 18,6. The reduction of the grip and pinch strength on both groups was less than 10%. The loss of metacarpo-phalangeal (MP) joint motion was on average 5 degrees. There were no nerve injuries, infections, device failures or reoperations recorded. Persistent instability was not observed in any of the patients. Controlled active range of motion exercises started 3 to 4 weeks after open surgical repair. Protective splinting was continued until the sixth week and unrestricted use allowed at 12 weeks after injury.

The authors concluded that these two methods are safe and effective for repair of complete tears of the ulnar collateral ligament of the first MP joint, verifying a slightly better DASH score with the reattach using miniature intra-osseus suture anchor. There were no significant statistical differences in the grip and pinch strength. In general both have yielded good joint stability and a near-full recover of range of motion, showing a good to excellent functional outcome.

Keywords:

How to manage a chronic periprosthetic infection after total wrist arthroplasty? - case report

List of authors:
Eduardo Ramalho Silva¹, Gonçalo Lavareda¹, Sofia Carvalho³, Filipe Machado³, Francisco Gonçalves³, Catarina Bispo³, João Neves

¹ Hospital Ortopédico Sant’Iago do Outão (Setúbal)

Objectives / Interrogation: The aim of this work is to present a clinical case of a chronic periprosthetic infection after total wrist arthroplasty (TWA) and to discuss and draw a possible therapeutic approach for similar cases.

Methods: The authors report a case of an individual, male, 58 years old, manual worker, that appears with pain and inflammatory signs with a sinus tract on the right wrist, that had undergone TWA 8 years before. The authors started with an empirical antibiotherapy and then they decided to do a revision procedure in 2 stages: the first one consisted on the removal of the implant, debridement and interposition of cement spacer with antibiotics and immobilization; the second one consisted on a radio-metacarpal arthrodesis with precast plate and interposition of autologous graft harvested on iliac crest. The time of follow-up was 5 years.

Results and Conclusions: After a successful first stage revision, the second one was performed and after 2 years of follow-up, the patient satisfaction had improved, he had no pain, the fusion was radiologic evident and the DASH score was 28. After 5 years of follow-up the DASH score had improved to 22. The algorithm that we propose is based on patient risk factors, blood tests, imaging exams and harvested material for microbiology and antibiogram. The treatment options mentioned are antibiotherapy (empirical and directed) and surgical treatment (two stages revision).

The improvement of the implants in recent years have contributed to the increasing use of arthroplasty as a treatment option. Although it presents itself with an attractive option in terms of future functional capabilities, arthroplasty remains with some risks and has a higher rate of complications in the medium and long term than fusion, so the selection of patients should be careful.

The wrist arthrodesis can always be seen as an ultimate salvation procedure in the treatment of failure of wrist arthroplasty, either a mechanical or infectious failure.

The Results of Surgical Treatment for Osteoarthritis of the Thumb Trapeziometacarpal Joint: The Correlation With Tenosynovitis

List of authors:
Hirofumi Imai*, Masatoshi Takahara, Daichi Ota, Mikiro Kondo
1 International Center for Lymphedema, Hiroshima University (Hiroshima)
2 Izumi Orthopedics Hospital (Sendai)

Objectives / Interrogation: Tenosynovitis has occasionally occurred after Ligament Reconstruction without Tendon Interposition (LR without TI) for osteoarthritis of thumb trapeziometacarpal joint. The aims of this study were to investigate the relationship between pre/postoperative changes of Trapezial Space Height (TSH) and tenosynovitis and the influences of tenosynovitis to the results.

Methods: This retrospective study was composed of 33 patients (37 hands) who underwent LR without TI. After ligament reconstruction the K-wires were inserted to stabilize the thumb for 4 weeks. We assessed the TSH on the x-rays preoperatively and postoperatively at 2 weeks, 3 months and 12 months. We also assessed pain visual analog scale (VAS) preoperatively and postoperatively at 6 months and 12 months. 7 postoperative tenosynovitises were retrieved from the medical record. We found postoperative trigger finger of thumb with 1 patient, index finger with 4 patients and middle finger with 1 patient and carpal tunnel syndrome (CTS) with 1 patient. We diagnosed tenosynovitis 5.6 months postoperatively. 5 trigger fingers had been treated with corticosteroid injection 5.4 months postoperatively, 1 trigger finger without additional procedures and 1 CTS with endoscopic carpal tunnel release 8 months postoperatively. We compared the TSH and pain VAS between tenosynovitis and non-tenosynovitis group.

Results and Conclusions: Results: The mean TSH of tenosynovitis and non-tenosynovitis group were 12.8mm and 12.3mm preoperatively (p=0.48), 7.1mm and 9.3mm 2 weeks postoperatively (p<0.01), 6.0mm and 6.9mm 3 months postoperatively (p=0.24) and 5.5mm and 6.1mm 12 months postoperatively (p=0.47). The mean degree of TSH shortening from preoperatively to 2 weeks postoperatively was 5.7mm and 3.0mm (p=0.01), from preoperatively to 3 months postoperatively was 6.8mm and 5.5mm (p=0.11) and from preoperatively to 12 months postoperatively was 8.1mm and 6.2mm (p=0.07). The mean pain VAS was 6.4 and 5.3 preoperatively (p=0.32), 2.2 and 1.9 6 months postoperatively (p=0.71) and 1.1 and 1.3 12 months postoperatively (p=0.89).

Conclusion: 2 weeks postoperatively, tenosynovitis group had significantly shorter TSH and larger degree of TSH shortening from preoperatively than non-tenosynovitis group. But there was no difference in pain VAS due to the treatment of tenosynovitis. We suggest that it may be preferable to insert the K-wires without compression the thumb toward proximal side after ligament reconstruction to minimize the potential of tenosynovitis.

Vascularized Bone Flaps in Upper Extremity Reconstruction: A Case Series

List of authors:
Corinne Wee*, Daniel Ruter, Jason Hehr, Steven Schulz, Geoffroy Sisk, Julie West, Ian Valerio
1 Case Western Reserve University (Cleveland)
2 Albany Medical College (Albany)
3 The Ohio State University (Columbus)

Objectives / Interrogation: Upper extremity composite tissue defects encompassing bone and/or isolated bony defects can be challenging; re-establishing a bony framework is critical for successful limb salvage. Vascularized bone flaps (VBFs) can provide a one-stage solution for autologous bony replacement in situations with large or complex bone defects and are often superior options compared with nonvascularized bone grafts or non-bone internal fixation techniques.

Methods: A retrospective review of VBFs performed by a single surgeon over a seven year period was conducted.

Results and Conclusions: Thirty-three total VBFs were completed for traumatic, oncologic, and congenital cases; seventeen of these were performed in the upper extremity. Patient age ranged from 5 to 64 years with the majority of patients being younger than 30 years old. Etiology of injuries included 11 traumatic and 6 oncologic (all 6 of which were pediatric cases). Successful union or bone healing was observed in 12 of 13 cases; at this time, 4 of the cases do not yet have an adequate follow-up period to determine union. There was 1 case of complete resorption of a fibula bone flap requiring salvage with an expandable megaprosthetic and additional soft tissue flap coverage.

VBFs have critical roles in successful limb salvage outcomes where certain bony defects are encountered. As evidenced in our series, VBFs provide reliable single-stage autologous bony reconstructions with relatively low and acceptable complication rates while achieving more functional outcomes. This series demonstrates the utility and success of VBFs for a variety of clinical situations.

Evaluation of Factors Influencing Nerve Recovery after Reconstruction of Nerve Transection Injuries with Processed Nerve Allograft

List of authors:
Gregory Buncke*, Dominic Power2, Ian Valerio3, Sonu Jain3, Leon Nesti4, Fraser Leversedge5, Desirae Mckee6, Brendan MacKay7, Jozef Zoldos8, Bauback Safa1

1 The Buncke Clinic (San Francisco)
2 Queen Elizabeth Hospital (Birmingham)
3 Ohio State University (Columbus)
4 Walter Reed National Military Medical Center (Bethesda)
5 Duke Health (Durham)
6 Texas Tech University (Lubbock)
7 Texas Tech University (lubbock)
8 Arizona Center for Hand Surgery (Phoenix)

Objectives / Interrogation: Reported factors historically known to influence outcomes after the repair of peripheral nerve injuries include age of the patient, mechanism of injury, nerve injured, gap length, smoking status, and repair time. Processed nerve allografts (PNA) have been shown to be a safe and effective option to repair nerve gap injuries in a growing number of clinical studies. We sought to evaluate how these factors influenced recovery outcomes of injuries reconstructed with PNA. Here we report from an ongoing international nerve registry on PNA for upper extremity injuries spanning up to 70mm.

Methods: The database was queried for nerve repairs in the upper extremity using PNA (Avance® Nerve Graft, AxoGen) with sufficient follow-up. An evaluation of outcomes by age, mechanism of injury (MOI), gap length, smoking status, and repair time was conducted. Outcome data were incorporated into the MRC scale for sensory and motor function. Meaningful recovery was defined as S3/M3 or greater on the MRC scale. Further covariate analysis was performed to further characterize the sub-groups. Chi-square analysis and Fisher's exact test were performed with significant difference set at p> 0.05.

Results and Conclusions: The current registry has sufficient quantitative outcomes data on 413 repairs. The mean age was 42 ± 17 (18 - 81) years with mean repair time of 102± 384 (0, 4451) days. The mean gap was 22 ± 13 (3 - 70) mm with an average follow up time of 13 months. Meaningful recovery was observed in 85% of all repairs. No significant differences were found by age, repair time, gap, or MOI overall. Differences were noted when evaluating these factors by nerve type. Significant differences were found by MOI between lacerations and complex injuries in the hand. Non-smokers performed significantly better than smokers in mixed and motor repairs. No related adverse events were reported.

This registry is currently the largest multi-center study on PNA. Analysis of 413 nerve injuries demonstrates meaningful recovery in 85% of repairs. Study wide outcomes are consistent across covariates. Subgroup analysis indicates certain factors such as mechanism of injury and smoking may influence recovery outcomes, but these outcomes are still within expected ranges for nerve autograft and exceeded synthetic conduit historical data. The registry will continue to collect prospective data to help further define the role of PNA in peripheral nerve injuries.

Clinical Outcome of Fixation Versus Conservative Management of Basal Fractures of the Ulnar Styloid Following Volar Plate Fixation of the Distal Radius

List of authors:
Ahmed Affifi*1
1 Kasr Al-Ainy Faculty of Medicine, Cairo University (Cairo)

Objectives / Interrogation: To compare functional outcome after fixation and conservative management of basal fractures of the ulnar styloid after volar plating of distal radius fractures without DRUJ instability.

Methods: This is a prospective randomized control trial conducted at an academic Level 1 Trauma Center between 2015 and 2017. The study included 31 patients (22 males and 9 females). The mean age was 36 years (20-50 years). The dominant hand was affected in 14 cases and the non-dominant hand was affected in 17 cases. Patients were divided into 2 groups; the first group included 15 patients to whom ulnar styloid fixation was done. The second group included 16 patients with conservative management of ulnar styloid. Randomization was done by using the double blind method. Patients were assessed for pain by Visual Analogue Scale (VAS) and grip strength compared to the sound side. Functional evaluation was performed by using the Modified Mayo Wrist Score (MMWS) the Quick-DASH (Disabilities of the Arm, Shoulder and Hand) questionnaire.

Results and Conclusions: In the first group, the mean postoperative visual analogue scale (VAS) for pain was 0.46 (range, 0 to 2), the mean quick DASH score was 26.23 (range, 17 to 35) and the mean postoperative Mayo modified wrist score (MMWS) was 75 (range, 65 to 85). The mean grip strength was 61.33 % of the sound side (range, 45 to 80%).

In the second group, the mean postoperative visual analogue scale (VAS) for pain was 0.44 (range, 0 to 2), the mean quick DASH score was 23.67(range, 16 to 34) and the mean postoperative Mayo modified wrist score (MMWS) was 72.78 (range, 70 to 85). The mean grip strength was 54.38 % of the sound side (range, 30 to 80%).

To conclude, results were comparable in both groups and differences were statistically insignificant.

Algorhythmical approach in Ulnar Impactation Syndrome and presentation of a special case: UIS with DRUJ instability

List of authors:
Sándor Szlovák*

1 National Center of Medical Rehabilitation, Hungary (Budapest)

Objectives / Interrogation: Ulnar wrist pain is frequently caused by Ulnocarpal Impactation Syndrome (UIS) or Ulnocarpal Abutment. As an introduction we clarify the terminology, outline differential diagnosis. The purpose of our presentation to demonstrate our algorhythmical approach based on the experiences of the last four years.

Methods: Our treatment algorhythm will be shown as a flowchart with key points as follows: always conservative therapy at first, in case of DRUJ arthrosis/instability or limited pro/supination, consider Sauve-Kapandji procedure or DRUJ reconstruction, when having significant radius malalignment, consider corrective osteotomy, if only ulna plus is present and it exceeds 2-3 mm, consider extraarticular ulna shortening, otherwise arthroscopical/open wafer resection of the ulnar dome.

We didn't have early postoperative complications, however, implant removal was needed in 3 cases due to local sensitivity or allergic response to the metalwork inside. We had one non-union following extraarticular ulna shortening. Regarding to the 6 months outcome, based on the patients opinion, 0 bad, 1 acceptable, 5 good and 17 excellent results has been reported. We demonstrate our algorhythm with solution of a rare case of UIS with DRUJ instability.

Results and Conclusions: When handling Ulnar Impactation Syndrome, the nonsurgical therapy should be considered as a first line of treatment. It is very important to exclude the other factors in ulnar wrist pain (e.g. ulnar impingement, TFCC pathology, ECU tenosynovitis etc.). Due to the difficult differential diagnosis one should use a well devised, reasoned algorhythmical thinking to get a better outcome.

Keywords: ulnar wrist pain, ulnar impactation syndrome
Opportunities of distraction osteosynthesis in eliminating post-traumatic defects of middle and distal finger phalanges

List of authors:
Igor Obukhov*
1 Ural State Medical University (Yekaterinburg)

Objectives / Interrogation: The objective is evaluating the effectiveness of distraction osteosynthesis (DO) applied to finger phalanges in patients with defects in middle and distal phalanges (DMDF).

Methods: 48 patients aging 16 to 48 were treated (29.2±5.3 years old average). In 38 cases the DMDF were consequences of traumatic amputation, 3 cases were burns, 7 cases were frostbites. 19 patients had DMDF in multiple fingers (79 cases total). Indications for surgery were DMDF to their proximal part.

In all cases, the DO by external fixation apparatus (EFA) was applied individually taking into account the type and location of phalanx defects. With the phalanx shortened less than 50% of the primary stump length, the traditional distraction was carried out in the mode of 0.5-0.8 mm per day. When stump was lengthened by a large amount (120% or more) of its primary length, the distraction regenerate mineralization slowed down, and therefore the second stage after the lengthening was an intermediate autoplasty with a graft from an ilium crest.

The articular cartilaginous area of the stump was moved to the joint, and an autograft was inserted into the interval, which then was fixed in the EFA. The general duration of fixation in EFA during traditional lengthening did not exceed 12 weeks, while two-stage technique required 16 weeks.

Results and Conclusions: Immediate and long-term treatment results (in 6 months, 1 year or more after the surgery) was evaluated according to the DASH and VAS systems, assessing the phalanx shape and length by radiography. Phalanx elongation was achieved in all cases, and averaged 72% of the primary stump length. When using DO with intermediate bone autoplasty, anatomical growth of the phalanges had reliably speeded up in 2.7 times compared to using traditional techniques of phalanx lengthening.

Finger grip function was significantly improved in the restored fingers because the adjacent joint preserved its motions. The restored finger aesthetic appearance became better. Also, nail plate revealed partial restoration, even when it previously had subtotal defects.

Distraction osteosynthesis is effective in eliminating finger phalanx defects. Defects of the distal or middle phalanx with a length loss of more than 50% should involve intermediate bone autoplasty, which ensures restoring the length and shape of defective fingers in a shorter time.

distracttion, osteosynthesis
Percutaneous corrective osteotomy for malunited metacarpal and phalangeal fractures

List of authors:
Christopher Jenkins*, Adam Smith¹, Matthew Howard¹, Grey Giddins¹
¹ Royal United Hospital (Bath)

Objectives / Interrogation: We evaluated the outcomes of a percutaneous corrective osteotomy technique stabilised with K-wires.

Methods: Technique: The osteotomy is performed by passing multiple 1.1mm K-wires across the bone and then closed manipulation to create a low energy fracture. Once the alignment is corrected, it is held with one or more K-wires supported with a plaster cast for five to six weeks.

Review: We retrospectively reviewed the 21 patients who had a percutaneous corrective osteotomy operated between 2003 and 2014. The mean time from injury to osteotomy was 29 (range: 3-105) months. There were 17 women and 4 men with a mean age at surgery of 30 (range: 11-84) years. Of the 19 phalangeal malunions, 2 had a combined angulation and rotational deformity, 11 had an angulation deformity and 6 a rotational deformity. There were 2 metacarpal malunions, 1 with an angulation deformity and 1 a rotational deformity. The long-term subjective outcome was assessed using QuickDASH, Michigan Hand Outcome and Patient and Observer Scar Assessment Scale (POSAS) Questionnaires at a mean of 96 (range: 5-149) months post-surgery. The long-term objective outcome was assessed by measuring ranges of motion and grip strength at a mean of 63 (range: 2-140) months post-surgery.

Results and Conclusions: Results: Full correction of the pre-operative deformity was achieved in 17 patients (81%), with full correction of all the rotational components. All osteotomies had united. Other than 1 patient with dystrophy, resolving within 3 months, no intra-operative or post-operative complication occurred. The mean QuickDASH score was 20.7 and Michigan Hand Outcome score was 78.7. The PSOAS patient scale total score was 8.4, with an overall opinion of the scar score of 2. The mean ranges of motion, compared to the contralateral uninjured side, were 100% at the MCP joints and 89% at the PIP joints. Grip strength measurements of the operated side averaged 70% of those in the uninjured hand.

Conclusion: Percutaneous osteotomy is an effective and reproducible technique to correct post-traumatic metacarpal and phalangeal malunions, particularly metaphyseal and rotational deformities, with a low complication rate.

Subtypes of Radial Polydactyly bifercating at the Metacarpophalangeal Joint Level

List of authors:
Wenyao Zhong¹, Wen Tian¹, Junhui Zhao¹
¹ Dept. of Hand Surgery, Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: Among different types of radial polydactyly, cases bifercating at the metacarpophalangeal (MP) joint level is the most common, and it can be subdivided into 11 subtypes according to X-rays of the thumb.

Methods: From Jan 2015 to Dec 2017, 256 cases of radial polydactyly bifercating at the MP Joint Level were reviewed. For the radial and ulnar thumb in one case, the relative degree of development, the deviation from the main axis and the angulation of the interphalangeal (IP) joint were analysed in the x-rays.

Results and Conclusions: The radial thumb developed approximately equally to the ulnar one in 170 cases. 84 cases had the obvious hypoplastic radial one and 24 of them did not articulate with the metacarpal. Only 2 cases had the hypoplastic ulnar thumb. For the deviation, both thumbs were divergent in 175 cases, and 1 case showed radial deviation for both. 80 cases had the obvious deflective radial one but the ulnar thumb seemed in line with the main axis. Angled IP joints were presented in both radial and ulnar thumbs in 61 cases, and 69 cases did not have angled IP joints. 114 cases only showed angulation in the radial one, while 12 cases in the ulnar thumb. In conclusion of all the X-rays, we found 11 subtypes.

11 subtypes of radial polydactyly bifercating at the MP Joint level were found in the x-ray and different surgical strategies were indicated.

Split thickness skin graft from the instep region: no recommendation in pediatric palmar burn

List of authors:
Evi M. Morandi*, Christoph Tasch, Schwabegger Elisabeth, Gabriel Djedovic, Gerhard Pierer, Eva Maria Baur  
1 Plastic, Reconstructive and Aesthetic Surgery, Innsbruck Medical University (Innsbruck)  
2 Department of Plastic, Reconstructive and Aesthetic Surgery, Academic Hospital Feldkirch (Feldkirch)

Objectives / Interrogation: Contact burn injuries to the palm are common in toddlers. Full-thickness burns without signs of reepithelization after two weeks need to be skin grafted. The use of split thickness skin grafts from the instep region of the foot has been recommended in adults in order to replace like with like. While split thickness skin grafts from the instep region might show an excellent color match and the texture of glabrous skin, they are prone to scar contraction in pediatric patients.

Methods: We performed a retrospective analysis of all pediatric patients who were referred to our hospital between January 2009 and December 2017 due to a contact burn injury of the palm. Among 109 contact burn injuries in total, 82 patients were between 0 and 4 years old (mean age: 21 months, range: 7-48 months) representing the typical age group concerned by contact burns and were included in the study (n=82 patients).

Results and Conclusions: In this case series, we critically discuss the use of split thickness skin grafts from the instep region and explain our concerns about the use of split skin technique in children.

Full thickness skin grafts remain the reference standard of care in pediatric patients. Children with burn scars should have regular check-up examinations until they are grown up.

Effect of Insurance Status on Rate of Operative vs. Non-operative Management of Clavicle Fractures

List of authors:
Dominick Congiusta*1, Kamil Amer1, Aziz Merchant1, Michael Vosbikian1, Irfan Ahmed1
1Rutgers New Jersey Medical School (Newark, New Jersey)

Objectives / Interrogation: The majority of closed clavicle fractures are treated non-operatively. Recent literature has reported differences in the treatment of clavicle fractures based on insurance status in America. Such research has socioeconomic implications and may highlight discrepancies in healthcare delivery. We aimed to conduct the first analysis of a national database, representative of the entire United States, to identify any associations with insurance status and rate of operative fixation of clavicle fractures.

Methods: The Nationwide Inpatient Sample database (NIS) 2001-2013 was queried for closed clavicle fractures using the International Classification of Diseases, 9th Revision (ICD-9) diagnostic codes. Surgical intervention was determined by using ICD-9 procedural codes. Chi square analysis was performed to determine significant predictors of operative intervention. Multivariate logistic regression was then used to account for demographic and other significant variables. Results were recorded as odds ratios (OR) and 95% confidence intervals (95% CI), and significance was defined as p<0.05.

Results and Conclusions: A total of 76,470 inpatients with clavicle fractures were included in the final analysis. Rate of clavicle surgery was 8.6% (n=6,539). Multivariate analysis revealed that having private insurance was predictive of operative fixation (OR 1.55 [95% CI 1.44-1.67]) compared to non-private insurance (p< 0.01). In addition, age >60 years, female sex, Caucasian race, elective admissions, use of emergency services, and fractures of the shaft were significantly associated with operative fixation (p<0.01).

Table 1 and 2: Descriptive Data and Predictors of Operative Fixation of Clavicle Fractures
Having private insurance is independently predictive of undergoing operative fixation of clavicle fractures. While we identify different in rates of surgery, this does not necessarily indicate a disparity in care. We highlight a socioeconomic factor that may play a role in patient education and utilization of healthcare resources.

The Effects of Static Cold Storage, Pulsatile Hypothermic Perfusion, and Pulsatile Near-Normothermic Perfusion on the Metabolism and Function of Rat Hind Limb Allografts

List of authors:
Kagan Ozer¹, Emre Gök¹, Carrie Kubiak¹, Erin Guy¹, Steve Kemp¹
¹University of Michigan (Ann Arbor, Michigan)

Objectives / Interrogation: Static cold storage (SCS) is currently the standard of care for the preservation of vascularized composite tissue allografts. This approach not only limits the time available to perform the procedure, but also has detrimental effects on the muscle microcirculation, resulting in extensive damage particularly during the reperfusion phase. Continuous machine perfusion may have the potential to change the current practice. However, ideal perfusion parameters including the perfusate and the temperature are currently unknown. In this study, we aimed to test competing perfusion modalities on a cost effective VCA model established to study neuromuscular regeneration.

Methods: Sixty male Lewis rats were distributed into 8 groups according table 1. Amputated limbs in groups 6, 7, and 8 were perfused using custom-made mini ex-situ perfusion system for 6 hours. All transplantations were performed between Lewis rats (isograft) eliminating the confounding effects of potential immune rejection. Evaluations were performed at the completion of sciatic nerve regeneration in 3 months after the transplantation. Extensor digitorum longus (EDL) muscle force was used as the primary outcome measure in this study. Metabolomic results including 5 energy pathways and nerve axon counts are currently pending.

Results and Conclusions: Among perfusion groups and SCS, near-normothermic pulsatile perfusion using diluted blood and plasma exchange provided the best outcome after 6 hours of perfusion. Maximum twitch and titanic force measurements in this group showed no statistically significant difference compared to immediately transplanted limbs with 75 minutes of ischemia (p>0.05), while other groups had significantly lower values (p<0.05) on both parameters. Interestingly, cold preserved allografts (static G5, and dynamic pulsatile G6) demonstrated very low CMAP amplitude indicating axonal loss, despite relatively preserved twitch and titanic forces.

In conclusion, 1. Pulsatile perfusion at hypothermic temperatures using HTK is superior to SCS in protecting limb allografts after 6 hours of perfusion.
2. Pulsatile perfusion at near normothermic temperatures is superior to all other modalities only if combined with continuous plasma exchange.
3. Hypothermic temperatures appear to affect the nerve structure more than the muscle.

Keywords: Ex-situ perfusion, composite tissue allografts, transplantation, normothermic
Closed screw fixation versus open reduction and bone grafting in delayed union scaphoid fractures

List of authors:
Saskia Kamphuis*, Julia Sproedt
1 Cantonal Hospital Winterthur (Winterthur)

Objectives / Interrogation: In acute scaphoid fractures, immobilization up until 12 weeks may be required. However, literature describes that when any resorption at the fracture site suggests that the fracture will not heal by continued immobilization alone it will require surgery. Also, fractures that were delayed in diagnosis may show signs of failed healing and may require an operation.

Methods: We retrospectively investigated our patient cohort with scaphoid fractures which had a delay in diagnosis or showed delayed fracture healing, and were treated by percutaneous screw fixation. We compared them to patients from the same cohort, who were treated by open reduction, bone grafting and screw fixation. The method of treatment was decided by cyst or resorption seam diameter. Patients who needed wide resection of a pseudo-arthritis were excluded. We investigated the time to radiographically confirmed fracture healing, range of motion and return to work.

Results and Conclusions: We included six patients, 1 female and 5 males, treated by closed reduction and percutaneous screw fixation with a mean of 63.5 days since trauma and compared them to six patients, all male, who were treated by open screw fixation and bone grafting after a mean of 68.3 days. In the openly treated group, the mean diameter of cysts or seam formation was 3.2 mm, in the closed group 1.9 mm. Exclusively in the open treated group, two patients with dislocated fractures were treated. The patients in the closed reduction group had a mean age of 36.7 years, the openly treated patients 31.2 years. The percutaneously treated fractures all healed after a median of 11.5 weeks. In the openly treated group, one fracture did not heal and needed surgery using the Matti-Russe technique 14 months postoperatively. The remaining fractures healed after a median of 9 weeks. Range of motion extension/flexion in the closed group was 70/0/70 degrees, in the open treated group 56/0/59 degrees. Patients in the open reduction group returned to work after a mean of 13 weeks, the patients in the closed reduction group after a mean of 9.6 weeks.

Concluding, in our experience, in case of failing signs of fracture healing in the scaphoid, delayed percutaneous screw fixation is a good option in case of a resorption seam with small cysts or no cyst formation at all. In case of larger cysts or dislocation, open reduction with screw fixation shows to be effective in most cases in our cohort.

Outcome of modified hemihammate arthroplasty in patients presenting after six weeks of injury

List of authors:
Mohammed Tahir Ansari*
1 All India Institute of Medical Sciences (Delhi)

Objectives / Interrogation: To assess the functional and radiological outcome of modified hemihammate arthroplasty in patients presenting after six weeks of injury

Methods: This is retrospective study included 7 patients presented to us between Jan 2015 to Jan 2018 with comminuted and or displaced (unstable) palmer lip fracture. Mode of injury was sports in 3, road traffic accident in 2 and fall in 2 patients. Shotgun approach was used in all patients. Average middle phalangeal articular involvement was 62% on CT scan while volar lip involvement was 60%. In all patients we have used hemihamate autograft and fixed with 2 1.3 mm ao screw. Average timing of presentation was 12 weeks (8-15). Average time to surgery was 85 days (60-110). Range of motion, stability, and grip strength were measured at a mean follow-up evaluation of 12 months. Radiographs were evaluated for union, graft incorporation, and/or collapse.

Results and Conclusions: Results: All the patients had average of 90 degree of flexion at PIP and average of 60 degree of flexion at DIP. There was an average of 5 degree of extension lag. In all patients pain was not a complaint in follow up rather swelling persisted for long and took 6-8 month to resolve. All patients had bony union in follow up and grip strength was 80% of normal side. They were able to return their daily routine on average 3 month post surgery. 6 patients were very satisfied while one is satisfied.

Conclusion: Hemi hamate arthroplasty with modification in surgical technique is one of the reliable and reproducible surgical option for reconstruction of the articular surface of the base of middle phalanx in patients of fracture dislocation of the PIP joint who present late.

Keywords:
proximal phalanx, hammate, fracture
Arthroscopic Staging and Treatment of Stage III Scaphoid Instability with and without Carpal Chondromalacia

List of authors:
Houshang Seradge*, Winfred Parker PA, Carrie Baer, CHT, Cyrus Steppe, Ashley McKenzie, Misti O’Dell
1 Seradge Medical (Oklahoma City)

Objectives / Interrogation: To report on the prevalence of associated chondromalacia and other pathologies in patients with Dynamic Scaphoid Instability Garcia Elias (GE) stage III and to report on the efficacy of arthroscopic treatment for stage III with and without chondromalacia.

Methods: From 191 consecutive wrist arthroscopies, 150 were diagnosed with dynamic scaphoid instability. 79 (53%) were classified as GE stage III. 71 (47%) were classified as GE stage III with additional chondromalacia and other associated intercarpal pathologies. Average age at time of arthroscopy was 42 years old and average follow-up was 5.1 years. (range 1-10 years).

Results and Conclusions: Results:
58% of wrists with true GE stage III were treated by arthroscopy debridement alone and did not require further treatment. Average follow-up was 4.7 years. 42% required dynamic stabilization of the scaphoid (Dynadesis).
47% of wrists were classified as GE stage III with chondromalacia of the ulnar column and other disorders (52% radial styloid impingement, 23% hamate chondromalacia, 16% Triquetrum chondromalacia, 50% TFCC tear, 11% ulna head chondromalacia) and were treated by arthroscopy debridement and abrasion arthroplasty, partial carpectomy, TFCC excision, and radial styloidectomy. 62% did not require further treatment and 73% of this group reported no wrist pain. The average follow-up was 5.7 yrs. 38% of GE stage III with chondromalacia required additional surgery (Dynadesis and/or indicated stabilization procedures).

Conclusion:
Dynamic scaphoid instability of GE stage III can include chondromalacia and other associated wrist pathology. We suggest this group be called stage GE3+.
Arthroscopy treatment alone was successful in more than 50% of the GE 3 and GE 3+ patients with an average of 5 years follow-up. We anticipate that with a longer follow-up some of these patients will eventually require further surgery.

arthroscopy, dynamic scaphoid instability, chondromalacia, staging, Dynadesis, SLIL tear, scaphoid instability, treatment
10 years' single center experience over different surgical techniques in treatment of carpal tunnel syndrome.

List of authors:
Efstratios Athanaselis*¹, Fotios Papageorgiou¹, Apostolos Fyllos¹, Dimitrios Deligeorgis³, Ioannis Antoniou¹, Konstantinos Malizos³, Sokratis Varitimidis¹
¹ Orthopaedic Dpt, University Hospital of Larissa (Larissa)

Objectives / Interrogation: Carpal tunnel syndrome (CTS), combined compression and traction on median nerve at wrist level, is the most common entrapment neuropathy in upper extremity and its decompression one of the most frequently performed procedures in hand surgery. We evaluated the effectiveness of different operative techniques.

Methods: Between August 2008 and March 2018, 976 operations for carpal tunnel decompression took place in our department. 643 (65.8%) were performed via a classic open approach (group A) and the rest using minimally invasive techniques such as Knife Light in 144 cases (14.7%) (group B) or two mini incisions at the proximal and distal ends of carpal tunnel in 189 cases (19.3%) (group C). Patients' records were retrospectively studied in terms of operation technique and postoperative complications.

Results and Conclusions: The majority of open procedures and all minimally invasive operations were performed by experienced hand surgeons. There was no recorded iatrogenic nerve injury, excessive hematoma formation, or deep infection. The complications included recurrence in 6 pts of group A (0.93%) and 2 pts of group B (1.4%), Complex Regional Pain Syndrome (CRPS) in 8 pts of group A (1.2%) and 2 of group C (1.0%), painful scars in 12 pts of group A (1.7%) and 2 of group B (1.4%) and pillar pain in 9 of group A (1.4%). It seems that the rate of morbidity is low, almost equally distributed in the different groups with slightly better results in groups B and C concerning volar pillar pain and scar formation.

Mini open techniques offer attractive alternative techniques in CTS operative treatment in terms of pillar pain and scar formation. However, comparable rates of complications in conjunction with required caution regarding anatomical variants and structures, learning curve and cost-effectiveness rationalize the fact that open carpal tunnel release remains the most commonly selected procedure for CTS.

Using wide-awake local anesthesia in the secondary reconstructive surgery after wrist replantation

List of authors:
Dun Hao Chang*1, Chi Ying Hsieh1, Ke Chung Chang1
1Far Eastern Memorial Hospital (New Taipei city)

Objectives / Interrogation: Previous studies have shown that tenolysis and tendon transfer were the most common secondary procedures following distal forearm and wrist amputations. Recently, wide awake local anesthesia with no tourniquet (WALANT) became more and more popular in hand tendon surgery because it can ensure tendon gliding and adequate tension during the surgery. However, little literature has addressed the safety and effectiveness of WALANT in secondary reconstructive surgery in patients who have had a wrist replantation.

Methods: We report a 17-year-old young man who suffered a nearly total amputation at left radiocarpal joint. He underwent successful replantation. But misconnection of flexor digitorum superficialis (FDS) tendons among thumb, index and middle fingers was found post-operatively. He underwent tenolysis and corrective tendon repair at 1.5 months after replantation. At 6 months post-replantation, he also underwent tendon shortening, pulley reconstruction for the extensor pollicis longus (EPL) tendon bowstringing and subsequent extension lag.

Results and Conclusions: Results
These two operations were done successfully under WALANT, and we injected 80cc and 40 cc 0.5% lidocaine with 1:200,000 epinephrine respectively. During the operation, correct flexor tendon repair was revised and checked by asking the patient to bend his fingers one by one. And the tension of EPL tendon after shortening was also adjusted by intraoperative active extension. The hand and finger circulation remained well post-operatively, and the finger flexion and thumb extension function had achieved satisfactory improvement at the 18-month follow up. We are going to demonstrate with videos the way we injected the local anesthetics and the process of the surgery.

Conclusion
WALANT allows the tendon to move actively and test tendon function intraoperatively ensuring the tendon is properly repaired before leaving the operating table. It is also safe and feasible for patients who have had replantation before.

local anesthesia, tenolysis, tendon repair, wrist replantation
A new approach in treatment of rheumatoid arthritis in metacarpophalangeal and interphalangeal joints

List of authors:
Igor Obukhov*
1 Ural State Medical University (Yekaterinburg)

Objectives / Interrogation: Improving the treatment of patients with rheumatoid arthritis (RA) of the metacarpophalangeal joint (MCPJ) and proximal interphalangeal joint (PIPJ).

Methods: We have conducted a retrospective study of 14 female patients (aged 22 to 64) with hand RA treated in the period from 2010 to 2017. The rheumatoid process duration was 8 years or more (average 10.5 years). In total, there were affected 17 hands (72 MCPJ and PIPJ). The finger joint damages comprised a) ulnar MCPJ deviation with palmar phalanx subluxations of the "walrus fin" type (48 cases), b) 15 deformities of "boutonniere" type and c) 9 "swan neck" deformities.
All patients indicated significant deterioration in their life quality: weakness of their hand grips, pain when performing hand grips, joint deformities. In 100% of cases, the joint deformities were accompanied by failures of basic finger grips and prominent contractures with movement restriction of more than 60% compared to normal movement.
All patients underwent total synovectomy of the affected MCPJ or PIPJ. The external fixation distraction device was mounted.
Fixation and subsequent distraction with finger stabilization was carried out for 5-6 weeks. After removing the external fixation device, the patients worked out their finger movements.

Results and Conclusions: Immediate and long-term (12 months or more after surgery) results were studied in all patients according to DASH disability questionnaire. All patients had an average decrease in DASH points from 116 to 34 points in the end of 6 month after the surgery. After 6 months, we noted that the position of the operated joints had been preserved correctly, the movements in MCPJ and PIPJ were restored up to average 91% and 84% of the norm, respectively. In the long term (1 year after surgery), the correct position of fingers in the affected joints was observed in 65 cases out of 72, and 62 cases (86.1%) observed complete restoration of MCPJ and PIP joint movement amplitude. In one year or more after the operation, according to radiography, there were no cases of progressive destruction in the affected joints. Of the 8 patients observed in period of more than 3 years, the cases of deformity relapse in the operated finger joints have not been registered.
Applying synovectomy to affected joints in combination with distraction method demonstrates high efficiency. This technology allows restoring the correct bone positions and proper movements in the MCPJ and PIPJ, which helps to improve the life quality of patients.

3D printing assisted accurate arthroscopic treatment of scaphoid fracture and nonunion

List of authors:
Wendong Xu*1, Huawei Yin1
1 Hand surgery department, Huashan hospital, Fudan university (Shanghai)

Objectives / Interrogation: Scaphoid fractures are the most common fractures of the wrist, with a high clinical incidence. The fracture line without dislocation is often not obvious in X-ray image at the initial stage, which causes a high misdiagnosed risk, and leads to scaphoid nonunion. The commonly used clinical treatment is open reduction and internal fixation with bone graft. However, open surgery, due to certain damage to blood supply, might affect the healing rate. The development of wrist arthroscopy has transformed many wrist diseases from open surgery to minimally invasive surgery. The application of 3D printing guiding plate technology has made the operation of clinical surgery more precise and further reduced the surgical related trauma. In our previous paper, 3D printing was applied to treat acute scaphoid fracture. In this paper, we introduced the using 3D printing assisted technique and results for patients with scaphoid nonunion.

Methods: 8 cases with scaphoid nonunion underwent preoperative CT scan and DICOM data were obtained, which was imported to a 3D designing software. According to the location of the nonunion, three fixing axes were designed, and then the percutaneous plate was designed around the skin surface. 3D printing was used to produce the plate with a material with medical compatibility. The plate was used during the surgery to introduce precisely k-wire percutaneous fixation, intraoperative application of arthroscopy graft technology was used at the following procedure.

Results and Conclusions: There were 8 patients, all male, with an average age of 26.9 years (20–41 years), 6 patients on the left and 2 patients on the right. All the patients got union in the last follow-ups. The VAS score and the PRWE score got improved with a satisfying functional recovery. 3D-printing assisted arthroscopic bone graft fixation of scaphoid nonunion is an effective clinical treatment with a good union rate and wrist function recovery.

Keywords: 3D-printing, scaphoid nonunion
Distraction osteosynthesis in treatment of acute distal radius fractures

List of authors:
Igor Obukhov*, Razmik Raisian
1 Ural State Medical University (Yekaterinburg)

Objectives / Interrogation: A retrospective group study was carried out to evaluate the effect of the external Ilizarov apparatus on treating acute intra-articular fractures.

Methods: Between September 2015 and December 2017, 58 patients with articular distal radius fractures were treated by closed reduction and external fixation with Ilizarov apparatus. The mean age at the time of surgery was 63.7 (ranging 47 to 69 years old). The fractures were categorized according to the AO system: 16 cases of B2,B3 and 42 cases of C1,C2. The follow-up period was 19 months (ranging 8 to 24 months). In 35 cases, the traditional osteosynthesis (with typical Ilizarov apparatus) was performed which implied inserting K-wires (6-7 pins total) into the proximal and distal radius fragments. In 23 cases, under local anesthesia, the osteosynthesis was performed by Ilizarov apparatus on an outpatient basis. Simplified Ilizarov constructions allowed implementing ligamentotaxis, while the radius and metacarpal bones were fixed by only 3-4 K-wires. The fixation time in the external fixation apparatus averaged 33±4 days. After removing the external fixation apparatus, the patients were engaged in exercise therapy of wrist joint and finger joints for 1.5-2 weeks.

Results and Conclusions: All fractures were healed in a mean of 5.2 weeks (ranging 4 to 7 weeks). At the final follow-up (in 6 months after the surgery), the average motion range was 77.3±10.3 in flexion, 59.6±3.9 in extension, 68.5±9.8 in pronation, and 62.4±12.3 in supination. The overall clinical and functional outcomes, according to the Gartland and Werley scoring system, showed that 22 patients (31.4%) had excellent results, 36 (51.4%) had good results, 9 (12.9%) had fair results, and 3 (4.3%) had poor results.

Patients who underwent traditional surgical treatment had positive results in 68.5% of cases, satisfactory results and poor results totalled 31.5% of cases in the form of persistent wrist joint contractures and malunions. In the group of patients who underwent surgical treatment with a simplified Ilizarov apparatus, positive results were achieved in 86.9% of observations, while 13.1% revealed wrist joint contractures. Malunions were not detected.

Closed reduction and external fixation with the Ilizarov apparatus is useful and effective in management of displaced comminuted articular fractures of distal radius. Simplified Ilizarov apparatuses should be preferred.

distraction, osteosynthesis, distal radius fractures
Computer Assisted Double Osteotomy (CADO) for Madelung Disease, A New Approach of Treatment

List of authors:
Julian Suarez-Gomez*, Julian Hernandez-Beltran1, Dario Fernandez-Loaiza1
1 Fundacion Universitaria de Ciencias De La Salud, Hospital de San Jose (Bogota)

Objectives / Interrogation: Establish the applicability and reproducibility for the treatment of an advanced case of Madelung Deformity (MD) in a young patient using computer assisted double osteotomy (CADO).

Methods: It was the case of a 12 year old female with an advanced bilateral MD who was seen in our Hospital with complains of progressive deformity, pain and limitation of wrist extension. Initially it was planned to perform a CADO using X rays and CAT scan with tridimensional reconstruction, determining the length of the ulna, radius and the radioulnar joint angles, then comparing the results with the same measurements of a healthy person of same sex, age and height, same measures that were used as a mold to develop customized cutting guides and fixation plates for both extremities performing the surgeries at first for the left forearm and 6 months later after gaining full recovery for the right forearm. Also an epiphysiodesis of the ulna was performed on each side to stop its growth to prevent an ulnar impactation syndrome in the future. The patient's bone angles, range of motion of the radioulnar and radiocarpal joints, grip strength were measured preoperative. Recovery was followed with the Quick DASH scale and X rays to follow the consolidation of the osteotomies as well as all the same parameters were measured.

Results and Conclusions: Results: Applying CADO led to a short intraoperatory time, improvement in exact location for the osteotomies, leaving enough bone to place the fixation plate and good bone surface contact in the osteotomies places to allow correct consolidation and start early rehabilitation. The patient's deformity, arcs of movement of the radioulnar and radiocarpal joints, grip strength and pain improved and were demonstrated with the measures in the Quick DASH scale. Conclusion: In the case of this young age patient with an uncommon pathology with advanced deformity and functional limitation, the decision was made to operate applying the CADO instead of the usual release of the Vicker's ligament and performing an epiphysiodesis, as it was considered not indicated based on the severity of her case, nor waiting for a more advanced age to perform a Sauve-Kapandji or another salvage procedure. It was found that applying a CADO using the measures of a healthy person of the same sex, height and age as a mold to develop cutting guides and a customized fixation plate, gave a much better aesthetic and functional result than with the conventional treatments.

Arthroscopic assisted treatment of distal radius fractures combined with TFCC injuries

List of authors:
Huawei Yin*, Wendong Xu
1 Hand surgery department, Huashan hospital, Fudan university (Shanghai)

Objectives / Interrogation: Distal radius fracture is the most common fracture in emergency room, for which open reduction and internal fixation is often performed. However, wrist arthroscopy might be needed in those patients with intra-articular fractures both in the acute phase and in the post-fixation phase. This study introduces our technique and preliminary results of arthroscopic assisted treatment of distal radius fractures combined with TFCC injuries.

Methods: 23 patients with acute DRF and 19 patients with second stage after DRF fixation were included and undergone the wrist arthroscopy. Wrist arthroscopy was used to facilitate the reduction of the articular surface. TFCC were explored and recorded if there were injuries.

Results and Conclusions: With Wrist arthroscopy, big gaps were often found between the fragments after routine open reduction and internal fixation. DRF was often accompanied by type I injury, especially the Type ID and IB injuries. In addition, DRF often accompanied by ulnar styloid injury, which led to TFCC tension disappearing. Adhesion bundle after DRF fixation was often found at the radial-carpal joint in the post-fixation phase. Regular follow-up after DRF found that Positive ulnar variance may increase. We found that better reduction of the articular surface could be achieved with wrist arthroscopy. TFCC tension will recover after ulnar styloid fixation. IF type II injury occurs, positive ulnar variance should be corrected as early as possible.

Tree Man Syndrome: World's Third Reported Case

List of authors:
Tanveer Ahmed, Md. Abul Kalam, Hedayet Ali Khan, Nurunnahar Begum
1 Plastic Surgery, Dhaka Medical College (Dhaka)
2 Dhaka Medical College (Dhaka)

Objectives / Interrogation: Epidermodysplasia verruciformis or tree man syndrome is a rare inherited skin disorder which creates wart-like lesions anywhere on the body. It is caused by abnormal susceptibility to human papillomaviruses (HPVs), which eventually leads to the overgrowth of widespread skin eruptions, including wart-like lesions and reddish-brown pigmented plaques, especially on the feet and hands. He was not able to maintain his normal activities without others assistance.

Although several types of HPVs contribute to this condition, HPV types 5 and 8 are most commonly associated with tree man illness. Notable cases include a Romanian man named Ion Toader who was diagnosed with the condition in March 2007, and the Dede Koswara, from Indonesia. Our case, Mr. Abul Bazander is the third reported case of the world who was treated successfully.

Methods: We evaluated the patient and the histopathology report revealed Filiform viral wart (verruca) without dysplasia or evidence of malignancy. 14 high risks and 5 low risks strains of HPV from wart tissue were isolated by real-time PCR.

We applied a special technique of dressing to make the lesions soft, termed as ‘surgical marination’. The bark-like lesions were excised gradually using electro-dissection and surgical scissors. It took 24 surgical sessions under regional block to make his limbs free of lesions.

Results and Conclusions: The hands and lower limbs were free from the lesion and the tree man was able to maintain his personal care and day to day activities without help. So, it is a success story for a developing country.

Keywords: Tree man syndrome; Epidermodysplasia Verruciformis
Trigger Digit Incidence after Carpal Tunnel Release: Z-Plasty Reconstruction Vs Traditional Carpal Tunnel Release

List of authors:
Ignacio Esteban-Feliu*, Irene Gallardo-Calero, Sergi Barrera-Ochoa, Nuria Vidal-Tarrasón, Alex Lluch-Bergada
1 Vall Hebrón Hospital, Hospital Quiron Dexeus - Icatme (Barcelona)
2 Vall Hebrón Hospital (Barcelona)
3 Sant Joan de Deu Hospital, Hospital Quiron Dexeus - Icatme (Becelona)
4 Vall Hebrón Hospital, Institut Kaplan (Barcelona)

Objectives / Interrogation: The development of trigger digit after carpal tunnel syndrome release surgery has been widely reported. Anterior displacement of the flexor tendon has been reported after carpal tunnel release (CTR), causing it to lose its pulley function increasing flexor tendon friction at the proximal digital pulleys. Lluch described Z-plasty reconstruction of the flexor retinaculum to prevent such complication.

Methods: We conducted a retrospective review to determine whether patients who undergo Z-plasty reconstruction have a lower incidence of trigger digit postoperatively. One thousand fifty patients were included, 865 whom had undergone traditional carpal tunnel release and 185 Z-plasty reconstruction.

Results and Conclusions: No differences were found in terms of incident trigger digit after surgery (9.3% of the patients who underwent traditional release versus 11.9% in the Z-plasty group, p>0.05). Neither difference was found when comparing mean time to development of trigger digit. The thumb was the most frequently (41%) involved digit. In the absence of randomized long-term studies comparing traditional and Z-plasty CTR, given our results, we see no reason to favor Z-plasty reconstruction over standard carpal tunnel release as a means to prevent postoperative triggering of digits.

Keywords:
trigger digit; carpal tunnel release; Z-plasty reconstruction
Osteoid osteoma of the hand and wrist - a report of 5 cases

List of authors:
Judit Réka Hetthéssy, Noémi Szakács, János Kiss, László Balog
1 Semmelweis University, Department of Orthopedics (Budapest)
2 Fejér County Szent György University Teaching Hospital (Székesfehérvár)

Objectives / Interrogation: The hand and wrist bones are infrequent sites for osteoid osteoma. Diagnosis of this tumor could be difficult and challenging. It consists of a well-demarcated osteoblastic mass that is surrounded by a distinct zone of reactive bone sclerosis. It is associated with characteristic clinical features, like local pain, usually more severe at night and often completely responds to aspirin and other NSAIDs. However, initially the lesion causes unspecific symptoms, and the radiographic changes are discrete. An accurate clinical history and a high index of suspicion are required.

Methods: Records of 5 patients who had osteoid osteoma of the hand and wrist were reviewed and analyzed in a retrospective study. All patients underwent surgery between 2014 and 2018, the patient data included symptoms, history of trauma, night pain, relief of pain by NSAIDS and duration from onset of symptoms to operation.

Results and Conclusions: There were 4 men and 1 woman, with an average age of 21.6±1 (range:21-23) years, 3 lesions on the right, 2 lesions on the left side. 2 cases involved the proximal phalanx of the middle finger, 2 cases the distal phalanx of the thumb and 1 lesion at the hamate. All patients had severe pain, which was worse at night, 2 of them were not responding to NSAIDs. None of the patient reported history of trauma. One patient had previous synoviectomy because of PIP joint synovitis one year before her presentation to our department, her complaints were not decreased after the surgery, there were no signs of osteoid osteoma on the X-rays. The duration of the symptoms was from 6 to 28 months. Physical examination at presentation revealed local swelling and point tenderness. In the phalanges, osteoid osteoma induced marked fusiform soft tissue swelling. Distal phalanx involvement caused finger clubbing. All patients had preoperative X-rays, but only two cases showed obvious signs of osteoid osteoma. High resolution CT scans were performed in all cases and showed the osteoid osteoma in every case as an obvious lytic lesion with a central granular opacity surrounded by a well-defined sclerotic margin. One patient underwent a CT-guided percutaneous ablation, but his symptoms recurred after 5 months. All the patients were treated surgically, by removal of the tumour, with complete resolution of all symptoms. The diagnoses were confirmed by histological examination. There were no recurrence during the follow up period (6 months - 12 months).

Examining the Accuracy of the Hand Examination

List of authors:
Kathryn Dickson*, Darren Chester
1 University Hospital Birmingham (Birmingham)

Objectives / Interrogation: Diagnosis of the injured hand tests anatomical knowledge, examination skills and bedside manner. An accurate examination is crucial for good management of patient expectations and efficiency in planning theatre. The majority of hand assessments are undertaken by juniors, without the benefit of clinical experience.

The aim of this retrospective audit was to identify areas where juniors require more support to improve their examination of the injured hand, by assessing the accuracy of the hand examination in our unit.

Methods: The first two hundred hand operations performed in August were collected electronically. Duplicates and elective cases excluded, and the 187 remaining cases underwent an electronic notes review. Operative findings were compared to documented examination findings of the hand team. An assessment of accuracy was made, and missed diagnoses and over diagnoses recorded.

Results and Conclusions: Pathologies were grouped into categories of structural damage (82), fingertip and nailbed injuries (33), fractures (35) and infection (4). The most commonly inaccurate group was structural damage with 62.2% of examinations incorrect. The most commonly missed diagnoses were extensor tendon injuries (38.9% of true injuries missed) and nerve injuries (38.5% of true injuries missed). The most commonly overdiagnosed were nerve injuries (28 instances of overdiagnosis). Sensitivity of hand examination was 67.5%, and specificity 11.6%.

Assessing the performance of a test allows the user to better understand a test result, and identifies areas for improvement. This audit has allowed us to identify commonly made mistakes, and to create a targeted hand curriculum for future teaching.

Patient radiation exposure in fluoroscopically guided injections

List of authors:
Michelle Spiteri*a, Sean McGurk2
1 Nuffield Orthopaedic Centre (Oxford)
2 Churchill Hospital (Oxford)

Objectives / Interrogation: The increased awareness of radiation exposure in the general population has led to patients enquiring about radiation risk following treatment for fracture fixation or guided injections. This study evaluates patient radiation exposure following the use of a Mini C-arm for guided joint injections in the hand and wrist.

Methods: The records of all patients who underwent injections during a four month period in a dedicated clinic were reviewed to assess the total dose area product (DAP) and screening time for the various sites injected. The patient effective dose was then estimated using a DAP to effective dose conversion factor of 0.01mSv/Gycm2 for extremity x-rays.

Results and Conclusions: 138 injections were performed during this time. The majority, 49%, were for first carpometacarpal joint osteoarthritis. Other injection sites were the scaphotrapeziotrapezoid, radiocarpal, distal radio-ulnar and pisotriquetral joints, in addition to various metacarpophalangeal and interphalangeal joints. Patients underwent injections at single (78%), bilateral (12%) and multiple sites (10%). The estimated mean effective dose was 0.08µSv for a single injection site; 0.18µSv for bilateral sites; and 0.11µSv for multiple injections. The most commonly performed injection into a unilateral first carpometacarpal joint had an estimated mean effective does of 0.08µSv. In order to appreciate these values with regard to cancer risk, 0.35µSv results in a 1 in 50,000,000 risk of developing cancer later in life, therefore the above doses provide negligible risk. In the country where this study was performed, the natural background radiation dose is 6.6µSv per day, hence exposure from any of the above injection procedures does not exceed more than approximately one hour of natural background radiation.

Radiation exposure risk should always be taken into consideration when planning patient management. This study shows that patients can be reassured that the risk of fluoroscopically guided injections in the hand and wrist using a Mini C-arm is negligible.

Upper Extremity Reconstruction Following Sarcoma Extirpation: A Case Series

List of authors:
Jason Hehr*, Andrew O'Brien¹, Julie West¹, Ian Valerio¹
¹ The Ohio State University Wexner Medical Center, Department of Plastic and Reconstructive Surgery (Columbus)

Objectives / Interrogation: Sarcomas are rare tumors that make up roughly 1% of all malignancies, and complete resection remains a mainstay of current treatment guidelines for localized disease. Post-extirpative defects following sarcoma resection often pose a difficult challenge to the reconstructive surgeon. Sarcoma resection commonly results in large soft tissue and/or osseous defects requiring a multitude of reconstructive techniques to restore form and function. Here, we report a single surgeon’s experience in upper extremity reconstruction following sarcoma resection.

Methods: An IRB-approved retrospective review of all patients undergoing upper extremity reconstruction by a single surgeon following sarcoma resection at a single institution was conducted.

Results and Conclusions: Between 2015 and 2018, a total of 13 patients were identified as having underwent reconstruction by the senior author following upper extremity sarcoma resection. Our patients consisted of 10 males and 3 females, with an average age of 64.7 yrs (range 54-87) at time of reconstruction. Common comorbidities included hypertension 54%, diabetes 31%, coronary artery disease 23%, and 46% of patients with history of smoking. Types of sarcoma treated include: fibrosarcoma (3), epitheloid sarcoma (3) chondrosarcoma (2), synovial sarcoma (1), osteosarcoma (1), leiomyosarcoma (1), and undifferentiated sarcoma (2). 38% of patients had underwent previous radiation therapy and >50% of patients were undergoing resection of recurrent disease; nearly 25% of patients required post-operative chemoradiation. Immediate reconstruction was performed in 85% patients. Reconstruction options included amputation with concomitant targeted muscle reinnervation (TMR) (38%), free tissue transfer (23%), pedicled tissue transfer, adjacent tissue transfer and skin grafting. Our overall complication rate was 30% (4). Minor complications included neuroma, cellulitis and dehiscence. Major complication requiring reoperation included pseudoaneurysm of recipient vessel requiring vein grafting after a free ALT flap. There were no flap losses. Mean follow-up time was 224 days.

Upper extremity reconstruction following sarcoma resection presents challenging cases, requiring a myriad of reconstructive options. Reconstruction must be tailored for each patient in conjunction with a multidisciplinary team to deliver the patient optimal treatment and reconstruction.

Functional and radiographic assessment in rheumatoid patients submitted to total wrist arthroplasty - 4 years of follow up

List of authors:
Pedro Teixeira Mota*, Cláudia Rodrigues, Ana Ribau, Miguel Trigueiros, César Silva, Alexandre Pereira
1 CHTMAD (Chaves)
2 CHP (Porto)
3 Hospital Santa Maria (Porto)

Objectives / Interrogation: The purpose of our study is to determine clinical and functional outcomes and analyze radiological evolution of total wrist arthroplasty (TWA) in patients with rheumatoid wrists, with a minimal follow up of 4 years.

Methods: We performed a retrospective study and included patients diagnosed with a rheumatoid wrist, submitted to TWA in our institution. Pain was assessed using visual analogic scale for pain (0-10). Active ROM and pinch and grip strength were obtained. Radiological assessment was performed at immediate postoperative period and at 1, 2 and 4 years to analyze alignment, osteolysis, loosening and heterotopic ossification. We also registered complications.

Results and Conclusions: 22 patients, with an average age of 56 years, were submitted to TWA with the same implant. No patient was submitted to revision surgery nor conversion to joint fusion. We had a superficial wound dehiscence that resolved without further procedures but evolved to a relevant stiffness. Most of the patients experienced complete or very significant symptomatic relief (VAS - 1,14). ROM was 38º of extension, 36º of flexion, 7º of radial deviation, 15º of ulnar deviation, and 83º of pronation/supination arc. Grip and pinch strength was, at 4 years, 9,7 Kg and 4,1 Kg, respectively. Radiological assessment demonstrated heterotopic ossifications in 5 patients. Peri implant osteolysis was found to be frequent, next to radial dome in 8 patients and adjacent to carpal component in 8 patients as well, remaining stable over the years. We did not find unequivocal signs of loosening. Clinical and functional outcomes, with 4 years of follow-up, are extremely satisfactory. The procedure did not imply an increased risk of complications. The procedure did not imply an increased risk of complications. It is important to recognize that heterotopic ossifications are frequent but they do not have correlation with clinical outcomes. Peri implant osteolysis is common but its significance remains unclarified and is not synonym of loosening. Although represents a procedure with a notable learning curve, TWA is an excellent solution for rheumatoid wrists, allowing good clinical and functional results in the medium term.

Ligamentoplasty of the palmar ulnar radial ligament at the distal radioulnar joint by bone ligament transplant from the extensor retinaculum - technique and preliminary results

List of authors:
Heinrich-Geert Tünnerhoff*  
1 Praxis und Belegabteilung f Handchirurgie (Marbach)

Objectives / Interrogation: For painful instability of the distal radioulnar joint (DRUJ) in some cases a ligament reconstruction is necessary. The ulnar radial ligaments may be replaced by a free tendon graft either by reconstructing the whole complex or -more simply- by replacing only the ulnar part ascending from the fovea fixing this to the remnants of the ligaments at the radius. In the many cases, in which due to the secondary stabilizers only the palmar translation of the radius in relation to the ulna is clinically evident and needs to be addressed a reconstruction of only the palmar ulnar radial ligament is sufficient. However all these reconstructions using tendons as a graft are prone to secondary loosening. A new technique of a bone ligament transplant to overcome these problems is presented.

Methods: A bone ligament transplant taken from the extensor retinaculum is used. The bone taken as graft by chisels between the 2nd and 3rd compartment is cut to shape by a fine rongeur and pressed by a template block to be a cylinder which fits into a 6,0 mm drill hole made in a oblique direction from the ulnar neck towards the fovea. The exit at the fovea is only drilled to 4 mm, so the exit of this channel is narrower than the entry and the graft is firmly pressed into the bone. The ligamentous part, which includes fibres from the extensor retinaculum towards the 6th and the 1st compartment is grasped by a multiple looped thread and pulled out of the end of the channel in the fovea and is interwoven to the remnants of the palmar ulnoradial ligament under adequate tension. The arm is immobilized for 6 weeks.

Results and Conclusions: From 2016 5 patients (4 female, 1 male, average age 36 y), all cases of recurrent instability after previous surgery, have been operated by this technique with a minimum of 6 months follow up. All of them regained free motion and stability of their DRUJ. Standard X rays of the wrist taken after 6 weeks showed good healing of the transplanted bone in all cases. No complications referred to the technique of taking and inserting the graft occurred. In one case an additional ulnar shortening was done at the same time. 4 patients are free of pain, one has a stable joint but pain due to arthritic changes at the radiolunate joint.

Replacing the ulnar part of the palmar ulnar radial ligament by a free bone ligament graft from the extensor retinaculum is an option to stabilize the DRUJ in the numerous cases of unilateral palmar instability (palmar subluxation of the radius against the ulnar head).

Keywords: distal radioulnar Joint, instability, ligament reconstruction, bone ligament graft
Objectives / Interrogation: Surgical repair of muscle belly lacerations remains a challenge for surgeons treating extremity trauma. We have previously described a technique for repair of mid-substance muscle belly lacerations using an orthogonally placed “anchor suture” to augment purchase in the muscle belly [REFERENCE01]. The purpose of study was to evaluate the integrity of this repair against that of a standard modified Kessler repair and an intact control specimen.

Methods: Fifteen hindleg specimens from fresh-frozen adolescent pigs were divided into 3 proportionate groups: an intact control group, a modified Kessler repair group (MK), and an anchor suture repair group (AS). Five specimens underwent repair with the modified Kessler technique. Each repair comprised of six Kessler constructs, producing twelve strands across the repair site. Another five specimens were repaired with the anchor suture (AS) technique as previously described by the authors [REFERENCE01]. A total of six anchor sutures were placed in the repaired specimens with a total of twelve strands crossing the repair site. The proximal and distal bony attachments of each muscle-tendon unit were secured in a custom-made cylindrical polymethylmethacrylate fixation apparatus which was then mounted on a robotic manipulator with a six-degree-of-freedom load cell to determine the tensile load through the muscle. Specimens were subsequently loaded to failure. Pattern of failure, strain, and ultimate tensile strength were determined for each specimen.

Results and Conclusions: Suture pullout was the principle mode of failure in each group. The ultimate tensile strength of the control group was found to be 608.1 ± 107.9 N. This was significantly (p<0.05) higher than the pullout strength of the MK and AS groups. The pullout strength of the AS group was 143.1 ± 36.7N, about twice that of the MK group who pullout strength was 69.8± 16.4N (p=0.11).

The Anchor suture proved to be a superior method of repair with ultimate tensile strength roughly twice that of the of the Kessler repair. The improved performance of the anchor suture may be due to the simple fact that more epimysium is incorporated into the repair. Similarly, the perpendicular orientation of each anchor suture allows for the recruitment of more muscle tissue per suture. To conclude, the anchor suture technique is a viable and robust option for repair of mid-substance muscle belly lacerations.

Earlier Intervention for Osteoarthritis of the Basal Joint Is Reflected to More Optimal Outcome

List of authors:
Ioannis Antoniou*, Efstratios Athanaselis¹, Fotios Papageorgiou¹, Dimitrios Morfis¹, Konstantinos Malizos¹, Sokratis Varitimidis¹
¹ General University Hospital of Larissa (Larissa)

Objectives / Interrogation: Thumb carpometacarpal joint (CMC) arthritis is a common hand degenerative joint disease, predominantly affecting women leading to pain, laxity, and weakness of the CMC joint. Surgical treatment is highly varied from partial or total trapezium excision alone, combined or not with suspensionplasty (SS) or ligament reconstruction and tendon interposition (LRTI).

Methods: Between March 2015 to June 2016, 20 patients, were operated for CMC joint arthritis, 3 with LR alone for Eaton stage I but hypermobile CMC and 17 with LRTI using flexor carpi radialis tendon. Partial trapeziectomy(PT) was performed in 9 patients with Eaton stage II and III and total trapeziectomy(TT) in 8 patients with Eaton IV arthritis. Each patient was assessed clinically at 2, 3, 6, 12, and 24 months after surgery. The assessment included pain (VAS score), thumb pinch strength, and thumb CMC joint range of motion. Standard anteroposterior and lateral radiographs of the thumb were also obtained and used to assess CMC joint subluxation or collapse.

Results and Conclusions: Follow-up ranged from 2 to 3 years. All patients were free of symptoms at the final evaluation. Those who underwent LR report pain relief 2 weeks post-operatively while PT and TT groups report an average pain plateau at 2 and 3 months respectively. Thumb pinch strength and range of motion showed improvement in accordance with pain relief. Height of the trapezial space only remained the same in LR group whereas PT group patients retained more space than those of the TT group.

Diagnosis of thumb carpometacarpal joint arthritis in an earlier Eaton stage might indicate a less invasive operation. A less invasive technique shows faster recovery in pain and function. Ligament reconstruction successfully stabilizes first metacarpal relative to the second metacarpal. The height of the trapezial space is best preserved the less trapezium is excised.

The Thoracic Outlet Syndrome - a new surgical approach

List of authors:
Franz Lassner*, Michael Becker
1 Pauwelsklinik (Aachen)

Objectives / Interrogation: The thoracic outlet syndrome represents a nerve compression syndrome at the root and trunc level of the brachial plexus. The diagnosis is a clinical one, no imaging or neurophysiological monitor system is available for diagnostic purpose. The clinical symptoms mainly center on a compression neuropathy of the inferior trunc. A substantial number of patients have unsuccessfully been operated for peripheral nerve compression syndromes. The surgical results of decompression at the truncular level lead to unsatisfactory results in a number of cases. With this study, a new surgical approach is presented.

Methods: From 10/02 to 3/17 142 operative decompressions were performed in our unit, in 28 cases bilaterally. Following the hypothesis, that resection of the first rib would not provide adequate decompression, one of the authors started in 2012 to perform an exarticulation of the first rib. We now present an evaluation of 80 exarticulations vs. 62 resections, with respect to the clinical outcome.

The underlying grading scheme uses 5 categories: 0 (no symptoms), 1 (Symptoms with heavy physical stress), 2 (Symptoms under moderate physical stress), 3 (Symptoms under light physical stress, frequent analgetic medication), 4 (permanent symptoms, sensory and motor deficits, permanent analgetic medication).

Results and Conclusions: Indication for operative decompression was a TOS stage 3 and 4. Evaluation was performed at a minimum of one year postop. The two groups were comparable according to mean age, female to male ratio and severity of symptoms at the time of operative intervention.

As a result, the exarticulation group presented with significantly better clinical outcomes. These results will be analysed with respect to the underlying anatomic causes.

Kamil Amer*, Jennifer Thomson, Irfan Ahmed, Michael Vosbikian
1 Rutgers New Jersey Medical School (Newark)

Objectives / Interrogation: Scapholunate advanced collapse (SLAC) of the wrist is one of the most common pattern of degenerative arthritis in the wrist. The hallmark of SLAC is scaphoid or scapholunate ligament injury with collapse on the radial side of the wrist. Surgical intervention is warranted for individuals with symptomatic SLAC and degenerative disease that affects the radioscaphoid joint with sparing of the midcarpal joint and the radio-lunar joint. There are currently two main options for motion-preserving reconstruction and treatment for this disease. These include four-corner arthrodesis (4CA) and proximal row carpectomy (PRC). There is a lack of consensus in the literature regarding which of the two procedures provides an overall better result and better clinical outcomes. We conducted a systematic literature review and meta-analysis to identify any differences in the clinical outcomes 4CA to PRC for scapholunate advanced collapse. Our Hypothesis is that proximal row carpectomy will have increased range of motion, increased grip strength, and decreased level of pain when compared to four-corner arthrodesis.

Methods: An electronic literature search of PubMed, Embase, OVID, and the Cochrane Library was conducted to identify studies published before January 2018. All randomized controlled trials and cohort studies evaluating clinical outcomes of four-corner arthrodesis versus proximal row carpectomy for the treatment of scapholunate advanced collapse were included. Primary outcome measures included flexion/extension range of motion, grip strength, and level of pain. Data were analyzed using Comprehensive Meta-Analysis (CMA) statistical software.

Results and Conclusions: Eight studies encompassing 355 patients met the inclusion criteria for the meta-analysis. Our meta-analysis indicated that when compared with 4CA, patients that underwent proximal row carpectomy had significantly increased flexion/extension range of motion by 14.2 degrees (p=0.008), significantly increased Grip strength by 7.2% (p=0.002), and reduced level of pain by 0.69 (p=0.011).

This study demonstrated that PRC is superior to 4CA for the treatment of scapholunate advanced collapse. Compared with 4CA, patients treated with PRC had increased range of motion, increased grip strength, and decreased pain. Limitation to these findings is the small number of studies available and the increased heterogeneity between the studies. Further studies need to be conducted to confirm these findings.

Total Wrist replacement using the MOTEC® PEEK Cup

List of authors:
Senthooran Raja*, Francesca Hill Cooper¹, Rami Estfan³, Gregory John Packer³
¹ Southend University Hospital (Essex)

Objectives / Interrogation: We aim to assess the efficacy, functional outcomes and safety of patients undergoing total wrist replacement (TWR) using the MOTEC® PEEK cup. All patients had debilitating wrist arthritis either primary or secondary. This new device is modular in design compared to the previous MOTEC Cup which used a pure cobalt chromium molybdenum alloy (CoCrMo) articulation. The new design introduces a carbon fibre reinforced PEEK articulation on CoCrMo. The intended properties of the PEEK cup include reduced stress distribution, elimination of metal on metal ion concerns and improved durability long term.

Methods: This is a prospective case series of 38 patients who underwent a MOTEC TWR between Nov 2016 & Aug 2018 across two hospital sites under two surgeons using the PEEK cup 15mm diameter. Indications for TWR included persistent pain, malalignment or instability, failure of previous surgery such as primary wrist replacement, four corner fusion, proximal row carpectomy, fixation or arthrodesis. We recorded functional outcomes pre- and post-surgery. Patients were followed up to minimum of 12 months. Functional assessments used were PRWE, MAYO, QuickDASH scores.

Results and Conclusions: Results
The series had a distribution of 20 male and 18 female patients, age range 33-83 (mean 62.6). Most patients were tertiary referrals and had surgery as a 23-hour stay. Using the PRWE, MAYO, QuickDash scores allowed us to determine post-operative function with minimal loss at follow up. There was a significant improvement in functional outcomes using the PEEK cup. There were no serious adverse events.

Conclusions
Overall the PEEK MOTEC cup showed safe and improved functional outcomes at 6 months and one-year post-surgery. There are no obvious safety concerns and patient satisfaction was rated high with patients being discharged from hand clinic rapidly after surgery.
Patients returned to improved levels of function with dramatically reduced pain. This case series shows that the PEEK MOTEC cup to be a safe and effective implant in TWR. It also reduces the metal on metal complications.

Subjective and Objective Assessment of Homodigital Neurovascular Direct Flow Flaps Used in Distal Phalangeal Amputations

List of authors:
Kadir Uzel¹, Velat Çelik¹, Yusuf Hakan Abacı², Metin Manouchehr Eskandari¹
¹ University of Mersin, School of Medicine, Department of Orthopaedics and Traumatology, Division of Hand Surgery (Mersin)
² University of Mersin, School of Medicine, Department of Orthopaedics and Traumatology (Mersin)

Objectives / Interrogation: Usage of homodigital neurovascular direct flow flaps (NVDFF) in reconstruction of distal phalangeal amputations lead to minimal donor site morbidity with high rates of patients' satisfaction. We aimed to assess the results of these flaps with an emphasis on their objective sensorial status in comparison with contralateral healthy fingers.

Methods: Study was done in patients who were operated for an unrepairable distal phalangeal amputation between January 2016 and July 2018. Eleven patients (2 women, 9 men) with completed assessments were included. Mean age of patients at the time of operation was 32 (3-62) years. There were 3 index, 2 middle, 4 ring and 2 small injured fingers. Eight of amputations were distal to the level of DIP joint while 3 were disarticulations through DIP. Nail matrix had been lost totally in 5 patients while the other 6 have still partial or total matrixes. All of the patients, except 3-year-old child, were operated under local anaesthesia. In all of them a triangular shaped volar neurovascular island flap was dissected. In two of them a skin grafting of donor site was required. Assessment of study parameters was done at a mean time of 13 (2-33) months postoperatively.

Results and Conclusions: There was no flap necrosis in any of the patients. Ten patients rated their sensorial status as good and 1 as moderate. Seven patients rated their flap softness as good and 4 as moderate. Ten of them had no cold intolerance while one stated intolerance in some degrees. Five patients rated their overall satisfaction as very good, 4 as good and 2 as moderate. There was no flexion contracture in PIP joints while there were 2 in DIP. There were nail deformities in 2 patients. Static two point discrimination test (2PDT) showed a significant difference (p=0,049) between the pulps of operated fingers (mean=4,45 mm, SD=1,57) and healthy contralateral hand fingers (mean=3,27, SD=1,00). Semmes Weinstein monofilament test (SWMFT) showed no significant difference (p=0,157) between the pulps of operated fingers (mean=2,73, SD=0,65) and healthy contralateral hand fingers (mean=2,36, SD=0,50).

Subjective results of NVDFF's remain in an overall range of good, although joint contracture, cold intolerance and nail deformity remain as probable postoperative problems. Subjective results are also supported by objective assessments in this small study group. As a more reliable objective test than 2PDT, SWMFT showed that there is no difference between operated and non-operated contralateral fingers.

Novel Technique of Vascularized Longitudinal Hemi-Metatarsal Second Toe Transfer for Reconstruction of Congenital Hand Differences

List of authors:
Roisin Dolan*, Henk Giele1
1 Oxford University Hospital NHS Foundation Trust (Oxford)

Objectives / Interrogation: As an alternative to pollicization, Chow et described a non-vascularized longitudinal hemi-metatarsal second toe transfer to reconstruct the CMC joint of the Blauth grade IIIb or IV hypoplastic thumb. Previously others described the whole second toe MTPJ transfer. We describe the novel microsurgical vascularized longitudinal hemi-metatarsal second toe transfer to reconstruct the CMC joint based on the dorsal metatarsal artery system, in Blauth grade III-IV thumbs or to provide vascularized growing bone grafts (VBG) in children.

Methods: We performed a retrospective analysis of nine patients who underwent vascularized longitudinal hemi-metatarsal second toe transfer at the Oxford University NHS Hospital Trust from December 2015 to December 2017. We will present the technique of harvesting and transfer, outcomes and the secondary surgery.

Results and Conclusions: Six hypoplastic thumbs Blauth grade IIIb-IV were reconstructed with a microsurgical vascularized longitudinal hemi-metatarsal second toe transfer. Three hemi-metatarsal VBG’s were performed to create digits in nubbins-type symbrachydactyly. Successful transfer of the split portions of the second toes occurred in all patients. Stable yet mobile CMC joint reconstruction occurred in all cases. Preservation of a fully functioning second toe is reported in all cases. Future secondary surgery will be required to improve functional mobility and use in the thumbs.

For those patients whose parents refuse pollicisation or whom present later in life, we report that microsurgical reconstruction of the severely hypoplastic thumb is possible using longitudinally split second toe metatarsal. When children require growing bone, the vascularized split second toe metatarsal reliably provides this with minimal donor site morbidity.

Anatomical correlation between the presence of a distal oblique bundle and the type of radioulnar joint according to the classification of Tolat.

List of authors:
Emmanuelle Richard*, PASCAL KOYOUUMDJIAN†, REMY COULOMB‡, OLIVIER MARES†
† Nîmes (Nîmes)

Objectives / Interrogation: The distal oblique bundle (DOB) is represented by obvious stretched fibers at the distal portion of the interosseous membrane (IOM) between the ulna and the radius below and on the outside. It has been shown as an important stabilizer of the distal radioulnar articulation (DRUJ) and is however only present in 40% of cases according to studies on cadaverous studies.

Tolat described in 1996 four types of incisures of the DRUJ in the frontal plane, from most stable to least stable: S-shape, C-shape, Ski-slope, and Flat face. [Ref1]

![Diagram of incisures types](image)

Fig 1. Type of sigmoid notch according to Tolat classification (JHS Oct 86)

The objective of this cadaverous study was to evaluate the existence of a correlation between the presence of a DOB and the type of DRUJ according to the classification of Tolat.

Methods: Twelve specimens (1 fresh frozen, 11 conserved) were dissected. The presence of a DOB was evaluated according to the description of Moritomo: the IOM was exposed in its distal portion to search for stretched fibers between the ulna and the radius below and on the outside.

The group of specimens was then evaluated by tomodensitometry to determine the type of DRUJ incisure according to Tolat’s description on frontal cuts at one centimeter from the DRUJ.
The statistical analysis was performed using the odds ratio.

**Results and Conclusions:** The DOB was found in 7 specimens, (58%). The presence of a DOB was more frequent in less stable incisures (4 flat face, 3 ski slope). They were never found in other more stable configurations according to Tolat’s classification.

The less stables configurations (such as flat-face and ski-slope) should deserve a reconstruction according to the native anatomy like the DOB orientation such as proposed by De Vries & al and Peter.R & al.

¹ Nîmes (Nîmes)

Objectives / Interrogation: The distal oblique bundle (DOB) is represented by obvious stretched fibers at the distal portion of the interosseous membrane (IOM) between the ulna and the radius below and on the outside. It has been shown as an important stabilizer of the distal radioulnar articulation (DRUJ) and is however only present in 40% of cases according to studies on cadaverous studies.

Tolat described in 1996 four types of incisures of the DRUJ in the frontal plane, from most stable to least stable: S-shape, C-shape, Ski-slope, and Flat face.

The objective of this cadaverous study was to evaluate the existence of a correlation between the presence of a DOB and the type of DRUJ according to the classification of Tolat.

Methods: Twelve specimens (1 fresh frozen, 11 conserved) were dissected. The presence of a DOB was evaluated according to the description of Moritomo: the IOM was exposed in its distal portion to search for stretched fibers between the ulna and the radius below and on the outside.

The group of specimens was then evaluated by tomodensitometry to determine the type of DRUJ incisure according to Tolat's description on frontal cuts at one centimeter from the DRUJ.
The statistical analysis was performed using the odds ratio.

**Results and Conclusions:** The DOB was found in 7 specimens, (58%). The presence of a DOB was more frequent in less stable incisures (4 flat face, 3 ski slope). They were never found in other more stable configurations according to Tolat's classification.

The less stables configurations (such as flat-face and ski-slope) should deserve a reconstruction according to the **native anatomy** like the DOB orientation such as proposed by De Vries & al and Peter.R & al.

Playing-related disorders among professional violinist

List of authors:
Maciej Bochenek*1, Marta Jokiel1, Piotr Czarnecki1, Leszek Romanowski1
1 Department of Orthopaedics, Traumatology and Hand Surgery (Poznan)

Objectives / Interrogation: Professional musicians are increasing, difficult group of patients. They often complain of playing-related musculoskeletal disorders (PRMDs) meaning chronic, unspecified pain, localized usually in neck or wrist, paresthesia, tremor or muscle weakness. It is a group of patients that postpone the visit to a doctor, because of intermittent character of symptoms and anxiety of being diagnosed and withdrawn from regular practicing in course of treatment, what implicate delayed visit in a doctors office, when the symptoms are usually advanced. The goal of our study was to functionally evaluate professional violinist according to their complains, as their background can not be compared with any other group - chronic, low intensity and long overload of motor units in a strained position.

Methods: 23 professional violinist underwent clinical examination focused on upper limb and cervical neck disorders(25 functional tests). To assess everyday living activities and playing restrictions DASH questionnaire was provided. Musicians were also evaluated due to the length of play and time of warm up before playing by the questionnaire prepared by authors.

Results and Conclusions: DASH result for violinist group was 8.63 ± 10.3 while in disorder group 15.3 ± 10.7 but the difference between groups was non-significant. Examination revealed most common symptoms in wrist area and ulnar nerve neuropathy in left hand. Average time of warm up was 13 ± 3 min. More than 55% of examined group complained also because of cervical neck disorders and headaches. During clinical examination positive result were registered with Cozens, Thomsons, and skin and joints laxity. Average time between beginning of the symptoms and medical appointment was 7-8 months.

Violinists complains are concerned mostly with the left upper limb and cervical neck which are responsible for holding violin up. Lack of significant difference in DASH and prolonged time of medical appointments suggest that symptoms increase slowly and with the proper diagnosis in time we could adjust better therapy.

Biomechanical characterization of ulnar styloid fracture size for instability of the distal radio ulnar joint

List of authors:
Mauro Maniglio¹, Il Jung Park², William Fraipont², Remy Flueckiger¹, David Wright³, Michael Kuenzler¹, Lilianna Bollinger³, Matthias Zumstein¹, Michelle McGarry⁴, Thay Lee⁵

⁵ Orthopaedic Biomechanics Laboratory, Congress Medical Foundation, Pasadena, CA (Long Beach)

Objectives / Interrogation: The deep component of the distal radioulnar ligaments (DRUL) inserts on the ulnar styloid and ulnar fovea and is considered as the most important stabilizer of the distal radioulnar joint (DRUJ). Ulnar styloid fractures (USF) may cause DRUJ instability depending on the fracture size. The aim of this study was to determine the relevant fragment size, leading to a significant increase in dorso-palmar (DP) translation and pronosupination.

Methods: Soft tissue was removed from a total of 8 cadaveric upper extremities (3 female) aged 60 to 77 years (mean: 66.4), preserving the interosseous membrane, extensor carpi ulnaris (ECU), pronator quadratus (PQ), and triangular fibrocartilage complex. The ECU and PQ were both loaded with 5N weight in a custom fixture, which permitted free rotation and DP-translation of the radius around the fixed ulna. For biomechanical testing, DRUJ stability in DP-Translation and pronosupination were evaluated. Four specific points on the DRUJ were chosen, to record the positional change of the DRUJ using a MicroScribe 3DLX. 1Nm of torque was applied to reach an endpoint in Pronosupination. DP-translation was measured in neutral, full pronation and 90° supination with 15 N translation loads. Measurements were repeated for four different ulnar styloid fractures done sequentially in the same specimen: intact, USF of the tip, basal USF and an USF including the fovea. Statistical analysis was performed using a repeated-measures ANOVA and Tukey multiple comparison post hoc tests.

Results and Conclusions: Compared to the intact condition (170.9°), the pronosupination significantly increased after all three fractures (Tip:181.5°, p<0.002; base: 184.3°, p<0.001; Fovea: 190.5°, p<0.001). The fovea fracture also showed a significant increase compared to the tip fracture (p=0.031). Total dorso-palmar translation significantly increased in neutral rotation after the fovea fracture (10.0mm) compared to the intact (6.8mm, p=0.002) and tip fracture conditions (7.8mm, p=0.029). There was also a significant increase in dorso-palmar translation in supination from intact (5.8mm) and tip fracture (5.9mm) to the fovea fracture (7.3mm, p<0.001 and 0.002). All tested fracture sizes of the ulnar styloid led to rotational instability of the DRUJ; however, the DRUJ remained stable in dorso-palmar translation unless the ulnar styloid fracture involved the fovea. Styloid fracture repair should be considered in fractures of the ulnar styloid involving the fovea.

Surgically Treated Brachial Plexus Tumours: the Oxford University Hospitals 20-Year Experience

List of authors:
Karishma Shah*, Aliabbas Moosa¹, Roisin Dolan¹, Henk Giele¹
¹ Oxford University Hospital NHS Foundation Trust (Oxford)

Objectives / Interrogation: Tumours of the brachial plexus region are rare. Whilst the majority of tumours are benign, patients can develop devastating neurological deficits and disabling pain. The aim of this study was, firstly, to assess the clinical presentation, and subsequent pathological diagnosis of patient’s presenting with brachial plexus tumours and, secondly, to assess motor functional outcomes, patient-reported upper extremity function, and pain following tumour extirpation +/- reconstruction.

Methods: We performed a retrospective analysis of 135 consecutive patients (n=135) who underwent excision of both primary and secondary brachial plexus tumours +/- reconstruction by a single-surgeon over a 20-year period. Data was collated from medical records, neuro-imaging, operative reports, and histopathological findings. Outcomes were assessed using the British Medical Research Council power grading system, quick Disability of Arm, Shoulder and Hand questionnaire, and Pain Visual Analogue Scale (PVAS).

Results and Conclusions: The mean age at presentation was 49.2 years (range: 9 - 89 years). The most common presentation was an expanding lump (87.3%). Additional presenting signs and symptoms included paraesthesia (44%), radicular pain (51%), local pain (15%), and motor weakness (10%). Duration of symptoms ranged from 2 months to 10 years.

Histologically, the cohort comprised a heterogeneous group of lesions, 76.3% (103/135) benign and 23.7% (32/135) malignant. Benign nerve sheath tumours were the predominant sub-type - namely schwannomas (41%) and neurofibromas (35%). Of the malignant tumours, soft tissue sarcomas occurred most frequently, 50% (16/32). The overall recurrence rate was 23.2% for the cohort at latest follow-up, 80% represented by malignant tumour recurrence.

Functionally, post-operative nerve preservation was achieved in 93.1% of patients at long term follow-up. Motor function (BMC) scores improved in 65% of patients. Quick DASH and PVAS response rate was n=56 of n=116 surviving patients (48.3%). At follow-up, the mean quick DASH score for this cohort was 26.1 (range 0-79.5). The mean PVAS score was 29.1 mm (range 3-100 mm).

To conclude, a multidisciplinary approach combined with early referral to specialist services, is vital to optimise outcomes for these potentially debilitating lesions. We report a low complication rate with good functional and patient self-reported outcomes following surgical intervention for brachial plexus tumours.

Subcutaneous spread of squamous cell carcinoma in the digit in association with primary radiotherapy

List of authors:
Christopher Deutsch*, Barbara Jemec
1 Royal Free Hospital (London)

Objectives / Interrogation: Squamous cell carcinoma (SCC) is the commonest malignancy encountered on the hand and is generally treated by surgical resection. Here we present a case managed by primary radiotherapy, which subsequently recurred locally with deep subcutaneous dorsal to volar spread along tissue planes, in addition to a literature search on the efficacy of radiotherapy for SCC.

Methods: A case report is provided with retrospective data and clinical photographs. A structured search of the Medline database was performed to include terms related to radiotherapy, SCC and hands.

Results and Conclusions: Case report. A 92-year old male with multiple co-morbidities was offered primary radiotherapy for a biopsy-proven, well-differentiated SCC on the dorsum of the middle phalanx of the left ring finger as primary surgical excision would have necessitated amputation of the digit. Following radiotherapy, an ulcerated lesion developed at the site which was confirmed to be a recurrent SCC. Amputation was performed to include the 4th metacarpal head. Subsequent histology demonstrated, unusually, SCC present at not the dorsal but the volar excision margin, with evidence of the cancer having spread through bone and along the flexor sheath to the base of the finger.

Discussion. SCC is generally managed surgically. Surgical excision with pre-defined margins has an approximately 95% clearance rate, with a 2% local recurrence rate even when margins are confirmed as histologically clear by standard histopathological techniques. However in some cases, radiotherapy is used as a first-line modality, and upwards of 90% cure rates are reported. The use of radiotherapy as a secondary modality where SCC is recurrent or refractory to surgical management is common, although data on the efficacy of this approach is lacking; in particular, data does not appear to exist with respect to rates of subsequent recurrence. Radiotherapy has an important role in managing cutaneous SCC in the hand, and may often be the patient's choice when given the alternative of amputation. However, this report highlights the potential pitfall of local recurrence, as well as an unusual type of local extension of disease which important implications for achieving complete surgical clearance.

**Functional Outcomes after Single-Bone-Forearm Surgery: A 3-Dimensional Analysis and Clinical Assessment**

**List of authors:**
Sebastian Farr*, Barbara Pobatschnig¹, Florian Schachinger³, Andreas Kranzl¹
1 Orthopedic Hospital Speising (Vienna)

**Objectives / Interrogation:** Several upper limb deformities can cause functional impairment and pain due to forearm instability and/or proximal migration of the radius. The creation of a single-bone-forearm has been shown to be a successful intervention to stabilize the forearm though at the cost of a loss of pro- and supination. Despite the reported good outcomes in small case series, it remains unknown how patients are capable to compensate for the lack of forearm rotation. This is particularly important as e.g. shoulder or wrist overuse may eventually lead to joint degeneration. The purpose of this study was therefore to analyse this patient cohort while performing well-defined functional tasks in order to obtain information about joint motion and potential compensation mechanisms.

**Methods:** We performed a prospective re-evaluation of 4 patients (3 children, 1 adult) who underwent single-bone-forearm surgery due to radial longitudinal deficiency (n=1), ulnar longitudinal deficiency (n=2), and a posttraumatic forearm deformity (n=1), respectively. Patients were clinically assessed using the Southampton hand assessment procedure (SHAP test) and Disabilities of the Shoulder, Arm and Hand (DASH) score, and a 3D-motion capture analysis was performed to specifically evaluate the performance of important tasks of daily life activities.

**Results and Conclusions:** Overall, a wide spectrum of functional impairment and deviation from the norm was observed. Both concerning the time to do certain tasks (e.g. turn a book page, pour a glass of water, rotate a key) as well as the quality of performance (linear index of function; LIF, and APS items), some patients showed normal behavior and function while others presented markedly altered mechanisms to achieve their tasks. Nevertheless, all cases were able to complete the tasks as requested. Compensatory movements were found in the trunk, shoulder, elbow and wrist, respectively (sagittal, frontal, transverse plane). No unique, distinct mechanism of compensation was however identifiable. Postoperative DASH scores ranged from excellent to poor (7 to 61 points).

Patients who received single-bone-forearm surgery are generally capable to perform important tasks of daily life. However, the time to achieve these tasks may be longer, and compensatory movements in several other joints are necessary to achieve these outcomes. Further long-term studies with more patients are warranted to assess any degenerative effects of these potential overuse movements.

Reconstruction of Long Tibia Bone Defect using Free Vascularized Fibula Graft and Locking Plate

List of authors:
Yeun Soo Kim*, Young Ho Lee¹, Hyun Sik Seok¹, Min Ho Lee¹, Yo Han Lee¹, Che Ho Lee¹, Young Ju Chae¹, Goo Hyun Baek¹
¹ Seoul National University College of Medicine (Seoul)

Objectives / Interrogation: Recent advances in multimodality treatment with chemotherapy and wide surgical resection margins have improved the prognosis of patients with musculoskeletal sarcoma. Following wide resection of the tumor, several reconstructive procedures have been applied for large bony defects, including mega-prosthesis implantation, as well as allograft and vascularized bone grafts.

The reconstruction of tibia defects following tumor resection remains a surgical challenge. Our group aimed to achieve biological reconstruction with living bone autografts. Free vascularized fibular graft (VFG) has become an established procedure for the treatment of massive bone defects. Bone defect of the tibia is reconstructed by various methods. Bone transport or free vascularized fibula graft are selected for the defect. We are to report the clinical outcome for the bone defect more than 15-cm long using free vascularized fibular graft.

Methods: We analyzed retrospectively 14 patients who sustained long tibia defect more than 15-cm long and underwent free vascularized fibular graft from contralateral side. Average follow-up period was 5 year and average age of the patients was 28 year-old. Operation was performed as following: free vascularized fibular graft was harvested from contralateral side and inset inlay method. Overlapped portion of the graft was fixated with locking plate and screw. The tibia-fibular graft construct was stabilized with long locking plate. The artery of the graft pedicled was anastomosed to the anterior tibial artery with end-to-side method, but veins were in end-to-end methods.

Graft survival was evaluated by bone scan in all cases. Bony union and hypertrophic changes of VFG and the occurrence of stress fractures were confirmed by plain radiographs obtained monthly for one year after surgery. Functional recovery was evaluated at final follow-up using the system proposed by the Musculoskeletal Tumor Society (MTS).

Results and Conclusions: All graft survival was confirmed with the bone scan. All patients obtained bone unions between the host bone and fibular graft. There were 3 metal failures of the locking plates, but implant changes with longer plate could induce the bone union.

Free vascularized fibula graft with locking plate could be considered as a reliable and safe method for the long tibia bone defect.

Bilhaut-Cloquet procedure: the type and aesthetic evaluation of nail deformity

List of authors: Weiyang Gao*, Jian Ding¹, Anyuan Wang¹, Long Wang¹, Zongwei Zhou¹
¹The Second Affiliated Hospital of Wenzhou Medical University, Yuying Childrens Hospital of Wenzhou Medical University (Wenzhou)

Objectives / interrogation: A retrospective review was made to classify the type of nail deformity and its aesthetic evaluation in radial polydactyly which was treated by the Bilhaut-Cloquet procedure (BCP).

Methods: From January 2005 to December 2015, the BCP was performed in 129 thumbs of 125 patients with radial polydactyly. 88 thumbs of 84 patients received more than 6 months of follow-up and were included in this study. The operation age was 7 to 216 months with an average of 31.4. There were 51 males and 33 females. Unilateral radial polydactyly was in 80 patients (left: 31, right: 49), bilateral in 4. According to the Wassel classification, there were 3 cases of type I, 20 of type II, 12 of type III, 3 of type IV, 6 of type VI, and 10 of type VII. The reconstructed nail were evaluated by Wang-Gao scoring system.

Results and Conclusions: The average follow-up period was 34.4 months (6-128 months). The occurrence of different nail deformities were as follows: abnormal nail flatness were found in 51 thumbs (57.95%), lunula malposition in 27 (30.68%), malposition of the nail fold in 22 (25.0%), abnormal nail width in 16 (18.18%), dehiscence of nail or growth failure in 7 (7.95%). According to Wang-Gao score (total 12), the score was 2-12 (average 9.18). Excellent results were in 58 thumbs (65.91%), good in 23 (26.14%), fair in 5 (5.68%) and poor in 2 (2.27%).

When the BCP were used, the improvement of the thumb volume and nail width was clear. The nail deformity varied in different types and its incidence was high. But it was mild and acceptable. Including more than 3 types of nail malformations in one thumb was the main cause of dissatisfaction among patients or family members, but the incidence was not high. Therefore, BCP is still a good choice for the patients with hypoplastic duplicated thumbs.

Treatment of closed unstable proximal phalangeal fractures in the long fingers with a reusable and inexpensive external fixation system

List of authors:
Sasa Hlede*, Oleg Stanic Gruden1, Mitja Oblak1, Krunoslav Margic1
1 SB Franca Derganca Nova Gorica, Department of Plastic and Reconstructive Surgery (Sempeter pri Gorici)

Objectives / Interrogation: The objective of our study was to evaluate the treatment of closed proximal phalangeal fractures with closed reduction and external fixation using a reusable external fixator.

Methods: A retrospective analysis was performed of data collected in a prospective database of all the patients with unstable isolated closed proximal phalangeal fractures of long fingers of the hand treated from 1999 to 2015.

The indication for external fixation was the inability to achieve and maintain a stable reduction with an intra-articular step or gap < 1 mm, an angulation < 10°, a shortening < 2 mm and without any rotational deformity.

Fluoroscopic closed reduction was performed under regional anaesthesia, K-wires were positioned perpendicular to the fracture and connected with a small external fixation system that uses a thicker K-wire as a frame. The K-wires were bended as needed to correct minor malalignment. Immediate postoperative active mobilization was encouraged and continued for 6 weeks. The external fixator was removed after 4 weeks and unrestricted usage of the injured finger was allowed after 8 weeks.

The results were assessed at 4 months and classified as excellent if the total active movement (TAM) was equal to the uninjured contralateral digit and good if the TAM was at least 230° or 85% of the contralateral digit. As poor were classified all the cases with TAM < 230°, an angulation >10°, any rotational misalignment or if any secondary procedure was required to improve the outcome.

Results and Conclusions: 88 patients were treated for closed isolated unstable proximal phalangeal fractures in the long fingers. Nine patients were excluded from the analysis, five due to poor compliance (drug or alcohol abusers or demented) and four due to lack of follow-up. Of the remaining 79 patients, 72 were males and 7 females, with an average age at trauma of 35,8 years. The results were excellent in 25 cases, good in 34 and poor in 20: 74,7% of the patients achieved a good or excellent result (TAM greater than 230°). In patients with poor results there was most frequently an extension deficit of the proximal interphalangeal joint.

The procedure was inexpensive as every set of fixators can be used on average for 20 or more procedures and the only material used were the K-wires.

With external fixation we achieve minimally invasive stabilisation of dislocated and fragmented phalangeal fractures with immediate active mobilization and good functional results while maintaining low running costs.

Nerve Diameter of the Hand: A Cadaveric Study

List of authors:
Ritsaart Westenberg*, Ricardo Ortiz1, Christopher Langhammer3, William Knaus1, Neal Chen1, Kyle Eberlin1
1 Massachusetts General Hospital (Boston)

Objectives / Interrogation: Nerve injuries in the hand are common and continue to pose a challenge to the upper extremity surgeon. Depending on the injury, means of coaptation include primary repair, hollow-tube (conduit) repair, and repair with autograft or allograft. Appropriate size matching, related to nerve diameter, is important for many of these techniques. The aims of this study were to 1) describe the nerve diameters of the hand and their relative differences and 2) investigate if there is a relationship between nerve diameter and external hand dimensions or body mass index (BMI).

Methods: We utilized eighteen freshly-frozen cadaveric hands from adult donors aged 20-86 of both sexes for this study. External hand dimensions were measured across three axes: length, width, and span. Two independent observers measured nerve diameter to the nearest 0.1mm using a digital caliper. Using the flexor zones as boundaries, we performed a total of 33 nerve measurements for each cadaveric hand (Fig 1). Provided values are based on the mean measurement of these two observers.

Results and Conclusions: Nerve diameter increased from the distal to the proximal flexor zones. The internal common digital nerves in flexor zone three were larger than the external digital nerves. The median nerve was found to be nearly two times larger than the ulnar nerve at two locations within the wrist. There was a positive correlation between BMI, hand span, hand width, and nerve diameter at several measured locations.

This study provides reference values for nerve diameters of the hand and wrist and describes their relative differences. It is important for surgeons to be aware of these differences and to consider this information as we advance our efforts to reconstruct the hand and develop technologies for nerve repair.

Keywords:
Hand; Peripheral Nerves; Upper Extremity; Adult; Ulnar Nerve; Median Nerve; Wrist; Body Mass Index
Objectives / Interrogation: The goal of surgery of the spastic upper limb is to rebalance forces between spastic and contracted muscles on one side, and paralyzed or pseudo-paralyzed antagonists. Surgery for contracted muscle involves various standard techniques of muscle lengthening. The spastic component is also amenable to surgical improvement through partial neurectomy, but this procedure has not gained much popularity yet, and reports on outcome are scarce in the literature. In light of our recent anatomical studies (96 cadaver dissections), new guidelines have been described and we have conducted a prospective study in order to re-evaluate the results of this treatment.

Methods: We performed a prospective study on 48 consecutive patients who underwent hyperselective neurectomy (HSN) of one or several spastic muscles of their upper limb(s). Indication of selective neurectomy was spasticity, exclusive of muscle contracture. Patient selection was based on repeated clinical evaluation and pre-operative botulinum toxin injections. HSN consisted in resecting 2/3 or more of every motor branch of the target muscle at the neuromuscular junction. Assessment performed pre-operatively, at 6 months and at last follow-up (average 22.2 months) was based on the resting position, active and passive motion, muscle strength, modified Ashworth and Tardieu scales, several functional scales, ADL questionnaires, and patient satisfaction (VAS).

Results and Conclusions: Twenty-nine adults and 19 children were enrolled in the study. HSN was performed in 56 cases, involving 185 muscles, mostly elbow and wrist flexors. Associated procedures (muscle lengthening, tendon transfers) were performed simultaneously in 35 cases. Results showed a statistically significant decrease of spasticity (Ashworth from 1.4 to 0.7 and Tardieu V1-V3 from 40° to 27° for elbow flexion and from 24.5° to 8° for wrist flexion) without weakening of the involved muscles, increase in the strength of antagonist muscles by 0.4, and improvement of all other parameters. Patient satisfaction averaged 8.5/10. The general trend indicated a minimal loss of correction between 6 and 12 months postop, and then the results remained stable over time.

Although spasticity is difficult to evaluate objectively, these results have been promising. They show effective reduction of spasticity without loss of strength, and improved motion and function. A larger cohort and a longer follow-up will be useful in order to confirm the evolutive trend.

Modified Bilhaut-Cloquet procedure: meticulous nail plasty, bone reconstruction and radial side incision

List of authors:
Weiyang Gao*, Jian Ding1, Anyuan Wang1, Long Wang1
1 The Second Affiliated Hospital of Wenzhou Medical University, Yuying Childrens Hospital of Wenzhou Medical University (Wenzhou)

Objectives / Interrogation: The complications of Bilhaut-Cloquet procedure, including nail deformity, joint stiffness and dramatic unaesthetic scar, were common. In this study, we analyzed the surgical results which were treated by Bilhaut-Cloquet procedure in our patients.

Methods: From January 2010 to April 2014, 39 thumbs of 36 cases acquired more than one year follow-up, including 21 boys and 15 girls (average age: 22.3 months). The right thumb was involved in 25 cases, left in 14 cases. All cases were hypoplastic and the nail width was less than index-finger or 80% of non-affected thumb. All thumbs were treated by our modified Bilhaut-Cloquet procedure: A modified nail fusion technique included nail lunula design, nail fold plasty, meticulous nail bed suture and nail plate replantation; Bone reconstruction remained intact interphalangeal (IP) joint and metacarpophalangeal (MP) joint; A new incision design retained an intact pulp. The results were evaluated by Tada scoring system and Wang-Gao scoring system.

Results and Conclusions: According to the Tada scoring system, excellent result were found in 30 thumbs, good in 8 and poor in 1. The total mobility of the IP and MP joint was more than 70° in 33 thumbs, 50-70° in 5 thumbs and less than 50° in 1 thumb. The axis deviation was less than 10° in 21 thumbs, 10-20° in 12 thumbs and more than 20° in 6 thumbs. The joint instability was found only in 3 thumbs. According to the Wang-Gao nail appearance scoring system, excellent results were in 32 thumbs, good in 7 thumbs. The nail width was 85% of the contralateral side in 37 thumbs. Smooth nail was found in 4 thumb, and ridge or gap was found in 35 thumb (mild: 33, severe: 2). The continuous curve of the lunula was found in 29 thumbs and lunula malposition was found in 10 thumbs (mild: 7, severe: 3). 28 thumbs had no nail fold malposition, and 11 thumbs had nail fold malposition (mild: 9, severe: 2). One nail was hypoplasia and one nail was dehiscence. 33 thumbs were satisfied by the patients or their parents, fair in 5, unsatisfactory in 1. The scar was hidden at the radial and distal side of the thumb, and the intact and plump pulp was found in all the cases.

The nail deformity is inevitable according to our technique, but the nail appearance and thumb function is satisfying. The modified Bilhaut-Cloquet procedure should be recommended as the first choice for duplicated thumbs in hypoplasia type.

Hugo Garlito Díaz\(^1\), Juan Carlos Márquez Ambite\(^1\), Marta Olmeda Lozano\(^1\), Daniel López Dorado\(^1\), Francesca Teodonno\(^1\), Raquel Serrano Serrano\(^1\), Rocío Mascaraque Ortiz\(^1\), Cristóbal Suárez Rueda\(^1\)
\(^1\)Hospital Universitario Infanta Elena (Madrid)

Objectives / Interrogation: Gout is uncommon in the upper extremity. Gouty involvement of hand is typically associated with an advanced stage of the disease in patients with uncontrolled hyperuricemia. The usual lesions are tophi, which are subcutaneous or bursal deposits of monosodium urate. The treatment is primarily medical. Surgery should be considered if the medical treatment is not tolerated by the patient or if the gouty deposits produce nerve compression, tenosynovitis or tendon rupture.

Methods: We present the case of a 49-year old patient with a previous hyperuricemic event that presents palmar nodules on 4th and 5th fingers of the dominant hand which limits the flexion with no prior traumatic event. The physical examination showed palmar nodules and a limited flexion of 4th and 5th fingers. An MRI was performed showing important synovial proliferation and distension concerning the common synovial sheath of the 4th and 5th flexor tendons, as well as partial rupture of flexor digitorum profundis and probable rupture of the flexor digitorum superficialis of 5th finger. It also showed an interphalangeal arthritis of 5th finger. A blood analysis confirmed hyperuricemia. The patient was referred to Rheumatology. A surgical treatment is then performed: A volar Brunner approach over the 4th and 5th fingers showed a partial rupture and proliferative tenosynovitis of the flexor digitorum profundis and a tenosynovitis of the superficialis of the 4th finger and a tenosynovitis of both tendons of 5th finger with an important degenerative arthropathy of the distal interphalangeal joint. Consequently, the surgery consisted in a reconstruction of the flexor tendon using an autograft of the palmaris longus for the flexor digitorum profundis and superficialis of the 4th finger and a distal interphalangeal arthrodesis of the 5th finger. The tenosynovial tissue was excised and sent for histological examination. The patient was immobilized with a forearm splint in flexion. After two weeks the surgery wounds were in good state with no signs of infection, and the splint was removed to allow early protected mobilization. The analysis of the tissue showed various gouty tophi and presence of synovitis.

Results and Conclusions: Patients with flexor tendon ruptures and degenerative arthropathy present an high disease activity. Prevention of tendon ruptures by early tenosynovectomy is advised, due to poor prognosis. Aside from surgery, the multidisciplinary management of gouty arthritis is necessary.

Madelung’s deformity - long-term results of ulnopalmar correction osteotomies in 12 wrists

List of authors:
Martin Franz Langer*, Britta Wieskoetter, Simon Oeckenpöhler, Sarah Breiter
1 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)
2 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster, Sektion Hand (Münster)
3 Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)

Objectives / Interrogation: Do the corrective osteotomies in the case of Madelung deformity have good successes over the long term and are therefore justified?

To date, we have performed 32 corrective osteotomies on Madelung deformities. To clarify this question, we reviewed 12 corrective osteotomies for Madelung deformity, which we operated in our own new technique between 1998 and 2008 for adolescents between 12 and 16 years, after at least 10 years.

The surgical technique we used consisted of a palmar correction osteotomy, an ulnopalmar extension of the radius, and an angle-stable plate osteosynthesis.

Methods: 1 boy with unilateral correction, 3 girl with unilateral correction and 4 girl with bilateral correction were followed up after at least 10 years. It examined subjective complaints, wrist mobility, pro- and supination, forearm length, and cosmetic outcome. Mayo wrist score and DASH-score.

Results and Conclusions: Although corrective osteotomy can never achieve complete anatomical reconstruction, many biomechanical values have improved.
Pro-and supination and wrist mobility are still better than pre-operative even after 10 years. Discomfort in the ulnar area of the wrist are not or only slightly present. All patients are very satisfied with the cosmetic result.
DASH and Mayo-wrist score are still under evaluation.

According to the preliminary results, the correction osteotomies are a very useful operation compared to the same age non-operated patients.

Pathology distribution of upper limb emergency cases admitted in plastic and reconstructive surgery department of SCUB - eighteen months retrospective study

List of authors:
Alexandru Stoian*, Andreea Grosu-Bularda, Crina Onciu, Ioan Lascar, Cristian-Sorin Hariga
1 Emergency Clinical Hospital Bucharest (Bucharest)
2 Emergency Clinical Hospital Bucharest, "Carol Davila" University of Medicine and Pharmacy (Bucharest)

Objectives / Interrogation: Since introduction and organization of major trauma centers worldwide, the overall mortality decreased significantly. This is a result of close multidisciplinary approach between surgical specialties as general, orthopedic, neurosurgery and plastic surgery. Furthermore progresses in microsurgery and their adaptation to trauma surgery have contributed consistently to the improvement of patients' outcome and postsurgical quality of life. The aim of the study is to show a precise picture of traumatic upper limb pathology distribution from our plastic surgery department.

Methods: We assessed all upper limb cases admitted in our unit between 1st of January and June 30th 2018, from which we excluded the tumoral emergencies and chronic pathologies.

Results and Conclusions: Our clinic is one of the busiest department from Romania in terms of acute surgical pathologies which requires a plastic surgeon expertise. From the number of 2064 acute upper limb cases 80% involved hand injuries, followed by forearm (16%) and arm injuries (4%). Males were three times more affected than women and the median age was 47. The leading causes of trauma were contact with different types of saws, sharp cuts, crushing injuries, infections and bites. All this produced a wide range of injuries from simple wounds to amputations of different levels. We identified in the top of pathology distribution tendon injuries (17%), followed by fractures (13%), simple wounds (12%), fingertips lesions, nerve lacerations, amputations.

Emergency Clinical Hospital from Bucharest deals with a wide palette of acute upper limb events, from simple lacerations to polytrauma patients who need an interdisciplinary approach. Within our trauma team the plastic together with orthopedic surgeons plays a pivotal role between other surgical specialties.

Fat graft interposition arthroplasty as a source of stem cells in radiocarpal arthrofibrosis treatment. A Case report of a novel technique.

List of authors:
Carlos Eduardo Torres Fuentes*, Julian Andres Hernandez Beltran¹, Dario Fernandez Loaiza¹
¹ Fundación Universitaria de Ciencias de la Salud, Hospital San José (Bogotá)

Objectives / Interrogation: Wrist arthroplasty is a therapeutic option in cases of joint pain that do not respond to other treatments. The use of stem cells is being highly studied for its potential application in different medical fields and has been become an alternative for the management of joint disorders due to its ability to regenerate cartilage and even bone. The aim of this article is to present a new technique in which we use fatty grafts as a source of stem cells for the treatment of radiocarpal joint arthrofibrosis.

Methods: We present the case of a 53-year-old male patient age with a history of left distal radius fracture with articular involvement and a Geisler II scapholunate ligament injury arthroscopically diagnosed that required open reduction, plate internal fixation and arthroscopically ligament debridement. Four months in the follow up the patient reported pain and limited motion arcs. Diagnostic arthroscopy was performed, a severe arthrofibrosis and synovitis of the radiocarpal joint was evidenced. Fatty grafts were placed through direct arthroscopic vision into proximal wrist joint.

Results and Conclusions: In a 1-year follow-up, we found pain improvement and increase in flexoextension, ulnar and radial deviation movement as well in the grip strength of the wrist. The use of stem cells in arthroplasty procedures is still under study however given the multiple applicability in regenerative processes, multiple donor sites and easy harvest, becomes an alternative for the treatment of degenerative joint pathologies.

Dorsolateral biplane closing radial osteotomy for Kienböck's disease: long-term follow up.

List of authors:
Claudia Lamas-Gómez*, Laura Velasco-González¹, Marta Almenara-Fernández¹, Alex Grau-Blanes¹, Roger Rojas-Sayol¹, Ariadna Da Ponte-Prieto¹
¹Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona (Barcelona)

Objectives / Interrogation: Purpose: To clarify long-term clinical and radiological results more than 8 years after dorsolateral biplane radial osteotomy for Kienböck's disease.

Methods: Methods: Twenty-one patients that had been classified as Lichtman stages II (7 wrists), IIIA (11 wrists) and IIIB (3) underwent dorsolateral radial biplane osteotomy for Kienböck's disease. This technique was performed to reduce radial inclination angle and the dorsal angle on the sagittal plane (ie, palmar tilt), thus achieving the dual effect of decompressing the lunate on the frontal and sagittal planes in Zero Variant cases. The mean follow up period was 10.3 years (8-17 y.). Clinical outcomes were quantified using the Disabilities of Arm, Shoulder, and Hand (DASH) questionnaire and the modified Mayo wrist score. Radiographic and Magnetic Resonance imaging (MRI) studies were performed in all patients preoperatively and at follow-up. A Statistical comparison of preoperative clinical, radiologic, and MRI studies with those performed before and after follow-up was performed using the wilcoxon test. Statistical significance was determined to be p< 0.05.

Results and Conclusions: Results: There were 10 males and 11 females with a mean age of 32 years (range, 18-72). Fifteen patients were asymptomatic and the remaining six had mild occasional pain. No patients complained of constant pain (p< 0.001). Average preoperative grip strength was 24 Kg. and average postoperative was 54 Kg (p< 0.001). The mean range of extension and grip strength significantly improved. The mean Mayo wrist score and DASH scores were 94 (range, 80-100) and 5 (range, 0-15), respectively. At follow-up, no progression of the Lichtman stage was found in any patient. There was no significant progressive lunate collapse in any patient. The MRI in fifteen wrist showed increased signal intensity of the lunate; the remaining 6 wrists had no alteration in signal intensity of the bone.

Conclusions: Our study demonstrated satisfactory clinical results after 8 or more years follow-up in patients who underwent dorsolateral radial osteotomy for Kienböck's disease. Although we found no improvement in signal intensity of the lunate in 6 wrists, unloading of the diseased lunate after dorsolateral radial osteotomy gives long-lasting symptom relief and may prevent lunate collapse.

CORRECTIVE OSTEOTOMY AND DISTRACTION TECHNIQUE USED IN DISTAL RADIUS MALUNION TREATMENT

List of authors:
igor obukhov*, Yekaterina Panchenko1
1 Ural State Medical University (Yekaterinburg)

Objectives / Interrogation: The goal of the work was to improve treatment of patients having distal radius ephysysis/metaphysis region malunion combined with persistent wrist joint (WJ) contractures.

Methods: Research materials and methods. We performed a retrospective investigation of 67 patients with distal radius ephyshis/metaphysis (DREM) malunion during the period of 2011 to 2017. The patients were 12 men and 55 women, aged 18 to 78. Time period elapsed after injury was 1.5 months or more (the average time was 79±18.7 days). The admission of patients for surgical treatment revealed: all 67 patients had a significant deterioration in their quality of life due to the weakness of the hand grips, pain when performing hand grips and axial load on the forearm. The post-traumatic deformities of the DREM were accompanied by 100% contracture in wrist joint (WJ). Flexion-extensor movement had 74 degrees limitation (52% of normal state) in average. Before surgery, control radiographs had determined: the fusion of radius was shorter than 3 mm, there also were radius articular surface axis violation with displacement of wrist bones (wrist collapse), subluxation or dislocation of ulna head. 48 (71.6%) cases revealed osteoporosis of distal forearm and wrist bones.

All 67 patients underwent radial bone osteotomy at deformation apex using the distraction method. On 6-7th day after the osteotomy, bone fragments reposition was gradually carried out (1 mm per day) using the distraction device. Distraction regenerate was formed and position of the radius fragments was stabilized after completing the restoration of articular surfaces of radius and ulna. The time of treatment in the device was 7-9 weeks.

Results and Conclusions: Conclusions. Immediate and long-term results (6 months or more after surgery) were studied in all 67 patients according to the DASH system. (Decrease from 88 to 23 points). Fusion of the radius in correct position was achieved in 63 cases out of 67 (94.0%), complete restoration of movement amplitude in wrist joint was achieved in 61 case (91.0%). In 3 cases, satisfactory results were obtained, and one case were bad due to premature removal of the device. Restoration of length and axis of the radius provides the elimination of WJ contractures. Distraction technologies allow simultaneous restoration of radius anatomy and WJ and forearm joint movements. The distraction method is effective in treatment of patients with DREM malunions in combination with DOUH, persistent WJ contractures.

Keywords:
distal radius malunion, distraction, wrist joint contracture.
Use of negative-pressure wound therapy to overcome venous congestion in fingertip reimplantation.

List of authors:
Maria Antonia Gomez Sierra*, Julio Cesar Bermudez1
1 Fundacion Santa Fe de Bogota (Bogota)

Objectives / Interrogation: Currently there is little literature on the use of negative pressure wound therapy (NPWT) to overcome venous congestion in fingertip reimplantation. As in free flaps, venous congestion has demonstrated to be one of the main causes of partial or total loss. In the literature NPWT has demonstrated a high success rate in salvaging free flaps with venous congestion. NPWT is known to increase local blood flow, decrease edema, stimulate granulation tissue, and decrease the concentration of reactive oxygen species hens reducing the likelihood of soft tissue infection. Given the forth mentioned we used NPWT in fingertip reimplantations, which suffered venous congestion. With this we wished to demonstrate NPWT could be successful in overcoming venous congestion in fingertip reimplantation, salvaging the reimplanted segment.

Methods: A retrospective analysis was performed on two cases of fingertip reimplantation in which NPWT was used to overcome venous congestion and persistent edema. Patients where followed for at least a year ensuring adequate functionality given by protective sensibility of the fingertip, movement that allowed day to day activities and return to normal life.

Results and Conclusions: Two patients with fingertip amputation where included, a male with a left thumb injury (Allen IV) and a female with a right index injury (Allen IV). In both cases venous congestion presented after reimplantation was carried out on an average of 2 days. Continuous NPWT was then applied improving the venous drainage and resolving tissue edema and venous insufficiency, which enabled total fingertip salvage. Both patients recovered protective sensibility, returned to their normal life activities and have a functional finger.

NPWT is a useful instrument in managing and improving venous congestion in fingertip reimplantation. Even though further and larger studies are necessary on the use of NPWT and its role in venous congestion in fingertip reimplantation it is a solution that has demonstrated high efficacy to salvage a fingertip that present venous congestion. It is a nonsurgical alternative that has demonstrated high success rate with minimal complication according to the results obtained in this report.

Saskia Kamphuis*, Riccardo Lorenzini¹, Abdul Rahman Jandali¹, Julia Sproedt¹
¹ Cantonal Hospital Winterthur (Winterthur)

Objectives / Interrogation: Osteoarthritis of the trapeziometacarpal joint is a common problem that affects up to 10% of women between the ages of 45 and 70. The majority of patients are treated by trapeziectomy, which can be associated with interposition- and suspension arthroplasty. Different ligament reconstruction techniques have been described over the years. However, there is a small group of patients who only have a temporary benefit from the first surgical treatment, or not have any at all. The persistence of symptoms such as pain or impaired range of motion after surgery is considered a failure of the treatment.

In our clinic, several revision surgeries using the Carpo Metacarpal Implant® (CMI®) were performed. The rationale behind this treatment, is that a neoarticulation through proximalization of the base of the first metacarpal base with scaphoid or trapezoid can be treated by resection of the articular surface of the first metacarpal base and replacing it with a non-cemented monopolar implant. This treatment has not been described in the literature before.

The goal of this study was to follow up patients who have had a trapeziectomy with tendon arthroplasty and who needed revision surgery because of neoarticulation through proximalization.

Methods: We examined patients who received a CMI® Prosthesis after failed trapeziectomy with tendon arthroplasty with a retrospective follow-up examination concerning pain, range of motion, grip and pinch strength and radiographic evaluation.

Results and Conclusions: We describe three female patients, with a mean follow up of 7 years. Mean age at treatment was 58 years, at revision 61 years. Primary surgery was performed by trapeziectomy with one FCR and two APL arthroplasties. At follow up, overall range of motion was 86.8% of the opposite extremity. Mean grip strength was 83.3% and pinch strength 59.7% of the contralateral side. Mean Quick DASH score was 12.1, mean VAS with maximal weight bearing was 3.7/10. Radiologically, no progressive proximalization was seen. One patient also had an MCP arthrodesis at the time of revision surgery. One patient showed no Z-deformity and the third patient developed a mild Z-deformity with MCP extension of 35 degrees. Subjectively, all patients were happy with the outcome despite of their residual complaints.

Concluding, in our opinion, the non-cemented monopolar CMI® Prosthesis is a good option for treatment of persisting pain after trapeziectomy because of neoarticulation through proximalization.

EARLY STIMULATION OF BONE CONSOLIDATION IN PATIENTS WITH PATHOLOGICAL PHALANGES FRACTURE: THE ROLE OF BIOPHYSICS STIMULATION

List of authors:
Francesco De Francesco*, Pierfrancesco Pugliese1, Pier Paolo Pangrazi1, Letizia Senesi1, Andrea Campodonico1, Michele Riccio1
1 Dpt of Reconstructive Surgery and Hand Surgery, AOU Ospedali Riuniti di Ancona (Ancona)

Objectives / Interrogation: The aim of a treatment when hand surgeon facing with a fracture is to promote bone healing. It is not always easy to understand if and with which probability, a fracture will evolve to a delayed consolidation or a pseudoarthrosis. Currently we do not have clinical, instrumental or laboratory investigations useful to identify "a pathological fracture", meaning as such a fracture that may require a longer time for healing or greater probability of incurring in non-consolidation. The aim of the present work is to evaluate the role of biophysical stimulation in the surgical treatment of simple and complex phalanges fractures. Biophysical stimulation was approved by the Federal Drug Administration (FDA) for treatment of delayed unions after long-bone fractures.

Methods: We treated with Capacitively coupled electrical field (CCEF), 40 patients divided in three groups: recent fractures, delayed consolidation and non-union. The segments involved were predominantly the phalanges and metacarpal bones. The patients underwent treatment with CCEF for an average time of 40 days (range 15 days - 120 days).

Results and Conclusions: Healing time was relatively shorter in the group treated with CCEF than expected considering the difficulties often occurring in the management of fractures and non-unions of the phalanges. Data were analysed with t-Student test.
The use of CCEF can shorten healing time of the bone, and consequently reduce the potential damages related to a prolonged immobilization. Biophysical stimulation can be an option in selected clinical situation: neither feasible surgical tretment nor accepted by patients with non-displaced and stable fractures, in case of delayed union, or lastly in non-union requiring bone flap or grafting as additional therapy after the surgery procedure.

Biophysical stimulation, CCEF, Osteobit, non-consolidation fractures, pseudoarthrosis
Results on Dupuytren disease course from a five-year follow-up cohort study

List of authors: Dieuwke Broekstra*, Paul Werker1, Edwin Van den Heuvel2
1 University Medical Center Groningen, dept. Plastic Surgery BB81 (Groningen) 
2 Eindhoven University of Technology, dept. Mathematics and Computer Science, Metaforum (Eindhoven)

Objectives / Interrogation: The exact natural course of Dupuytren disease (DD) is unknown. This study was aimed to determine the long-term natural course of DD in patients with different disease stages, and to find potential predictors for progression.

Methods: 258 DD patients (63% male, age at inclusion 66.4 SD 10.4 years) were included in this longitudinal cohort study. Measurements took place every 6 months, during 5 years. In total 17,645 observations were available for statistical analyses. Disease extent (surface area) and contracture severity (total passive extension deficit, TPED) were outcomes, and demographic, health-related, genetic, and lifestyle details were registered as potential predictors. Subject-specific mixed-effect models were used to estimate the natural disease course for both outcomes, and stepwise linear regression analyses on the acquired slopes were used to determine covariates associated with progression.

Results and Conclusions: Average yearly increases in disease extent were 0.50 [95% CI 0.41; 0.60] and 0.61 [95% CI 0.49; 0.72] cm² in area, for dominant and non-dominant hands respectively. An average yearly increase of 5.05 [95% CI 2.75; 7.36] and 14.3 [95% CI 8.8; 19.7] degrees of summed TPED was observed for dominant and non-dominant hands. About 11% to 16% of the participants did not show progression. Model fits ranged between 89.9-94.9% (R²). Several predictors for progression were found (e.g. Ledderhose's disease, first degree relatives, diabetes, and manual labour).

In conclusion, DD is progressive, although the speed of progression is variable across participants. Several suggested predictors for progression were identified, but a consistent view on DD progression across hands and outcomes was not found.

LONG-TERM OUTCOME OF INNERVATED DIGITAL ARTERY PERFORATOR FLAP

List of authors:
Ali Cavit*1, Haluk Ozcanli2
1 Uludag University Faculty of Medicine (Bursa)
2 Akdeniz University Faculty of Medicine (Antalya)

Objectives / Interrogation: The aim of study is to evaluate long-term clinical outcomes of the patients who underwent reconstruction with innervated digital artery perforator flap (IDAP) flap in the treatment of fingertip tissue loss.

Methods: 83 patients (93 fingers) who were operated due to fingertip amputations between August 2011 - October 2016 were included in the study. Acute or late reconstructions were performed to the fingertip injuries with the use of IDAP flap. Mean age of the patients was 35.2 years (range 5-65 years). Objective and subjective evaluations were performed in the postoperative controls. Statistical two-point discrimination (s2PD) and Semmes-Weinstein monofilament (SWM) tests were performed as objective parameters in comparison with contralateral hand. Range of motions of the reconstructed fingers were evaluated. Conditions that affect regional blood flow negatively (diabetes mellitus, vasospastic problems, smoking etc.) were questioned. Subjective assessment parameters consisted of hypersensitivity, cold intolerance and patient.

Results and Conclusions: The mean follow-up period was 33.1 months (range 12-60 months). The static 2-point discrimination measured on the flaps ranged from 2 mm to 6 mm (mean 3.7 mm); compared with 2 mm to 5 mm (mean 2.7 mm) on the contralateral fingers. Semmes-Weinstein test results ranged from 2.44 to 4.31 on the contralateral fingers, compared with 2.44 to 4.56 on reconstructed fingers. No partial or total flap loss was observed in any of the patients. There was no donor site morbidity. Superficial epidermolysis was observed in 4 fingers (4.3%). However, no second surgical procedure was applied to any patient. 4.3% of the 93 fingers (4 fingers) had hyperesthesia. Mild cold intolerance was observed in 18 fingers (19.3%). When evaluating both functional and aesthetic conditions of the patient, 75 patients (90.3%) reported being "very good" and 8 patients (9.7%) reported being "good".

The innervated digital artery perforator flap is a quick, sensory, reliable and versatile flap with excellent functional and aesthetic results, which can be used for early and late reconstructions of all types of fingertip defects.

UPPER TRAPEZIUS TO TRICEPS TRANSFER A NOVEL TECHNIQUE FOR RESTORATION OF ELBOW EXTENSION IN PATIENTS WITH BIRTH BRACHIAL PLEXUS PALSY

List of authors:
Praveen Bhardwaj*1
1 Ganga Hospital, Coimbatore (Coimbatore)

Objectives / Interrogation:
Restoration of elbow extension in patients with birth brachial plexus palsy has received much less attention in the literature. Restoration of elbow flexion is considered as a prime aim and recovery of elbow extension is relied on assistance by gravity. However, in absence of elbow extension, the capacity of the child to reach for objects especially above the shoulder level is greatly limited which henceforth dramatically limits the use of the hand. Lack of elbow extension causes the elbow (with the hand) to fall into flexion when the child abducts the shoulder overhead, again limiting the reach to the objects.

Methods: The techniques described for restoration of elbow extension include the posterior deltoid-to-triceps transfer and lower trapezius to deltoid transfer. In our experience, the posterior deltoid to triceps transfer gave good results but it was possible only when the function of posterior deltoid is normal. Most of the children with birth brachial plexus palsy have limited deltoid function. We have performed the described lower trapezius to triceps in four patients. Two of them achieved grade 2 triceps function but other two could not perform any active extension of the elbow. This operation has not given good results as reported for adults. So we modified the technique and used the upper trapezius to triceps transfer in six patients. The upper trapezius was extended with the fascia lata and connected to the triceps to restore elbow extension. In last two years, we have performed six cases of upper trapezius to triceps transfer (with fascia lata graft).

Results and Conclusions: All the six patients could actively perform elbow extension against gravity (grade 3). They reported that their ability to reach for objects has improved and overall function of the limb as well. Since the transfer also transverses the shoulder it also improved the shoulder abduction.

Differences in the Predictive value of Elixhauser Comorbidity Index and the Charlson Comorbidity in Patients with Hand Infections

List of authors:
Dominick Congiusta*, Kamil Amer, Aziz Merchant, Irfan Ahmed, Michael Vosbikian
1 Rutgers New Jersey Medical School (Newark, New Jersey)

Objectives / Interrogation: The Elixhauser and Charlson Comorbidity indices are two of the most commonly used measures of clinical prognosis. Superiority of one index over another largely depends on the condition or procedure being studied. To date, there is no analysis of a nationwide database comparing the two indices for complications of hand infections.

Methods: The Nationwide Inpatient Sample 2001-2013 database was queried for hand infections using International Classification of Diseases, Ninth Revision (ICD-9) codes for hand infections (10 codes). The Elixhauser (ECI) and Charlson (CCI) comorbidity scores were calculated based on defined sets of ICD-9 codes that have been previously validated. Primary outcomes included mortality, prolonged length of stay (defined as >95 percentile), discharge destination, and postoperative complications. Indices were compared using receiver operating characteristic (ROC) curves. If confidence intervals overlapped, statistical significance was determined using the DeLong method for correlated ROC curves. This is a previously validated, non-parametric comparison used for the calculation of the difference between two AUCs.

Results and Conclusions: A total of 316,397 patients were included in this study. The AUC (95% confidence interval) for mortality was 0.710 (0.699-0.720) and 0.726 (0.715-0.736) for the ECI and CCI, respectively. The differences in AUCs were uniformly significant (p<0.05).

Objectives / Interrogation: PURPOSE:
Present a bigger series (83 cases) of the new technique for fixation of the metacarpal and proximal phalangeal extra articular fractures.
Show that Hybrid Dynamic Minifix ® consist of a combination of intramedullary nailing and external fixation system.
Demonstrate that a hardware stable but not rigid fixation is achieved, then permits immediate motion without cast immobilization.
Enlarge the indications and present some modifications to the original technique presented by the former author in the last IFSSH 2016 congress.

Methods: METHODS

Results and Conclusions: Type of bone:5MTC (30%), 1MTC (20%) and 5 proximal phalanx (12%). Withdrawal of Minifix performed up 4 weeks in 90.3% of cases. Return to work 77.4% of cases less than a month after surgery, 22.6% between 1 to 2 months. Basic disabilities only 9.7% of patients were over 15 days with basic daily disabilities. Pain after surgery only 6.5% had high pain more than 3 days. Satisfaction: all patients were very satisfied. Regarding surgical complications just 6% had k-wire inflammation well-controlled by antibiotics. There were any cases of non union, delay in consolidation or sympathetic nerve dystrophy. Just one case had rotational deformity and only 5 cases had relative decreased of range of motion. We also apply this technique for correction of non-unions, segmental bone fractures, mal rotations deformities with successful results.

CONCLUSIONS:
Hybrido Dynamic Minifix (HDM®) technique represents a highly reproducible simple method, inexpensive, with successful results and a low rate of complications.
The time of return to daily activities or work is reduced due to immediate mobility, thus stimulating the consolidation and avoiding rigidity.
Modification technique using the non-injuried and parallel metacarpal bone showed the same security and success for the consolidation and represents an alternative to inset two k-wires for the same circular bone.
Hybrido Dynamic Minifix (HDM®) is presented as a new treatment option for percutaneous extra articular fractures of the proximal phalanx and metacarpals avoiding all risks associated with open surgery or prolonged cast immobilization.

Modified thumb CMCJ stabilisation, accounting for contemporary biomechanical evidence: a case report applying systematic review findings

List of authors:
Jeremy Rodrigues*, Justin Wormald, Luke Geoghegan, Raina Zarb Adami, Praveen Bhardwaj
1 NDORMS, University of Oxford (Oxford)
2 Imperial College Medical School (London)
3 Lister Hospital (Stevenage)
4 Ganga Hospital (Coimbatore)

Objectives / Interrogation: Early biomechanical studies focus on the volar beak ligament as the primary stabiliser of the thumb carpometacarpal joint (CMCJ). However, more recent work summarised in a systematic review highlights the role of dorsal ligament complex (DLC) in stabilising the joint.

A common approach to stabilising the thumb CMCJ joint uses flexor carpi radialis to reconstruct the ligament, akin to an LRTI following trapeziectomy.

Alternative approaches that account for the role of the DLC exist, such as Rayan's dorsoradial capsulodesis. However, such techniques tend to focus on one joint structure or the other.

We describe a novel modification of the FCR-based technique that simultaneously reconstructs the volar beak ligament and to DLC, and its use in a challenging case.

Methods: A 28-year-old right handed was treated for a recurrent left thumb CMCJ dislocation. The closed injury was sustained two months earlier in a motorbike road traffic collision and was initially treated with closed reduction and k wire fixation. However, the dislocation recurred after the wires were removed after 4 weeks.

Under regional block and tourniquet control, the FCR tendon was identified and divided proximally in the forearm and reflected into the hand maintaining its insertion. A drill hole was made through the base of the metacarpal and the cut end of FCR passed through this from volar to dorsal, as would be performed in an LRTI. This reconstructs that volar beak ligament.

Instead of immediately pulling the FCR around the metacarpal base and suturing it to itself as would be done in an FCR, the FCR was anchored to the dorsoradial aspect of the trapezium. This reconstructed the DLC.

This approach was supported by the biomechanical studies identified in a contemporary, PROSPERO-registered systematic review that combined index and free text searching of multiple databases.

Results and Conclusions: On table, the novel CMCJ stabilisation achieved immediate stability of the CMCJ throughout passive range of motion and was confirmed with image intensifier control.

The patient continues to make a good recovery.

In the systematic review, 55 studies were included of 345 identified from searches. The evolving understanding of the roles of the volar beak ligament and DLC from 1973 to the present demonstrates the importance of both.

This simple modification of CMCJ stabilisation demonstrates how systematic reviews can impact on clinical hand surgery practice.

REIMPLANT OF TRAUMATIC HAND: CASE REPORT RESOLVED IN FUSAT CLINIC.

List of authors:
Julio Echazabal*, Mario Andres Humeres Rios, Soledad Sanchez
1 Clínica Fusat, Hospital De Rengo (Santiago)
2 Hospital del Salvador, Universidad De Santiago De Chile, Hospital de Rengo (Santiago)
3 Hospital de Rengo (Santiago)

Objectives / Interrogation: The experience and ability to solve highly complex pathologies in reconstructive traumatology, integrate the management of complex wounds with multisystemic commitment and microsurgery. Secondary to complex traumatic subtotal hand amputation.

Methods: Male patient, 34 years old. Enter by subtotal amputation with circular saw. Start of cut dorsal area in the right distal ulnar region. Exposed radio-ulnar fracture (GIIIC), extensor apparatus damage in zone 8, radial nerve injury and partial radial artery section. Damage control. In pavilion, wound washing, identification of structures, control of bleeding with partial repair of radial artery, superficial closure and placement of external tutor. 48 hours later, withdrawal of external tutors, new wound washing. Reduction and radio-ulnar osteosynthesis is performed, after regularization of bone ends, with LCP plates. Identification of nervous, tendon and vascular tissue sectioned. Revision and new repair of the radial artery is performed, revision of flow without active bleeding. Epineurorrhaphy of radial nerve in zone 8 posterior regularization of ends, primary with suture without tension. Functional identification of extensor tendons, distal and proximal ends are identified. Primary tenorrhaphy of extensor tendons in all the compartments of 1st to 5th fingers at the level of the retinaculum with double point kessler plus point running between ends. Complete mobility check of the wrist is made with correct nerve tension and tendon, it is expected to achieve early controlled mobility. Operative wound closure. Placing of ante-brachial palmar plaster valve including phalanges.

Results and Conclusions: Repair of complex wounds with multisystemic compromise is a big challenge, secondary to that, Traumatic injury in February 2018, with circular saw. Complete repair 48 hours after first intervention with damage control. 2 weeks after performing surgery, removal of sutures, passive mobility test, sensitivity and pain scale. On the part of our rehabilitator, evaluation with DASH 70.8%. Great pain secondary to surgery. Follow-up was performed for 7 months. Achieving pain reduction, without complications such as complex regional pain, almost complete sensitivity, complete passive and active mobility and DASH (7 months) 18.3 with complete work reintegration. Good planning and achieving what is theoretically demonstrated (neurorrhaphy, tenorrhaphy), it is essential for a good result of the management of these complex wounds, it makes life easier for the surgeon and the patient is grateful.

The bony anatomy of the radius and ulna: AComputed Tomography study for implant design and related research.

List of authors:
HENRY PRETORIUS*, Marilize Burger¹, Nabeela Adam¹
¹ STELLENBOSCH UNIVERSITY, TYGERBERG HOSPITAL (BELLVILLE)

Objectives / Interrogation: Objectives: CT scans where utilized to measure multiple anatomical dimensions of the radius and ulna in a reproducible manner. Intramedullary fixation for length unstable forearm fractures could render favorable results and this information could aid in optimizing the size and design of these devises.

The specific objectives of the study will be to evaluate the radius and ulna structurally, especially the radius curvature and the canal diameters of both bones. This may aid with future implant design and for current implant modification. No current comparable descriptive or comparative studies are available in the literature.

Methods: Methods: We retrospectively looked at 100 CT forearm scans with unaffected radius and ulnas. We measured the length, radius of curvature, canal width and head measurement in both plains.

Results and Conclusions: Results: The length of the radius shows a mean of 238mm. The mean curvature will be an arc with a radius of 558.27mm. The radial head diameter in two planes are 23.84 and 23.24 respectively. The canal size shows a mean of 5.48mm. Radial inclination, radial styloid length and volar tilt show a mean of 21.57°, 10.47mm and 12.8° respectively. The maximum distal radius height 20.56mm. The length of the ulna shows a mean of 259.7 mm. The ulna head diameter in two plains show means of 19.48 and 16.76 mm respectively. The canal size in the ulna shows mean of 5.28. Radial length predicts ulna length, and both radius and ulnar length predict radius curvature. Radial head diameter predicts radial length and ulna head diameter predicts ulna length. Radial canal maximum diameter predicts ulnar canal minimum diameter.

Discussion: This anatomical measurements will aid with implant design and ranges. Radius: Implant length of 230-240 mm cover 95% of patients. Radius curvature can be set at the mean for most forearms at 558mm and this would correct the arc within 19mm for 95% of the patients. A 4 mm rod diameter will pass through most radial medullary canals. The distal height of the radius allows adequate space for the 6mm nail locking block.

Ulna: The ulna is consistently 20 mm longer than the radius which has prosthesis design implications. The ulnar nail should be longer than the radius range and anatomical bend of 12°. The proximal ulna entry point will accommodate a 6mm reamer. The ulnar shaft will easily accommodate a nail diameter of 4 mm.

Longterm outcome after Ulnar Tunnel Release

List of authors: RF Westenberg, NC Chen, Daphne van Hooven

1 Massachusetts General hospital (Boston)

Objectives / Interrogation: Ulnar tunnel syndrome (UTS) is a rare nerve compression syndrome with a variety of causative factors. The aims of this study are to describe the distribution of causes of ulnar tunnel syndrome, the rate of revision, and to evaluate the long-term outcome of ulnar tunnel release (UTR) in patients with UTS.

Methods: We identified 225 patients using Current Procedural Terminology code 64719 at two urban hospitals between 1/1/2003 and 12/31/2016. After manual chart review we included 143 adult patients with UTS. We excluded 54 patients with a direct injury of the ulnar nerve, four patients who had an UTR because of an infection and two patients who had an incomplete medical chart. Our retrospective cohort consists of 81 patients, of which 27 patients completed a follow up survey. The mean±SD age at surgery was 53.5±15.6 years and 39 (46.4%) patients were men. Fifty-one patients (63.0%) had an UTR and another concomitant nerve decompression procedure or carpectomy (Figure 1). The median time to last clinical visit was 4.6 months (IQR 1.8 -12.1) and the mean±SD to the follow up questionnaire is 7.1±32. years.

Results and Conclusions: The intra-operative findings for the cause of compression was ganglion cyst in 12 patients (15%), fibrous or muscular compression in 19 patients (23.5%), scar tissue in seven patients (8.6%), tumor in guyon canal in three patients (3.7%), compression by the pisohamate ligament in four patients (4.9%), bony impingement in two patients (2.5%) and unclear in 31 patients (38.3%). Two (2.5%) patients had a revision ulnar tunnel release. At time of last clinical visit, 18 (22%) patients still had residual pain, 57 (70%) had residual sensory or motor symptoms but 67 (82.7%) were noted to be improved (Figure 2). The mean±SD PROMIS score of all patients that had a UTR was 45.2±11.9 and 47.4±14.1 for all patients that solely had a decompression of Guyon canal (Table 1). The follow-up questionnaire revealed that 23 patients (85.2%) improved after UTR and that 25 (92.5%) would have the same surgery again if they were in the same situation.

Conclusion
Patients with UTS improve after UTR but residual symptoms may remain. Despite residual symptoms most patients would choose to have surgical treatment again if they were in the same situation again.

Is MRI better than CT in the diagnosis of occult wrist fractures?

List of authors:
Sue Fullilove¹, Ajay Sahu², Thomas Luff³, Tishi Ninan⁴, Charles Gozzard¹, Priya Suresh¹
¹ University Hospitals Plymouth (Plymouth)
² Northwick Park Hospital (Harrow)
³ Torbay Hospital (Torquay)
⁴ Swansea Hospital (Swansea)

Objectives / Interrogation: MRI has been shown to have high specificity and sensitivity in detecting occult wrist fractures. However it is more expensive and less widely available than CT scan. For patients with suspected scaphoid fracture, our practice is to use CT imaging. We invited patients with clinical suspicion of scaphoid fracture, but normal X-rays and CT to come for an MRI scan. Our aim was to identify those with MRI evidence of scaphoid fracture or other occult injury and thus demonstrate whether our current clinical pathway misses significant pathology.

Methods: Patients were reviewed 10-14 days after their initial injury. If there was ongoing clinical suspicion of a scaphoid fracture, repeat radiographs were performed. Those with normal radiographs but ongoing pain had a CT scan. Those with normal CT scans were invited back for an MRI scan. These patients also completed functional and pain scores at the time of assessment and 6 months post-injury.

Results and Conclusions: 100 patients were studied. 14 fractures were discovered in 13 patients:
Scaphoid - 6
Scaphoid plus capitate - 1
Capitate - 1
Lunate - 1
Trapeziun - 2
Distal radius - 2
Another patient had an SL tear, one had marked arthritis and 15 further patients showed equivocal findings with bone bruising or significant fluid.

Summary
Our results demonstrate that a significant proportion of patients with normal X-rays and CT scan have a scaphoid fracture, an alternative occult fracture, or other finding that might need intervention. These would not have been detected by our current pathway. The study shows that radiographs and CT scans fail to detect significant numbers of occult wrist injuries that are detectable on MRI scan.

**NERVE REPAIR AND REGENERATION BY BIOLOGICAL TUBULIZATION OF AMNION MUSCLE COMBINED GRAFT (AMCG): FROM BENCH TO BEDSIDE**

**List of authors:**
Michele Riccio*, Francesco De Francesco¹, Andrea Marchesini¹
¹ Dpt of Reconstructive Surgery and Hand Surgery, AOU Ospedali Riuniti di Ancona (Ancona)

**Objectives / Interrogation:** Peripheral nerve physiology and regeneration has been observed and investigated in literature but surgical applications to reconstruct and restore motor or sensory functions are still in a developmental phase. Recent surgical attempts to treat proximal nerve injuries include direct nerve restoration, transfer, and autografting measures with favorable results. In this report, we present a completely new tubulization method, the amnion muscle combined graft (AMCG) technique, that consists in the combination of the human amniotic membrane hollow conduit with autologous skeletal muscle fragments for repairing the substance loss of peripheral nerves and recover both sensory and motor functions.

**Methods:** In a series of patients with loss of substance of the median nerve ranging 3-5 cm at the wrist, excellent results graded as S4 in two cases, S3+ in two cases, and S3 in one case; M4 in four cases and M3 in one case were achieved. Moreover, we evaluate the final outcome of nerve regeneration morphologically and functionally, across the AMCG compared to nerve autograft in fourteen Wistar rats. Functional results were evaluated at 30, 60 and 90 days performing grasping tests. Morphological and stereological analyses were performed at T90 using high-resolution light microscopy and design-based stereology.

**Results and Conclusions:** Functional recovery was observed in both groups with AMCG conduits group showing lower values and a regeneration of median nerves with more myelinated fibres with the same axon size, but thinner myelin than the autograft group. Though the autograft remains the gold standard to restore wide nerve gaps, the AMCG conduit has proved to be effective in enabling nerve regeneration through a critical rat's nerve gap of 15 mm. No iatrogenic damage due to withdrawal of a healthy nerve from donor site was observed.

The amnion muscle combined graft (AMCG) conduits showed good clinical results in peripheral nerves gap repair. These results seem attributable to the biological characteristics of human amniotic membrane: Pluripotency, anti-inflammatory and low immunogenicity. The use of autologous sural nerve grafts is still the current gold standard for the repair of peripheral nerve injuries with wide substance losses, but with a poor rate of functional recovery after repair of mixed and motor nerves, a limited donor nerve supply, and morbidity of donor site.

Brachioradialis to Extensor carpi ulnaris transfer to address the radial deviation deformity in posterior interosseous nerve palsy

List of authors:
Praveen Bhardwaj* 1
1 Ganga Hospital, Coimbatore (Coimbatore)

Objectives / Interrogation: Radial deviation deformity after the tendon transfer for restoration of wrist and digital extension is frequently talked about. It is a great concern while performing tendon transfer for patients with posterior interosseous nerve palsy because these patients have a functioning extensor carpi radialis longus which is more of a radial deviator and secondary extensor in absence of paralyzed extensor carpi radialis brevis (main wrist extensor) and the extensor carpi ulnaris (main ulnar deviator). In such patients it has been suggested not to use the flexor carpi ulnaris as donor for extensor digitorum. Instead, flexor carpi radialis has been suggested to be transferred to the extensor digitorum. Preserving the flexor carpi ulnaris is an effective way of preventing a severe radial deviation deformity but some patients still continue to have a radial deviation deformity especially in wrist extension. Techniques described to prevent the radial deviation deformity include- transfer of the extensor carpi radialis longus to brevis for more central wrist extension; transfer of extensor carpi radialis longus to the third metacarpal or transection and transfer of the extensor carpi ulnaris to the extensor carpi radialis.

Methods: We have performed brachioradialis to extensor carpi ulnaris transfer to address the radial deviation deformity in these patients. It is much simpler and is much more effective as it restores the normal radio-ulnar balance of the wrist by providing a dynamic ulnar stabilizer. Moreover, there is no donor muscle deficit as brachioradialis is always available in these patients and is an expendable tendon.

Results and Conclusions: This tendon transfer was performed in five patients with good results in all. All patients could do an active ulnar deviation and extension. None had radial deviation deformity at the wrist. A balanced wrist was achieved in all the patients resulting in excellent cosmesis and function.

Stability of the distal radio-ulnar joint provided by the remnant distal radio-ulnar ligaments following ulnar styloid fracture including the fovea: A cadaveric biomechanical study

List of authors:
Mauro Maniglio¹, Il Jung Park², Victor Truong², Remy Flueckiger¹, David Wright³, Michael Kuenzler¹, Lilianna Bollinger³, Matthias Zumstein¹, Michelle McGarry⁴, Thay Lee⁵
¹ Inselspital Bern, University Hospital (Bern)

⁴ Tibor Rubin VA Medical Center, Congress Medical Foundation, Pasadena, CA (Long Beach)
⁵ Orthopaedic Biomechanics Laboratory, Congress Medical Foundation, Pasadena, CA (Long Beach)

Objectives / Interrogation: Clinical studies suggest that untreated ulnar styloid fractures (USF) and ulnar styloid non-unions do not affect patient outcomes. This may be due to the contribution of remaining soft tissues providing sufficient residual stability following USF. However, basal USF that include the fovea have a risk of causing distal radio-ulnar joint (DRUJ) instability, because they include deep portion of the distal radio-ulnar ligament (DRUL) insertions. This study investigated the importance of the remaining soft tissue attachment of the DRUL in USF involving the fovea for the stability of the DRUJ.

Methods: Seventeen cadaver forearm specimens (7 male; mean age 64.5) were tested in a custom DRUJ testing system. Soft tissue was carefully removed preserving the interosseous membrane, extensor carpi ulnaris, pronator quadratus, and triangular fibrocartilage complex. The positional change of the DRUJ was measured with a MicroScribe. DP-translation was quantified in neutral, full pronation and 90° supination applying 15 N of translational load. Pronosupination was measured with 1Nm of torque. All specimens were sequentially tested in intact condition, after an ulnar styloid fracture including the fovea, followed by transection of the remaining portions of the DRUL where in eight specimens the remaining dorsal ligaments were transected first and in 9 specimens the palmar ligaments first. Finally stability was tested with both portions of the ligaments transected. Differences were compared using ANOVA and Tukey post hoc tests.

Results and Conclusions: The pronosupination increased significantly compared to the foveal fracture (mean: 205.8°) after transection of both the palmar and the dorsal remaining soft tissue (mean 217.0°; dorsal first: $p=0.010$; palmar first: $p=0.031$). The DP-translation significantly increased after transection of both parts of the remaining soft tissue in neutral (dorsal first: $p=0.019$; palmar first: $p=0.018$) and supination (dorsal first: $p=0.012$; palmar first: $p<0.001$). Transection of one portion of the ligaments did not significantly increase translation; however, the percent increase in dorso-palmar translation was larger for the dorsal tear both when it was transected first or second.

In an USF including the fovea, there are still soft tissues attached to the ulnar head, giving residual stability to the DRUJ. The remaining dorsal portion of the ligaments may have a more important role in the DP-stability.

Sonographically guided percutaneous A1 pulley release in trigger finger - preliminary results

List of authors:
Damian Sutter*, Aline Treier¹, Esther Vögelin¹
¹University Hospital, Inselspital Bern (Bern)

Objectives / Interrogation: After a recent revisions of the insurance system for ambulatory treatment, certain operations have become a financial burden. Currently, the reimbursement for open release of the A1 pulley in stenosing tendosynovitis only covers 78% of the cost at our clinic. Percutaneous release of the A1 pulley has been around for many years with ever evolving techniques and instruments. Combined with sonography, we are able to visualize the A1 pulley, pinpoint the location of nerves and vessels and therefore safely release the A1 pulley percutaneously. Performed in the outpatient clinic, we expect percutaneous A1 release to be cost effective.

Methods: To establish a treatment protocol, 20 cadaver hands were used. The A1 pulley was evaluated sonographically, specifically noting the extent of the A1 pulley as well as the relative position of the nerves and vessels. Through a small incision just distal to the palmodigital fold, a cone tipped probe was inserted into the tendon sheath just distal to the A1 pulley and advanced between tendon and A1 pulley under sonographic guidance. Once correctly placed, a hook knife was inserted through a groove in the probe and the probe removed. After advancement of the knife to the proximal end of the A1 pulley the knife was retracted and in doing so the A1 pulley was released. Open inspection allowed for documentation of possible injuries. With very promising results in cadaver hands, we intend to proceed to a clinical trial series.

Results and Conclusions: Percutaneous release was attempted in all A1 pulleys except for the A1 pulley of the thumb (n=80). The A1 pulley was released in 64 attempts (80%). Upon open inspection, no injuries to the nerves or vessels were noted. 9 lesions of the tendons were found, of which 4 were suspected sonographically (1 ulnar slip FDS, 2 partial (60%, 5%) lesions FDP, 2 longitudinal FDS splits, 4 perforations FDS). However, these results include our very early experience and inadequate instruments. The final 24 procedures were performed with improved instruments, resulting in 100% pulley release rate and without injuries. As of yet, no clinical data has been collected. We intend to report on our first experience, as soon as they’re available.

We propose a sonographically guided, percutaneous A1 pulley release suitable for the outpatient clinic. However, as the results represent only preclinical experience many limitations apply. Furthermore, contrary to the open release, no inspection of the tendon and no synovectomy can be performed.

Pattern of arthritis noted during the surgery for stage 3B Keinbock's disease basis for classification & its clinical implication

List of authors:
Praveen Bhardwaj*  
1 Ganga Hospital, Coimbatore (Coimbatore)

Objectives / Interrogation: Kienbock's disease or avascular necrosis of the lunate is an uncommon condition affecting the wrist joint. The treatment basically depends on the radiological stage of the disease as described by Lichtman. Beyond 3B the salvage operations are generally recommended. The options include- proximal row carpectomy, scapho-trapezio-trapezoid (STT) fusion, scapho-capitate fusion, lunate replacement, or a total wrist fusion. Choice of surgery depends on the surgeon's personal preference and the pattern of arthritis seen during the surgery i.e. the involvement of the capitate articular surface or distal radius articular surface. However, the information regarding the arthritic pattern observed in Kienbock's disease is sparse in the literature.

Methods: The present study is a prospective observational study involving consecutive 48 patients of stage-3B Kienbock's disease considered for salvage surgery over period of 9 years. The pattern of arthritis involving the wrist joint during the salvage operation was noted.

Results and Conclusions: We noted that out of 48 patients- 22 patients did not have any arthritis whereas in 26 patients arthritis was noted. In 24 of these 26 patients the arthritis involved the lunate articular surface of the radius. In two cases the capitate articular surface involvement was seen without the lunate articular surface involvement. Only in one patient there was arthritis involvement of the scaphoid articular surface of the radius along with arthritis involvement of the lunate articular surface of the radius. These findings form a basis of the classification of the arthritis pattern observed in Kienbock's disease which has been described. Also, it helps in objectively deciding the type of salvage operation recommended. Since the lunate articular surface of the radius is commonly affected in Kienbock's disease one must observe this surface before proceeding for proximal row carpectomy as this surface must be arthritis free for doing a proximal row carpectomy. In such patient a scapho-capitate fusion or STT fusion should be performed. We observed that the scaphoid articular surface is the last to be involved in Kienbock's related arthritis and the lunate articular surface could be the earliest to get involved. This information has great implication when deciding the salvage option for stage-3B Kienbock's disease.

Professional violinist biomechanical and electrophysiological wrist and forearm muscles evaluation

List of authors:
Marta Jokiel*, Maciej Bochenek¹, Piotr Czarnecki¹, Leszek Romanowski¹
¹Hand Surgery Department Poznan (Poznan)

Objectives / Interrogation: Professional playing musicians are one of the most difficult group of patients because of constant overloads during prolonged time of play and reluctance to medical treatment. Because of specific upper limbs biomechanical work and often improper position while playing it is a great challenge for surgeons and physiotherapists to treat fingers, wrist, elbow and cervical neck disorders. Aim of the study was to assess muscles activity, overloads and biomechanical parameters during violin play.

Methods: 23 professional violinist (aged: 27 y.o) with average time of play 25 ± 7 years underwent examination of forearm muscles biomechanical parameters with Biodex System 4 Pro isotonic protocol. To assess muscles activity during play, wireless electromyography Noraxon Telemyo was used. Examined muscles: ECRB, FCR, FCU, biceps and triceps. To evaluate violinists muscles overloads standing position as control group was recorded. All examined participants had to play the same 3 instrumentals by Bach, Kreutzer and Wieniawski in the same order.

Results and Conclusions: The average peak velocity of wrist extensors was 180,2 ± 62,4 deg/sec, while the flexors was 295,8 ± 59,7 deg/sec. There were significant difference (p<0,05) between wrist flexors and extensors which influence the forearm muscles balance parameters. There were no significant difference in muscles activation between instrumentals. Right wrist extensors mean amplitude was 41 ± 3,1 uV, while the left wrist flexors was 38,9 ± 5,1 uV. The study revealed significant difference (p<0,05) between muscles overload during playing and control position in all examined muscles.

Conclusion:
Mean muscle tension shows that the symptoms are not provoked by an intensity of playing. Chronic overload by training may be more likely responsible for causing the symptoms then strained position itself. Imbalance of the forearm muscle may be responsible for aggravating the symptoms.

Diagnosis and treatment of median nerve entrapment at the elbow by isolated section of the lacertus fibrosus

List of authors:
Abdelkrim Hamouya*, Gero Meyer zu Reckendorf¹, Jean Luc Roux¹
¹ IMM, Clinique St Roch (Montpellier)

Objectives / Interrogation: Entrapment of the median nerve at the elbow has been reported in the literature to be rare and difficult to diagnose. The compression by the lacertus fibrosus (LF) has a predominant motor clinical expression differentiating it from other syndromes. The purpose of this study was to provide the different stages of management of median nerve compression by the LF at the elbow, from diagnosis to treatment, and to underline the benefits of a procedure under WALANT surgery.

Methods: 15 patients (7 female, 8 male), with a mean age of 42.5 years (28-56), were managed for compression of the median nerve at the elbow. 16 nerves (12 on the right, 4 on the left) were released. The diagnosis was made in the presence of the clinical triad: elbow pain in 13 patients, muscle weakness in all patients (Flexor Pollicis Longus (FPL), Flexor Digitorum Profundus of the index (FDP II), Flexor Carpi Radialis (FCR)) and a positive scratch collapse test (SCT) at the elbow in 14 patients. Tinel's sign was positive in 4 patients. The electromyogram revealed compression of the median nerve at the elbow in only one case. 8 patients had concomitant CTS and underwent endoscopic decompression at the same time. Neurolysis of the median nerve at the elbow was performed under WALANT surgery (7) or axillary block (9) if an associated procedure was indicated. Muscular testing was performed intraoperatively or the day after surgery.

Results and Conclusions: Neurolysis of the median nerve consisted of a simple section of the LF by an anterior minimally invasive approach of the elbow. All patients recovered full muscle strength of the median nerve innervated muscles. Return of strength was “immediate” when surgery was performed under local anesthesia. At 3 months' follow-up, pain had totally disappeared in all patients.

Diagnosis of entrapment of the median nerve at the elbow is often misunderstood. The clinical association of elbow pain, muscle weakness and positive SCT is very suggestive of the diagnosis. The EMG-study is most often normal but remains mandatory for the diagnosis of an associated CTS. The anatomical position of the nerve fascicles of the concerned muscles innervated by the median nerve when passing under the LF (anterior for the FCR, medial for the FPL and FDPII) could explain this specific symptomatology. WALANT surgery offers the advantage of performing intraoperative muscular testing to appreciate the immediate strength recovery after median nerve release in addition to simple postoperative care and low morbidity.

An anatomical study of the ulnar footprint of the distal radio-ulnar ligaments in relation to the ulnar styloid and the ulnar head

List of authors:
Mauro Maniglio*, Charles Lin, Il Jung Park, Nilay Patel, Remy Flueckiger, Michael Kuenzler, Michelle McGarry, Thay Lee
1 Inselspital Bern, University Hospital (Bern)
2 Tibor Rubin VA Medical Center (Long Beach)
3 Tibor Rubin VA Medical Center, Dept of Orthopaedic Surgery, Univ of CA, Irvine (Long Beach)
4 Tibor Rubin VA Medical Center, Congress Medical Foundation, Pasadena, CA (Long Beach)
5 Orthopaedic Biomechanics Laboratory, Congress Medical Foundation, Pasadena, CA (Long Beach)

Objectives / Interrogation: The distal radioulnar ligaments (DRUL) are considered major stabilizers of the DRUJ. The DRUL can be separated into superficial and deep layers and the dorsal and volar portions of each tighten reciprocally during forearm pronation and supination. Ulnar styloid fractures (USF) may affect the insertions of these ligaments and therefore the mechanics of the DRUJ. Knowledge of the topography of the DRUL insertions is essential to better understand possible instability that could accompany ulnar styloid fractures. The purpose of this study was to anatomically evaluate the location and size of the footprints of each portion of the DRUL in relation to the bony landmarks of the styloid.

Methods: 24 fresh cadaver forearm-wrist-hand complex were dissected free of soft tissue while taking care to retain the TFCC and the DRUJ capsule. Characteristic bony points were digitized to define the geometry of the ulnar styloid and head. The superficial and deep ligaments were sharply transected sequentially at their base and the circumference of each footprint was digitized. The area and distances between the footprints and bony landmarks were then calculated. Distances were also calculated in two dimensions along the long axis of the ulna to simulate a plain radiograph projection onto a 2D plane.

Results and Conclusions: The average styloid height (length from base to tip) was 17mm, the average anterior-posterior width was 6.5mm and the average fovea depth was 1.8mm. In the coronal plane, the superficial DRUL inserted from the tip of the styloid down to 87% of the styloid height. The deep DRUL inserted from 81% of the styloid height down to the fovea. The superficial footprint had an area of 10.6mm^2 on the radial face of the ulnar styloid. The deep DRUL attachment had two distinguishable parts: the dorsal portion (23mm^2) and the volar portion (7.8mm^2). The dorsal portion had a separate footprint in 47% of the cases.

This study quantified the relationships between the footprints of each of the component parts of the DRUL relative to the bony landmarks of the ulnar styloid. The deep portion attaches from the fovea up to 81% of the styloid. USF more distal that 81% may only minimally affect the DRUJ stability. Furthermore, the deep portion has distinct dorsal and volar footprints with the dorsal portion inserting more dorsal and radial. In the setting of an USF, whether the fracture traverses each of these footprints may result in preferential detachment of the DRUL and thus affect stability of the DRUJ.

Reconstruction of large volar skin and soft tissue defects of the digits using the radial artery superficial palmar (RASP) branch free flap: Case report and literature review

List of authors:
Hyo Seok Jang*1, Sang Hyun Lee2
1 Department of Orthopedic Surgery, Inje University (Pusan)
2 Department of Orthopaedic Surgery, Pusan national university (Pusan)

Objectives / Interrogation: Soft tissue defects of the fingertip vary shapes and sizes, and in most cases, they can be covered with secondary delayed healing, skin grafting or local flap surgery. However, in the case of relatively large volar soft tissue defect extending to the distal interphalangeal joint or more proximal, it is difficult to recover. The donor site skin condition for volar skin loss on the digit should be glabrous, sensate and provide padding or cushion. We report a case of reconstruction for large volar soft tissue defect on a finger using radial artery superficial palmar (RASP) branch free flap and discuss related literature.

Methods: A 61-year-old female patient had no history of diabetes or peripheral vascular disease. Her left hand rolled into a meat grinder and her 2nd and 3rd digits were crushed accompanying with the fracture of the distal and proximal phalanx. Emergency surgery was performed on the day of the visit. The index was subjected to arterial anastomosis using a vein graft after reduction and internal fixation of the fracture site, and for the middle, reduction and internal fixation of the fracture site and end to end artery and vein anastomosis was performed. Skin necrosis of the second finger was observed at 2 weeks after surgery. After debridement of the necrotic tissue, soft tissue coverage was performed with a 3 x 1.5 cm sized RASP branch free flap. At 6 months follow-up, the flap was well-engrafted without loss and showed a 9-mm static two-point discrimination at 1-year follow-up.

Results and Conclusions: For relatively large volar soft tissue defect of the digit, Homo or Hetero-digit island flap can be applied. However, If the defect is too large, donor tissue may be insufficient or the pedicle may be short. Also, finger stiffness may be retained due to donor scar formation. Therefore, it is often necessary to reconstruct the defect with a sensate free flap which has similar skin texture with skin pulp. Typical flaps satisfying these conditions include free flap from the foot and toes or palm. The thenar free flap has some advantages of obtaining a wider flap, showing similar skin color and less donor morbidity compared with the flap of the toe. In addition, the donor and recipient are in the same surgical field.

The radial artery superficial palmar branch free flap is a good indication for the reconstruction of large volar soft tissue defects on the digit which is not covered by locoregional flap or island flap, and it has the advantage of less donor site morbidity.

PIK3CA somatic mutation in a patient with Aberrant Muscle Syndrome and Lymphatic Malformation

List of authors:
Jessica Steele*, Tony Penington2, Michael Christie3, Chris Coombs2
1 Queen Victoria Hospital (East Grinstead)
2 Royal Children’s Hospital (Melbourne)
3 Centre for Translational Pathology, University of Melbourne (Melbourne)

Objectives / Interrogation: Aberrant muscle syndrome (AMS), a rare congenital hand difference, is characterized by unilateral non-progressive muscular hyperplasia of the upper limb. PIK3CA is an upstream regulator of the AKT-mTOR cell signalling pathway, and activating mutations of this gene promote cell proliferation. Multiple syndromes of overgrowth (CLOVES, FAO, Macroductyly) have been found to have associated mutations of PIK3CA, and the umbrella term ‘PIK3CA related overgrowth spectrum’ (PROS) has been created to characterise this group of conditions.

Two cases of AMS with mutations of PIK3CA have previously been reported. We report the first case of a patient with AMS and a lymphatic malformation, both found to have the same mutation of PIK3CA.

Methods: Targeted next generation sequencing of DNA extracted from formalin fixed paraffin embedded (FFPE) slides was undertaken on both skeletal muscle affected by AMS and tissue from a lymphatic malformation of the chest wall in one patient. Regions of interest from exon 15 of the BRAF gene, exons 9 and 20 of the PIK3CA gene, exons 2, 3, and 4 of both KRAS and NRAS genes, and exons 18, 19, 20 and 21 of the EGFR gene were amplified using multiplex PCR. Sequencing was performed on an Illumina MiSeq Next Generation Sequencer, and mutations were detected using MiSeq Reporter software.

Results and Conclusions: In the skeletal muscle a PIK3CA E542K (c.1624G>A, exon 9) mutation was detected with a mutation allele fraction of 19%. The same PIK3CA E542K mutation was detected in the lymphatic malformation tissue at a much lower mutation allele fraction of 0.22%.

Five common PIK3CA mutation locations have been determined within the PIK3CA Related Overgrowth Spectrum (PROS). Our case and the previously reported AMS cases all have mutations among the five canonical PIK3CA mutations previously described. The fact that the same PIK3CA mutation has been found in multiple different tissue types suggests that this mutation arises in a cell that contributes to the development of several tissue types during embryogenesis. This is the first description of the same PIK3CA somatic mutation in a patient with both AMS and a lymphatic malformation. Our case extends the breadth of clinical presentations of patients with PIK3CA mutations.

Loading the pronator quadratus improves distal radio-ulnar joint stability in the setting of an ulnar styloid fracture

List of authors:
Mauro Maniglio1, Il Jung Park2, Victor Truong2, Remy Flueckiger1, David Wright3, Michael Kuenzler1, Lilianna Bollinger3, Matthias Zumstein1, Michelle McGarry4, Thay Lee5

1 Inselspital Bern, University Hospital (Bern)

4 Tibor Rubin VA Medical Center, Congress Medical Foundation, Pasadena, CA (Long Beach)
5 Orthopaedic Biomechanics Laboratory, Congress Medical Foundation, Pasadena, CA (Long Beach)

Objectives / Interrogation: With a volar approach to repair distal radius fractures (DRF) the pronator quadratus (PQ) is often violated. The merits of repairing the PQ to restore pronation strength, protect flexor tendons and increase distal radioulnar joint (DRUJ) stability remain controversial. Several studies reported no change in clinical outcome due to PQ repair. DRFs are often associated with ulnar styloid fractures (USF), which have been shown to lead to a significant loss of DRUJ stability when the styloid fractures involve the fovea. The PQ may be key in reducing postoperative DRUJ instability in a DRF with a USF involving the fovea. Therefore the objective of this study was to quantify the effects of PQ loading on DRUJ stability in a cadaveric model of USF.

Methods: Soft tissue was carefully removed from 17 forearm specimens (7 male, 10 female; mean age 64.5; range 56-77), leaving the interosseous membrane, extensor carpi ulnaris (ECU), pronator quadratus (PQ), and triangular fibrocartilage complex. Forearms were mounted on a custom testing system and the ECU was loaded with 5N. A USF including the ulnar fovea was performed. Pronosupination was measured with 1Nm of torque and dorso-palmar (DP) translation was measured using 15N of load. DP-translation was measured in neutral, full pronation and 90° supination. Measurements were repeated with loading the PQ with 0N; 2.5N; and 5N.

Results and Conclusions: In full pronation with a 5N load, DP-translation decreased significantly compared to 2.5N (p<0.006) and 0N (p<0.001) loads. Significant decreases were also found in neutral with a 5N load compared to the 2.5N (p<0.001) and 0N (p<0.001) loads. Total pronosupination decreased significantly from 0N to 5N (p<0.001), changing on average from 206° to 203°.

Loading the pronator quadratus significantly decreased translation and rotation of the DRUJ. Even though the amount of change in stability was small repair of the pronator quadratus may be warranted if there are concerns about residual DRUJ instability.

Nerve Compression due to Benign Tumors or Ganglion Cysts in the Upper Limb—Case Series

List of authors:
Andreea Grosu-Bularda¹, Luana Lazarescu¹, Marius Popescu¹, Roxana-Maria Tomek-Enescu¹, Alexandru Stoian¹, Cristian Vancea¹, Serban Arghir Popescu¹, Daniel Vilcioiu¹, Ioan Lascar¹
¹ Emergency Clinical Hospital Bucharest (Bucharest)

Objectives / Interrogation: Tumor nerve compression in the upper limb are relatively rare, usually involving ganglion cysts and benign tumors. Accurate diagnostic and treatment are mandatory for adequate functional recovery.

Methods: We present a case series of five patients with peripheral nerve compression in the upper limb due to tumor or cystic masses—large median nerve schwannoma generating anterior interosseous nerve compression, voluminous lipoma compressing median nerve in the proximal forearm, superficial branch of radial nerve compression encountered in two patients by a lipoma respectively a synovial cyst and ulnar nerve compression in the Guyon tunnel due to a ganglion cyst—and highlight the particularities in diagnostic and treatment of these patients.

Results and Conclusions: In the beginning, those benign lesions are asymptomatic but, as they continue to grow adjacent to a peripheral nerve clinical manifestations appear progressively as compressive neuropathies. All the patients have received surgical treatment—excision of the compressive masses with consecutive releasing of the nerves with very good clinical results in terms of symptom remission and functional recovery.
In conclusion, after a preoperative imagistic analysis, tumor resection with careful microsurgical dissection in order to preserve the neurovascular structures is the elective surgical procedure in order to obtain an optimal functional outcome.

Biomechanical effects of ulnar styloid fracture repair techniques on distal radio-ulnar joint stability

List of authors:
Mauro Maniglio¹, Il Jung Park², Victor Truong², Remy Flueckiger³, David Wright³, Michael Kuenzler¹, Lilianna Bollinger¹, Matthias Zumstein¹, Michelle McGarry⁴, Thay Lee⁵
¹ Inselspital Bern, University Hospital (Bern)

⁴ Tibor Rubin VA Medical Center, Congress Medical Foundation, Pasadena, CA (Long Beach)
⁵ Orthopaedic Biomechanics Laboratory, Congress Medical Foundation, Pasadena, CA (Long Beach)

Objectives / Interrogation: Ulnar styloid fractures (USF) accompany up to 65% of distal radius fractures; however, the cases in which fixation of an USF are indicated is not conclusively defined. Approximately 10% of USF fractures are addressed surgically but there is no consensus as to the optimum fixation technique to restore stability. Therefore the objective of this study was to compare the pronosupination and the dorso-palmar (DP) translational stability of the distal radioulnar joint (DRUJ) following the repair of USF using four different surgical techniques.

Methods: 9 forearm specimens (1 male; mean age 64.0) were mounted on a custom jig, preserving the interosseous membrane, extensor carpi ulnaris, pronator quadratus, and TFCC. The positional change of the DRUJ was recorded with a MicroScribe. 1Nm torque was applied to measure Pronosupination. DP-translation was measured in neutral, full pronation and 90° supination with 15 N. Six sequential conditions were tested in the same specimen: intact, USF including the fovea and 4 repair techniques (2 K-wire, tension band wiring (TBW), headless compression screw (HCS), and suture anchor).

Results and Conclusions: The pronosupination increased significantly after the foveal fracture from an average of 202.5° for intact to 219.4° (p<0.001) and the DP-Translation in neutral from an average of 8.1mm for intact to 10.5mm (p<0.001). The DP-translation in neutral was reduced significantly with all 4 techniques (range: 7.2-8.9mm; K-wire p=0.006; the other techniques p<0.001). In supination the TBW and suture anchor significantly decreased DP Translation. In neutral rotation the TBW and suture anchor reduced the DP translation even below the intact condition. Only the K-wire fixation (215.1°; p=0.118) and the TBW (to 212.2°; p=0.657) restored the rotation to the intact condition.

All four ulnar styloid fracture repair techniques were effective in restoring DP translation in neutral rotation; however, only K-wire fixation and TBW techniques restored rotational stability. The TBW technique may be biomechanically superior to the other techniques as it was able to restore translational stability in different forearm rotations and also rotational stability.

CONNECT: CONduit Nerve approximation versus Neurorrhaphy Evaluation of Clinical outcome Trial

List of authors:
Bafiq Nizar*, Foster Mark1, Dominic Power1
1 Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: The gold standard treatment for a complete traumatic peripheral nerve lesion involves direct end-to-end microsurgical repair. Repair with higher magnification improve the macroscopic appearance and the potential for improved neurological regeneration. Conduits are established for bridging small gaps in peripheral nerves to avoid interposition grafts or suture with tension. The objective of this study is to evaluate the recovery following repair of digital nerves within the hand treated with direct microsurgical suture, suture with nerve conduits augmentation or nerve conduits apposition with remote suture distal to the injury site

Methods: A multi centre randomised controlled trial with three parallel groups and blinding of patient and assessing hand therapist will be conducted at a tertiary referral centre for the management of hand and peripheral nerve injuries in the UK. The study will enrol participants with traumatic injuries to the digital or common digital nerves within the hand and randomisation in a 1:1:1 ratio for each nerve injury. They will be stratified according to the age group. The power analysis estimates 62 nerves recruited to each group to demonstrate equivalence. 240 nerves will be recruited to allow a drop out of 30% with the modified Weber scale as a primary outcome measure of sensory recovery using static and moving two point discrimination at 12 months

Results and Conclusions: We present the data and results from our trial that has been recruiting since August 2017 of over 50 patients. The challenges that are faced in running the trial and also our experience in setting up multi-centre randomised controlled trials at the Birmingham Hand Centre

Arthroscopically assisted bone grafting reduces time to healing of scaphoid non-unions compared to percutaneous screw fixation alone

List of authors:
Robert Gvozdenovic*, Stig Joerring¹, Rasmus Wejnold Joergensen¹, Claus Hjort Jensen¹
¹ Gentofte/Herlev, Copenhagen University Hospital (Hellerup)

Objectives / Interrogation: Recently, minimally invasive techniques have been recommended in the treatment of stable scaphoid non-unions regardless of the presence of cystic formations or small contact area. The purpose of this study was to determine whether arthroscopically assisted bone grafting gave superior results in healing as compared to percutaneous screw fixation alone.

Methods: 164 consecutive patients with scaphoid non-unions were retrospectively analyzed. 148 patients were treated with the open grafting either with iliac bone or from distal radius, leaving 16 patients treated with minimally invasive techniques. The Mini Acutrac headless fully threaded compression screw system of Acumed, (Hillsboro, Oregon, USA) was used in all cases. Healing was assessed clinically and radiographically at a minimum follow-up of 12 weeks (range 4-56 weeks). In the group treated percutaneously (n=8), the median time from injury to operative treatment was 2,3 months (range 2 - 4 months) and it was 27,3 months (range 3-180 months) in the group treated arthroscopically (n=8). All patients were male except one female in the percutaneous group. The mean age was 42,5 years in the group treated percutaneously, 22 years in the arthroscopically treated group, (range 20-66) and (range 16-32), respectively. Data were calculated with two-tailed Mann-Whitney U test based on associated p-value of p<0.05 which was considered statistically significant. All patients were investigated with the CT scan to distinguish any humpback deformity of the scaphoid bone which also was the exclusion criteria. Postoperative CT scan were performed only in cases where radiographs did not show progressive healing to avoid unnecessary exposure to radiation. The postoperative regime was identical in both groups.

Results and Conclusions: We recorded no complications in any of the groups. All patients treated arthroscopically received cancellous bone grafting from the distal radius. They healed at median of 7,8 weeks (range 5-18). 7 patients in the percutaneous group healed at mean of 10,8 weeks (range 7-24). Mann Whitney U test showed the u value of 11, the critical value of U to be 13 (p<0.05).
Arthroscopically treated patients achieved significantly faster healing, despite significantly longer time from injury to surgery. Local bone grafting is considered as the main reason for this outcome. Younger population in the arthroscopically treated group may have influenced the result. A larger, randomised trial between different treatment methods is desirable.

Thumb Duplication Classifications - Still Need Improvement?

List of authors:
Ayse Sencan*, Mehmet Baydar2, Kahraman Ozturk1, Ethem Ayhan Unkar2, Ersin Demirkaynak3
1 Health Sciences University M.S. Baltalimani Bone Diseases, Teaching and Research Hospital, Hand Surgery Clinic (Istanbul)
2 Health Sciences University Adana City Hospital, Department of Orthopedics and Traumatology, Division of Hand Surgery (Adana)
3 Health Sciences University M.S. Baltalimani Bone Diseases, Teaching and Research Hospital, Department of Orthopaedics and Traumatology (Istanbul)

Objectives / Interrogation: Thumb duplication is seen 0.8-1.4 per 1000 live births in Caucasians and Asian countries. Wassel system is the most frequently used for the classification of the deformity. Wassel type IV is most frequently seen followed by type II and type VII, respectively. However, some modifications have been made additionally because of Wassel classification system is insufficient in anatomically complex cases. Rotterdam classification system combining Wassel system and Buck-Gramcko and Behren's intercarpal modification is proposed to indicate different complex deformities such as triphalangism and triplication. We aimed to compare these two classification systems in our thumb duplication cases.

Methods: Fifty patients with thumb duplications who were admitted to our hospital were evaluated with posteroanterior and lateral x-rays according to Wassel and Rotterdam classification systems. 29 patients were male, duplication was present in right hand in 28, in left hand in 21, and in both hands in a patient.

Results and Conclusions: According to Wassel classification system, type IV, type VI, type VII, type V, type III, and type II duplication was found in 27, three, five, two, four, and five patients respectively. Five patients could not be classified. 13 patients were type IVD, 11 patients were type IV H, three patients were type II, three patients were type III, two patients were type VI, seven patients had triphalangism, and three patients could not be classified.

Keywords: thumb duplication, Wassel classification, Rotterdam classification
Does Reconstruction of Proximal Pole Scaphoid Nonunions With Hamate Autograft Restore Carpal Kinematics?

List of authors:
Marion Burnier1, Alexander Hooke2, Bassem Elhassan2, Sanjeev Kakar2
1 Herriot Hospital (Lyon)
2 Mayo Clinic (Rochester)

Objectives / Interrogation: The purpose of the current study was to determine whether proximal pole scaphoid nonunion reconstruction with hamate autograft restore carpal kinematics.

Methods: Eight fresh-frozen cadaveric wrists underwent evaluation of their radiocarpal and midcarpal kinematics within the intact state, after fracture of the proximal pole of the scaphoid and after reconstruction of the proximal pole with a hamate autograft. A wrist stimulator was used to apply cyclical load to the flexor carpi ulnaris, flexor carpi radialis, extensor carpi ulnaris, extensor carpi radialis brevis and longus. Kinematic motion was captured using Moiré Phase Tracking 3-dimensional motion-tracking sensors to evaluate the radiolunate, radioscaphoid, scapholunate and lunocapitate angles for each condition.

Results and Conclusions: Proximal hamate reconstruction of the proximal pole after scaphoid fracture significantly improved wrist kinematics ($p<0.05$). During wrist flexion-extension, hamate to scaphoid reconstruction significantly corrected the abnormal motion of the scaphoid relative to the lunate in the coronal plane ($p<0.05$ (Figure 1)). During radio-ulnar deviation, the hamate reconstruction corrected the abnormal scaphoid kinematics to the lunate in the sagittal plane ($p<0.05$) (Figure 2).

Conclusion
After proximal pole scaphoid nonunion, reconstruction with a proximal hamate autograft improves wrist kinematics towards the native intact state.

Three-dimensional planning of corrective osteotomies for paediatric malunited diaphyseal forearm fractures: do we achieve the desired functional gain and the planned correction?

List of authors:
Kasper Roth¹, Eline van Es³, Edwin Oei¹, Max Reijman¹, Gerald Kraan², Jan Verhaar¹, Filip Stockmans³, Joost Colaris¹
¹ Erasmus University MC (Rotterdam)
² Reinier de Graaf Gasthuis (Delft)
³ KU Leuven (Leuven)

Objectives / Interrogation: Conservative treatment of both-bone forearm fractures in children can result in a malunion with impairment in pronosupination. Three-dimensional (3D) planned corrective osteotomy has been described as a promising technique for accurate reconstruction of these malunions. The objective of this study is to evaluate the functional outcome and accuracy of the achieved correction after 3D-planned corrective osteotomies for malunited diaphyseal both-bone forearm fractures in children.

Methods: Patients with paediatric malunited diaphyseal both-bone forearm fractures underwent 3D-planned corrective osteotomy. Inclusion criteria were a paediatric both-bone forearm malunion with a pro- or supination of <50°, unsatisfactory improvement after conservative treatment and a minimum age of 10 years. Exclusion criteria was an osseous deformity of the contralateral forearm. A 3D-planned corrective osteotomy was performed according to the following steps: (1) CT scans of both forearms are obtained; (2) the location and degree of deformity is determined by overlaying a virtual model of the malunited bones on a mirrored version of the healthy contralateral side; (3) virtual cutting planes are set to best match the contralateral side; (4) patient-specific guides are 3D-printed and used during surgery. Our primary outcome measure was the gain in pronosupination at 12 months follow-up. Our secondary outcome measure was the accuracy of the achieved correction on CT relative to the preoperative plan.

Results and Conclusions: Six participants underwent 3D-planned corrective osteotomies for paediatric malunited both-bone forearm fractures. There was a median age at trauma of 9 and a median age at osteotomy of 14 years. Pre-operatively there was a mean pronosupination of 66° compared to 150° of the contralateral side, a deficit of 66%. At 12 months follow-up there was a pronosupination of 118°, a remaining deficit of 21% compared to the contralateral side. An anatomical correction in coronal, sagittal and axial direction was achieved in 10 out of the 12 operated forearm bones, as confirmed by CT. There was one case of overcorrection of the radius (9° dorsally) and one case of overcorrection of the ulna (5° radially, 4° dorsally).

This prospective study demonstrates that 3D-planned corrective osteotomy for paediatric malunited diaphyseal both-bone forearm fractures provides an accurate correction and leads to a reliable improvement in pronosupination.

Metabolic Syndrome is an Independent Predictor of Unplanned Re-Operation After Operative Fixation of Forearm Fractures

List of authors:
Dominick Congiusta¹, Kamil Amer¹, Aziz Merchant¹, Irfan Ahmed¹, Michael Vosbikian¹
¹Rutgers New Jersey Medical School (Newark, New Jersey)

Objectives / Interrogation: Metabolic syndrome is increasing in prevalence in the United States and around the world, producing an enlarging burden on healthcare systems. Previously defined by a simplified, 3-comorbidity index consisting of hypertension, diabetes, and obesity (BMI>30), metabolic syndrome has been shown to be predictive of adverse outcomes after a variety of orthopaedic surgeries. To date, there is no analysis of a nationwide database assessing the impact of metabolic syndrome on outcomes after operative treatment of forearm fractures.

Methods: The 2005-2014 National Quality Improvement Program Database (NSQIP) was retrospectively queried for patients undergoing operative fixation of radial and/or ulnar fractures based on 31 current procedural terminology (CPT) codes. Open and closed treatments were included. Primary outcome was unplanned readmission after surgery. Univariate analysis was conducted on comorbidities with Pearson's Chi Square. Binary logistic regression was performed with significant comorbidities and demographics.

Results and Conclusions: A total of 21,082 patients were included in our analysis. Approximately 30% of patients were of age 65 or older, and the majority were Caucasian. Metabolic syndrome was present in 616 (2.9%) of patients, and unplanned reoperation occurred in 303 (1.4%) of cases. Mortality rate was 0.4% (86 patients).

\(^a\)COPD Chronic Obstructive Pulmonary Disease

* significance defined as p<0.05

Patients in our cohort with metabolic syndrome undergoing operative fixation of radial or ulnar fractures have 2.95 increased odds of having an unplanned reoperation. Metabolic syndrome is an independent risk factor for adverse outcomes after surgery and presents an increasing burden on healthcare systems worldwide.

Keywords:
Metabolic Syndrome, Forearm, Fracture, NSQIP
Bilateral Endoscopic Carpal Tunnel Release versus unilateral carpal tunnel release

List of authors:
Cristobal Greene*, Andres Garcia, Lorena Parra, Aldo Villavicencio, Guillermo Droppelmann
1 CLINICA MEDS, HOSPITAL DIPRECA (SANTIAGO)
2 DIPRECA (SANTIAGO)
3 Clinica MEDS (Santiago)

Objectives / Interrogation: Evaluate functional outcome in patients treated by mini Open Carpal Tunnel Release (mOCTR) and Endoscopic Carpal Tunnel Release (ECTR, one portal Agee technique, Microaire®) with Bilateral Endoscopic Carpal Tunnel Release (BECTR)

Methods: Patients with CTS seen between in our Hospital with failure of conservative treatment and confirmation with electrodiagnostic studies were operated by mOCTR or ECTR and BECTR. Boston score and grip strength, were evaluated at pre op, and 2 and 12 weeks. Patients with previous carpal tunnel surgery, acute CTS and with concomitant hand pathology that needed surgery were excluded. Approval of the hospital ethics committee was obtained for this study. Statistical analysis was done with programs IBM SPSS Statistic version 20 and STATA and the Friedman Test for the analysis for Boston Carpal Tunnel Questionaire (BCTQ), and Wilcoxon Test to compare between techniques.

Results and Conclusions: in this retrospective non randomized study, a total of 63 patients meet the inclusion criteria (BECTR 12, ECTR 29, OCTR 21 in each group). Demographics of both group were comparable. Boston score were similar in the pre op evaluation in all groups and at the 2 weeks control decrease in almost the same way with no statistical difference between groups using the Wilcoxon rank sum test (p=0.19, p=0.18). At 12 weeks, we found statistical difference between group with a better outcome in the BCTQ for the Endoscopic techniques. Grip strength had a similar behaviour in all groups, having diminished than preop at 2 weeks evaluation. At 12 weeks all groups had better strength than 2 weeks and pre op. No significant differences were established between groups. Conclusion: no difference between de BECTR and ECTR or OCTR after surgery, which it's beneficial in patients with indication for surgery in both hands in terms of Operating Room, sick leave and costs for the BECTR Group vs the staged procedures (ECTR and OCTR).

Anatomy, frequency and distribution pattern of plantar fibromatosis (Ledderhose's disease)

List of authors:
Martin Franz Langer*, Simon Oeckenpöhler, Britta Wieskoetter
1 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)
2 Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)
3 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster, Sektion Hand (Münster)

Objectives / Interrogation: The distribution pattern of the palpable nodes on the sole of the foot was documented in 174 patients with Ledderhose disease and the concomitant diseases from Dupuytren diathesis were recorded. After years of collection, the evaluation should be made.

Methods: Most of the patients were requisitioned by the Dupuytren contracture on the hand. The sole of the foot was divided into 25 zones and the tactile knots were drawn and photographed. Any contractures on the toes were also recorded. The first appearance on the foot, on the hand, Garrod's knot and Peyroni's disease, Grade of the disease in the hand and foot were documented.

Results and Conclusions: The frequency of Ledderhose disease in patients undergoing Dupuytren surgery is 12.3%. Only a few patients (11) had no signs of Dupuytren's disease. The central zones of the 1st and 2nd toes are by far the most frequently affected. An infestation of the toes was found only in 3 patients - without contractures. Garrod's knots were found in twenty-six patients. Only 1 patient was simultaneously treated urologically with Peyronie's disease. Only 10 patients were operated on due to disturbing large nodes on the foot. The postoperative recovery time is long, so that an indication for surgery is only made in exceptional cases.

Though the anatomy of the plantar aponeurosis has a lot of similarities to the palmar aponeurosis, the distribution of the affected parts differs a lot.

Open Reduction and Internal Fixation with Headless Compression Screws for Coronal Shear Fractures Dubberley Type 3. Outcomes at a Mean Follow-up of 7 Years.

List of authors:
Ezequiel Zaidenberg*, Mariano Abrego¹, Jorge Boretto³, De Carli Pablo¹, Gerardo Gallucci¹
¹ Italian Hospital of Buenos Aires (Buenos Aires)

Objectives / Interrogation: Background: To evaluate the sustainability of the early clinical and radiological outcomes of a series of patients with Dubberley type 3 fractures of the distal humerus at long-term follow-up.

Methods: Methods: Twelve consecutive patients with capitellum and trochlear fractures who underwent to open reduction and internal fixation using headless compression screws with minimum of 6 years of follow-up were evaluated. Functional and radiological outcomes at one year and final follow-up were compared. We assessed Mayo Elbow Performance Score (MEPS), Quick-Disability of the Arm Shoulder and Hand (Q-DASH) and modified-American Shoulder and Elbow Surgeons Scores (m-ASES). Radiological evaluation included Broberg and Morrey classification and Hastings classification for heterotopic ossification.

Results and Conclusions: Results: The mean age of patients was 70 years, with a median follow-up was 7 years. At final evaluation, mean flexion, extension, supination and pronation were 127°, 20°, 87° and 90°, respectively; mean MEPS, m-ASES and Q-DASH scores were respectively 92, 95, and 5 points. There was no statistical difference between early and final follow-up range of motion, MEPS and Q-DASH. However, radiological changes were observed in 75% of the patients at final follow-up. Five patients underwent reoperation and one of them required revision with a total elbow prosthesis.

Conclusion: Our results suggested that satisfactory clinical outcomes at early follow-up could be maintained over time. However, a high early reoperation rate and osteoarthritic changes at long-

² Rehasport Clinic (Poznan)
³ Poznan Hand Surgery Department (Poznan)

Objectives / Interrogation: Degenerative changes in the wrist and metacarpophalangeal joint (CMC I) are a very common degenerative joint (OA) disease, especially of women. If conservative treatment has not been successful, surgical treatment is recommended.

CMC I arthroscopy allows for easy diagnostics, classification, and treatment of OA.

Methods: 17 patients (16 K, 1 M, mean age 59) with diagnosed OA of CMC, who underwent arthroscopy in 2011-2015. The treatment included -synovectomy, debridement of the articular surfaces, in 4 cases micro-fractures were performed, one patient required APL interposition additionally. Clinical evaluation before and after surgery of the patients included pain scales according to VAS, evaluation of the thumb function, (satisfaction), provocative tests, X-ray.

Results and Conclusions: There were no indications for reoperation. In earlier observations, there was a reduction of pain (before surgery: 5 severe pain, 12 very severe pain after 5 pain and moderate pain 12) and improvement of the thumb function where patients reported a significant dysfunction before surgery. The provocative tests were evaluated and improved. No complications or revision/reoperation were reported.

Conclusions
Arthroscopy of the CMC I joint allows more accurate diagnostics and effective and minimally invasive treatment of degenerative changes.

Labral Tape suture as an Internal Brace Augmentation for a subacute scapholunate injuries

List of authors:
Laura Velasco-González*, Marta Almenara-Fernández¹, Sara Wahab-Zuriarrain¹, Claudia Lamas-Gómez¹
¹Hospital de la Santa Creu i Sant Pau (Barcelona)

Objectives / Interrogation: Scapholunate (SL) injuries are the most common intercarpal ligament injury according to severity as predynamic, dynamic, static reductible, static irreductible or arthritic.
There is a new technique that incorporates a combination of a biologic tendon graft and a ligament augmentation repair.
The aim of our study is to describe our results using the all dorsal SL reconstruction with this new technique.

Methods: We included two cases of a subacute SL injuries. There were two men with ages of 39 and 42 years-old respectively.
We explore the patients and did x-rays and a Magnetic Resonance Imaging (MRI) to confirm the diagnosis.
Ligament reconstruction was performed using two 3,5x8,5mm Dx Swive Lock SL suture anchors, a 2mm wide extensor carpi radialis brevis (ECRB) tendon autograft and Labral Tape suture as an Internal Brace augmentation. The strenght of the repair was testes intraoperatively.
The minimun follow-up was 12 months.

Results and Conclusions: Patients had pain with the activities but they had not constant pain. Visual analog scale was 2. The range of motion decreased in the two cases. The mean postoperative wrist extension was 65º, flexion 60º, radial desviation 15º and ulnar desviation 12º. In both patients grip strength decreased if we compare with the contralateral side. Postoperative x-rays and MRI showed a SL gap of 4mm in one patient and 5 mm in the other.
In our cases we restore the correct motion of the wrist without pain at rest and with daily activities. Nevertheless, there is still a SL gap despite the strenght of the repair was correctly tested intraoperatively. Although our study is preliminary and there are few patients, we can not say that this new technique can perfectly correct, as in other ligaments located in the shoulder the scapholunate junction.

¹ GENERAL HOSPITAL KAT (ATHENS)

Objectives / Interrogation: Closed carpal dislocations are complex rare injuries, usually a result of a fall on the outstretched hand. Active youngsters are mostly affected, amongst which adolescents are rarely mentioned in the literature. We present a rare case of a fracture dislocation in a 14 year old female adolescent, treated with primary lunocapitate arthrodesis

Methods: A 14 year old female patient was evaluated at the emergency department after sustained a fall in a motorcycle accident, 6 hours before administration. The patient reported pain and inability to complete any motion of the left carpus, immediately after the fall. During clinical examination extended edema of the carpus and weak grip was documented. No neurovascular deficit was documented. On plain radiographs a perilunate volar dislocation was demonstrated. Computed Tomography (CT) was unavailable at the time and the young patient was moved to the operation room. Under tourniquet and brachial block anesthesia a dorsal incision through the 3rd and 4th extensor compartment was performed. Lunate was identified volarly and reduced. Due to extensive bone loss of the lunate, it was decided to perform a primary lunocapitate arthrodesis, with the use of K-wires. Ligaments were reconstructed using absorbable sutures and anchors. A volar plaster cast was used for rest and immobilization

Results and Conclusions: Results: K-wires and the plaster cast were removed 6 weeks after surgical operation. The young patient started intense, but gradual physiotherapy. At 3 years follow up the patient had an almost painless wrist with 450 volar and 450 dorsal wrist flexion, early primary carpal arthritis and complete pinch and grip strength, compared to the healthy one.

Conclusion: A closed volar perilunate fracture dislocation is a rare and complex injury. Anatomical reduction and partial fusion of the wrist is an option, when the reduced lunate is anatomical unaffected. In cases where bone loss is adequate, a primary lunocapitate arthrodesis is a satisfying treatment, so as to prevent against future collapse of the wrist. Although bibliography lacks treatment options in adolescents, we believe it can be performed with safety, minimal chances for pseudarthrosis and fair results, as far as wrist kinematics are concerned.

Frailty is a Predictor of Unplanned Reoperation in Management of Forearm Fracture

List of authors:
Kamil Amer¹, Dominick Congiusta¹, Jennifer Thomson¹, Irfan Ahmed¹, Michael Vosbikian¹
¹ Rutgers New Jersey Medical School (Newark, New Jersey)

Objectives / Interrogation: Frailty is an important predictor of surgical outcomes. It has been quantified by several models, including the modified frailty index (mFI), which has demonstrated applicability in many surgical subspecialties. We aim to conduct the first decade-long retrospective analysis of frailty and unplanned reoperations after forearm fractures.

Methods: We used the American College of Surgeons National Surgical Quality Improvement Program (NSQIP) database 2005-2014 to identify closed radial and/or ulnar fractures using ICD-9 and ICD-10 codes. The mFI was calculated based on the presence or absence of 15 possible comorbid conditions. Our primary outcome was unplanned reoperation. Chi square and multivariate logistic regressions were used to identify significant predictors of outcomes.

Results and Conclusions:

Total arthroplasty in the treatment of previous infection of the elbow. Two-stage surgery

List of authors:
Gerardo Gallucci*¹, Julieta Puig Dubois³, Ezequiel Zaidenberg³, Agustin Donndorff¹, Jorge Boretto¹, De Carli Pablo¹
¹Italian Hospital of Buenos Aires (Buenos Aires)

Objectives / Interrogation: The total replacement after a previous infection is a procedure well reported in some articulations like hip and knee; but it is not overly reported in the elbow. The infection is a difficult condition that can be associated with bad results. The two-stage surgery with an antibiotic cement spacer and a Total Elbow Arthroplasty can be a good option of treatment.
The aim of this study is to report the results of an infected elbow treated in a two-stage surgery with a total elbow arthroplasty.

Methods: We report 6 patients with a prior infection of the elbow, treated with the same procedure. First stage: debridement of the infected tissue and introduction of the antibiotic cement spacer, and reconstruction, in a second stage, with a Total Elbow Arthroplasty.
Three were women and 3 men with a mean age of 62 years old (35-80). The causes of the infection were: 1 psoriatic arthritis, 1 reumatoid arthritis, 1 chronic elbow dislocation, 1 Total Elbow Arthroplasty and 2 distal humerus fractures. All the spacers were impregnated with vancomycin.
The most commonly isolated germ was staphylococcus epidermidis. The second stage was performed at an average of 82 days. The Conrad-Morrey prosthesis was used in all cases. Allografts were used in 4 of the cases. The number of previous surgeries was 1,8 (1-8). Mean pain according to VAS was 6,5. Mean DASH was 43. Average follow-up was 83 months (30-120)

Results and Conclusions: Flexo-extension was 133-22°. Pain was 2 (0-4) and DASH 31. MEPS was 86. The strength of extension was M5 in 3, M3 in two and M4 in one. Two complications were present, 1 ulnar nerve paresthesia and 1 earlier decoupling of the peg.
All patients presented normal laboratory parameters and no reactivation of the infection was reported. According to Morrey classification 3 patients had no loosening of the implant, one type 1, one type 2 and one type.
The two-stage procedure for the reconstruction of the elbow with a Total Elbow Arthroplasty in the context of a previous infection is a good option of treatment with no reactivation of the infection at an average of 7 years of follow-up.

Keywords:
Management of avascular necrosis of the carpal bones- a clinical study

List of authors:
Daniel Vilcioiu*, Ioan Cristescu, Andrei Ursache, Dragos Zamfirescu
1 Zetta Clinic (Bucharest)
2 Clinical Emergency Hospital of Bucharest (Bucharest)

Objectives / Interrogation: Avascular necrosis of the carpal bones is a relatively rare condition of the wrist and can be divided into degenerative and post-traumatic. Post-traumatic necrosis is very common after neglected fractures or dislocations of the scaphoid or the lunate. Our aim was to create local protocols based on results and patient's satisfaction. We also present clinical cases and compare different techniques, complex or simple.

Methods: We present a prospective study that included 16 patients with carpal bone necrosis. We divided the patients into degenerative and post-traumatic necrosis and the surgical interventions were represented by reconstructive procedures such as: vascularized (free and local) or non-vascularized bone grafts, salvage procedures or even modern replacement implants. Distal radius and medial femoral condyle were most common donor places.

Results and Conclusions: Reconstructive procedures was found in 14 patients without a second intervention. Two patients needed a secondary intervention and the final results were satisfying. The wrist range of motion was improved in all the patients with reconstructions and the pain was significantly decreased or totally gone.

The avascular necrosis of the carpal bones can be very challenging and the indications have to be really precise. Reconstruction of the wrist is sometimes technically demanding surgery and the rehabilitation of the patients can be prolonged and difficult. If a standard protocol is used for all the patients, the results will significantly improve and the patient's satisfaction too. Replacement implants are technical demanding procedures but also promising due to its bone-like properties.

Keywords:
carpal necrosis, bone grafting, scaphoid, microsurgical reconstruction, implants
Case Report: Acute calcific periarthritis of metacarpophalangeal Joint presented with acute pain and swelling.

List of authors:
Amal Sharaf*, Sharmila Jivan
1 Mid Yorkshire Hospitals NHS Trust (Wakefield)

Objectives / Interrogation: Acute calcific periarthritis is a subset of acute calcium deposition disease which is characterised by the presence of calcium hydroxyapatite crystals in the periarticular soft tissues. It is frequently seen around shoulder joint and greater trochanter of the hip. Hand and wrist are rarely affected.

Methods: Case Report:
A 47-year-old right-handed lady presented with a 4-day history of worsening pain and swelling of her left ring finger metacarpophalangeal joint (MCPJ). She has no past medical history and reported no history of hand trauma. On examination, swelling and tenderness over A1 pulley were noticed with limited range of movement due to pain. There was no evidence flexor sheath infection. WCC, CRP and serum urate were all normal.

X-rays were requested and showed amorphous calcifications in relation to the left fourth MCPJ in keeping with acute calcific periarthritis. Symptoms settled after four days of resting splint, hand elevation and non-steroidal anti-inflammatory medications. Resolution of calcification was seen on follow-up x-rays eight weeks after onset of symptoms.

Results and Conclusions: Acute calcific periarthritis is idiopathic self-limited monoarticular periarticular inflammation which is characterised by sudden onset of pain and swelling. These painful periarticular calcifications were described by Painter CF in 1907. In 1938 Standstrom reported that of 329 cases with acute calcium deposits, only eight (2.4%) involved the hand and wrist.

Due to it is low incidence in the hand as well as its clinical resemblance of other acute presentations, many cases were reported to be misdiagnosed and, unnecessarily, treated aggressively with antibiotics and surgical intervention. Hand surgeons should be aware of this pathology and associated radiological signs in order to avoid unnecessary intervention.

Keywords:
acute calcific periarthritis, acute calcium deposits, hand
Syndactyly of the index and thumb, "functional limitation and frustration".

**List of authors:**
Julián Hernández*, Iván Ramírez1, Ana Pineda3
1 FUCS Hospital San José (Bogotá)

**Objectives / Interrogation:** To describe the case of a female patient with syndactyly of the index and thumb and its clinical repercussions and to contrast it with literature published

**Methods:** A literature review was made using Pubmed database between May to September 2018 using the key words Sindactyly, thumb, first commissural space, first digit, hand, thumb/physiology and English language restriction was used. Articles whose topic were syndactyly of the foot or acquired syndactyly were excluded. We searched for articles that included epidemiological data, physiology description of the thumb and index, emotional impact of the hand malformations and age and surgical technique indicated

**Results and Conclusions:** It was found that congenital syndactyly of the hand that compromises the first web space is the most infrequent and it has less female presentation. At functional aspect it generates inabilty to make thumb opposition and thus grip objects, also it causes deformities mainly on the index finger, and all of these difficulties cause sometimes anxiety and frustration in patients. The 12-month patient with syndactyly of the index and thumb presented the functional and emotional alterations found in the reviewed literature.

In the syndactyly of the hand and especially the one that compromises the digits at its edges, an adequate and timely surgical intervention is fundamental in order to avoid the functional and emotional consequences derived from this malformation.

Pedicled Vascularized Bone Graft Versus Induced Membrane Technique for Reconstruction of Forearm Medium Size Bone Defects

List of authors:
Ezequiel Zaidenberg¹, Martin Pastrana², Fernando Juarez Cesca³, Carlos Zaidenberg⁴
¹ Italian Hospital of Buenos Aires (Buenos Aires)
² Sanatorio guemes (Buenos Aires)
³ Hospital San bernardo (Salta)
⁴ Practica Privada (Buenos Aires)

Objectives / Interrogation: Induced membrane technique has proven satisfactory results for reconstruction of infected nonunion. However, more complex techniques such as vascularized bone grafts (VBG), are usually indicated in the presence of prior graft failure or a poor soft tissue bed. The purpose of this study is to compare the clinical and radiological outcomes of a series of patients treated for ulnar nonunion with medium size bone defects. Patients were treated with either pedicled distal radius VBG, or induced membrane technique (IMT).

Methods: Twelve patients who underwent surgery for reconstruction of infected forearm nonunion with bone defects up to 6 centimeters (minimum follow-up, 2 years) were selected retrospectively. We excluded patients with bone defects smaller than 3cm or articular involvement. Seven patients underwent to distal radius pedicled VBG (group A) and five patients underwent to reconstruction with the induced membrane technique (group B). Mean follow-up was 34 months. The time between the original injury and the index procedure was 16 months (range, 11-20). The mean age was 42 years (range, 26-64). Patients were evaluated clinically and radiographically. The number of previous surgeries was recorded. Elbow and wrist range of motion, Visual Analogue Scale (VAS) for pain, the Quick-DASH questionnaire, and Mayo Elbow Performance Score (MEPS) were assessed. Complications and the need for reoperations were recorded.

Results and Conclusions: Results: All nonunion were healed at final follow-up. The average defect size was 5.3 centimeters (range, 4.2-6). The average number of previous surgeries in the VBG group was 4.2 (range, 3-7) and in the IMT group was 2.8 (range, 2-5). The average time to union was 3.8 months (range 3-6) for group A and 4.6 (range 4-6) for group B. Active ROM did not differ significantly between groups. Average Quick-DASH was 13, and average MEPS was 83. At the 2-year follow-up, there were no significant differences in the VAS pain score (1.3 in group A; 0.9 in group B). There were two complications. In the VBG group, one patient required implant removal and in the IMT group, one nonunion required autogenous iliac crest bone graft. Final results were satisfactory for both. No fracture or persistent donor site pain was observed in the VBG group.

In this limited series, both techniques showed favorable results, and could be considered surgical alternatives for the treatment of infected ulnar nonunion.

Pedicled VBG showed a shorter time to union when compare with induced membrane.

Mid- and Longterm Results after Transosseous TFCC Refixation

List of authors:
Gerhild Thalhammer*, Thomas Haider1, Martin Lauffer2, Heinrich-Geert Tünnerhoff2
1 Department of Orthopedics and Trauma Surgery, Medical University of Vienna (Vienna)
2 Praxis für Handchirurgie (Marbach/Neckar)

Objectives / Interrogation: The Triangular Fibrocartilagious Complex (TFCC) is composed of the articular disc, the meniscus homologue, the ulnolunate and ulnotriquetral ligaments, the dorsal and palmar radioulnar ligaments (RUL) and the extensor carpi ulnaris (ECU) tendon sheat. The palmar and the dorsal ulnoradial ligament are considered the primary stabilizers of the distal radioulnar joint (DRUJ) during rotation. Lesions of the TFCC especially the ulnoradial ligaments may be the cause of ulnar sided wrist pain. Different surgical procedures addressing the instability problem with open, arthroscopic or arthroscopically assisted repair of the foveal attachment have been described. Short-term outcome reports of these methods indicate favorable results, but the long-term outcome remains to be reported. In the present study, we report the clinical mid- and long-term outcome of patients treated with arthroscopically-assisted transosseous reattachment of the deep TFCC insertion.

Methods: We included patients suffering from TFCC avulsions classified as Palmar type 1B with arthroscopically evaluated avulsion of the radio-ulnar ligaments who were treated with wrist arthroscopy and transosseous re-fixation of the TFCC between 2000 and 2009. Functional and clinical outcome of the patients were objectively measured with the Mayo Modified Wrist Score (MMWS), a Disabilities of the Arm, Shoulder and Hand (DASH) Score and a Patient Rated Wrist Examination (PRWE) score.

Results and Conclusions: We included 27 patients (18 female, 9 male) in this study. The first follow-up examination was at a mean of 25 months. All evaluated clinical measures significantly improved at first follow-up investigation compared to measures obtained preoperatively. At a mean of 84.5 months (range 32 - 128 months) the final follow-up examination was performed. Compared to preoperative measures, DASH score, mayo wrist score, and VAS remained significantly improved. Stability assessment showed a stable DRUJ in 17 patients (62.9%). In 9 patients (33.3%) moderate instability was assessed, while in 1 patient (3.7%) clear instability was observed. We did not observe differences in the MMWS and PRWE score between patients with stable, patients with moderate instability, and patients with unstable DRUJ. We found overall satisfying results at both evaluated time points with mainly excellent clinical outcome and high rates of patient satisfaction. Our results are comparable to short-term and mid-term outcome reported in literature.

THE VALUE OF INITIAL RADIOGRAPHIC CHARACTERISTICS OF DISTAL RADIUS FRACTURE IN PREDICTION OF ASSOCIATED LESION OF TRIANGULAR FIBROCARTILAGE COMPLEX

List of authors:
Katerina Kasapinova¹, Viktor Kamiloski²
¹ University Surgery Clinic "St. Naum Ohridski", Medical Faculty, UKIM, Skopje (Skopje, Macedonia)
² University Surgery Clinic "St. Naum Ohridski" (Skopje, Macedonia)

Objectives / Interrogation: Our purpose was to determine the correlation of initial radiographic parameters of distal radius fracture with the presence of associated injury of the triangular fibrocartilage complex (TFCC).

Methods: In a prospective study, 85 patients with surgically treated distal radius fracture were included. Wrist arthroscopy was used to identify and classify TFCC lesions. Initial radial length and angulation, dorsal angulation, ulnar variance and distal radioulnar distance were measured.

Results and Conclusions: Wrist arthroscopy identified TFCC lesion in 45 patients. Statistical analysis did not identify a correlation of any single radiographic parameter of the distal radius fracture with the associated TFCC lesion, as well as the type of the TFCC lesion. In between the group with intact and the group with injured TFCC there was no significant difference of the initial radiographic characteristics of the distal radius fracture. The initial radiography of the distal radius fracture was not a significant predictor of associated TFCC injury.

VALIDITY OF THE "SCRATCH COLLAPSE TEST" FOR THE DIAGNOSIS OF THE CARPAL TUNNEL SYNDROME.

List of authors:
Belén García-Medrano*, Clarisa Simón Pérez, Montserrat Ocampos Hernández, Miguel Ángel Corella Montoya, Miguel Ángel Martín-Ferrero, Pedro J Delgado Serrano, Fernando Corella Montoya
1 Hand and Microsurgery, HM Montepríncipe (Madrid)
2 Hospital Clínico (Valladolid)
3 Hospital Infanta Leonor (Madrid)
4 Data Scientist, Geoblink (Madrid)
5 Hospital Infanta Leonor, Quirón Hospital (Madrid)

Objectives / Interrogation: Analyze the Scratch Collapse Test in an objective way, by replacing the subjective evaluation made by the physician with an objective evaluation measure, made with a digital dynamometer.

Methods: An observational study was carried out, in 90 patients divided into three groups. The first two groups were patients clinically and electromyographically diagnosed of carpal tunnel syndrome CTS (moderate and severe) and the third group, without CTS. The main variable to analyze is the external rotation strength. It was measured with a dynamometer. The purposes are: firstly describe if there were differences in the strength between the three attempts per patient of each group, and secondly analyzed if there were differences in the strength in the four different situations (no scratch test, scratch test in the carpal tunnel, dorsum of the wrist and shoulder).

Results and Conclusions: There were no discrepancy in the result of the scratch-collapse test in patients with moderate carpal tunnel. That existed in the result of the test in patients with severe carpal tunnel. But this statistical difference is only 0,08 kg, in the mean and this such a small difference is clinically undetectable; and in any case, it would be able to collapse the strength of external rotation.

Scratch Collapse Test is not a valid diagnostic exam if the strength is measure directly by the physician. A complete collapse of external rotation has not occur in any of the groups and a small loss of strength has been detected only in those patients with the highest grade of severity in carpal tunnel syndrome. If a physician wants to use this test for carpal tunnel, our advice is to measure the strength with a dynamometer.

Keywords: Scratch Collapse Test, objetive measure, carpal tunnel syndrome
HAND REANIMATION: FREE FUNCTIONAL GRACILIS VERSUS TRANSFER OF THE BICEPS TO THE LONG FLEXORS OF DIGITS AND THE FLEXOR POLLICIS LONGUS

List of authors:
Raquel Bernardelli Iamaguchi¹, Gustavo Bersani da Silva³, Alvaro Baik Cho³, Teng Hsiang Wei³, Rames Mattar Jr¹
¹ University of Sao Paulo (SAO PAULO)

Objectives / Interrogation: Hand reanimation of the hand is still a challenge and in most cases of upper limb paralysis is the last treatment of reconstruction cascade. The objective of this study is to describe cases of patients without hand function and to compare functional results of cases of free functional gracilis transfer and cases of transfer of the recovered biceps to the long flexors of digits and the flexor pollicis longus

Methods: Results were evaluated and described with both techniques

Results and Conclusions: Case 1: male, 41 years, electric shock injury, SCIP flap for wrist contracture. Submitted to functional free gracilis for fingers flexors with neurotization with motor branch of the pronator teres Case 2: male, 38 years, total brachial plexus palsy, Submitted to free gracilis for elbow flexion and free gracilis for fingers flexors with intercostal nerve Case 3: male, 17 year, total brachial plexus palsy with absence of hand function recovery. Submitted to free gracilis for finger flexors. Case 4: female, 32 years total brachial palsy. Submitted to a lower trapezius transfer for external rotation. Transfer of the biceps to finger flexors with fascia lata graft Case 5: male, 38 years with total traumatic brachial plexus injury, submitted to shoulder arthrodesis and latter to biceps for fingers flexors with semitendinosus graft Case 6: female, 24 years patient with forearm avulsion work-related accident. Macro-replantation was performed and an Anterolateral thigh flap for skin necrosis. Submitted to biceps transfer for hand reanimation. The difficulty of resuscitation of the hand are known and still without definitive algorithm for treatment of these serious lesions. Initially, neurological reconstruction with nerve graft should be attempted when possible. In late cases, we perform functional free muscle transfers for hand reanimation when muscle transfers are not possible. However, the free transfer of functional muscle is a highly complex surgery with variable results in these cases hand reanimation. In 2009 Oberlin et al and Goubier and Teboul described the transfer of biceps for finger flexors. Similar results were obtained in our patients with both techniques, with fingers flexion for bimanual activities.

We consider the transfer of biceps for long finger flexors and flexor pollicis longus, a viable alternative for the treatment of patients without hand function, with reduced technical difficulties and surgical team when compared with free functional gracilis

Contribution of the integrity of the vincula tendinum in the delay of the repair of the flexor digitorum profundus tendon in zone II

List of authors:
Laura Velasco-González¹, Marta Almenara-Fernández¹, Gonzalo Pérez-López¹, Alex Grau-Blanes¹, Claudia Lamas-Gómez¹
¹Hospital de la Santa Creu i Sant Pau (Barcelona)

Objectives / Interrogation: Isolated laceration of the flexor digitorum profundus (FDP) tendon appears when the section is in zone I or and sometimes in zone II. In some cases, due to a delayed diagnosis or to a fail of the primary suture, the reparation is performed some weeks after the injury. In most of these cases, the intact vincular system prevents the retraction of the FDP tendon and this can be repaired as would be done in a primary repair. Finger in which the vincular system was not disrupted had greater final total active motion than had those without intact vincula. The objective of the study was to explain our experience and outcomes in the delayed treatment of the lacerations of the FDP tendon without tendon retraction due to the presence of the intact vincular system.

Methods: Between 2005 and 2016, 8 patients were operated with delay reparation of the FDP tendon without retraction of the same in zone II. The injury was diagnosed clinically and with MRI. The injury was localized in the proximal interphalangeal (PIP) joint in 5 cases and in middle phalanx in the other 3.
Surgery treatment and outcomes were analysed. Visual analog scale (VAS) scale, range of motion and Disabilities of the Arm, Shoulder and Hand (QuickDASH) score were evaluated at the final of the follow-up.

Results and Conclusions: There were eight patients with FDP tendon lacerations. There were 5 men and 3 women with a mean age of 27 years old. Reparation was performed after 3.3 weeks (3-5). The initial injury was located in zone II in all the cases. The lacerations were in the index finger in two cases, long finger in 2, little finger in 3 and in ring finger in one case. Minimum follow-up was 12 months.
The intraoperative findings found the intact VLP (vinculum longum profundus) in all cases that avoided the proximal retraction of the FDP. A modified Kessler suture was performed in all cases. All patients had good functionality measured with the Quick-DASH score at the final of the follow-up.
The integrity of the VLP could be one reason of the lack of retraction that occurs sometimes in FDP tendon injuries. When it occurs and the diagnosis is delayed, tendon suture can be performed like an acute primary repair. In cases of intact VLP, the vincular blood supply in combination with the synovial fluid nutrition maintain tendon viability and permits tendon healing after tendon repair.

4D CT scans of the DRUJ - a novel method in identifying and describing instability

List of authors:
Alistair Hunter*, Daniel Williams, Kannan Rajesparan
1 University College London Hospitals, Department of Orthopaedics (London)
2 University College London Hospitals, Department of Radiology (London)

Objectives / Interrogation: This novel radiological protocol allows temporal imaging of a cross section of the DRUJ with movement of the forearm from pronation to supination. The aim of this study was to optimise the imaging for 4D CT scanning in investigating instability of the DRUJ and describe the displacement of the ulnar head at the sigmoid notch with movement and time.

Methods: This was a prospective study. Adult patients with acute or chronic symptoms and signs of DRUJ instability presenting to our Institution from 2017 were included. Patients were identified in the outpatient clinic. Clinical information was gathered using the electronic health records. The imaging was viewed on PACS and the 4D viewer on the Osirix system. The point of maximal displacement of the ulnar head from the sigmoid notch was identified and measured using a modification of the radioulnar ratio method. The results were analysed on a spreadsheet.

Results and Conclusions: The optimal radiological protocol is described. The patient demographics and clinical presentation of six patients are described. The maximal radioulnar ratio for each patient is currently being analysed and will be presented. The degree of displacement at the sigmoid notch with time, from supination to pronation is also described. This is compared to the unaffected side. The clinical utility of this imaging modality is discussed.

Patients with instability at the DRUJ present a diagnostic and management challenge. Using this novel protocol, 4D CT scanning of these patients allows a much improved understanding of the degree of instability at the DRUJ with movement and time. This is shown to aid in clinical decision making. Further studies using this protocol in investigating the variety of patterns in DRUJ instability are warranted.

Stimulated Grip Strength Testing: Validation of Novel Method for Functional Assessment

List of authors:
Philip Hanwright*, Jennifer Rath¹, Nicholas von Guionneau¹, Thomas Harris¹, Karim Sarhane¹, Stephen Kemp², W.P. Andrew Lee¹, Ahmet Hoke¹, Paul Cederna², Sami Tuffaha¹
¹Johns Hopkins University School of Medicine (Baltimore)
²University of Michigan School of Medicine (Ann Arbor)

Objectives / Interrogation: Accurate and reliable assessment of functional recovery remains a challenge. Grip strength testing is a validated method for measuring function of the median nerve-innervated extrinsic digital flexors. Because the rat must be dangled by the tail to elicit grasp of the force transducer bar, this method is limited by behavioral variability and poor control of the vector and speed of distraction. Isometric tetanic force testing (ITFT) is accurate and reliable but does not allow for serial in vivo measurements. Combining aspects of these methods, we developed a novel technique for functional assessment in which grip strength is measured with percutaneous electrical stimulation of the median nerve to elicit grasping via isometric, tetanic contraction of the extrinsic digital flexors. We hypothesize that stimulated grip strength testing (sGST) provides greater accuracy and reliability than volitional grip strength testing (vGST) and similar quality data as ITFT with the added benefit of allowing for serial in vivo measurements. (Fig 1)

Methods: Function in both the right and left forelimbs was measured with sGST, vGST, and ITFT (n=10 rats), with the assumption that a perfect test would produce an average ratio (L/R) approaching one.

Results and Conclusions: sGST is more accurate than vGST in measuring side-to-side equivalence (p<0.05) and demonstrates comparable side-to-side equivalence as ITFT, but with less variability in measurements (Fig 2). It is less technically demanding and time-consuming than ITFT and requires less expensive equipment to perform.
Figure 1: Photographs demonstrating volitional grip strength testing (above) and stimulated grip strength testing (below).
Figure 2: Average side-to-side concordance ratios per testing modality. Error bars depict standard error. * denotes p<0.05

**Objectives / Interrogation:** First dorsal metacarpal artery flaps (1.DMF) are used for reconstruction of thumb distal amputation stumps or other fingers’ dorsal defects. The aim of this study was assessment of the results of these flaps with special emphasis on the objective sensorial status in comparison with contralateral healthy regions.

**Methods:** The study was done in 7 patients whose traumatic defects were repaired by 1.DMAF between September 2015 and March 2018. Four of them had unrepairable thumb distal phalangeal amputations. Amputation was distal to IP joint level in one patient, at IP in 2 and at MCP in another one. Two of the dorsal defects were over the 3rd finger and one over the dorsum of the hand. Mechanism of injury was crush in all of them. All of patients were men with a mean age of 43 (min:24-max:66) years. Operations were performed under local anaesthesia in 4 and general anaesthesia in 3. Mean dimensions of the flaps were 2X1.5 cm and included the dorsal cutaneous branch of radial nerve. A tunnel was developed under the skin to advance the flaps toward the defects in thumb amputations. Donor site was closed by skin graft. Assessment of study parameters was done at a mean time of 20,14(6-36) months postoperatively.

**Results and Conclusions:** There was no flap necrosis in any of the patients. Four patients rated their sensorial status as good, 2 as moderate and 1 as weak. Five of the patients stated no cold intolerance, 1 stated minimal and 1 moderate intolerances. Four patients rated their overall satisfaction as good and 3 as moderate. There was flexion contracture in thumb MCP joints in 2 patients. There was thumb nail deformity in 1 patient.

Static two point discrimination (2PD) test showed no significant difference (p=0,084) between the flap sites (mean=7.00 mm, SD=3,56) and similar healthy contralateral hand regions (mean=4,29, SD=1,38). Semmes Weinstein monofilament (SWM) test showed a significant difference (p=0,007) between the flap sites (mean=3,43, SD=0,79) and similar healthy contralateral hand regions (mean=2,29, SD=0,49).

Regarding the patients’ point of view, subjective results of 1.DMAF’s remain between overall ranges of moderate to good. But regarding the results of SWMF, as a reliable objective test in assessment of protective sensation loss, although innervated this flap type has no good sensorial results. We think that static 2PD remains as an unreliable tactile perception test.

Reconstruction of distal oblique bundle of the interosseous membrane of the forearm by percutaneous ligamentoplasty.

List of authors:
Belén García-Medrano*, Beatriz Fernández Bran, Fernando Polo Simón, Ricardo Kaempf De Oliveira, Mario Gil de Rozas, Pedro Delgado Serrano
1 Hand and Microsurgery, HM Montepríncipe (Madrid)
2 Hospital Povisa (Pontevedra)
3 Hospital Mae De Deus, (Porto Alegre)
4 HM Montepríncipe (Madrid)

Objectives / Interrogation: Describe indications, technique and results of the reconstruction of the distal oblique bundle (DOB) for longitudinal instability of the distal radioulnar joint (DRUJ) of the wrist.

Methods: 5 patients with DRUJ instability in the period between January 2016 and June 2018. The indication for surgery was pain and loss of pronosupination of the forearm. All cases had a previous radial head fracture. In 4 of the 5 cases they presented partial lesions of the interosseous membrane verified by MRI and ultrasound of the forearm.

All the cases were operated according to the technique described by Brink et al: percutaneous ligamentoplasty with autologous palmaris longus, crossing from radius and fixing on ulnar bone with an interferential screw. Pre-operative and postoperative clinical and radiological parameters were evaluated. The mean follow-up was 14 (3-26) months.

Results and Conclusions: The average age was 26.3 (15-32) years and all were male. In 100% pain disappeared and they recovered the complete arch of movement, without signs of instability. There were no recurrences or new necessary surgeries.

The DOB reconstruction indications are still under debate. In our experience this plasty is a useful technique in patients with longitudinal radio-ulnar instability, sequela of an injury in radial head and longitudinal stabilizers of the forearm. Bigger series with longer follow-up are needed to be able to verify these results.

Comparative Analysis of Three Techniques of Scapholunate Reconstruction for Dorsal Intercalated Segment Instability

List of authors:
Scott Wolfe, Marion Burnier*, Rishabh Jethanandani, Kate Meyers, Alfonso Alfonso Perez, Steve Lee
1 Hospital for Special Surgery (New York)
2 Herriot Hospital (Lyon)

Objectives / Interrogation: The scapholunate interosseous ligament (SLIL) is the most commonly injured ligament in the wrist. No reconstructive technique has been demonstrated to have better outcomes for a patient with reducible DISI than another. The purpose of this study was to compare the biomechanical and radiographic outcomes of the tri-ligament tenodesis (TLT) (1), Anatomic Front and Back (ANAFAB) reconstruction, and the Reduction and Association of the Scaphoid and Lunate (RASL) for reducible DISI deformity.

Methods: Scapholunate instability and DISI (defined as an absolute increase in RLA>15°) were created in 15 fresh-frozen cadaveric specimens by cutting the SLIL, long radiolunate ligament (LRL), dorsal inter-carpal ligament (DIC) and scaphotrapezo-trapezoidal (STT) ligaments. Specimens were randomized to receive the TLT, ANAFAB (Figure 1) or RASL procedures. Cadaver limbs were mounted onto a biomechanical testing jig in the clenched fist position with attached loads. Fluoroscopic images were taken in standardized PA and lateral positions to measure scapholunate gap (SLG), dorsal scaphoid translation (DST), radiolunate angle (RLA), and scapholunate angle (SLA). The specimens were cycled and compared radiographically in 3 states: intact, all ligaments cut and after reconstruction.

Results and Conclusions: The mean difference between intact and post-reconstruction measurements for RLA was 1.1°, 12° and 16.7° respectively for the ANAFAB, TLT and RASL groups, with a significant difference (Figure 2; p=0.024). The mean difference between the reconstruction and the intact status for SLA was -1° for both RASL and ANAFAB and 8° for TLT, with a significant difference (p=0.012). The mean difference of the DST between intact and reconstruction was 0.63 mm, 0.92 mm and 0.12 mm respectively for ANAFAB, TLT and RASL procedures (p=0.581). Compared with the measurements with all ligaments cut, the ANAFAB reduced the SLG 4.2mm, the TLT 3.9mm and the RASL 3.6mm, with no significant difference (p=0.878). Considering the different radiographic measurements, we noted no significant difference between the 3 techniques in maintaining the reduction after loading (p>0.05).

The ANAFAB procedure offered significantly improved correction of the RLA relative to the modified TLT and RASL procedures. The ANAFAB technique was the only reconstruction that addressed the volar and dorsal extrinsic stabilizers of the proximal carpal row. Further biomechanical studies are needed in order to confirm these results for several wrist positions.

Diaphyseal and proximal ulnar non-union: anatomical and epidemiological risk factors.

List of authors:
Laura Velasco-González¹, Marta Almenara-Fernández¹, Luís Trigo-Lahoz¹, Claudia Lamas-Gómez¹
¹Hospital de la Santa Creu i Sant Pau (Barcelona)

Objectives / Interrogation: Non-union after operative treatment of an ulnar fracture is very uncommon. There are severely disabling and challenging to treat. Multiple factors have been associated with the establishment of this non-union. Many non-unions are associated with soft tissue damage, fracture site vascularity, persistent instability, infection, and the surgical treatment technique. This study analysed the systemic conditions and local factors associated with the failure of bone fracture healing.

The aim of our study was to identify the risk factors for ulnar nonunion.

Methods: We retrospectively reviewed a cohort of ulnar fractures treated surgically with open reduction and internal fixation (ORIF), during a period of 10 years (2007-2016). We identified 211 ulnar fractures, 16 distal, 52 diaphyseal, 143 proximal. All patients had a minimum follow-up of 1 year. We defined non-union if there was no radiological consolidation of the fracture after this period, and we classified them according to Weber classification. We assessed risk factors like: fracture site vascularity, surgical treatment technique, biological factors of the patient, and the fracture's mechanism. Data were analysed using SPSS software system version 21. Multivariate regression analysis was performed to assess independent risk factors of ulnar non-union. Chi square test or Fisher exact test was used to compare categorical measurements. Statistical significance was considered as p less than 0.05.

Results and Conclusions: We found 17 ulnar non-union (8,1%), 13 diaphyseal and proximal ulna (6,2%). The 94% were hypertrophic non-union, and 6% of atrophic non-union. There were 12 male and 5 female. The mechanism of the fractures was high-energy traumatism in 30%. The 30% of patients smoked, 10,4% have diabetes mellitus, the 40,7% have vascular pathology. The fractures were open in 15,2%, the 72,5% were isolated ulnar fracture, the 25,6% were comminuted. We analyzed the ORIF and the 93,8% were well done (according to AO principles). We obtained statistically significant results in the relationship of high-energy injuries (p=0,0001), comminution (p=0,0001) and suboptimal fixation of the fracture (p=0,013), with the risk of developing nonunion. We didn't find statistically significant results in relation to the others clinical data analyzed.

Our results showed that a high-energy injury, a comminuted fracture, and a suboptimal treatment of the fracture, are risk factors of an ulnar nonunion.

**One-bone forearm technique for chronic post-traumatic forearm instability: a case report.**

**List of authors:**
Inma Puig de la Bellacasa*, Saioa Quintas1, Jordi Salvador1, Pablo Castillon1, Javier Abarca1
1 Hospital Universitari Mutua Terrassa (Terrassa)

**Objectives / Interrogation:** To present a case of severe longitudinal instability treated by one-bone forearm technique with good functional and painless result.

Is one-bone forearm (OBF) technique an effective salvage procedure in patients with longitudinal forearm instability?

**Methods:** We present a 52-year-old patient with longitudinal forearm instability secondary to a traumatic accident 30 years ago. She had suffered a subtotal amputation of the left hand with a severe neurovascular injury associated to ulnar open fracture that produced severely impaired hand with little grip function but well tolerated for daily activities. 3 years ago she consulted to our hand unit because of severe lateral elbow pain secondary to a chronic non union ulna fracture and forearm instability. Xrays showed an elbow osteoarthritis with radiocapitellar impaction. She was managed surgically with a proximal radio-ulnar synostosis. 8 months later, the patient presented a stress fracture in the middle shaft of the radius, secondary to excessive torque forces that was treated with an open reduction and internal fixation in more pronation with a good result in terms of radiological healing, pain-free, good range of motion. She doesn't need further intervention.

**Results and Conclusions:** OBF is the ultimate salvage procedure for a forearm instability. The procedure attempts to create a single, stable, bone bridge between the ulnohumeral and radiocarpal joints to rescue a chronically unstable forearm. The postraumatic etiology, is the one with higher complication rates because of multiple prior surgical procedures. Despite some published series, it is an uncommon procedure and there is no clear agreement regarding the best indication, which is a symptomatic, angular, axial or rotational radioulnar instability in the setting of segmental bone loss or refractory non union. There is either no consens in which technique to use. Autologous bone grafting at the fusion site is highly recommended. The best rotational position of the fusion is at neutral or 10 degrees of pronation, although this is something that must be treated with the patient.

The OBF technique provides a stable forearm with good functional and cosmetic results as well as patient satisfaction. This reconstructive technique has a high complications rate, but once is healed appears to be a satisfactory option in extremities without many alternatives.

THE USE OF JOSHI EXTERNAL FIXATOR (JESS: JOSHI EXTERNAL STABILIZATION SYSTEM) IN HAND FRACTURES: THE BEST COST-BENEFIT RATIO

List of authors:
simona odella*, federica olivero1, alessandro crosio3, jacopo flore3, federico palumbo3, ugo dacatra3, paola del bo3, pierluigi tos3
1 asst pini cto (milano)

Objectives / Interrogation: The objective of present study is to review the surgical technique (different kind of mounting) in a group of 225 fractures of phalanxes and 285 fractures of metacarpals. The objective is to have an algorithm in kirschner wire positioning and mounting of ex-fix for each pattern of fracture. We also analyze, time of healing, the number of complication as non union, defect of rotation or residual stiffness.

Methods: We reviewed 410 frame metacarpals and phalangeal fracture operated between 2012 and 2017 in our unit (285 metacarpals and 225 phalanges). The mean age is 37 years (min 12 years max 75 years) with a 3/1 man-woman ratio; of these patients 213 metacarpal fractures and 166 phalanges fractures were treated in a closed manner by reduction and percutaneous synthesis with k-wires and positioning of Joshi external fixator, under scopic control.
K-wires were positioned parallel in case of 5th 4th and second metacarpal, in few cases a inter-fragmentary k-wire has been also positioned to effort more stability and permit early motion.
This technique is useful even in case of Bennet or Rolando fractures, it's important stabilise the first metacarpal bone to the second metacarpal bone and trapezium after the reduction of the fracture.
In case of P1 base fracture K-wires has been positioned crossed, fixing the fragment to the diaphysis, or parallel in case of diaphyseal fracture,
in case joint PIP fracture the JESS has been used as a distractor
in case of Bush fractures, the Jess has been used to avoid k-wire migration in Ishiguro technique.
The position of k-wires in case of third or forth finger fracture is with a 40 degrees inclination.
The EF was removed after a 40-days (min 35 max 45 days) from surgery; active mobilization was started the day after surgery treatment.
We evaluated, at 6 months follow up, in 200 pts ROM and eventual complications.

Results and Conclusions: The treatment of hand fractures using JESS resulted in an average radiographic healing time of 40 days, complete recovery of ROM in 75 days; we had greater rigidity in extension recovery in case of phalangeal fractures, no case of deep infection or superficial irritation occurred.
In case of multiple metacarpal fracture we observed there could be a delayed x ray healing and stiffness, we had in one head P2 fracture 1 mm mal-rotation but the patient was satisfied about functional result.
Use of JESS external fixator in case of hand trauma is a valid solution to treat fractures without performing open surgical access.

**Congenital hand anomalies in patients with polydactyly of the foot - a single unit experience.**

**List of authors:**
Helen Stark\(^1\), Sophie Butterworth\(^1\), Lucie Wright\(^1\), Susan Stevenson\(^1\), Brid Crowley\(^1\)

\(^1\) The Newcastle upon Tyne Hospitals NHS Foundation Trust (Newcastle upon Tyne)

**Objectives / Interrogation:** To study a cohort of patients with congenital hand anomalies associated with polydactyly of the foot.

**Methods:** Retrospective review of patient notes, online records, radiology and medical photography. Hand anomalies in patients with polydactyly of the foot were recorded along with family history, associated anomalies and genetic work-up.

**Results and Conclusions:** Of thirty six patients with foot polydactyly, nineteen had congenital hand anomalies. Eleven patients had 5th ray polydactyly of the foot, five had first ray polydactyly, two had bilateral polysyndactyly and one had central polydactyly. In most patients the anomaly of the hands was mirrored in the feet with radial anomalies associated with first ray polydactyly of foot, ulnar anomalies with fifth ray polydactyly of foot. Sixteen cases had bilateral hand anomalies. Types of hand anomaly observed included nine type A ulnar polydactyly, three bilateral triphalangeal thumbs, two polysyndactyly, one third web space syndactyly, one patient with a left type A and right type B ulnar polydactyly.

Nine patients had a positive family history for anomalies of the hands or feet. Six patients had an associated congenital anomaly. These anomalies included Bardet Biedl syndrome, 22q11 (with cleft and cardiac anomalies), laryngomalacia and left sensorineural hearing loss. The majority of patients were referred to genetics for assessment. Of these one was found to have GLI3 mutation, one to have Grieg cephalopolysyndactyly syndrome (caused by mutation in GLI3 gene), one autosomal dominant polysyndactyly and one triphalangeal thumb polydactyly syndrome (abnormality in LMBR1 gene).

Our cohort is similar to the second group described by Burger et al (Acta Orthopaedica 2018; 89 (1): 113-118) in their population with foot anomalies i.e. combined hand and foot anomalies without severe anomalies in other parts of the body. However it was highlighted in their paper that subtle craniofacial features of Greig syndrome may be missed. Many of these patients will test positive for GLI3 mutation. We had two patients with confirmed GLI3 mutation. We hope reporting on our population will add to the knowledge of what are rare phenotypes and aid future investigation in this field.

Advantages of radiolucent PEEK-circular plates in midcarpal arthrodeses

List of authors:
Sven Kirsten*
1 MediClin-Hospital (Plau am See)

Objectives / Interrogation: 1. Known problems with conventional metal-plates
2. Comparable usability and results with PEEK-plates
3. Advantages of PEEK-plates because of radiolucency

Methods: About 20 patients with conventional metal-plates were compared to about 20 cases with PEEK-plates concerning:
- adequate mid-term functional outcome in four-corner-fusion
- X-ray-analysis on accuracy and time of determination of consolidation

Results and Conclusions: PEEK-midcarpal-plates have the same biomechanical potential for similar clinical outcomes as conventional materials, but they offer a much better and earlier evaluation of the fusion rates. (Tables will follow soon!)

So PEEK is much more reliable not only for the operating specialist, but also for surgeons outside when deciding the end of splinting and start of physio and increasing load. PEEK even might help shorten rehabilitation time, because assessing the X-rays is reliable earlier and possible for at least two weeks (vs. up to 3 months).

3 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster, Sektion Hand (Münster)

**Objectives / Interrogation:** Fractures healed with torsional malunions have major functional impairments. The correction of these misalignments must be made very precisely in several levels, so that the fingers do not cross over or diverge.

**Methods:** Since 2005, we have been using the rotation correction plate (Synthes) for these corrections, but have also used the plate primarily for fractures without anatomical evidence of correct torsion (eg, in replantation).

The plate was inserted 51 times, 38 times for the correction osteotomy of the metacarpals and 13 times for the primary fracture supply.

Case presentation of illustrative cases and eye openers.

**Results and Conclusions:** For the correction osteotomy, a 90° transverse osteotomy is created. The plate can then be steplessly rotated by a total of 36° and corrected several times intraoperatively, which considerably simplifies the exact setting. In debris fractures, the plate can be used by its angular stability as an internal fixator with fine adjustment options. For mid-range replacements, the position of the fingers can still be corrected when all fingers have received their osteosynthesis.

Complications: Only once after a correction osteotomy did a plate fracture occur. All other operations went without complications.

Operation time was very short.

The Rotation Correction Plate is a plate that have to be in the Armamentarium.

Palmar mutilation of the hand - a case report

List of authors:
Ayse Sencan*, Mehmet Vakif Keskinbicki¹, Murat Iptec¹, Mehmet Eren¹, Kahraman Ozturk¹, Serkan Aykut¹
¹Health Sciences University M.S. Baltalimani Bone Diseases, Teaching and Research Hospital, Hand Surgery Clinic (Istanbul)

Objectives / Interrogation: The traumatic total and subtotal amputations of the upper extremity are those with a complex management of treatment, which can result in serious morbidities. The aim of this study was to present a rare case of coronal plan injury in the distal radius, ulna, as well as carpal bones extending from the middle arm of the forearm to the palm.

Methods: A 37-year-old male mechanic was admitted to the emergency department with a subtotal amputation of the right hand. The patient had an injury in the form of an open book in the frontal plane extending from the radial and ulnar side to the palm from the right forearm 1/3 middle distal junction. This injury was classified as IIC1 according to tic-tac-toe classification.
When exploration was performed, it was seen that radial artery princeps pollicis branch, all finger flexors, common digital artery and nerves were cut, radius of distal radius and ulna, all carpal bones and 1. metacarpal base were separated in coronal plane. After marking the nerve and artery ends under surgical microscope, osteosynthesis was performed with K-wires and headless cannulated compression screws. Following that, only deep flexor tendons and FPL tendon were repaired. Princeps pollicis and 2 common digital artery were repaired with vein grafts and all other arteries were repaired by end-to-end anastomosis. Digital nerves were also repaired. External fixator was used to bridge the wrist. The ulnar side was left open while closure sutures were placed on the radial side and one week later groin flap was performed to close the ulnar side defect.

**Results and Conclusions:** After 10 months of follow-up, pulp to palm gap was 2.5 cm. Grasp and pinch were less than 50% of the opposite side. The patient recovered a subnormal sensitivity of the hand especially in the territory of the median nerve and he had no cold intolerance. Protective sensation of the 2. finger, good sense of the 3., 4., 5. fingers is recovered. Wrist extension 30°, flexion 60, forearm supination 80° and forearm pronation were 60°. Days off from work was 4 months.

**Keywords:**
Advantages of Arthroplasty vs Trapeziectomy for the Treatment of Thumb Carpometacarpal Joint Osteoarthritis.

List of authors: Ravikanth Mallina*, Al- Achraf Khoriati¹, Hiba Khan¹, Gemma Green¹, Johnathan Craik³, Ritesh Sharma¹, Najab Ellahee¹
¹ Epsom & St Helier NHS Trust (Epsom)

Objectives / Interrogation: The gold standard operative procedure for treatment of thumb basal joint osteoarthritis is to perform a trapeziectomy. For OA at other sites, joint replacement is now the treatment of choice. Benefits of prosthetic replacement in the thumb have been overlooked due to fear of risk of dislocation, infection or implant failure. Advantages of prosthetic joint replacement surgery include comparable functional outcome, preserving range of motion and providing stability.

The aim of the study was to evaluate the advantages following trapezio-metacarpal joint replacement with an uncemented prosthesis, for patients beyond conservative treatment with splints or injections.

Methods: Over a 5 year period thumb CMCJ arthroplasty was evaluated in 150 patients using the ARPE prosthesis (Biomet), via a volar approach, in a NHS hospital by a single surgeon. Outcomes were measured using clinical and radiological assessment, with the use of functional scores and patient questionnaires. Follow up was conducted over a minimum of 2 years.

A similar cohort of patients who underwent a trapeziectomy were used as a control for comparison to gold standard treatment. All patients underwent a 6 week rehabilitation protocol with splinting and hand therapy.

Results and Conclusions: Both treatments resulted in significant improvements in functional scores. When matching patients according to pre-operative function, patients receiving ARPE arthroplasty had better post-operative function (Quick DASH). More patients receiving the ARPE arthroplasty were satisfied with their treatment and would have the same treatment again. The ARPE also resulted in less thumb shortening. It is associated with a higher complication rate (6% dislocation), but implant survival was 95%.

The majority requiring further surgery presented at initial follow-up within 2 weeks. Most reported an incident which may have predisposed to dislocation. All these patients underwent early surgery to relocate the prosthesis and the majority had a favourable outcome at 3 months.

There were no reported infections and the volar approach avoided any injury to the superficial radial nerve.

Trapezio-metacarpal arthroplasty is an effective treatment option for thumb CMCJ osteoarthritis. Arthroplasty may offer potential advantages in terms of post-operative function and patient satisfaction. The results allay the risk of complications, although requirement for further surgery is greater and must be carefully considered during patient selection and pre-operative counselling.

Ultrasound in carpal tunnel syndrome - the inlet and outlet ratio

List of authors:
Hirsiger Stefanie*, Esther Vögelin
1 Handchirurgie, Inselspital Bern (Bern)

Objectives / Interrogation: Carpal tunnel syndrome is the most prevalent nerve compression syndrome in the upper extremity. To confirm median nerve compression, sonographical and electrophysiologic examinations have been described. The cross-sectional area (CSA) at the inlet and outlet of the carpal tunnel are used as diagnostic markers. As CSA of the median nerve varies with gender and occupation, a wrist-to-forearm-ratio has been proposed. As diagnostic sensitivity is still limited, the goal of this study was to retrospectively analyse CSA measurements and compare associated ratios.

Methods: 33 patients (44 wrists) diagnosed with CTS between 06/2016 and 08/2018 were included in the study. 23 were female, 10 male. Mean Age was 51 (range 21-89) years. Diagnosis was confirmed by nerve conduction studies. Measurements of CSA were performed using the continuous tracing method and a 17 or 18.5 MHz Linear Array Transducer (Philips iU22 Medical system or Philips 70 Affinity, Bothell, WA, USA). The absolute values of CSAForearm, CSAInlet, CSATunnel and CSAOutlet and the ratios CSAI/CSAF (Rforearm), CSAI/CSAT (Rpre) and CSAO/CSAT (Rpost) were compared. Data were analyzed using Excel (descriptive) and GraphPad for unpaired student t-test.

Results and Conclusions: Mean CSAF was 12.816 (SD 2.801), CSAI was 14.970 mm² (SD 4.618), CSAT was 9.002 mm² (SD 2.664) and CSAO 13.798 mm² (SD 3.539). CSAF, CSAI and CSAO were significantly higher than CSAT (p< 0.0001). When referring to published cut-off values ( >12.6 mm² for CSAI and >13.2 for CSAO), only 29 (64.4%) respectively 22 (48.9%) of 45 pathologic wrists were identified. When only analyzing the 11 wrists that would have been missed with the cut-off CSA values, mean ratios were 1.508 for Rpre, 1.611 for Rpost, and only 0.914 for Rforearm.

Conclusion
In these 33 patients, CSA values before and after the carpal tunnel were significantly higher than under the retinaculum. Nevertheless, 25% of pathologic wrists would have been missed if using absolute CSA reference values. If comparing the ratios, Rpre and Rpost had higher mean values compared to Rforearm, suggesting a higher sensitivity. These measures merit further evaluation in a prospective randomized study with a control group.

Pediatric Median Nerve Neurofibroma

List of authors:
Kahraman Ozturk, Bilge Ozkan, Ayse Sencan, Zeki Gunsoy, Rustam Jalilov
1 Health Sciences University M.S. Baltalimani Bone Diseases, Teaching and Research Hospital, Hand Surgery Clinic (Istanbul)

Objectives / Interrogation: Neurofibromas are benign tumors which originates from neural fascicles. The peak age of presentation of solitary neurofibromas is between 20-40 age and they are rarely seen in childhood. Our case had a large solitary neurofibroma affecting the two fascicles of the median nerve.

Methods: A 15 years old male patient was admitted to our clinic with the complaint of numbness and weakness in the first, second and third fingers of the left hand for the last year. Sensory examination was normal. Left-hand grip strength decreased by 60% compared to the other side. Radiographic evaluation and EMG test were normal. In the MRI, the median nerve at the wrist level of the mass was 3 cm in diameter and 8 cm in length and within the fascicles, the continuity of the median nerve fiber was observed on the ulnar side of the tumor (Figure 1).

Incisional biopsy revealed neurofibroma and excision was performed. During the surgery, it was observed that the mass infiltrated two nerve fascicles and pushed other median nerve fibers. Existing motor branches were divided using nerve stimulator and the two fascicles passing through the mass was considered the cutaneous branch and were excised(Figure 2).
These two fibers were coapted as end-to-side fashion to the median nerve distally. In postoperative follow-up, muscle strength and grip strength were normal in first two lumbrical and thenar muscles. The physical examination of the patient revealed sensory deficits in 2nd ulnar side of the second finger and radial side of the third finger.

**Results and Conclusions:** Large solitary neurofibromas can also be seen in childhood. The tumoral mass can be removed without causing motor and sensory deficits.

Identification of perforant to the realization of hypothenar fat flap in the management of the recidivant carpal tunnel syndrome

List of authors:
Julián Hernández*, Jaime Forigua1, Ingrid Aponte1, Ana Pineda1
1 FUCS Hospital San José (Bogotá)

Objectives / Interrogation: The release of the transverse carpal ligament as a management of the obstructive syndrome of the median nerve generally brings good results, however some patients persist with symptoms that are attributed to an incomplete release or a fibrous process in the periphery of the nerve, thus there are descriptions other surgical techniques whose purpose is to interpose tissue between the nerve and the scar as the hypothenar fat flap. The purpose of the article is to describe the results obtained with the identification of a preforant for the placement of the hypothenar fatty flap in the management of recurrent carpal tunnel syndrome.

Methods: We present the case of a 60-year-old female patient with a history of conventional release of the right-side carpal tunnel of 1 year of evolution, with persistence of paresthesias, allodynia, dysesthesia and decreased strength associated with alterations in postoperative electromyography and neuroconduction. So an incomplete release is interrogued. Surgical management with hipotenar fatty flap was decided, for which a perforator was marked at the level of the hypothenar region with the help of an 8Mhz Doppler

Results and Conclusions: The persistence of symptoms after the release of the carpal tunnel may be secondary to an incomplete release of the transverse carpal ligament, to scar compression or to both noxas. The literature indicates surgical management in which the use of hypotenar fat flap has given satisfactory results, in the patient also the use of Doppler was implemented as a guide evidencing safety, easiness and effectiveness in the procedure.

Effects of Growth Hormone Therapy on Nerve Regeneration, Functional Recovery, and Allo-Immune Response in Vascularized Composite Allotransplantation

List of authors:
Jennifer Rath*, Xianyu Zhou¹, Philip Hanwright¹, Neha Amin¹, Nicholas von Guionneau¹, Chia Na Min¹, W.P. Andrew Lee¹, Gerald Brandacher¹, Sami Tuffaha¹
¹Johns Hopkins University School of Medicine (Baltimore)

Objectives / Interrogation: Functional recovery following upper extremity transplantation remains poor, primarily as a result of prolonged denervation and resultant muscle atrophy. Growth hormone (GH) has well-established trophic effects on neurons, myocytes, and Schwann cells and represents a promising therapeutic strategy to accelerate axonal regeneration and also maintain muscle and Schwann cells prior to reinnervation. The aims of this study were to confirm the positive effects of GH on nerve regeneration and functional recovery and to evaluate the effects of GH treatment on the immune response in the setting of vascularized composite allotransplantation.

Methods: Rats underwent orthotopic forelimb transplantation with full MHC-mismatch received either porcine-derived GH (0.6 mg/kg/day) or no treatment (n=10 per group). All animals received tacrolimus (2 mg/kg/day) for graft maintenance. Animals underwent functional assessments every four weeks using electrically-stimulated grip strength testing. Animals were monitored for clinical signs of rejection. Skin biopsies and serum cytokine levels were obtained at the mid- and end-point to evaluate for subclinical rejection. Animals were sacrificed at 16 weeks or if they demonstrated advanced rejection (grades III/IV). Quantitative histological assessments of axonal regeneration, neuromuscular junction reinnervation, muscle atrophy, and Schwann cell proliferation were performed on muscle and nerve specimens upon sacrifice.

Results and Conclusions: Grip strength was improved with GH-treatment as compared to the control group at weeks 4 and 16 (p=0.03 and p=0.05, respectively; Fig. 1). There was a greater number of regenerative axons and decreased muscle atrophy in the GH-treated group (p>0.05). Rates of clinical rejection did not significantly differ among groups. Remaining data is pending. In conclusion, GH treatment may allow for improved functional outcomes in VCA via accelerated axonal regeneration and maintenance of denervated muscle.
Figure 1: Post-transplantation functional recovery as measured by grip strength. Error bars depict standard error.
Cancellations in emergency plastic surgery: A three month experience in a tertiary referral centre.

List of authors:
Dominika Michno*, Wojciech Konczalik, Prateush Singh, Riaz Agha, Mohammed Akhavani, Neil Toft
1 Royal Free Hospital (London)

Objectives / Interrogation: Retrospective cohort study of emergency surgery cancellations in a busy tertiary plastic surgery centre. The primary objective was to calculate the cancellation rate. Further patient-specific data was extracted to evaluate for preventable cancellations and introduce departmental changes to improve the service.

Methods: Review of all cancellations in emergency plastic surgery over a three month period from May to August 2018. Data pertaining to patient demographics, proposed surgical procedure and reason for cancellation were extracted from both electronic and paper records. Both the cancellation rate and the average delay in surgical intervention as a result of the cancellation were calculated.

Results and Conclusions: 157 cancellations were identified. 67% of these were cancelled on the day of surgery and 33% were cancelled in advance via the phone and having the dates of their surgical appointments changed. The overall cancellation rate was 19.1%, with 13% of patients being cancelled on the day of their proposed operation. 5.4% of cases were cancelled on more than one occasion. More than half of all cancellations required further surgical appointments and their surgery was delayed by an average of 2.22 days as a result. The most common reasons for same day cancellations were as follows: operation not necessary, surgical list overbooking and patients not attending their appointments. A sub-analysis of operations cancelled on the grounds of not being clinically warranted revealed that infections, fractures and fingertip injuries were the most common. Patients who failed to attend their appointments were more frequently young males with small injuries and no functional deficit.

At 13%, our same day cancellation rates are in keeping with similar studies in the field. Our study also incorporated patients who were cancelled a few days in advance of their surgery and found that almost 20% of all patients who get scheduled to undergo emergency plastic surgery will have this appointment changed. A large proportion of cancellations were due to the operation being not necessary - we have addressed this issue by introducing formal teaching sessions and improving availability of senior clinicians in the decision making process. Furthermore, we have also optimised several administrative processes to further minimise cancellation rates.

Irreducible dislocations of the metacarpophalangeal joints - history and 24 cases

List of authors:
Martin Franz Langer*, Britta Wieskoetter¹, Simon Oeckenpöhler³
¹ Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätshospital Münster (Münster)
² Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätshospital Münster, Sektion Hand (Münster)
³ Universitätshospital Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)

Objectives / Interrogation: Irreducible dislocations of the metacarpophalangeal joints were described very early in the literature, as the therapy initially appeared simple, but then often ended in a disaster. Only about 400 cases of this dislocation could be found in the literature. Most affect the thumb and are dorsal dislocations. The palmar dislocations are also much more often in the fingers. Palmar dislocations are a great rarity.

Methods:
We report very inessential cases from 250 years of literature, a classification of irreproducible dislocations and our 24 cases, where we can present 2 palmar dislocations of the thumb and 2 palmar dislocations of the fingers with very interesting injury mechanisms.

Results and Conclusions: The opposing repositioning obstacle is very different on the thumb, while it is always the palmar plate on the fingers. A closed reduction is possible only after the Roser-Hey principle (1856) and Farabeuf (1878) principle. Operatively, dorsal dislocations are easiest after Farabeuf of posterior with cleavage of the palmar plate. In palmar dislocations both collateral ligaments are always torn and need a primary reconstruction. Nevertheless, the prognosis of palmar dislocations is poor.

Section of 2nd to 5th flexor tendons in zone 2 of the hand with interdigital nerve injury: case report

List of authors:
Julio Echazabal*, Mario Andres Humeres Rios², Soledad Sanchez³
¹ Clinica Fusat, Hospital De Rengo (Santiago)
² Hospital del Salvador, Universidad De Santiago De Chile, Hospital de Rengo (Santiago)
³ Hospital de Rengo (Santiago)

Objectives / Interrogation: Want to present the experience in restructuring medicine and advanced microsurgery, in a new center of traumatology and orthopedics

Methods: Case of male patient, 32 years old, without morbidities suffers cut with kitchen knife in zone 2 of flexor in hand, with interdigital nerve involvement from the 2nd to 5th finger of the right hand. Surgical wound dressing in the emergency room. It is performed 24 hours after the accident, definitive surgery, with primary tenorrhaphy with double kessler points. Under magnifying glasses and microscope Identification of interdigital nerve ends, primary epineurorrhaphy without tension is performed. Passive intraoperative passive mobility verification, closing of wounds and temporary immobilization for protection of surgery. Patient was sent home 24 hours after surgery, temporary immobilization in situ, 2 weeks later, withdrawal of points. is sent to therapy, for controlled early mobilization. Follow-up and therapy for 6 months. Progress is reintegrated into common life and work progressively. Full reintegration at 7 months.

Results and Conclusions: The performance of reconstructive medicine and microsurgery in highly complex wounds is challenging. Especially in areas where you do not have the necessary supplies for the correct execution. that is why we recommend the timely resolution of highly complex pathologies as long as you have the correct technology and instruments. We believe that a good planning should always be carried out, correct follow-up of the advice based on evidence on nerve and tendon repair, only with them is it possible to obtain good results. always thinking about the best for the patient and the total recovery of functionality.

Keywords: Hand, epineurorrhaphy, Microsurgery
Residual rotation of forearm amputation: Cadaveric study

List of authors:
Chang-Hun Lee*, Wan-Sun Choi, Sung-Jae Kim, Joo-Hak Kim, Kwang-Hyun Lee
1 Eulji University (Seoul)
2 Ajou University (Suwon)
3 Hallym University (Hwasung)
4 Hanyang University (Seoul)

Objectives / Interrogation: The purpose of this study was to investigate the residual rotation of the patient with forearm amputation and the contribution of involved muscle to the residual rotation. Finally, we tried to determine the optimal amputation level for the forearm bionic arm.

Methods: Testing was performed using 5 fresh-frozen cadaveric specimens that were surgically prepared by isolating muscles involved in forearm rotation. Amputation was implemented at 25cm (wrist disarticulation), 18cm and 10 cm from tip of olecranon. The supination and pronation in the amputation stump was simulated with traction of involved muscle (supinator, biceps brachii, pronator teres, pronator quadratus) using an electric actuator. The degree of rotation was examined at 30°, 60°, 90° and 120° in flexion of elbow.

Results and Conclusions: Average rotation of 25 cm forearm stump was 148° (SD 23.1). The rotation was decreased to 117.5° (SD 26.6) at 18 cm forearm stump and to 63° (SD 31.5) at 10 cm forearm stump. Tendency of disorganized rotation was observed in close proximity of the amputation site to the elbow. Full residual pronation was achieved with traction of each pronator teres and pronator quadratus. Although traction of supinator could implement residual supination, the contribution of biceps brachii range from 4% to 88% according to the degree of flexion.

Close proximity of the amputation site to the elbow decreased the residual rotation significantly and the preservation of pronosupination was 80% at 18 cm forearm stump. Although the pronator teres and the pronator quadratus could make a full residual pronation separately, the supinator was essential to a residual supination.

Keywords: Forearm amputation, residual rotation
Outcome assessment of closed distal radius fracture and ulnar styloid fracture treatment with volar plate and screw fixation

List of authors:
Luís Mata Ribeiro*, Miguel Botton², Mota da Costa²
¹Hospital São José, Centro Hospitalar Lisboa Central (Lisbon)
²Hospital CUF Descobertas (Lisbon)

Objectives / Interrogation: Ulnar styloid fracture is very frequently associated with distal radius fractures. Nonetheless, its clinical impact and specially its treatment are still highly debatable. The main goal of this study is evaluating the clinical outcomes of patients submitted to volar plate fixation of the radius and screw fixation of the ulna styloid.

Methods: Retrospective study including all adult patient with closed distal radius fractures and ulnar styloid fractures operated in an orthopaedic department since June 2015 to June 2017 (2 years). Patients with concomitant hand fractures, with cognitive deficits or with a history of degenerative or traumatic wrist injuries were excluded from the study.

Variables studied included age, sex, associated injuries, dominant hand function, comorbidities as well as complications after surgery.

Preoperative radiographs were analysed and patients were operated by two senior surgeons using internal fixation with a volar locking plate for the radius and percutaneous/mini-open fixation with a screw for the ulna. In type B and C distal radius fractures (AO classification), arthroscopic assistance was used during the procedure.

To assess the clinical outcomes, DASH score, PRWE score and satisfaction and pain Visual Analog Scale (1-10) were completed 12 months after surgery. Radiographic assessment and range of motion measurement were also evaluated.

Results and Conclusions: A total of 26 patients were included in the study comprising 15 female and 11 male patients. Patients age varied from 30 to 68 years old.

Average Total DASH score was 20.46 points and total PRWE score was 23.33 points. These values are in accordance with most data found in the literature. Average Paint at rest VAS score was quite low, 1.66 points. The average satisfaction VAS score was 8.88.

Radiographic control showed good bone consolidation in all patients. All patients, except one, recovered complete mobility of the wrist. The only exception was a patient with flexor tenosynovitis that needed plate removal 10 months post-op.

Conclusion
Ulnar styloid fixation produces good clinical results, allowing complete recovery of wrist mobility and significantly reducing pain complaints with very few complications. In cases of distal radius fractures and ulnar styloid fracture it seems that fixing both fractures gives better results.

ulnar styloid; screw fixation; wrist
Radial Polydactyly: The not so innocent floating radial duplicate

List of authors:
Lisa Ng1, Susan Stevenson1, Jane Maraka1, Helen Stark1, Victoria Lockwood2, Rui Diogo3, Brid Crowley1
1 Department of Plastic and Reconstructive Surgery, Newcastle upon Tyne Hospitals NHS Foundation Trust (Newcastle upon Tyne)
2 Centre for the Advanced Study of Human Paleobiology, Department of Anthropology, The George Washington University (Washington)
3 Department of Anatomy, Howard University College of Medicine (Washington DC)

Objectives / Interrogation: In radial polydactyly radiological and clinical appearances can belie the underlying anatomical complexity. The floating radial duplicate we define as a radial duplicate with soft tissue attachment only to the ulnar duplicate. Such duplicates are often perceived to be straightforward, associated with a normal ulnar duplicate and suitable for management by simple excision. We report our experience of anatomical surgical management of radial polydactyly with floating radial duplicates.

Methods: Operative anatomical data was collected prospectively for 75 consecutive thumbs at primary surgery. Cases with floating radial duplicates were identified. Detailed schematics were constructed providing a highly visual representation of the anatomy.

Results and Conclusions: 19 thumbs with floating radial duplicates were identified. In 3 cases the ulnar duplicate was triphalangeal.

Thenar muscle:
In 4/19 thumbs abductor pollicis brevis(APB) inserted on both duplicates. Anomalies included: APB inserting on the radial duplicate solely; APB inserting into the flexor and extensor mechanism at IPJ level; APB inserting distal to IPJ of ulnar duplicate; hypoplastic APB inserting on the neck of 1st metacarpal.

Extensor:
8/19 thumbs demonstrated insertion on both duplicates. Anomalies included: interconnections extensor-flexor; atrophic EPL ulnar duplicate; hypoplastic EPB ulnar duplicate; EPB inserting radial duplicate only.

Flexor:
15/19 floating radial duplicates had no flexor tendons. FPL inserted on both duplicates in 4/19. Eccentric FPL insertion and deficient pulleys in the dominant ulnar duplicate were observed.

Surgical procedures:
The radial duplicate skeleton was excised in 14/19 cases. MCPjt instability in the ulnar duplicate was treated in 2 cases. 3 thumbs with a triphalangeal ulnar component underwent excision of middle phalanx. A new IP joint was formed. The radial collateral ligament of IPjt was reconstructed in 2 cases.

Tendon procedures included transfer of EPB to the dominant duplicate; division of anomalous interconnections; division of anomalous flexor slips; pulley reconstruction; division of anomalous APB insertions.

Discussion
Radial polydactyly cases with floating radial duplicates are often perceived as straightforward with “normal” ulnar duplicates. Our experience does not support this perception. We identified anomalous anatomy in both the floating radial duplicate and the dominant ulnar duplicate. A systematic anatomical approach to primary surgery is advocated.

FESSH Travel Fellow Award: continued training in hand surgery.

List of authors:
Belén García-Medrano*, Andrea Atzei, Fernando Polo Simón, Pedro J Delgado Serrano

1 Hand and Microsurgery, HM Montepríncipe (Madrid)
2 Hand and MicroSurgery, Treviso (Treviso)

Objectives / Interrogation: To analyze the clinical and professional utility of the grant from the experience lived by the awardees, based on personal travel.

Methods: Professional opportunity to complete continuing education in hand surgery, based on the selection of a referenced center or surgeon from Europe, setting goals for the travel: to participate in outpatient clinic, to assist in surgery room, and to attend teaching sessions.

Results and Conclusions: In 2018, 10 scholarships were granted, with an average of 2 weeks of travel. The awardees achieve the initially proposed objectives: to expand our knowledge in hand surgery with a focus on wrist surgery and biomechanic, to observe different clinic's routine including rounds, clinic hours and surgeries and to learn new approaches to well established diagnosis.

This fellowship has motivated awardees to continue studying, and to strengthen arthroscopic and microsurgical skills. This fellowship contributes significantly to our development as a hand surgeons.

Surgically treated Closed Distal Radius Fractures in adult working patients - Outcome analysis in occupational vs nonoccupational injuries

List of authors:
Luís Mata Ribeiro*, Miguel Botton, Mota da Costa
1 Hospital São José, Centro Hospitalar Lisboa Central (Lisbon)
2 Hospital CUF Descobertas (Lisbon)

Objectives / Interrogation: Distal radius fractures (DRF) are one of the most common traumatic injuries worldwide. The main goal of this study is evaluating the clinical outcome of patients treated with internal fixation for an accidental DRF in comparison to an occupational injury. Secondary goals are identifying good/bad prognostic factors that impact the clinical outcomes.

Methods: Retrospective study including all adult patient (with less than 65 years old) with closed distal radius fractures operated in an orthopaedic department since June 2015 to June 2017 (2 years). Patients with concomitant ulnar or hand fractures, with cognitive deficits or with a history of degenerative or traumatic wrist injuries were excluded from the study.

Variables studied included age, sex, associated injuries, dominant hand function, comorbidities as well as complications after surgery.

Preoperative radiographs were analysed and patients were operated by two senior surgeons using internal fixation with a volar locking plate. In type B and C fractures (AO classification), arthroscopic assistance was used during the procedure.

To assess the clinical outcomes, DASH score, PRWE score and satisfaction and pain Visual Analog Scale were completed 12 months after surgery. Radiographic assessment and range of motion measurement were also evaluated.

Results and Conclusions: A total of 51 patients were included in the study comprising 28 female and 23 male patients. 19 cases were work related and 32 were caused by accidental injuries.

On average, all outcomes were worse in the occupational group. DASH score was 46,4 vs 15,8 (non-occupational group). PRWE score was 52,86 in the work-related group against 19,7 in the accidental group. Accordingly, the scores for pain at rest in the occupational group were also higher (4,14) against 1,45 in the other group. scores for patient satisfaction were very similar between the two groups (8,3 vs 8,5).

Conclusions/Discussion:
The surgical treatment of distal radius fractures with internal fixation seems to be highly effective and reliable. Nevertheless, it seems that patients injured in work-related activities have a worse result. Prospective studies are needed to confirm these results.

The main limitations of the study are the low number of cases, the multiple types and patterns of fractures analysed and its retrospective nature.

Do we need an opioid for the pain control after carpal tunnel release? : a randomized controlled study

List of authors:
Chang-Hun Lee*, Wan-Sun Choi, Sung-Jae Kim, Joo-Hak Kim, Kwang-Hyun Lee
1 Eulji University (Seoul)
2 Ajou University (Suwon)
3 Hallym University (Hwasung)
4 Hanyang University (Seoul)

Objectives / Interrogation: Few studies have examined the appropriate pain control after carpal tunnel release (CTR). The goal of this study was to compare the effectiveness of paracetamol for the pain control with that of codeine analyzing patients' subjective perception.

Methods: A prospective comparison of consecutive patients' subjective perception for pain after outpatient CTR was conducted. Patients were randomized to receive either a codeine or a paracetamol for pain control after CTR. All operations were performed with the same mini-open CTR surgical technique. Visual analogue scale for pain of both groups was compared from the day of surgery to the 3rd day following the surgery.

Results and Conclusions: Mean VAS score at the day of surgery was 4.9 (range 2–8) and the score was decreased 3.8 (range 2–6) at the first day following the surgery, 2.4 (range 0–5) at the second day following the surgery, and 1.8 (range 0–5) at the 3rd day following the surgery in the codeine group. In the paracetamol group, the mean VAS score was 4.2 (range 0–8), 3.3 (range 0–6), 2.5 (range 0–5), and 2.2 (range 0–5) at the equivalent day of the codeine group. Mean VAS scores were not different significantly from the day of surgery to the 3rd day following the CTR (p=0.31 at POD 0, p=0.43 at POD 1, p=0.94 at POD 2, p=0.61 at POD 3).

Paracetamol was effective to relieve the pain after outpatient CTR comparing with the codeine. Our results suggest the clinicians might avoid unnecessary prescription of the opioid after outpatient CTR.

The stability of intra-articular distal radius fractures using volar locking plate with unicortical and bicortical screws

List of authors:
ANTONIO TUFIFEDER FILHO*, NILTON MAZZER, ANA PAULA MACHEDO, LEONARDO BATAGLION, ANTONIO SHIMANO

1 USP/FMRP (Ribeirão Preto)

Objectives / Interrogation: OBJECTIVES: Evaluate the mechanical properties of unicortical and bicortical fixations in a model of intra-articular fracture of the distal end of the radius, classified as AO 23C3, under simulated physiological loads.

HYPOTHESES: 1- The mechanical behavior of the model using unicortical screws in the fixation of volar plates in intra-articular fractures of the distal end of the radius is equivalent to the model using bicortical screws.
2 - Cyclic loading, using a frequency of 1Hz per 1000 cycles, affects the mechanical behavior of volar plate fixation models in intra-articular fractures of the distal end of the radius using unicortical and bicortical screws.

Methods: Forty-four fourth-generation left-hand radius models (Sawbones; model 3407) were used in this study. In each model, a volar plate was used for variable angle distal radius (Matrix 54-25276; Stryker, Freiburg, Germany) in a systematic and reproducible way, ensuring distal screw placement in the subchondral bone. All bone models, in their proximal region, were included with JET® polymethylmethacrylate cement. After inclusion, the bones were sent to the Precision Office to perform cuts to simulate bone failure, characterizing a fracture of the distal radius in 4 parts with a wedge of dorsal metaphyseal resection. The 10 mm dorsal base wedge in the metaphyseal region was made to characterize instability. The models were divided into six groups, so that each model underwent only one type of test, thus it did not affect any of the overlapping tests. Three groups had unicortical assembling and three groups with bicortical assembling. Each of the groups received seven models. The mechanical tests were axial compression (AC), dorsal flexion (DF), and volar flexion (VF). After the first static test, the models underwent a cyclic loading to simulate the wrist movements during the six-week period after fracture. Then another static test. After tests in the elastic phase, the models underwent extreme loads until failure occurred, each group in its corresponding type of test.

Results and Conclusions: According to our results and comparing them to the literature, we agree that at least 75% length of the unicortical screw has mechanical properties similar to those of the bicortical screw in volar plate assembling of the distal radius, thus we recommend using unicortical screws in intra-articular fractures of the distal end of the radius.

Locked metacarpophalangeal joint - a simple approach

List of authors:
Martin Franz Langer¹, Britta Wieskoetter², Simon Oeckenpöhler³, Sarah Breiter³
¹ Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)
² Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster, Sektion Hand (Münster)
³ Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)

Objectives / Interrogation: Blocked MP joints have a poor prognosis in the shelf when operated on a palmar access. We report on the pathomechanism and a new simple method of surgery.

Methods: The MP joints, which are mostly blocked at 50 ° flexion, are band structures that stick to a spur of the metacarpal heads. Usually this spur is removed via a palmar access. Most patients treated in this way have a very long convalescence period and the results are only moderately good or bad.

Our dorsal access technique is simpler and involves a severing of the trailing fibers.

Results and Conclusions: 6 patients with entrapment MP-joints could be treated successfully. The convalescence period was very short.

Global First Web Release in Clasped Thumb - An Anatomical Approach to Treatment

List of authors:
Lisa Ng*, Yeru Chin1, Brid Crowley1
1 Department of Plastic and Reconstructive Surgery, Newcastle upon Tyne Hospitals NHS Foundation Trust (Newcastle upon Tyne)

Objectives / Interrogation: Congenital clasped thumb is a thumb flexion adduction deformity that may present as an isolated anomaly or as part of a spectrum of complex congenital anomalies. First web release may be indicated in selected cases. We present experience of our surgical technique using a systematic anatomical approach to first web release.

Methods: A casenote based retrospective review of global first web release procedures undertaken to treat clasped thumb in our unit between 2013-2018 was performed.

Results and Conclusions: 16 first web releases were undertaken in 11 patients. 8/11 patients had a diagnosis of arthrogryposis. Three patients had a defined syndrome (1) Klinefelter's syndrome (2) Pena-Shokeir Syndrome (3) Freeman-Sheldon Syndrome. Associated congenital anomalies included gastroschisis and ventricular septal defects.

Mean age at primary surgery was 58 months. An anatomical approach to first web release was undertaken addressing sequentially skin, palmar fascia, flexor retinaculum, thenar muscle, adductor pollicis, first dorsal interosseous, flexor pollicis longus, joints. A curvilinear incision was made extending from the free margin of the first web to the wrist. Augmentation of palmar skin shortage was by transposition flap from the index finger (10/16), full thickness skin graft (12/16), Z-plasty (7/16). In cases with significant finger flexion deformity we inset the index finger flap transversely in the palm. Release of anomalous fascial bands was required in all hands. Release of flexor retinaculum (15/16) reduced the deforming force of tight thenar muscle. Additional release of thenar muscle origin was required in 4/16 hands. Adductor pollicis origin was released in 4/16 hands, intramuscular tenotomy of insertion in 7/16. 1st dorsal interosseous origin was released (2/16), tendon step-lengthened (1/16). Flexor pollicis longus intramuscular tenotomy was required in 3 cases. K-wires were used to temporarily stabilize the metacarpophalangeal joints/maintain 1st web in 6/16 webs. Concomitant procedures were undertaken for (i) finger flexion deformities (7/16), (ii) to augment extensor function (3/16).

Treatment of the first web in congenital clasped thumb can be challenging. The principles of surgical management - sequential release and augmentation of web structures can be achieved in different ways depending on operative findings. Here we demonstrate our anatomical technique and approach to the first web.

Versatility of medial femoral condyle flap for phalangeal and metacarpal bone reconstruction

List of authors:
Chung-Chen Hsu*, Cheng-Hung Lin¹, Yu-Te Lin¹, Shih-Heng Chen¹, Chih-Hung Lin¹
¹ Department of Plastic and Reconstructive Surgery (Taoyuan)

Objectives / Interrogation: The medial femoral condyle (MFC) flap has become a popular option for small bone defects or calcitrant nonunions. The potential of chimeric design also provides flexibility and versatility for bone reconstruction. We aim to describe outcomes after MFC flap treatment of phalangeal or metacarpal bone defects.

Methods: A retrospective chart review was performed on all patients undergoing Free MFC flaps by between March 2012 and August 2018. Patient demographic data intraoperative, and postoperative data were collected.

Results and Conclusions: We identified 12 patients for inclusion (8 phalangeal bone and 4 metacarpal reconstructions) treated with the MFC flap for diagnoses including bone defect (8) bone tumor (2), congenital deformity (1) and nonunion (1). There were 7 males and 5 females, aged from 4 to 54 y/o (28.8 years in average). Follow-up time was from 2 to 34 months (10.6 months in average). With regards to the flap design, there were 3 chimeric osteocutaneous flaps, 7 periosteocancellous flaps, 2 periosteal flaps. Bone union was achieved in all the patient at 5 to 18 weeks postoperatively (8.1 weeks in average). There were no intraoperative flap complications or donor site morbidity.

Conclusions: Phalangeal or metacarpal bone reconstruction using the MFC flap results in a fast bone regeneration and union with minimal donor morbidity.

Spare-part surgery for reconstructing a basic hand function

List of authors:
Alperen Bingöl¹, Tobias Mett¹, Ramin Ipaktchi¹, Andreas Jokuszies¹, Nicco Krezdom¹, Peter Vogt¹
¹Hannover Medical School (Hannover)

Objectives / Interrogation: Spare-part surgery became widely known and recognized in the reconstruction of extremities after devastating injuries or illnesses. Despite the mutilating character of the surgical procedures, they still are of big importance. Sometimes they offer the surgeon and the patients an option for reconstructing basic functions. Because of the absence of standardized techniques, the surgical therapy must be customized for the patients. With this case we present a reconstruction of key grip hand function by using spare-part surgery.

Methods: Necrosis of both feet, the left forearm and the distal part of the right hand occurred in a patient due to high-dose catecholamine therapy and septic thrombo-embolization. We used the lower leg as a free osteocutaneous flap to reconstruct a basic hand function after amputation of nearly all extremities. Parts of the fibula were located alongside the remaining first metacarpal bone. Osteovascular on top-plasties were performed by docking two of the metacarpal stumps onto the remaining two metacarpals. Due to thrombosis of the princeps pollicis artery, a venous interposition graft from the right forearm was dissected and used. Furthermore, the flap was microsurgically anastomosed end-to-side to the ulnar artery which was the only remaining arterial supply to the hand. The size of the buried fibula was reduced to the necessary thumb length and fixed to the metacarpal I stump in a next step. Secondary procedures like z-plasties were performed optimize the results.

Results and Conclusions: After all the surgical procedures and fitting of the necessary prosthesis, the patient is now able to manage most of the daily life. The patient can grasp objects and even write, after fixing a pen in the first webspace. This is the first description of successful microvascular transfer of a wrap-around type osteocutaneous free flap from an amputated lower leg to our knowledge. This technique might be useful in similar cases in the future.

Large Schwannoma of the Median Nerve at the Distal Third of the Forearm-Case Report

List of authors:
Dejan Vulovic*
1 Clinical Centre Kragujevac Centre for Plastic Surgery (Kragujevac)

Objectives / Interrogation: Schwannoma is a rare nerve benign tumour, called by a German physiologist Theodor Schwann. Tumour develops from the Schwann cells of the nerve sheath. There is also a malignant form of the schwannoma, but it is very rare (about 1%) Schwannoma can occur anywhere, but the most often it affects the vestibular nerve. Different sizes of the peripheral nerves schwannoma are described. So, the aim of this report is to present relatively rare and large form of this tumour at the median nerve.

We present the case of a 46 years old male patient with subcutaneous visible tuberous tumour of the anterior region on the lower border of the distal third of left forearm, which existed about one year. Tumour was round, well-defined, soft, non-pulsatile, painful on palpation. Ultrasound and MRI examinations were done. Under the tourniquet control, extirpation of the tumour was done with complete preservation of the median nerve. Dimensions of the tumour were 5.1x4.8x3.8cm. Pathological examination, including immunohistochemistry, showed benign schwannoma. One year after the surgery, there were no signs of recurrence, and hand function was normal.

Methods: Case report.

Results and Conclusions: Schwannoma, also known as neurilemmoma, is the most common peripheral nerve tumour. This tumour is seen in all ages, both sexes, and in all regions of the body. This is a solid tumour. Growth of the schwannoma is slow, and often painless. Median nerve is described as one of the localization of the schwannoma. Other tumours of this nerve are also possible. The term large tumour is usually used when it affects significant part of the organ or some region.

Every subcutaneous mass should be taken seriously, especially if it is long lasting, large, and located in some specific parts of the body. Besides careful physical examination, additional diagnostic procedures are sometimes necessary, such as ultrasound, CT and MRI. Distal forearm and hand are one of important regions because of the fact that many different structures are located on small areas. Proper diagnostic procedures, surgery under tourniquet control and trained surgeon for hand surgery, as well modern histopathological examination are mandatory. Despite the fact that many common subcutaneous masses in this regions, such as lipoma and ganglion are the more frequent, detailed examination should be done before surgery, as we can see from this relatively rare case.

Propionibacterium acnes infection: a first reported case in the native wrist joint

**List of authors:**
Andrew McKean*, Angelos Assiotis¹, Sami Hassan¹, Michael Elvey³, Luke Moore³, Rupert Eckersley¹
¹ Chelsea and Westminster Hospital NHS Foundation Trust (London)

**Objectives / Interrogation:** Propionibacterium acnes (P. acnes) is an anaerobic organism that commonly colonizes the human skin. It is the most prevalent organism associated with deep prosthetic shoulder joint infections. It has never been implicated in rapidly progressive arthritis of the native wrist joint.

**Methods:** A 59-year-old retired, right hand dominant office worker was referred with a 6-week history of progressive pain and swelling in her left wrist after multiple local healthcare visits. There was no history of preceding trauma, foreign travel and tuberculosis contacts. She was systemically well and denied any constitutional symptoms. Clinical examination found pain on palpation over the radiocarpal and distal radioulnar joints, with diffuse swelling over the dorsum of her wrist, and an exaggerated pain response to both active and passive range of movement.

Serial radiographs showed rapidly progressive degenerative changes within the wrist along with raised inflammatory markers suggesting possible underlying infection. She underwent urgent exploration, washout and bone/synovial biopsies for microbiology and histological analysis prior to administration of antibiotics. Prolonged enrichment culture specimens grew P. acnes. Fungal cultures, acid alcohol fast bacilli cultures and histopathology were all unremarkable. She was commenced on 6 weeks of oral co-trimoxazole. Her acute symptoms and inflammatory markers improved.

**Results and Conclusions:** We describe a case of rapidly progressive arthropathy of the native wrist secondary to infection with P. acnes. This is the first time this has been described in the literature. It is imperative to request and wait for prolonged enrichment cultures to aid microbiological diagnosis.

Treatment of Distal Radius Fractures by Wrist Prosthesis

List of authors:
Jean-Luc Roux*
1 Institut Montpellierain de la Main, Clinique Saint Roch (Montpellier)

Objectives / Interrogation: Management of distal radius fractures (DRF) by wrist prosthesis is a solution proposed by some French surgeons in cases of comminuted intra-articular fractures in the elderly. This concept has long been used successfully in the hip, shoulder, elbow. We report our experience with a replacement and resurfacing prosthesis of the distal radius.

Methods: Since 2005, 29 prostheses were implanted on 29 patients (27 women and 2 men), the mean age was 77 years old, from 38 to 102. 27 cases concerned elderly and osteoporotic women: 22 times for complex intra-articular fractures and 5 times for malunions. In 2 cases the procedure concerned men: a middle-age with low functional demand and complex intra-articular fracture, a young man with a pathologic fracture (Giant cell tumor).

Results and Conclusions: 25 patients were reviewed with one year follow-up. A 90 years old woman died 4 months after surgery, she retained a good result at the wrist. 3 patients have less than 1 year of follow-up. 20 patients were satisfied or very satisfied, 4 patients were moderately satisfied, 1 patient was dissatisfied. 16 patients had no pain (VAS=0), 8 patients complained of pain during strength activities or barometric pain, 1 patient was painfull with a CRPS. DASH score was 26. Mean mobilities were: extension 62°, flexion 37°, ulnar deviation 26°, radial deviation 21°, pronation 72°, supination 68°. Mean strength was 79 % of the controlateral strength. The implants were perfectly stable on the x-rays, in 16 cases we found peri-prosthetic ossifications. At the longer follow-up, none of the prosthesis needs a revision. A Darrach procedure was performed for a painful DRUJ, after 3 years of follow-up on a patient with rheumatoid arthritis.

The optimal treatment of complex DRF in elderly is controversial. Wrist hemi-arthroplasty is a simple solution particullary indicated when metaphyseal instability and intra-articular comminution are associated. The clinical results are obtained more quickly and with fewer complications than with ORIF. Other French surgeons have designed prostheses for DRF. These prostheses replace only the distal carpal facet and not the sigmoid notch, so a distal ulna resection must frequently be associated.

Management of DRF by a prosthesis is a solution we can now propose in elderly, particularly in cases of intra-articular comminution and metaphyseal instability. Our choice prosthesis is an hemi-arthroplasty resurfacing not only the carpal facet but also the sigmoid notch.

Dorsal wrist ganglion in teenager: what else is there?

List of authors:
Carla Ricardo Nunes*, Pedro Xavier Fernandes¹, Joaquim Rodeia¹, Raquel Teixeira¹
¹ Hospital São Francisco Xavier (Lisbon)

Objectives / Interrogation: Dorsal wrist ganglions may be related to underlying wrist pathology. They are not often described in paediatric population. The purpose of this study was to evaluate their clinical presentation, associated lesions and outcome.

Methods: We evaluated retrospectively the patients operated between April 2012 and June 2018, with a 15.6 months follow up. There were 8 patients, average age 15.6 (10 to 19), 5 female and 3 male. All had a ganglion cyst emerging from the scapho-lunate space and pain during activity. Four practiced sports regularly and 2 competition sports. These 6 reported relevant traumatic events as the origin of the ganglion cyst. Of these 3 had clicking while eliciting the Watson test, but not a clear positive test. There were no other signs of instability or ulnar border pathology. None had range of motion loss. Simple and stress x-rays were normal. Three had MRI which was negative for ligament injuries.

Results and Conclusions: The patients were submitted to wrist arthroscopy, dry technique, observing radio-carpal and mid-carpal compartments. In all cases the cyst was debrided through the mid carpal radial portal with a shaver. Four (50%) had luno-triquetral instability and were submitted to arthroscopic capsule-ligamentous repair though a volar portal, using 3-0 pds suture. One of these had a TFCC type IB distal tear (Atzei classification) repaired with suture. The other 4 had no wrist pathology other than the cyst. None had scapho-lunate instability. Post operative protocol was for those with instability 6 weeks in a short upper limb cast and physiotherapy and gradual increase in strength for the following 6 weeks. For the simple cysts was 3 weeks in a Robert-Jones bandage and gradual return to usual activity.

There was one recurrence in a simple cyst. There were no other complications. All were pain free and back to their previous activities, including sports, at 3 months time.

Symptomatic ganglion cysts in paediatric population may often have underlying pathology. All those with luno-triquetral instability reported sports practice and relevant trauma. Luno-triquetral tears may have unclear manifestations such as ganglion cyst and clicking while testing wrist stability. These injuries are often missed in dynamic x rays and MRI.

APPLICATION OF CURRENT CONCEPTS IN HANDLING EXPOSED FRACTURE OF THE HAND; EXPERIENCE AND LOCAL RESULTS

List of authors:
PATRICIO PEREZ*1
1 UNIVERSIDAD DE LA FRONTERA, HOSPITAL REGIONAL DE TEMUCO (TEMUCO)

Objectives / Interrogation: Fractures of the hands' fingers constitute the 1.5% of the urgent consultations, 5% of them correspond to exposed fractures, of predominance in masculine sex (70 - 90%), they present variable severity in function of multiple associated factors. In accordance to literature, there is enough evidence to demonstrate that the infection rate in these lesions is low, being the main factor, the early administration of antibiotics, showing no correlation between debridement time and infection rate.

The objective of this paper is to present the results obtained from the management of exposed hand fractures, performed by general doctors at a local hospital in the Araucanía region, Chile, during the year 2018, applying the classification of Tulipan and Iliyas

Methods: Thirty patients with exposed hand fractures admitted in 2018 were evaluated in the period from January to August of this year; 26 men and 4 women, within an average age of 43 years. All patients received antibiotic prophylaxis with cefazolin + tetanus vaccine, 10 of them classified as I / Ia were handled by general practitioners in a definitive way, patients with more complex lesions were referred to a more complex hospital for evaluation and management by a specialist, of which 6 required pavilion and 4 of them osteosynthesis

Results and Conclusions: During patients' evolution, only 1 of them presented signs of local infection, being managed promptly with ambulatory oral antibiotic scheme, presenting good response and without any surgical intervention needed. From the patients managed in emergency box and in ward, all were kept in serial clinical control, evolving favorably, without signs of infection of the operated site or other associated complications.

From the above, it can be concluded that exposed fractures classified as I-III without modifier, do not require emergency surgical treatment, and can be managed on an outpatient basis, with administration of antibiotic prophylaxis on time, associated with adequate debridement in emergency box.

The application of the new classification of Tulipan has shown promising and consistent results, since a large number of patients could be managed efficiently by general doctors with an adequate prior training, with good and excellent results, achieving the decrease in the need for pavilion and management by specialists, and hence optimize resources.

Comparison of Isokinetic power between Pronator quadratus sparing technique and conventional technique in simple Distal radial fracture using Volar plate fixation

List of authors:
Hyung Gyu Cho*, Byung Taek Kwon¹, Hongje Kang¹
¹ Wonkwang University hospital (Iksan)

Objectives / Interrogation: We compared the isokinetic power between the patients who had pronator quadratus sparing and conventional technique done when they went through internal fixation using volar plate after distal radial fracture.

Methods: The subjects were the patients who had internal fixation using volar plate done for simple distal radial fracture in our hospital from January 2014 to January 2016 and whose follow-up was available more than at least 6 months. The subjects were 34 patients whose muscle power was measured 6 months after the surgery. 16 patients who had pronator quadratus sparing technique done were classified into group 1, while 12 patients who had pronator quadratus excised as the conventional way were classified into group 2. We compared pronation, supination, grip strength which were measured at the time of 6 months after the surgery of both affected and unaffected sides in the two groups. We measured isokinetic power to check muscle power. For statistical management and analysis, comparative analysis was done with independent T-test.

Results and Conclusions: The average follow-up period was 21±4.2 months and the average age was 47.3 in group 1 and 50.4 in group 2. The patients were composed of 13 males and 21 females. There was no significant difference between the two groups regarding follow-up period, age and sex. The mean peak torque of pronation power was 84.4% in group 1, compared to the unaffected side, and 73.5% in group 2. The mean peak torque of supination power was 91.7% in group 1, compared to the unaffected side, and 90.8% in group 2, which showed no significant difference between the two groups. Grip strength was 85.3% in group 1 and 81.3% in group 2, which showed no statistically significant difference. Using pronator quadratus sparing technique in internal fixation with volar plate after radial fracture is considered to be able to preserve pronation power.

Keywords: distal radial fracture, volar plate, sthenometry
Is skyline view accurate for detecting protruded screw in volar plate fixation of distal radius fracture? : Compared with intraoperative mobile-mini CT

List of authors:
Kyunghoon Lim*, Byung Taek Kwon¹, Hongje Kang¹
¹ Wonkwang University hospital (Iksan)

Objectives / Interrogation: Our purpose is to compare and analyze intraoperative fluoroscopy (skyline view) and mobile-mini computed tomography (CT) for detecting protruded screw in volar locked plating of distal radius fracture.

Methods: We did a prospectively analysis on 20 patients (6 males and 14 females) who had both intraoperative fluoroscopy (skyline view) and mini CT taken, among the patients who had volar locking plate fixation for distal radial fracture at our institution from January 2017 to March. In all cases 4 to 5 locking screws were used at distal row to fix the plate, and skyline view and mobile-mini CT were undergone before pronator quadratus and skin suture. After axial view parallel to the screw was reconstructed on CT, distance between screw tip and dorsal cortex (STCD: screw tip cortex distance) was measured by saving the images on PACS. STCD measured by mobile-mini CT and skyline view were compared.

Results and Conclusions: In skyline view, STCD was 1.68mm, 2.08mm, 2.16mm, 2.84mm, 4.51mm from radial side, respectively. In mobile-mini CT, it was 1.79mm, 1.22mm, 1.20mm, 1.62mm, 5.79mm, respectively. Regarding the 2nd and 3rd screws, STCD measured by skyline view was significantly longer compared to that by mobile-mini CT (p value<0.05). 2 cases showed protruded 3rd screw in CT, while they did not seem so in skyline view. These screws were replaced with shorter ones. In our study, screws looked less protruded at skyline view compared with mobile-mini CT. Additional caution is needed especially when inserting 2nd and 3rd screw.

Keywords: distal radius fracture, volar locking plate, skyline view, mobile-mini CT
Cost Analysis of Trigger Finger Release Performed in Clinic versus in the Operating Room

List of authors:
T J France*1, Sonu Jain1
1 Ohio State College of Medicine (Columbus)

Objectives / Interrogation: Trigger finger release (TFR) is a simple hand procedure that has routinely been performed in the operating room (OR) under sedation but is now being more frequently done as wide-awake, local anesthetic, no tourniquet (WALANT) surgery. This study seeks to compare hospital and patient costs, as well as payer reimbursement for both single and multiple TFRs performed in the office versus in the OR.

Methods: We reviewed patients having received TFR by board-certified hand surgeons from January 1, 2015 to January 1, 2018. Cost data were compiled in the form of direct and indirect costs, and stratified according to the number of TFR each patient underwent. In addition, payer information and reimbursement rates were calculated.

Results and Conclusions: There were a total of 523 patients included: 477 in the OR and 46 in the clinic. Of the OR group, 359 (75%) underwent a single TFR that incurred an average cost of $997. The total average cost of 2 and 3 simultaneous TFR in the OR group was $1200 and $1558, respectively. The cost for single and multiple TFR in the clinic group is fixed between $111 and $115. Payer reimbursement for the OR group was between $778-$2293 (78-230% of cost) for one TFR, $600-$2676 (50-223% of cost) for two simultaneous TFR, and $0-$2726 (0-175% of cost) for three simultaneous TFR. For the clinic group, payer reimbursement was between $272-$895 (240-790% of cost).

TFR in the clinic compared to the OR had an overall cost reduction of $882 for a single finger and up to $1443 for three fingers. On average, reimbursement varied greatly depending on payer type (commercial, Medicaid, Medicare, self-pay, worker’s comp, and other). As a percentage of cost, payer reimbursement for clinic TFR was consistently greater than that for OR TFR independent of the number of fingers released. The higher payer reimbursement percentage in addition to lower overall cost for clinic TFR decreases the cost transferred to the patient. Overall, the office setting can provide a significant cost savings benefit to both hospital and patient, and should be considered for routine TFR procedures.

Harvesting the sural flap with covered pedicle: outcomes and advantages in 7 cases

List of authors:
Alvaro Baik Cho*1, Carlos Henrique Vieira Ferreira2, Priscilla Goes Medea de Mendonça2, Luiz Sorrenti1, Leandro Yoshinobu Kiyohara1
1 IOTFMUSP, Grupo de Mao e Microcirurgia da FMABC (Santo André)
2 Grupo de Cirurgia da Mao e Micocirurgia da FMABC (Santo André)

Objectives / Interrogation: To evaluate the feasibility of harvesting the sural flap with a skin extension covering the pedicle, analysing the flap survival rate and the potential benefits of this modification

Methods: A prospective cohort of 7 consecutive cases were evaluated in terms of flap viability and the amount of skin graft required to cover the pedicle or donor site of the flap. Of these patients six were male and one female. 01 flap was performed for a tumor lesion, 01 for post-operative coverage of achilles tenorrhaphy and 5 for post-traumatic lesions. Seven patients were treated for soft tissue defects located at the middle third of the tibia, ankle or hindfoot. The flap design was exactly the same as described by Masquelet (1992). The only modification was the inclusion of a strip of skin (1 to 2 cm in width) over entire length of the dissected the pedicle, so the final shape of the flap was similar to a long racquet. After the flap elevation, the intermediary skin between the donor site and the soft-tissue defect was incised and the skin was undermined to accommodate the pedicle without any undue compression or tension. The flap was inset and sutured at the defect and the skin over the pedicle was also suture to the undermined skin

Results and Conclusions: All cases had a satisfactory evolution, with adequate healing of the wounds and flaps' integration. The donor site was primarily closed in all cases and a minimal amount of skin graft was required in 2 cases, at the base of the pedicle. In one patient the flap developed a superficial epidermolysis in the distal tip that healed by secondary intention without need for further intervention. The inclusion of a strip of skin covering the pedicle of the sural flap was feasible, without any technical issues. This modification did not negatively impact the survival rate of the flaps and provided an easier and safer accommodation for the flaps' pedicles, since none of the pedicles were tunneled. It also diminished the necessity for skin graft at the pedicle

sural flap, soft-tissue defects, leg, pedicle coverage
Surgical Anatomy of Medial Femoral Based Vascularized Bone Graft Arterial Pedicle

List of authors:
Nicholas Pulos*, Alexander Y. Shin¹, Allen T. Bishop¹
¹Mayo Clinic (Rochester)

Objectives / Interrogation: The arterial anatomy of the medial femoral condyle (MFC) vascularized bone graft has been extensively studied in cadaveric specimens. Both the descending genicular and superomedial genicular vessels can be used as the dominant pedicle to the vascularized medial femoral condyle and trochlea grafts. A majority of cadaveric studies have limited numbers of specimens but data from these studies are extrapolated to the surgical environment. The purpose of this study is to evaluate the vascular anatomy of the medial femoral condyle to correlate surgical experience to cadaveric data.

Methods: A retrospective review of operative reports was conducted of medial femoral condyle and trochlea vascularized bone grafts performed by the senior two surgeons between 2005 to 2018 at the Mayo Clinic, Rochester. A total of 95 patients were included in the study. Operative reports were reviewed to determine arterial anatomy as well as dominant pedicle harvested. Demographic data, preoperative diagnosis and type of graft harvested were collected.

Results and Conclusions: The descending genicular artery off the superficial femoral artery was the dominant pedicle, encompassing 76.8% of all donor vessels. 77% of MFC cases (68 of 88 total) utilized the descending genicular. It was also dominant for medial femoral trochlea bone grafts with 5 out of the 7 (71.4%) cases. The superomedial genicular artery was the dominant pedicle in 23% (22 of 88 total) of all cases. Within this group, there were 6 patients who did not have a descending genicular branch thus necessitating the use of the alternate pedicle. The primary finding for all patients in whom the descending genicular was not utilized was inadequate vessel caliber. The superomedial genicular artery was absent in 2% (2 of 95 cases). Pedicle length was adequate for all cases.

Arthroscopic reduction/Internal Fixation for common articular fractures of the Metacarpophalangeal joints

List of authors:
Alejandro Badia*1
1 Badia Hand to Shoulder Ctr (Doral)

Objectives / Interrogation: Fractures of the Metacarpophalangeal joints (MCP) are relatively common but frustrating fractures to address surgically. This can include Thumb bony skier’s thumb injuries, diepunch fractures of the proximal phalanx bases, or articular dome fractures of the metacarpal head amongst others. Lesser fractures, including ones with small fragments, are often treated conservatively with unpredictable clinical results, while more severe fractures are addressed via extensile open approaches where the treatment may be as deleterious as the fracture itself.

Methods: ARIF (arthroscopic assisted reduction/internal fixation) utilizes a minimally invasive approach via a 1.9 scope (Nexus Salt Lake City, UT) where visualization of the fracture site is superior to open means, associated soft tissue lesions and synovitis can be addressed, and anatomic reduction is superior due to direct observation of the articular surface at time of stabilization. Applying internal fixation via percutaneous technique, with arthroscopic visualization, also avoids the consequent stiffness that invariably results from violating the joint capsule/Sagittal hood in open surgery.

5 representative clinical cases will be presented to outline the basic principles of this methodology designed to leverage newer small joint technologies to encourage superior clinical outcomes.

Results and Conclusions: Arthroscopic reduction followed by internal fixation is a superior method for obtaining an anatomic reduction of a critical joint surface for hand function. Arthroscopy provides superior visualization, allows concomitant soft tissue injury management, synovectomy and better confirms the quality and accuracy of the articular reduction. Surgeons should begin to train in small joint arthroscopy methods in order to provide patients with the best option for these challenging fractures of the MCP.

Botulinum toxin injection as a prediction of surgical outcomes in cerebral palsy patients with upper limb deformities

List of authors:
Josephine Wing-Yuk Ip*¹
¹ Queen Mary Hospital, The University of Hong Kong (Hong Kong)

Objectives / Interrogation: Many studies report the outcome of hand function after treatment with botulinum toxin type A injection in the management of spastic CP deformities. Upper limb surgeries in carefully selected cerebral palsy patients as surgical interventions tend to improve their activities of daily living and quality of life. The aim of this study was to review our results of management of upper limb deformities in cerebral palsy patients with a view to using botulinum injections as a prediction of surgical outcomes.

Methods: This was a retrospective review of 25 consecutive CP patients who had intramuscular botulinum toxin type A injection (Botox® (BTX-A), Allergan, Ireland) or surgical correction or both for spastic deformities of the upper limbs from June, 1982 to October, 2010 at the Duchess of Kent Children Hospital (DKCH). There was no standardised management protocol as treatment was tailored to meet the specific needs of each patient in terms of dose of BTX-A injection, sites of intramuscular injection, interval between doses, number of injections, physical therapy sessions, types of splints used and required number and nature of surgical procedures needed.

Results and Conclusions: For group A (n=13), the mean increase in AROM of the wrist joint was 21.15 degrees while for group B (n=9), it was 60.56 degrees (t=2.850; p 0.010). In group A (n=15), the mean increase in the House score was 1.27 as against that of group B (n=10) which was 2.10 (t=1.287; p 0.211)

The use of BTX-A injection and surgical interventions are beneficial to CP patients with spastic upper limb deformities, when indicated, as evidenced by the improvement in the range of motion of a joint and functional outcome of the upper limbs using the HFCS.

The long term benefit of surgical correction (with BTX-A injection) in improving the AROM of the wrist joint is at least three times better than that obtained from BTX-A injection alone

Does Ligament Reconstruction and Tendon Interposition (LRTI) destabilise the carpus?

List of authors:
Sten Deschuyffeleer*, Luc De Smet
1 University Hospitals Leuven (Leuven)

Objectives / Interrogation: Ligament Reconstruction and Tendon Interposition (LRTI) is a commonly performed surgical intervention for trapeziometacarpal osteoarthritis. It entails removal of the trapezium, thus damaging the scaphotrapeziotrapezoid (STT) ligamentous complex. Despite the common use of this intervention, little is known about its effects on carpal stability. Only one retrospective study has actively researched this subject, analysing 22 wrist undergoing trapeziectomy as part of a variety of procedures, with a follow-up of 8.5 months. Results showed significantly increased radiolunate (RL) angles and revised carpal height (RCH) ratio. No corrections for differences in wrist flexion between pre- and postoperative radiographs were made. We present the results of the first prospective study specifically analysing the effect of LRTI on carpal stability.

Methods: 58 patients were enrolled, of which 25 were excluded because of loss to follow-up or inadequate radiographs. Pre- and postoperative PA and lateral radiographs from 34 wrists with a follow-up of at least one year were analysed for radioscaphoid (RS), radiolunate (RL), and radio-third metacarpal (RMC3) angles, as well as the revised carpal height (RCH, Natras method). The effect of wrist flexion (as measured by the RMC3 angle) on the RL angle was corrected for by subtracting half of the difference in RMC3 angle from the RL angle. Statistical analysis of the change in SL angle, RL angle and RCH was done with the paired t-test.

Results and Conclusions: We found a change in SL angle from 56.3° preoperatively (SD 10.1) to 56.8° postoperatively (SD 11.1), p = 0.7. The change in RL angle (uncorrected for wrist flexion) was from 6.0° (SD 9.4) to 7.4° (SD 11.8), p=0.4. When correcting for wrist flexion, the change in RL angle was from 0.3° (SD 13.5) to 3.2° (SD 11.8), p 0.04. There was no significant change in RCH, as the ratio changed from 1.61 to 1.58; p=0.3).

In conclusion, we found no statistically significant changes in SL angle or RCH, and a statistically significant but clinically insignificant change of the RL angle. These results seem to suggest that the short-term development of carpal instability should not be a concern after LRTI. Limitations of this study are the relatively short follow-up time, small sample size and the variation in wrist flexion between pre- and postoperative radiographs.

Capitellum fracture sequelae treatment

List of authors:
Óscar Izquierdo1*, Pilar Aparicio1, Enric Domínguez2, José Torres1, Juan Castellanos1
1 Parc Sanitari Sant Joan de Déu (Barcelona)
2 Consorci Mar Parc de Salut (Barcelona)

Objectives / Interrogation: Treatment for the sequelae of capitellum fractures is not commonly described in the literature. Anconeus interposition arthroplasty has been described as a technique to treat radiocapitellar arthritis as well as joint replacement.

We present a unique case of a capitellum reconstruction with a vascularized osseous graft from the second metatarsal bone.

Methods: A woman of 53 years old fell down and presented a capitellum fracture that was fixed with two cannulated screws, after 6 months the radiograph showed signs of necrosis of the capitellum, the patient was disabled and a surgery was offered. We reconstructed her capitellum by means of a vascularized osteochondral flap from the second metatarsal bone, and end-to-side anastomosis to the radial artery was performed and two cannulated screws were used to fix the graft to the humeral lateral column. The patient required 2 operations after the reconstruction, one because of diastasis of the olecranon osteotomy, the second because of a superficial infection which was solved with local debridement and oral antibiotic.

Results and Conclusions: After one year the range of movement is -30°-110° with complete pronosupination, and no pain.
Anconeus interposition arthroplasty and joint replacement have been described as palliative methods for treating the radiocapitellar arthritis, however the new treatment we describe is based on microsurgery techniques and provides a more anatomical solution to this severe problem in a young, active patient.

Digit preservation treatment for type IIIB or IV hypoplastic thumb using a non-vascularized metatarsal transfer and staged reconstruction

List of authors:
Bo Liu*, Shanlin Chen1, Pengcheng Li1, Jin Zhu1
1 Beijing Ji Shui Tan Hospital (Beijing)

Objectives / Interrogation: The patients of severe types (Blauth type IIIB and IV) of hypoplastic thumb are classically treated by pollicization. However, pollicization is not equivocally acceptable due to differences in parents’ expectations. Furthermore, the concept of a 4-digit hand is culturally unfavorable, particularly in Asian countries. The objectives of this study was to introduce the method of digit preservation treatment for type IIIB or IV hypoplastic thumb using a non-vascularized metatarsal transfer and staged reconstruction and report the early results.

Methods: From June 2013 to June 2016, a digit preservation treatment method was performed for 42 type IIIB and IV hypoplastic thumbs using a non-vascularized metatarsal graft and staged functional and aesthetic reconstruction. The 4th metatarsal was transferred for the reconstruction of the 1st metacarpal and CMC joint. The iliac bone graft or half of the 3th metacarpal was used to reconstruct the donor metatarsal defect. The Huber procedure or the ring finger FDS transfer was performed at the second stage for opponensplasty. The free fat graft or local flap was performed to improve the cosmetic appearance of the reconstructed thumb as required.

Results and Conclusions: Thirty-three cases had complete follow up data. The average follow-up was of 27 months and the average age at operation was 19 months. All patients achieved reasonable hand function and all the parents were satisfied with the appearance of the 5-digit hand. There were 3 partial skin flap necrosis at the recipient site. There is one bony nonunion at the recipient site and healed with iliac bone graft. There was no obvious complication at donor site. The staged functional and aesthetic reconstruction is a feasible method for patients with type IIIB and IV hypoplastic thumb. It allows the preserving of a 5-digit hand with acceptable functional and cosmetic outcome.

Osteoid Osteoma of the Carpal bones

List of authors:
Wakako Sakamoto1, Keikichi Kawasaki1, Yasuo Yoshida2, Katsunori Inagaki1
1 Showa University (tokyo)
2 Showa University, Shiroyama Hospital (tokyo)

Objectives / Interrogation: Osteoid osteoma predominantly develops in the cortex of long bones and the spine, but rarely in the carpal bones. We report two cases of osteoid osteoma in the carpal bones, one in the hamate and another in the capitate.

Methods: Case 1] A 10-year-old girl who danced hip-hop presented with pain and swelling in the back of the right hand 1 month earlier. The ROM associated with pain was 45° for dorsiflexion (DF) and 60° for palmar flexion (PF). X-ray revealed sclerosis in the hamate. CT revealed a concave area in the cortex of the articular surfaces of the hamate and triquetrum, with shadows indicating bone fragments. T1- and T2-weighted MRI revealed decreased intensity at the same site. As she reported that she often spun on her hands during dance performance, osteochondritis dissecans of the articular surfaces of the hamate and triquetrum was initially suspected; thus, conservative treatment was initiated. However, the pain did not improve after 6 months, and X-ray revealed bone atrophy. As aspirin was markedly effective, osteoid osteoma was suspected, but no tumor was detected in the CT-guided biopsy. One year after the initial visit, she underwent curettage of the hamate followed by iliac bone grafting, which improved the symptoms.

Case 2] A 29-year-old male firefighter presented with a chief complaint of pain in the left hand. Six months earlier, pain occurred on the ulnar side with no apparent cause, which made push-ups difficult and led to his visit to our hospital on referral by his local physician. The dorsum of his left hand was mildly swollen, with tenderness on the dorsal aspect of the capitate. The pain ROM as 80°/70° = DF/PF. The grip strength relative to the unaffected hand was reduced to 78%. Pain intensified at night but was alleviated by Bufferin. CT and contrast-enhanced MRI revealed a nidus in contact with the articular surfaces of the capitate and hamate. En bloc excision was performed via the dorsal side under conduction anesthesia, immediately followed by CT to confirm that the nidus had disappeared. The pathological examination results were assessed, and iliac bone grafting was later performed. On pathological examination, a newly formed osteoid was found. Complete bone healing was observed. At 13 months later, the pain had disappeared. The ROM was still mildly restricted, but the grip strength increased to 105%. Imaging results indicated no tumor recurrence and bone healing.

Results and Conclusions: Though rarely, an osteoid osteoma can be accompanied by pain and swelling in the hand.

RegJoint disc spacer use in traumatic trans MCP joint amputation of index finger - CASE REPORT

List of authors:
Tea Jedlovcnik*, Bostjan Lah
1 General hospital Novo mesto (Novo mesto)

Objectives / Interrogation: RegJoint is an implant made of bio absorbable material. Indications for implantation is arthroplasty of small joints in hand and foot, following joint destruction because of rheumatoid arthritis or osteoarthritis. In our case 55-year-old patient was administrated after total trans-MCP joint amputation of the left index finger and loss of articular surface on the head of second metacarpal bone. RegJoint implant was used in primary reconstruction of the second MCP joint.

Methods: We performed replantation of left index finger. X-ray image made preoperatively, indicated in destruction of articular surface of the second metacarpal bone head, which was confirmed during operation. Plan was to keep some mobility in the injured MCP joint after replantation. Methods at our disposal were: interpositional arthroplasty with tendon spacer made of FCR or PL, Swanson finger joint implant and RegJoint disc spacer implant. We decided to use RegJoint implant for arthroplasty of the injured joint, because we wanted to avoid making an additional trauma to the hand, and because we have great results using it in threatening rizarthrosis. Postoperatively patient underwent through standard rehabilitation program. Progress was evaluated using VAS, ROM, TAM and QuickDASH score, 2-PD test and aesthetic aspect was observed. First evaluation was made after 12 weeks. 20 weeks after replantation tenolysis was performed due the lack of motion, it was discovered that adhesions between FDP and FDS formed and re-rupture of FDP occurred. Again patient went through rehabilitation program.

Results and Conclusions: Patient was followed throughout rehabilitation. After 12 weeks results were - TAM (5°), QuickDASH (54,5). 20 weeks after the tenolysis was performed. At the end of the rehabilitation program, 26 weeks after, patient was subjectively happy with the result and without pain. TAM (50°), QuickDASH (45,4), VAS (0).

RegJoint can be considered in primary reconstruction of the small joint after hand injury. In this case it is an option in threatening some kind of intraarticular fractures as an alternative to arthrodesis.

Quantitative relationship between palmar contact forces and carpal tunnel pressure

List of authors:
KAZUTOSHI KUBO*1
1 Showa University Hospital (Shinagawa-ku Hatanodai)

Objectives / Interrogation: Carpal tunnel syndrome is the most common entrapment neuropathy occurring in upper limbs. The etiology, however, has not been fully understood yet. The increase of carpal tunnel pressure is considered as the common pathophysiological pathway. It has been identified that forces applied to the palm would affect the carpal tunnel pressure. However, the quantitative relationship between the palmar contact force and carpal tunnel pressure is not well known. The purpose of this study was to quantitatively evaluate the relationship of palmar contact forces and carpal tunnel pressure.

Methods: Eight human cadaver hands were used. The carpal tunnel pressure was measured with a diagnostic catheter-based pressure transducer inserted into carpal tunnel. A custom made device was used to apply forces to the palm until the desired carpal tunnel pressure was attained. Palmar contact forces corresponding to the determined carpal tunnel pressure level were recorded respectively. The testing was repeated with different ranges of tension applied to the flexor digitorum superficialis tendon of the third finger. The tensions were constant at 50 gram for the other flexor tendons and median nerve. Statistically, two-way ANOVA of repeated measures were used to compare the palmar contact forces between tendon tensions as well as carpal tunnel pressures. Pair-wise comparison was conducted through post-hoc Bonferroni test. In addition, in order to build the quantitative relationship between palmar contact force and carpal tunnel pressure, linear fitting was implemented to find out the equation and coefficient of determination was also calculated to determine how fitted they were.

Results and Conclusions: The results showed that carpal tunnel pressure increased linearly with the force applied to the palm. However, no significant increase in applied forces was found when tendon tension increased. When carpal tunnel pressure was 30 mmHg, mean values of the contact force to the palm was 293 (SD: 15.2) gram-force including all tensions. These results would help to understand the effect of daily activities with hands on carpal tunnel pressure. Further evaluation in vivo study is aimed to realize in more detail the relationship between palmar contact forces and carpal tunnel pressure in the future.

Excellent functional recovery of posterior interosseous nerve injury after periprosthetic radial fracture by using antebrachial cutaneous nerve graft

List of authors:
JENTO WANG* 1
1 TAINAN MUNICIPAL HOSPITAL (Tainan city)

Objectives / Interrogation: Background:
The early diagnosis of posterior interosseous nerve (PIN) injury is difficult if combined with bony fracture. Autologous nerve grafting is gold standard when a nerve gap exists, but the result is unpredictable. Aim and Objectives:
We reported a case of periprosthetic radial fracture leading to PIN gap which was reconstructed by ipsilateral antebrachial cutaneous nerve. Excellent functional recovery was achieved at 1-year follow-up.

Methods: A 16-year-old female patient suffered from periprosthetic radial fracture due to repeated trauma over left forearm. During exploration, a 2-cm gap was identified in PIN. Lateral antebrachial cutaneous nerve (LACN) in the same operation field was used to reconstruct the nerve defect by double cable nerve graft

Results and Conclusions: Results:
Comprehensive rehabilitation program and electrical nerve stimulation were initiated since post-operative 2 weeks. One year after operation, full functional recovery was achieved in all digits. No sensory deficit was observed over lateral forearm. Conclusion:
PIN injury in prosthetic radial fracture is rare but noteworthy issue. LACN is an ideal donor nerve with minimal sensory loss. Excellent functional recovery results from early diagnosis, suitable reconstruction, and comprehensive rehabilitation programs.

Keywords:

Should we repair TFCC in distal radius fracture

List of authors:
margaret fok*¹, Christian Fang¹, tak wing Lau¹, Boris Kwok Keung Fung¹, Yin-kwong FUNG², Frankie Ka Li Leung¹
¹ Department of O & T, 5/F, Professorial Block, Queen Mary Hospital (Hong kong)
² Department of Occupational Therapy, David Trench Rehabilitation Centre (Hong kong)

Objectives / Interrogation: Distal radius fractures are associated with a high incidence of triangular fibrocartilage complex (TFCC) tears. Healing of TFCC tears is postulated after anatomical fixation. This study aims to evaluate the status of TFCC after the union of distal radius fractures and to assess its functional outcomes.

Methods: 80 patients who were elected for the removal of implants after union of distal radius fractures were recruited. Concomitant wrist arthroscopy was performed to assess the status of TFCC. Repair of TFCC was attempted for patients with symptomatic distal radioulnar joint (DRUJ) instability. The follow-up period was at least 1 year post wrist arthroscopy.

Results and Conclusions: There were 18 extra-articular distal radius fractures out of 80 fractures. 45 patients had ulnar wrist pain and 54 were noted to have DRUJ instability on examinations. Their average DASH score was 39. The findings of wrist arthroscopies revealed 16 patients with intact TFCC. There were 64 complete tears and 26 incomplete tears showing signs of healing. Tears were significantly associated with DRUJ instability (p=0.02) on physical examination and the presence of ulnar styloid fracture but not with ulnar wrist pain (p=0.28). 32 tears were repaired and 32 were not repaired, based on patients’ symptoms and whether the tear was deemed repairable.

When we evaluated the 3 subgroups, i.e. intact TFCC, unrepaired TFCC tear and repaired TFCC, we found that there was no statistically difference in their pain score, range of movement, power grip and their DASH score prior to the removal of implants. At 12 months post wrist arthroscopy, all groups had significant improvement in pain score, ROM, power and the DASH score, when compared with pre-arthroscopy. In addition, the group with intact TFCC had a significant higher grip strength than the 2 TFCC tear groups, irrespective whether they have been repaired or not (102% vs 85% vs 86% p=0.015) at 12 months. There was no statistically difference in other parameters including pain, range of movement and DASH score.

A large majority of TFCC tears remained to be unhealed after fracture union. Yet their functional outcome may not differ from those with intact TFCC. Repair of all TFCC tears at the time of fracture may be overkill. A delayed repair for those with symptomatic instability appear to give satisfactory outcome.

TFCC, distal radius fracture, wrist arthroscopy, DRUJ instability, ulnar styloid fracture, ulnar wrist pain
Effects of Endoscopic Carpal Tunnel Release on Biomechanical Interactions between the Thenar Muscles and Transverse Carpal Ligament

List of authors:
Peter Evans*, Hui Zhang², Jeremy Loss², Zong-Ming Li²
¹ Cleveland Clinic, A40, Ohio (Cleveland)
² Cleveland Clinic, ND20, Ohio (Cleveland)

Objectives / Interrogation: The purpose of this study was to understand the biomechanical consequence of endoscopic carpal tunnel release (ECTR) on the interactions between the thenar muscles and transverse carpal ligament (TCL) in cadaveric hands. We hypothesized that ECTR would lead to greater changes in carpal arch height (CAH), width (CAW), and area (CAA) under thenar muscle loading compared to the intact condition.

Methods: Three female specimens (aged 60±1 years) without musculoskeletal pathology were dissected to expose the flexor pollicis brevis (FPB), the opponens pollicis (OPP), and the abductor pollicis brevis (APB) for loading. Magnitude for loading was set as 15% of each muscle's maximum physiological force production. Loading directions were determined by the muscle's anatomical orientation with the thumb placed in an abducted and pronated position. Loads on the individual and combined thenar muscles were applied in a randomized order with 30 sec ultrasound videos recording morphological changes at the distal TCL. After initial testing, each specimen underwent ECTR, and the same testing procedures were repeated. Custom LabVIEW programs were used to track carpal arch morphological changes.

Results and Conclusions: The FPB failed alone in one specimen and the FPB and the OPP failed in one specimen. For pre-release hands, APB loading generated a CAH increase of 0.049±0.046 mm, a CAW decrease of 0.23±0.31 mm, and a CAA increase of 0.32±0.24 mm². After ECTR, APB loading generated a CAH decrease of 0.041±0.21mm, CAW increase of 0.35±0.25 mm, and a CAA decrease of 0.53±1.58 mm².

Overall, our preliminary results showed APB loading generated small morphological changes in carpal arch for both the intact and released TCL, suggesting that ECTR may not affect the muscle-ligament biomechanics under low muscle contraction force. The small changes may be explained by the relatively low muscle force of a single muscle. It is likely that synergistic muscle contraction by all three thenar muscles with higher force magnitude would generate more appreciable carpal arch changes, allowing for better understanding of the biomechanical implications of carpal tunnel release. This data will be completed with additional specimens by the time of presentation.

Keywords: wrist surgery, transverse carpal ligament, thenar muscle
Arthroscopically assisted Sauvé-Kapandji procedure for distal radioulnar joint (DRUJ) disorders

List of authors:
Yoon-Soo Kim*1, Takayuki Nemoto1, Koji Iwasaki1
1 Hand Care Center, Ota General hospital (Kawasaki)

Objectives / Interrogation: The Sauvé-Kapandji procedure is useful for treatment of pathological conditions of DRUJ. The purpose of this study was to describe a novel technique of arthroscopically assisted Sauvé-Kapandji procedure. This procedure is many advantages compare with conventional Sauvé-Kapandji procedure.

Methods: The criteria for this procedure for DRUJ disorders were osteoarthritis, chronic instabilities of DRUJ except Rheumatoid arthritis with chronic pain, stiffness, and disability. Arthroscopies of the radiocarpal, midcarpal joint and DRUJ are performed. Make a longitudinal incision along ulnar border of distal ulnar. Exposed the distal ulnar in the interval between the extensor carpi ulnaris and flexor carpi ulnaris tendons. Resect a segment ulnar shaft, which leaves 15mm of ulnar styloid distal and removal of a 10-15mm cuff of ulnar shaft to create an ulnar neutral variance. The ulnar articulation with the sigmoid notch of the radius and articular surface of ulnar head are shaved off cartilage and expose the subchondral bone. If TFCC preserved, we perform using DRUJ approach not to excise from TFCC. After a through debridement of the DRUJ, a bone graft can be placed at the arthrodesis site arthroscopically. The cancellous bone graft can be harvested easily from the segment of ulnar shaft that we resected. The DRUJ is fixed using Kirschner wire (K wire) and cannulated screw. Finally, pronator quadratus interpose in the gap in the ulnar shaft to prevent reossification. Five patients treated with arthroscopically assisted Sauvé-Kapandji procedure reviewed retrospectively. We evaluated functional and radiological outcome. The parameters evaluated modified Inoue's clinical evaluation score included pain (wrist, ulnar stump), range of motion (pronation, supination), grip strength.

Results and Conclusions: Five patients (3 women, 2 men) who sustained DRUJ disorder were treated with a mean age of 60 years. At an average follow-up period 13.4 months, the functional results according to the criteria of modified Inoue's clinical evaluation score were excellent in 4 cases, good in 1 case. In all patients, bone union was obtained. Wrist arthroscopy has been recognized as one of the most effective diagnostic modalities for ulnar wrist pain. The advantages of this technique are exact diagnosis of ulnar wrist pain, its less invasive, preservation of soft tissues, faster rehabilitation, and a better cosmesis.

Treatment for iatrogenic spinal accessory nerve injury by a part of ipsilateral posterior C7 root transfer

List of authors:
yundong shen*, wendong xu1
1 Huashan Hospital, Fudan University, Jingan District Central Hospital (shanghai)

Objectives / Interrogation: Iatrogenic spinal accessory nerve (SAN) injury was one of serious operative complications of cervical lymph node biopsy, cystectomy or thyroid surgery. Comprehensive shoulder pain and weakness were common complaints, and even shoulder abduction paralysis. However, it was not always available to repair the SAN by nerve graft because of the proximal nerve retraction and local scar proliferation. Here an alternative method was introduced about a part of ipsilateral posterior C7 root transfer to repair SAN injury.

Methods: Six cases with iatrogenic SAN injury were included in this study. 4 cases were injured from cervical cystectomy, 1 case from neck lymph node biopsy and 1 case from thyroidectomy. According to the previous anatomic study, the available fascicle length of posterior part of C7 root was long enough to be transposition to the distal end of SAN at susceptible site of injury. Also, an optimal route was designed for part of posterior C7 root transfer. All the operations of 6 cases were performed successfully, and the distal end of SAN was repaired by the C7 fascicle transfer directly without nerve graft. The results of recovery were recorded.

Results and Conclusions: The mean available length of the donor C7 nerve fascicle was 4.3cm in 6 cases. Early signs of reinnervation of trapezius were observed by electrophysiological testing at 3 months after surgery in most cases, the latency was 7-8ms, and improved to 6ms at 6 months postoperatively. The results of electromyography(EMG) of the superior part of trapezius were a small number of nascent motor unit action potentials at 3 months postoperatively, which were about 3 months sooner than that in the middle and inferior parts of the muscle. Complex repetitive discharges were observed by EMG at 9months to 1 year after surgery in all cases. The atrophic trapezius muscle preoperatively had visible signs of improvement from grade M0 to grade M3 at 6 months postoperatively and M4 strength at 12 months after surgery. The comprehensive shoulder pain was reduced greatly at 3 months after surgery in all cases and disappeared by the time of 6 months to 1 year. The method of a part of ipsilateral posterior C7 root transfer to repair iatrogenic spinal accessory nerve injury was an effective alternative approach for those cases in which the proximal nerve of SAN could not be available duration operation.

ARTHROSCOPIC STT OSTEOARTHROSIS TREATMENT

List of authors:
PAu Lopez Osornio\textsuperscript{1}, JOAQUIM CASANAS\textsuperscript{1}, Cristobal Martinez Andrade\textsuperscript{1}
\textsuperscript{1}traumaunit. Centro Medico Teknon (SANT CUGAT DEL VALLES)

Objectives / Interrogation: STT osteoarthritis is the second most frequent localization of degenerative disease of the wrist. Open distal pole resection with or without interposition was the classical treatment. We introduce the STT osteoarthritis treatment performing an arthroscopic distal scaphoid resection.

Methods: From 2012 to 2016, 32 patients have been surgically treated by arthroscopic distal pole resection. Midcarpal radial, volar and dorsal STT portals have been used, age ranges from 42 to 75 yo, 4 males and 28 females. Three cases were associated with a volar cyst. Thumb traction was done in all cases, no tissue or tendon interposition was done. Midcarpal and SL instability was checked and treated when found. Three cases had previously been treated by complete trapecectomy but STrapezid remained clinically affected.

Results and Conclusions: All cases were completely done arthroscopically, mean time for surgery was 42 min. Mean follow up is 2.8 years. Three months postoperative pain relief was achieved in 71% of the cases. Pinch strength was restored between 120 and 80% compared to the contralateral hand in 87% of cases. Grade III and IV Geisler SL instability was surgically detected in 11 cases and shrinkage and cast immobilization was performed. Four cases had recurrences for impairment of SL instability and needed further treatment. Three cases needed secondary surgery because of incomplete volar pole resection.

CONCLUSIONS
STT osteoarthritis when is properly diagnosed it can be treated successfully by arthroscopic distal pole of the scaphoid resection. Better control for SL instability is a clear pearl and simultaneous treatment that can be done. Volar and complete distal pole resection is a challenge for successful results.

Encapsulated Hematoma in hand secondary to cutting wound, in non-hemophilic patient

List of authors:
Solange Ferraguti*¹
¹ hospital de Clínicas (Buenos Aires)

Objectives / Interrogation: Background Encapsulated hematomas are also known as hemophilic cysts, because their presentation is more frequent in patients with this disease patients suffering from this disease. It is a complication that occurs in 1-2% of patients with severe cases of hemophilia, and its presentation in non-hemophilic patients is even more infrequent.

Methods: Materials and Methods An 18-year-old male patient with no relevant medical history, who consulted for presenting a rapid, painful, pulsating growth of a tumor in the palm of his right hand. He had suffered a sharp cut with a glass in the palm of his right hand 15 days before the consultation.

Results and Conclusions: Results The histological image was linked to an encapsulated hematoma. After 10 months from surgery, the functionality of the hand is preserved and painless.
Conclusion The descriptions in the literature are developed around hemophilic patients, and the cases are usually chronic and slow-growing, so the treatments are aimed at preventing this type of injury, and the reduction of its size by anticoagulants. Surgery is indicated only when they are large or aggressive. We consider it to be an infrequent complication of a cutting wound, however it should be considered as an option in persistent and rapidly growing hematomas.

Outcomes of local bone graft and fixation of proximal pole scaphoid non-unions

List of authors:
Chaitanya Mudgal\textsuperscript{1}, Kristin Shoji\textsuperscript{1}
\textsuperscript{1}Massachusetts General Hospital (Boston)

Objectives / Interrogation: Scaphoid fractures often present in delayed fashion as they are frequently perceived as minor wrist injuries. Proximal pole scaphoid fractures are thought to be at increased risk of nonunion due to the tenuous blood supply about this location. It is generally agreed upon that scaphoid waist nonunions are treated with screw fixation and bone graft; however, there are many proposed treatment options for proximal pole scaphoid fractures, and current literature has focused prevalently on vascularized bone grafts. The purpose of this study was to review a single surgeon's experience with proximal pole scaphoid nonunions that underwent surgical fixation with autogenous bone graft and screw fixation.

Methods: After obtaining IRB approval the EMR of one tertiary care center was queried for patients with the diagnosis of "proximal pole scaphoid fractures" over an 11-year period from 2006 through 2017 that underwent surgical fixation by a single surgeon (CSM). Fifteen patients met initial query criteria; upon review of records, 4 patients were excluded due to the acute nature of the fracture and 1 was excluded as surgical fixation included a vascularized bone graft.

Results and Conclusions: The final study cohort consisted of 10 patients with a total of 10 proximal pole scaphoid nonunions. Six patients underwent a pre-operative magnetic resonance imaging (MRI) and two patients were found to have signs of dysvascularity of the proximal pole on MRI. Volumetric measurements of the scaphoid fractures on CT were performed: average total volume of the fracture fragment was $2.4 \pm 0.48 \text{ cm}^3$ and the average volume of the proximal pole fragment was $0.38 \pm 0.15 \text{ cm}^3$. Eight patients underwent local bone grafting, and bone graft was inserted at the site of fracture in 7 patients and in the screw track in 1 patient. Union was documented by postoperative CT scan; seven showed signs of union at the time CT was obtained and three demonstrated partial union. None required additional procedures and there were no complications.

Proximal pole scaphoid fractures are thought to be at an increased risk of nonunion due to the tenuous blood supply. Current literature includes many proposed treatment options for proximal pole scaphoid fractures. The volume of the proximal pole fragment does not seem to correlate with increased risk of nonunion. Proximal pole scaphoid nonunions treated with surgical fixation and autogenous localized bone graft go on to union.

Aesthetic reconstruction of fingers with re-shaped 2nd toe in one-stage operation

List of authors:
Yaping Liu*, Linjun Tang¹, Taian Cui¹, Hua Zheng¹, Shaoyong Zhou¹, Hang Zhang¹
¹ Sichuan Modern Hospital (Chengdu)

Objectives / Interrogation: Although the 2nd toe-to-hand transfer has been the main choice of finger reconstruction since 1965, the reconstructed finger still results in a toe appearance when the 2nd toe was transferred to finger without any re-shape. Various technical refinements have been used to optimize the appearance of reconstructed fingers, but few attempts have been made to define the specific indications for these techniques or for considering which procedures are applicable in certain circumstance. This study was to provide useful guideline for selection of the proper one-stage re-shape procedures of 2nd toe and make the reconstructed fingers present a relatively-normal appearance and perform their functions.

Methods: The 2nd toe was classified, and then one-stage re-shape procedures were proposed for each classification. In total, Fifty-seven fingers with different levels of defects in 41 cases were reconstructed with 2nd toe transfer since 2007. Various surgical procedures were performed to re-shape 2nd toe according its type and the measured data.

Results and Conclusions: Twenty cases were lost to follow-up, and only 21 cases including 33 fingers attained 6 months to 9 years (averaged 4.2 years) follow-up, with 51.2% follow-up rate. We referred to the assessment criteria after toe-to-hand transfer issued by International Federation of Societies for Surgery of the Hand and Hand Surgery Association of China Medical Association, ATM:100°-215°, ADL:15-20 points, Static two-point discrimination: 4-10mm. Eight cases were “very satisfied” with the shape of fingers, and 13 cases were classified as “satisfied”. Twenty fingers out of 13 cases were excellently recovered, and 13 fingers out of 8 cases were acceptable recovered. Totally, 100% of fineness was reached. Conclusions: Therefore, it suggests that the classification and one-stage re-shape procedures of 2nd toe varying with each type are effective to reconstruct aesthetic fingers.

Validation of a Novel Rabbit Model of Compression Neuropathy in the Setting of Perineural Adhesion

List of authors:
Steven Koehler*, Neil Shah¹, Westley Hayes¹, William Chin¹, John Carter¹, Adriano Martins¹
¹ SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)

Objectives / Interrogation: Nerve injury initiates an inflammatory cascade that results in nerve scarring, fibrosis, and adhesions, leading to development of compression neuropathy. Rabbit nerve models more closely mimic human biology. This study sought to develop a novel, rabbit model to simulate compression neuropathy secondary to perineural adhesion.

Methods: Sciatic nerves of five adult, 3-4kg New Zealand White Rabbits were surgically-exposed. Left hindlimbs underwent sham surgery. Perineural adhesions were generated via bipolar electrocautery on 10 mm of the nerve bed, and the epineurium was fixed with microsuture to the cauterized wound bed (right). Rabbits were maintained for six weeks. Exposure of the sciatic nerve was performed bilaterally, with proximal and distal nerve transection, at which point peak pull-out force (N) required to break adhesions via pulley-mounting on a uniaxial biomechanical testing frame was measured.

Results and Conclusions: Scarred nerves required greater peak pull-out force than control nerves (2.51 N vs. 0.50 N, p=0.021).
Peak pull-out force for control and experimental scarred hindlimbs

TA muscle mass was significantly lower in the setting of induced neuropathy when compared to sham surgery (6.56 g vs. 8.52 g, p<0.001). We developed and validated a model to simulate compression neuropathy. Additionally, we created a novel means to measure peak pull-force required to break perineural adhesion as a quantitative surrogate for perineural scar. This model will provide surgeons a validated, animal model to pursue translational study of compression neuropathy.

Microsurgical Approach to the Management of Chronic Osteomyelitis

List of authors:
Linjun Tang¹, Taian Cui¹, Hua Zheng¹, Shaoyong Zhou¹, Hang Zhang¹, Xianhe Li¹, Lin He¹, Yaping Liu¹
¹ Sichuan Modern Hospital (Chengdu)

Objectives / Interrogation: In this study, Microsurgical approach was utilized to manage chronic osteomyelitis in different parts of limbs, and optimal procedure and therapeutic effects were described and discussed.

Methods: During this treatment strategy, local blood supply of the infected skeletal tissues was taken into serious consideration before operation. Necrotic and infected skeletal tissues were debrided. Muscle flap or musculocutaneous flap were transferred to dead space to improve local blood supply. When no suitable muscle flap could be transferred from adjacent area, antibiotic bone cement blocks were filled in the dead space with following skin flap covering. They could provide a highly vascularized soft tissue bed, which can then be used as a future graft repository. Finally multiple modalities were successfully utilized to graft into the soft tissue bed. These measures included the use of autogenous cancellous bone graft, bone graft with vascular pedicle, bone graft with vascular anastomosis, and distraction osteogenesis bone transport techniques. In this study, 89 cases were treated with this approach.

Results and Conclusions: Chronic osteomyelitis of all cases have been successfully treated with this microsurgical approach in this study. With an advantage of improving local blood supply, microsurgical approach has unique superiority to treat chronic osteomyelitis.

Pyrocarbon Hemi- Wrist arthroplasty: 16 cases; Mean follow up two years.

List of authors:
Allan Ibsen Sorensen*, Peter Axelsson1
1 Sahlgrenska University Hospital (Gothenburg)

Objectives / Interrogation: To report our early experiences of a Pyrocarbon Hemi-Wrist prosthesis.

Methods: The RCPI pyrocarbon prosthesis was used for un-cemented hemi-wrist joint arthroplasty. Patients were evaluated pre- and postoperatively for ROM, grip strength and key-pinich. Visual Analogue Scales (0-100 mm) for pain and satisfaction, Quick-DASH and PRWE questionnaires were used as patient reported outcome measures. Radiographs were obtained pre-operatively and at latest follow-up. The procedure was performed in 16 patients (8 men and 8 women). Mean age was 50 years (range 20-68). Mean follow-up was 25 month (range 12-75). The rationale for the procedure was Kienboeck's disease in combination with degenerative arthritis (5 wrists) and posttraumatic arthritis (11 wrists). Five patients had previously undergone wrist surgery. Change between preoperative- and last follow-up measurements were analyzed with Wilcoxon signed rank test.

Results and Conclusions: Wrist extension and flexion were preop 45/40 degrees and at last follow-up (LFU) 40/30 (p=ns). Radial/ulnar deviation was 15/35 degrees versus 15/25 at LFU (p=ns). Grip strength, was preop 19 kgF (range 4-43) and at LFU 26 KgF (range 12-44, p=ns). VAS pain was preop at rest/activity; 55/75 and at LFU; 29/43 (p<.05). Quick DASH and PRWE scores were preop: 60 respectively 67 and at LFU: 38 respectively 32, (p<.05) respectively (p<.01). VAS for Patient's satisfaction were 66 mm (8-100).

No infections was encountered. Two prosthesis were revised, one to a total wrist arthroplasty because of persistent unexplained pain and one to an interposition arthroplasty because of ulnar dislocation of carpus. One patient underwent radial styloidectomy due to impingement. There were no loosening of any implant, but radiolucency in the capitate bone was detected for one patient. There were little change in ROM and Grip strength but significant improvements of pain, Quick DASH, PRWE scores. Patient's satisfaction was comparatively high and we found the complication rate to be acceptable. Our early results indicate that Pyrocarbon Hemi-Wrist arthroplasty could be a viable option in patients with selected types of wrist arthritis.

**Retrograde headless screw fixation for proximal scaphoid non-union with the guidance of preoperative 3D simulation**

**List of authors:**
Kozo Shimada*1, Keiichiro Oura2, Ko Temporin2, Hiroyuki Nakamura3
1 Dept. of Emergency/Sports medicine, JCHO Osaka Hospital (Osaka)
2 Dept. of Orthopaedic surgery, JCHO Osaka Hospital (Osaka)
3 SOAI Orthopaedic Clinic (Takarazuka)

**Objectives / Interrogation:** Surgery of scaphoid nonunion is still challenging especially in case the nonunion site is proximal and wedge bone graft is needed. For proper fixation, we have tried preoperative simulation with 3D guidance obtained by CT. We report a case of retrograde fixation combined with wedge bone graft for proximal scaphoid nonunion with humpback deformity in which the target point is very restricted.

**Methods:** For a case of proximal small fragment of scaphoid non-union with humpback deformity, (Figure1-left, center)

![Figure 1: Preoperative CT and simulation of wedge bone graft](image)

we simulated correction of the deformity with use of contralateral 3D-CT images. We simulated two patterns of guide-pin insertion; After correction by wedge bone graft, 1) usual guide-pin insertion from the scaphoid tubercle and 2) trans-trapezium insertion. This simulation showed the target of the screw was strictly limited in the way of 1), although proper placement of the guide-pin centering both the wedge bone graft and tiny proximal fragment in the way of 2). (Figure1-right)

**Results and Conclusions:** At the operation, the guide-pin was inserted in the way of 2) from mid-trapezium according to the preoperative simulation and reproduced CAD models. (Figure2-left, center)
Figure 2: Simulation of 3D CAD and postoperative radiography

It was penetrated to dorsal wrist and a cannulated headless screw was inserted successfully in retrograde fashion. (Figure2-right) 3D simulation of guide-pin and screw placement simulated by preoperative CT was quite useful for such a difficult case in which the targeting fragment is small and bone graft insertion is also needed.

Pyrocarbon disc interposition for CMC thumb joint osteoarthritis; Difference in use of the FCR or APL tendon?

List of authors:
Cecile van Laarhoven¹, Mark van Heijl², Arnold Schuurman³, Brigitte van der Heijden⁴
1 Erasmus Medical Center (Rotterdam)
2 Diakonessenhuis (Utrecht)
3 University Medical Center Utrecht (Utrecht)
4 Jeroen Bosch Hospital (’s Hertogenbosch)

Objectives / Interrogation: For treatment of CMC thumb joint osteoarthritis, a pyrocarbon disc can be used after distal hemicapitatectomy as interposition arthroplasty. This disc can be secured with either a strip of the Flexor Carpi Radialis (FCR) or Abductor Pollicis Longus (APL) tendon. We analyzed outcomes after both techniques in a large cohort.

Methods: Out of 188 pyrocarbon disc interposition arthroplasties, we analyzed 30 discs secured with the FCR tendon and 76 discs secured with the APL tendon, operated between 2006 and 2011 by 2 independent surgeons. As primary outcome we used Patient Reported Outcome Measurements (PROMs); DASH, PRWHE, MHQ and satisfaction. As secondary outcome we analyzed hand measurements, such as power of grip (JAMAR dynamometer), power of pinch (pinchmeter) and range of motion (Kapandji and pollexograph).

Results and Conclusions: Baseline characteristics of both groups were quite similar. Difference in men and women in the groups was not significant (p=0.150). Mean follow up was 8.1 years for the APL group and 9.1 years for the FCR group. In the APL group 67 discs were in situ at time of follow up, in the FCR group 29 discs. In both groups 35% of the patients had bilateral complaints. Results are shown in image 1.

Table 1. Results for both groups for PROMs and hand measurements. Significant differences are highlighted with red stars.

Results for PROMs and hand measurements for both groups

For the primary outcomes, the PROMs questionnaires, there were no significant differences. For the secondary outcome, the different hand measurements, the FCR-group showed significant better JAMAR, tippinch and abduction, the APL group showed significant better keypinch.

Pyrocarbon disc interposition arthroplasty can be performed with an APL or FCR tendon, both with acceptable results. At long term follow up there were no significant differences in the different measured PROMs. For the hand measurements, grip power, tippench and abduction in range of motion were significant better in the FCR group, and keypinch was significant better in the APL group. When a patient specifically wishes more range of motion and grip power, the use of the FCR tendon can be recommended for pyrocarbon disc interposition arthroplasty.

Proximal Interphalangeal Joint (PIP) Arthroplasty for Osteoarthritis (OA) of the Index Finger

List of authors:
Tomos Richards¹, Laura Ingham¹, Scott Stevens¹, Ian Russell¹, David Newington¹
¹ Department of Orthopaedic Hand Surgery Swansea (Swansea)

Objectives / Interrogation: To determine the durability and functional outcome of PIPJ arthroplasty of the Index finger in patients with Osteoarthritis

Methods: Between 2005 & 2018 46 silastic PIPJ arthroplasties were undertaken in 38 patients at our Hand Unit. All were performed under local anaesthetic ring block. Eight patients underwent PIPJ arthroplasty in both Index fingers. Twenty six women and twelve men made up the cohort with a mean age of 62 years. Six patients had conversion from a previous arthrodesis to arthroplasty.

A retrospective analysis of all patients has been undertaken to determine the clinical results with particular reference to the development of angular deformity in an ulnar direction. Mean follow up was 8.2 years.

Results and Conclusions: Eight index fingers developed ulnar deviation greater than 10 degrees (2 in one patient) and there was one revision for a snapped prosthesis. There was a significant improvement in arc of movement from 10-35 degrees to 5-60 degrees with dramatic improvement in pain/VARs. All patients stated they would undergo their surgery again.

Silastic Interposition arthroplasty of the PIPJ of the Index finger is a durable procedure with excellent clinical outcomes. Our large study refutes the established technique of arthrodesis for Index finger OA with a low incidence of ulnar deviation and excellent patient satisfaction.

Giant cell tumor of the tendon sheath on the digits - functional outcome in tumor recurrence

List of authors:
Laura Siegwart, Valentin Haug, Christoph Hirche, Berthold Bickert
1 BG Klinik, Klinik für Hand, Plastische und Rekonstruktive Chirurgie, -Schwerbrandverletztenzentrum (Ludwigshafen)

Objectives / Interrogation: Giant cell tumor of tendon sheath (GCTTS) is a common benign soft tissue tumor in the hand. Its feature is a solid growth on both, the palmar and the dorsal aspect of the finger. High recurrence rates, reported up to 45% in the literature, associated with multiple excisions, and the close contact of GCTTS to valuable structures might provoke collateral damage and diminish finger function. The aim of our study was to evaluate functional outcome following recurrent GCTTS excision on the digits. Procedural risk factors in surgery were analyzed in our own patient collective.

Methods: Monocentric retrospective study with clinical follow up. Patients with GCTTS on the digits operated from 01/2009 to 12/2017 were screened for inclusion criteria. Patient specific and procedural parameters were analyzed. Functional outcome was evaluated with the Ten Test, the two-point discrimination, the range of motion, the DASH score, and VAS for pain. Tumor recurrence was evaluated by clinical and sonographic examination.

Results and Conclusions: A total of 21 patients were operated in our clinic. 20 patients (14 females, 6 males, mean age 56 [25 to 90] years) were included (13 primary tumors, 7 recurrent tumors [4x1st, 2x2nd, 1x6th recurrence]), 1 patient with a fresh injury caused by a slicer was excluded. Digital block anesthesia was used in 4 cases, brachial plexus block or general anesthesia in 16 cases. OP-time was on average 45 [7 to 90] minutes. 5 patients had revision surgery (25%) (3 recurrent tumors [15%, 1x1st, 1x3rd and 1x7th recurrence], 1 neuroma, 1 scar). The patient with 7th recurrence of GCTTS wished for amputation of the digit. The follow-up examination (mean 46 [12 to 112] months post-OP) highlighted a significantly (p<0.05) impaired functional outcome in patients with recurrence compared to primary tumor excisions. In recurrent tumor patients, sensitivity was diminished in 7 out of 8 patients (Ten test mean 5/10 [3/10 to 7/10], 1 amputation), movement was reduced in 6 out of 8 patients (max. deficit in extension 40° (2/8), max. deficit in flexion 50° (3/8), 1x ankylosis of the DIP joint, 1x amputation). In 12 patients with primary surgery, sensitivity was diminished in 1 patient (Ten test 5/10), movement in 2 patients (max. deficit in extension 30° (1/12), max. deficit in flexion 40° (1/12)). DASH score and pain on VAS were in normal range in all but one patient with finger amputation. Short operation time and digital block anesthesia were associated with high risk for revision surgery.

What is the role of psychological distress, pain catastrophizing and illness perceptions in pre-operative pain of CMC-1 patients?

List of authors:
Mark van der Oest¹, Lisa Hoogendam¹, Ralph Poelstra³, Guus Vermeulen², Harm Slijper², Ruud Selles¹, Ana-Maria Vranceanu³, Jarry Porsius¹
¹ ErasmusMC, kamer EE-1589 (Rotterdam)
² Xpert Clinic (Eindhoven)
³ Massechusetts General Hospital, Integrated Brain Health Clinical and Research Program (Boston)

Objectives / Interrogation: In recent studies the role of psychology in hand surgery patients is being investigated, particularly in first carpometacarpal osteoarthritis (CMC-1). Several studies suggest an influence of psychological factors on pre-operative pain in CMC-1 patients. However, the role of illness perception - the set of beliefs that a patient holds about their illness - and its relative importance compared to other better studied psychological constructs in explaining pain has not been studied before. We aimed to assess the relative contribution of psychological distress, pain catastrophizing and illness perceptions in pre-operative pain of CMC-1 patients.

Methods: Between September 2017 and September 2018 patients with CMC-1 OA who were scheduled for surgery after at least three months of treatment with a hand orthosis and hand therapy were included. Patients were excluded from the analysis when they had not completed the Dutch translation of Michigan Hand Questionnaire before surgery and had not completed the psychological screening questionnaires before surgery. All measurements were part of routine outcome data collection. A hierarchical linear regression analysis was used to assess the relative contribution of patients' characteristics, psychological distress and pain catastrophizing and illness perceptions.

Results and Conclusions: 214 patients were included in the analysis, of which 59% female with an average age of 59 (7 SD). Patients mean (± SD) pain (0 = severe pain - 100 = no pain) was 35 ± 13. The hierarchical model showed that 8% of the variance in pain was explained by patient demographics, 21% was explained by psychological distress and pain catastrophizing and an additional 12% was explained by illness perceptions. In the final model, more pain was significantly associated with female sex, pain catastrophizing and more negative illness perceptions.

Conclusion
Modifiable psychological factors were independently associated with pre-operative pain in CMC-1 patients explaining considerably more variance than other nonmodifiable patient characteristics such as female sex. These outcomes suggest that psychological interventions targeting pain catastrophizing and illness perception may improve pre-operative pain.

Costs of productivity loss after surgery for first carpometacarpal osteoarthritis (CMC-1 OA)

List of authors:
Mark van der Oest\(^1\), Joris Teunissen\(^1\), Ralph Poelstra\(^1\), Reinier Feitz\(^2\), Harm Slijper\(^2\), Jarry Porsius\(^1\), Alex Burdorf\(^3\), Ruud Selles\(^1\)
\(^1\)ErasmusMC, kamer EE-1589 (Rotterdam)
\(^2\)Xpert Clinic (Eindhoven)
\(^3\)ErasmusMC (Rotterdam)

Objectives / Interrogation: Recent studies on first carpometacarpal osteoarthritis (CMC-1 OA) have focused on establishing the optimal treatment and determining prognostic factors for this treatment. However, little is know about the cost that are associated with productivity loss after surgery. This study aim to determine the duration until patients returned to work and the associated costs in patients with CMC-1 OA.

Methods: We included all patients that were surgically treated for CMC-1 OA and had a paid job at the time of surgery. Return to work was measured by questionnaire that was administered as part of routine care. All patients that did not provide information on return to work were excluded. Cox analysis was used to calculate the time until patients returned to work. The human capital method was used to calculated the costs of productivity loss.

Results and Conclusions: 629 patients were included in the final analysis, their mean (±SD) age was 55 (±6). One year after surgery 79% of all patients had returned to performing their original work. The median time to return to work was 12 weeks (Q1 - Q3, 6 - 22). Median costs of productivity loss were 11.448 euro (Q1 - Q3, 5.724 euro - 21.000 euro). Performing physically heavy work was associated with a later return to work and thus with higher costs of productivity loss.

Conclusion
Surgical treatment of CMC-1 OA results in a long period of absenteeism and thus high indirect costs of the treatment. Additional interventions in the follow-up of the surgery designed to expedite the return to work may therefore be considered to reduce the indirect costs of surgery.

Burn depth determination by Hyperspectral Imaging

List of authors:
Dominik Promny*1, Moritz Billner1, Nicole Hofmann1, Bert Reichert1
1 Clinic for Plastic, Reconstructive and Handsurgery (Nuremberg)

Objectives / Interrogation: The most common diagnostic method for the evaluation of burn depth is the clinical inspection and the tactile examination. The conventional histological analysis is still considered the gold standard, but due to its invasiveness and time expenses it is not suitable in acute diagnostics. Currently, Hyperspectral Cameras with specially programmed software are occasionally used to support the burn depth evaluation. It needs to be determined to what extent these devices can facilitate and objectify the assessment of burn depth, especially in hand burns.

Methods: The physical measurement principle of the so-called remissions spectroscopy is to irradiate the burn wound with white light and to evaluate the reflected light with a special spectral camera unit. In the superficial wound layers (up to 6 mm deep), the light is reflected differently due to the inhomogeneity of the tissue. Remitted light contains information about tissue structures and especially tissue damage. Using a proprietary software, the parameters tissue oxygenation (sO2), tissue hemoglobin index (THI) and near-infrared perfusion (NIR perfusion) are recorded. A recently available advanced software is able to extract even more accurate data from the recorded spectra. The procedure is non-contact, unburdening for the patient and in the current implementation quickly and easily applicable.

Results and Conclusions: In selected cases, the spectral camera is used to aid in the evaluation of burn wounds. With ongoing data acquisition and now extended software, certain correlations can already be deduced from the recordings and linked to a “burn index”.
Burns of a deeper degree clearly show lower levels in the superficial and in the deep blood circulation.

Ideally, the use of these spectral cameras should not only make it possible to objectify the evaluation, but in addition, the deeper wound layers can also be assessed. This is particularly important in the differentiation of deeper burns and differently affected burn degrees, so that sufficient surgical treatment can be initiated early on. Currently, it is important to optimize the respective reference values of the individual burn degrees for an objectified assessment.

Use and Advantages Of An Anticoagulation Therapy Based In Non-Fractioned Heparin In A Case Series Of Extremity Reconstruction With Free Flaps

List of authors:
Constanza L. Moreno-Serrano¹, María A. Gómez², Julio Bermúdez¹
¹ Fundacion Santa Fe De Bogotá University Hospital, Universidad de los Andes (Bogotá)
² Universidad de los Andes (Bogotá)

Objectives / Interrogation: Local thrombosis is one of the most frequent causes of failure of flaps and one of the main causes of total or partial loss. Surgery causes hemostatic changes which trigger the coagulation cascade, leading to a hypercoagulable state characterized by increased platelet activity, decreased levels of endogenous anticoagulation factors and diminished fibrinolysis all leading to a pro-thrombotic state.

Based on the forth mentioned and given that there is no consensus in the literature on how to safely use anticoagulation in microvascular surgery, it was evident that there was a need to ensure that properly made anastomosis would not fail by a physiological problem preventable through the use of thromboprophylaxis.

The objective is to evaluate how the implementation of a non-fractioned heparin based protocol directed toward preventing small vessel thrombosis without increasing the risk of hematoma formation.

Methods: All patients in which a free flap was done to reconstruct an extremity since 2005 were identified and included in the database. Information regarding the type of flap, age, risk factors, indication, time of ischemia, the anticoagulation protocol used, and complications was taken.

The cases were divided between non-fractioned heparin scheme used and others anticoagulation systems, and we reported the differences in complications between the groups.

Results and Conclusions: After evaluating the medical charts we found that we could intervene ensuring prevention in the formation of thrombi in a well-done anastomosis without increasing the risk of bleeding by implementing the presented protocol.

Most of the patients involved in this protocol did not have thrombosis or bleeding complications. Patients who required surgery to revise the anastomosis were studied independently, and factors that could have favored complications were identified. There were no cases of thrombocytopenia caused by heparin.

By establishing this protocol we did not find the formation of hematomas and thrombus. This led to a decrease in the ratio of total and partial loss of free flaps at our center. As a result, we recommend that in centers where reconstruction with the microvascular technique is performed, an anticoagulation protocol should be established.

The Pennington's modification of the Kessler repair: unexpected observations through 3-D modelling

List of authors:
Amitabha Lahiri*, Sandeep J Sebastin¹, Kyрин J. Liong², Teemu Karjalainen³
¹ Department of Hand and Reconstructive Microsurgery, National University Hospital (Singapore)
² National University of Singapore (Singapore)
³ Central Hospital Central Finland (Jyväskylä)

Objectives / Interrogation: The modified Kessler repair as described by Pennington is possibly the most widely used method for tendon repair.

In his original paper, Pennington used a 'finger and twine' model to demonstrate this concept. He observed that in this configuration the longitudinal part of the string was superficial to the transverse part. He translated this configuration to his tendon suture technique and stated that "placement of the transverse part of the suture superficial to the longitudinal part would result in such a loop configuration".

However, on dynamic fluoroscopic studies we observed that in the suture configuration obtained using the Pennington's technique did not reveal the expected behaviour.

The suture was seen to fail without demonstrating the grasping effect of the loops around the tendon substance. Our aim was to perform a detailed analysis of the suture configuration and its behaviour under traction.

Methods: We recreated three models

1. The finger and twine model described in Pennington's original paper.

2. Tendon suture configuration described by Pennington on a transparent silicone cylinder in his original paper.

3. Three-dimensional computer generated of the suture configurations of the finger and twine model and the Pennington's suture technique to analyse the differences.

4. Solid models of the two configurations using malleable material

Based on these models we qualitatively analysed the fundamental topological differences between the loop configuration seen in the finger and twine model and the actual configuration produced by the suturing technique.

Results and Conclusions: We found that the suture configuration described by Pennington although resembled the loop configuration seen in the 'finger and twine' model, there were some marked differences.

The ‘finger and twine’ model demonstrated the topological properties which allowed the twine to tighten around the fingers, however when it was translated on to the tendon, the intended configuration was lost.

The sole condition of placement of transverse part of the suture superficial to the longitudinal part, as stated by Pennington, was not sufficient for formation of true loops, resulting in the observed behaviour of the repair under longitudinal strain.

Through the use of computer modelling, we were able to analyse and point out the fundamental topological conditions that were necessary for effective loop configurations.

Ligament constraint of the first carpometacarpal joint

List of authors:
Wan Mohd Radzi Rusli*, Eushaa Mirza¹, Sarah Tolerton², Sarah Yong², Riem Johnson², Maxim Horwitz², Angela Kedgley¹
¹ Bioengineering Department, Imperial College London (London)
² Department of Hand Surgery, Chelsea and Westminster Hospital (London)

Objectives / Interrogation: The objective was to determine the role of the ligaments surrounding the first carpometacarpal (CMC) joint in maintaining stability of the joint.

Methods: Eleven specimens (mean = 49.2 years; 5 right hands and 6 left hands) were used in this study. The first and second metacarpals, trapezium and trapezoid were removed from each specimen, taking care not to violate the first CMC joint capsule. Each of the first CMC joints was oriented in neutral using a personalised 3D-printed jig. The distal end of the first metacarpal was fixed in a specimen holder using polymethylmethacrylate. Trapezium, trapezoid and the proximal end of the second metacarpal were fixed in the similar manner. An Instron testing machine equipped with a customised jig was used to apply external loads to the specimen. Translation of the first CMC joint was measured using linear variable differential transformers. Each specimen was tested during intact and ligament sectioning conditions. Four ligaments were included in the sequential sectioning - anterior oblique ligament (AOL), ulnar collateral ligament (UCL), intermetacarpal ligament (IML) and dorsal radial ligament (DRL). For each condition, load was applied to the specimen in four different directions - volar-dorsal (VD), dorsal-volar (DV), radial-ulnar (RU) and ulnar-radial (UR) - while the joint was compressed with 10N to maintain contact of the articular surfaces. The position of the joint in the intact state was taken as the baseline.

Results and Conclusions: Friedman tests indicated significant differences in the translation of the first CMC joint after the ligaments were sectioned, except in the dorsovolar direction when load was applied in both VD and UR directions. Post-hoc analysis showed that when load was applied in the VD, DV and RU directions, there were significant differences (p<0.008) in the translation of the joint after each of the ligaments were cut (Figure 1).

The absence of the DRL can cause instability of the first CMC joint in the dorsovolar direction. This can cause high stress at the interface between the volar beak of the first metacarpal and trapezium.

Aspects of toe to hand transfers in children with the macrodactyly of the hand

List of authors:
Tatiana Tikhonenko*, Sergey Golyana
1 The Turner Institute For Childrens Orthopedics (Pushkin)

Objectives / Interrogation: Purpose of the study is to determine the role of microsurgical toe to hand transfer in the treatment of children with isolated macrodactyly, based on a comparative analysis of various types of surgical interventions

Methods: In the department of reconstructive microsurgery from 2013 to 2017, 25 children with congenital macrodactyly of the hand were examined and surgically treated. Out of 25 patients, in 13 there was a macrodactyly of the 2nd, 3rd fingers, which was 52%. At the same time, of the total number of hyperplastic hand segments (n = 45), 17 rays had hyperplasia greater than 25%.

Results and Conclusions: Stage-by-stage modeling resections of enlarged segments were performed in all children with hyperplasia of the ray of about 25% of the size of intact fingers, in 4 cases excision of soft tissues was combined with marginal resection of phalanges. When hyperplasia of the segment reached up to 10% of macrodactyly, it was performed in the child the single isolated modeling resections of soft tissues and bones. Repeated modeling operation in 16% (n = 4) children were accompanied by the formation of gross postoperative scars with the development of secondary angular deformities and loss of functions of interphalangeal joints.

9 patients (n = 14) underwent amputation of hyperplastic fingers followed by microsurgical reconstruction of rays by the method of autografting of the toes. In 4 cases, the first finger was reconstructed. In other 5 cases, two toes of both feet were transplanted to the position of 2, 3 (n = 4) and to the position of 3, 4 fingers (n = 1). It was revealed that with a significant hyperplasia of the affected segments of the hand (1.5 - 2 times), the method of microsurgical autografting of the toes is more effective and acceptable compared to the method of bone and soft tissue resections.

With segment hyperplasia less than a quarter of the normal size, the optimal surgical interventions are stage by stage modeling resections;

An alternative method of surgical treatment of children with hyperplasia of more than 25% is microsurgical transplantation of the toes into the position of the involved into process rays of the hand, which allows obtaining good cosmetic and functional results in these patients.

Pediatric fingertip replantation: minimum 10-year follow-up

List of authors:
Feng Zhu*1, Hong Chen1
1 Ningbo 6th Hospital (Ningbo)

Objectives / Interrogation: Pediatric fingertip replantation is a challenge microsurgery for finger replantation. Reported results at a long time (under 10 years) follow-up of children digital replantation consistently show surprised good sensation, poor cosmetic, and satisfaction with good growth rate with good blood circulation. We hypothesized that children fingertip replantation would provide a high level of satisfaction and function at a minimum of 10 years.

Methods: Twenty-five digits in 20 patients, including 3 infants, underwent fingertip replantation for traumatic injury at an average age of 7 years. Patients returned for radiographic and clinical evaluation, and the cosmetic evaluation (pulp atrophy & nailbed deformity) and sensory function (2PD test) were used. Follow-up was a minimum of 10 years (average, 15 years).

Results and Conclusions: Results Nineteen digits (80%) underwent no further surgery at a minimum 10-year follow-up. The average time to undergo additional procedures to improve function, was 0.4 procedures. Fifteen of 20 patients who continued to be satisfied, with minimal pulp atrophy and minimal decrease in pulp sensation compared the contralateral digits. Average 2PD test was 6.8mm. The nailbed deformity was six digits, and severe pulp atrophy was three digits. The DIP joints flexion-extension arc was 35 degrees, and pinch strength was 87% of the contralateral side. All patients returned to their original life. There was significant correlation between good fingertip blood circulation and satisfaction level. The additional procedure revealed high risk of growth plate injury and epidermis injury in patients who undergone fingertip replantation.

Conclusion Pediatric fingertip replantation provides satisfaction at a minimum of 10 years. Whereas we recommend no severe growth plate and nail epidermis injury for fingertip replantation, crushed and avulsion injury should not be excluded as children fingertip replantation candidates; these patients should undergo appropriate preoperative counseling of their fingertip replantation and the increased additional procedures after replantation.

Distal Radius Nonunion: Subjective Hand Functional Impairment and Mid term Results after Radial Consolidation

List of authors:
Pablo De Carli*, Nicolas Atala¹, Laura Tripodi¹, Jorge Boretto¹, Gerardo Gallucci¹, Agustin Donndorff¹, Ezequiel Zaidenberg¹
¹Hospital Italiano de Buenos Aires (Buenos Aires)

Objectives / Interrogation: To evaluate repercussion on the hand of Distal Radial Fracture Nonunion and analyze hand functional improvement after Radius stabilization.

Methods: 15 patients with Distal Radius NonUnion were treated between 2005 and 2012. Inclusion criteria were: distal radius established non union; preoperative clinical and functional evaluation from patients' charts; surgical fixation-stabilization of the Nonunion and minimum follow up of 3 years. Initial X rays were AP and lateral. CT scan was taken in those cases with articular fracture or for distal radial fragment size evaluation. Final X rays evaluated consolidation. Preoperative and final evaluation data included: DASH score, Visual Analogic Scale (VAS) both for pain and function and Swanson Scale for pain; Signs of Complex Regional Pain Syndrome (CRPS) - pain at rest and finger stiffness. The possibility of closing the fist was recorded before surgery and at final follow up.

Results and Conclusions: 10 patients met inclusion criteria: 7 were female and 3 male. The average age was 65 years-old (52-85). Preoperative results: pain was VAS 7.2 (8 of 10 patients had VAS 7 or higher). Four had pain at rest, 2 with light tasks, 3 with moderate efforts and 1 with strong efforts. 3 of 10 patients could make a fist reaching the palm of their hand with the tip of the fingers. Six had signs of CRPS. DASH averaged 62 (22-89). In six cases radius non union was treated with radial reconstruction. Four cases had a salvage procedure: two Radio-Lunate-Scaphoid arthrodesis and two Total Wrist Arthrodesis. Final follow up was 75 months (43 to 125). Pain resulted in VAS 0.3 (0 to 1). Five patients had no pain at all, and 5 had light pain with great efforts. All could make a complete fist touching the palm with all the finger pulps and no one had signs of CRPS. Final DASH averaged 11 (0 to 20). Final functional VAS averaged 8 (5 to 10). Three patients complicated and had a second surgery to obtain bone fusion. Finally, all nonunions and arthrodesis consolidated.

Conclusion: Distal Radius Non Union carries a significant functional impairment, not only in the wrist itself but even more in the affected hand: pain, stiffness, subjective dysfunction, and Complex Regional Pain Syndrome affecting activities of daily living. Achieving Radius stabilization, either by Radius reconstruction or by partial or total wrist arthrodesis, resulted in significant improvement in hand function and in pain relief.

Comparison of surviving rates of digital replantation after more than 10 hours of delay versus immediate replantation

List of authors:
Chao Chen*, Liwen Hao¹, Zengtao Wang¹
¹ Shandong Provincial Hospital (Jinan)

Objectives / Interrogation: The purpose of this study was to analyze the surviving rates of digital replantation after over 10 hours of intentional delay versus immediate replantation.

Methods: We reviewed the patients with digital replantation in our department treated between December 2017 and May 2018. These fingers were classified into three groups according to the time between injury and beginning of replantation: (1) within 5 hours after amputation; and (2) more than 10 hours. The fingers with delay of more than 10 hours were those of intentional delay for surgical replantation because operational rooms or surgical team were not available for earlier replantation surgery. The severed fingers were preserved in low temperature (about 4 degrees centigrade) for delayed replantation. We compared surviving rate of finger replantation in the two surgical groups.

Results and Conclusions: Results: There were 15 fingers (13 patients) with immediate replantation within 5 hours after amputation. There were 37 fingers (30 patients) with intentional delay of finger replantation. The survival rate of the 15 fingers with immediate replantation was 93% with failure of one finger. The survival rate of the 37 fingers with intentional delay of finger replantation was 94.6% with failure in two fingers. Statistically, the difference in surviving rate not statistically significant (p < 0.05, Chi-square test).
Conclusions: We conclude from our data that intentional delay of finger replantation over 10 hours does not affect the surviving rate of digital replantation provided that the amputated parts were kept in low temperature. We suggest that replantation surgery can be routinely delayed without adverse influence to survival of the replantation when the surgical team or operation room are not readily available.

COMPLICATIONS IN PATIENTS WITH FRACTURES OF THE DISTAL RADIUS

List of authors:
MERIDA VICTORIA CHOQUIN SALES¹, EDGAR PINILLA², CONSTANZA LUCIA MORENO SERRANO², JULIO BERMUDEZ², RAMON DE BEDOUT²
¹ Boulevard Minerva 8-80 condominio valle nuevo casa 250 (Mixco)
² Bogota (Bogota)

Objectives / Interrogation: Identify the complications that occur in patients with fractures of the radius during the first year of follow-up

Describe the epidemiological characteristics
Estimation of the incidence of complications
Determine the factors related

Methods: Study Descriptive, cross-sectional

All patients with diagnosis of fracture of the distal radius from January 1 2010 to December 31 2015

Patients older than 18 years
Patients with treatment and follow-up by one of the 4 hand's surgeons

Results and Conclusions: 745 patients with 758 fractures were included in the study. Our patients range from 18 to 95 years, 61% (456 patients) of the population is female and 39% male (289 patients), the majority of our patients perform activities of low demand were housewives or pensioners (41%). The most affected side was the left with 53%, and in 1% the patients presented bilateral fractures. The mechanism of the injury in 459 fractures (61%) was low energy being the most frequent falls. In our 745 patients, with 758 fractures evaluated over 6 years, different complications were identified which are detailed below: 129 patients reported 142 complications, the most frequent being those related to tendons with 37 patients (4.8%), related to nerves (paresthesia) 26 patients (3.4%), Scar problems 16 patients (2.1%), Carpal tunnel syndrome 9 patients (1.18%), Surface infection 6 patients (0.79%), complex Regional Pain Syndrome 7 patients (0.9%), NO radio union 3 patients (0.3%), Mal union 23 patients (3%), then we found some less frequent complications.

The majority of complications occurred in patients older than 50 years (92 patients representing 12% of 17% of total complications). There are not relationship between the incidence of complications and the presence of a medical history of Diabetes Mellitus, Hypothyroidism, Inflammatory Diseases, Neoplasms, Osteoporosis and the use of non-steroidal anti-inflammatories.

CONCLUSIONS
In our Hospital, 17% of complications are reported in patients with distal radius fractures.

Most complications are associated with tendons and nerves.

Most complications occur in patients older than 50 years and female patients.

The relationship between the incidence of complications and the presence of a medical history of Diabetes Mellitus, Hypothyroidism, Inflammatory Diseases, Neoplasms, Osteoporosis and the use of non-steroidal anti-inflammatories, was not confirmed.

Repair of injuries of the triangular Fibrocartilage complex with foveal avulsion by transosseous tunnels

List of authors:
Fabio Andres Tandioy-Delgado, Laura Sanchez Presiga, Estaban Arrubla Rojas, Andres Felipe Rendon Montoya
1 Clinica Las Americas (Medellin)

Objectives / Interrogation: The objective of this study was to investigate the clinical results and functional outcomes of the patients with Triangular fibrocartilage Complex (TFCC) foveal tears with were repaired by arthroscopy and transosseous tunnel.

Methods: We retrospectively rewind the result of five patient (5 men) who underwent a surgical procedure for the treatment of TFCC foveal avulsion at our clinic. The patient's progress was followed up for a mean 8 months. The average age was 31 years. Postoperative clinical and functional outcomes, grips strength, mobility of the wrist, the Modified Mayo Wrist Score, were quantitatively evaluated. The Disabilities of the arm, shoulder and hand questionnaire served to assess each patient's subjective outcomes.

Results and Conclusions: Results
At the mean follow-up of 8 months, all patients had a significant reduction in wrist pain. The average grip strength at 44. The mean modified Mayo Wrist Score was 85. The Disabilities of the arm, Shoulder and Hand Score came out at 24,16. All patients were able return to work.

Conclusion
Arthroscopic reattachment of avulsed TFCC to the ulnar foveal by the described technique is a vacuum alternative for treating avulsion of the foveal TFCC insertion.

Surgical technique of the trapeziometacarpal and scapho-trapezoid-trapezoidal pyrocarbon "burger arthroplasty"

List of authors:
Camilo Chaves*, Philippe Bellemère2
1 Université Paris XI (Le Kremlin-Bicêtre) 
2 Institut de la main (Saint Herblain)

Objectives / Interrogation: Trapezo-metacarpal and scapho-trapezotrapezoid arthroplasty based on pyrocarbon resurfacing implants is known as "burger arthroplasty". This technique was proposed in 2014 for the treatment of early stages of symptomatic and debilitating peritrapezial osteoarthritis.
This presentation exposes a video of the detailed the surgical technique.

Methods: A double approach is required. A dorsal approach to access the base of the carpo-metacarpal joint and a palmar approach to access the scapho-trapezoid-trapezoidal joint.

Through the dorsal approach, the extensor pollicis longus and brevis are dissected and protected. The articular capsule is opened, and the proximal base of the metacarpal is prepared.
Medial and lateral osteophytic metacarpal horns are resected. The metacarpal articular surface is prepared in a "champagne cork" shape.
Trapezial horns are resected. Both surfaces are gently blurred in order to homogenize the surfaces.
At this point the trial implant are tested for size and stability and the final implant is selected.

Through the palmar approach the scapho-trapezoid-trapezoidal joint is accessed. Scapho-trapezoid surface is prepared by resecting the subchondral surfaces and the surfaces are gently blurred to assure homogeneity. At this point the trial implant is tested for stability and size.
Preoperative fluoroscopy confirms the stability of the trial implants and the final implants are interposed between the surfaces. The articular capsules are sutured, and the carpo-metacarpal capsule is reinforced by an anchor fixed on the dorsal aspect of the first metacarpal.

Results and Conclusions: The trapezo-metacarpal and scapho-trapezotrapezoid arthroplasty based on pyrocarbon resurfacing implants is known as "burger arthroplasty" is a new technique to treat early stages of symptomatic and debilitating peritrapezial osteoarthritis.
This technique offers a new therapeutic tool to hand surgeons that aim to propose a more conservative procedure compared to trapeziectomy or arthroplasties.

THORACIC OUTLET AND INTERSCALENE TRIANGLE VARIATIONS - ANATOMIC RESEARCH

List of authors:
Luciano Poitevin*
1 Buenos Aires University Hospital (Buenos Aaires)

Objectives / Interrogation: Thoracic Outlet Syndrome (TOS) remains controversial. Pathologic fibrous bands as well as a Scalene Minimus muscle have been advocated as causes. However, many authors deny its existence in the absence of a cervical rib.
Are there anatomic variations at the interscalene triangle (IST) that may explain this entity? Fibrous bands may be normal variations? How often can these possible variations produce symptoms?

Methods: 50 Supraclavicular unembalmed regions were dissected. Number, origin & insertion of scalene muscles were recorded. Interscalene (IS) distance on the 1st rib was measured and correlated with subclavian artery height over the rib. Insertion, tendon shape & relationship with the trunks of the brachial plexus were registered. Narrow passageways between scalene muscles were defined. Potential compression and/or impingement sites were described.

Results and Conclusions: The scalene muscles originate as a single mass (SM) extending from the cervical spine to the 1st. rib and the suprapleural membrane. This SM becomes fragmented by the growth and distal migration of the hand & upper limb bud. The subclavian vein passes in front of this mass, while the subclavian artery & brachial plexus pass through it. The remnant muscle in front of the neurovascular bundle (NVB) become the Anterior Scalene (AS); and that behind the NVB become Middle (MS) and Posterior Scalene.

Muscle remnants of the intermediate part of the SM were identified as: a) The Superior Intermediate Scalene (SIS) = 18%, extending from the C-VI vertebra to join the AS; b) The Inferior Intermediate Scalene (IIS = Scalene Minimus) = 50%, running from C-VII to the 1st rib & suprapleural membrane.

This arrangement divides the IST into several passageways, reducing its size and potentially compressing the NVB. In 6%, the IS distance at the level of the 1st rib is 0. (Mean = 9.76mm, range 0-18.2mm) This arrangement lifts the artery and the lower trunk. Also, the MS tendon often displays a concave sharp edge which impinges on the lower trunk.

The IIS is sometimes replaced by a transverse-septo-costal ligament which is not a pathologic fibrous band. As these are normal anatomic variations; therefore we feel that number, size and shape of the scalene muscles should be associated with extreme sustained positions of the upper limb (e.g. Hyperelevation or shoulder girdle descent) in order to produce NVB symptomatic compressions. We present surgical examples of these symptomatic variations mimicking cubital tunnel or carpal tunnel syndromes.

The Importance of the Distal Oblique Band in Forearm Longitudinal Stability: A Biomechanical Comparative study

List of authors:
Felix Riano*, Robert Kalapos, Matin Lendhey
1 Naples Hand Arth (Naples)
2 Naples Hand Arthr (Naples)

Objectives / Interrogation: Recent attention has been paid to the carpus-forearm-elbow as a functional unit for longitudinal stability of the forearm. We know the radial head plays an important role, and Essex Lopresti described its fracture associated with DRUJ dislocation. The TFCC and the Interosseous Membrane (IOM) are also key components, and their rupture disrupts the vectors of load and forearm stability. The main focus of IOM reconstructions has centered to restoration of the central band. Recent studies have shown the importance of the Distal Oblique Band (DOB) both for DRUJ and forearm longitudinal stability. We present the strengths and load to failure results when biomechanically comparing a standard central band vs central band plus distal oblique band reconstructions.

Methods: Three pairs of matched fresh frozen cadaver specimens were utilized for our biomechanical testing. We performed a central band (CB) reconstruction with Palmaris Longus graft and FiberTape (Arthrex, Inc. Naples, FL) augmentation on 3 specimens (Group 1), and a central + distal oblique band reconstruction with Palmaris Longus graft and FiberTape augmentation on the other 3 specimens (Group 2). BioComposite 4 x 10 Tenodesis screws (Arthrex, Inc. - Naples, FL) were used for construct fixation. Once the constructs were performed, we proceeded to transect the entirety of the IOM, TFCC, DRUJ, and annular ligaments to isolate the bands we wanted to test. Axial load was applied to the sample at a rate of 20mm/min using an INSTRON® ElectroPuls Dynamic Testing System (INSTRON, Canton, MA). A t-test was performed to identify any statistically significant differences in maximum load and load at clinical failure between the groups, (###=0.05). Clinical failure was defined as the load corresponding to 10 mm of longitudinal displacement.

Results and Conclusions: The average maximum load to failure for the Group 1 was 266.81 N (127.7 - 365.07 N) and for Group 2 was 377.8 N (279.37 - 495.82 N). The mechanism of failure was by screw pull out; only one specimen displayed graft stretching. The results of the t-tests indicated that the maximum load and load at clinical failure were both significantly higher for CB + DOB reconstructions (p=0.002, for both comparisons). These results might have clinical relevance when deciding the type of reconstruction when dealing with acute and/or chronic longitudinal forearm instability. We also noticed that as opposed to a pure tendon reconstruction, the Internal Brace augmentation prevented graft stretching.

1015 peripheral nerve injuries of the upper extremity - Epidemiology and Cost analysis

List of authors:
Leila Harhaus*, Konstantin Bergmeister1, Patrick Rhodius3, Luisa Große-Hartlage1, Marius Beyersdorff1, Arne Böcker1, Ulrich Kneser1
1 BG Klinik Ludwigshafen, Klinik für Hand-, Plastische und Wiederherstellungschirurgie (Ludwigshafen)

Objectives / Interrogation: Nerve injuries are considered to be highly cost intensive due to the specialized therapy, rehabilitation and long healing processes. So far only few European cost analyses are available from small Swedish and Swiss collectives (<100 patients) and none for the German collective. Therefore, even the international treatment guidelines have no strong data to refer to. This study evaluates for the first time the epidemiology and costs of peripheral nerve lesions within the German health system of more than 1000 patients.

Methods: All patients who were treated with a peripheral nerve lesion of the upper extremity between 01/2012 and 12/2017 were retrospectively analyzed for epidemiological and economical aspects. For cost analysis patients were divided into work-related and private causes due to the different insurance covering. Within this period, the costs of inpatient treatment (diagnostics, operation, ward days) and rehabilitation were calculated.

Results and Conclusions: A total of 1015 patients were identified, of which 556 (55%) were work related and 431 private injuries. Mean age of patients was 39.9 yrs, 85.2% were male, mean hospital stay was 7.03 days. 47% of patients had a median nerve injury, 32.1% an ulnar nerve injury and 20.5% a radial nerve injury. 40.8% of patients had a combined injury of two nerves. 66.8% were sensory finger nerve injuries, 78% were complete transections, 11.6% partial and 10.4% were lesions in continuity. In 40.8% 1-3 tendons were additionally injured, in 45.2% 1 artery was additionally injured. 82.8% of cases were operated within 24 hrs, main treatment was primary coaptation. 16% required inpatient rehabilitation, mean absence from work were 166.79 days. Mean costs of sensory nerve lesions (finger level) were 2.673,15E and increased in combined motor and sensory nerve injuries (arm level) up to 10.822,14E. Median nerve injury resulted in mean costs of 4.526,56E, radial nerve injury in mean costs of 6.861,47E and single ulnar nerve injury revealed 6.253,67E. Combined injury with tendon or artery lesions increased the costs significantly. Mean inpatient rehabilitation costs were 5.842,35E.

Injury to the peripheral nerves has a major impact on the function of the arm and hand, the patient's life and employment. With the analysis of more than 1000 cases we answered the need to obtain objective and reliable data on the epidemiological and economical structure of these injuries.

Fifth Metacarpal Neck Fractures in the United States: Trends in Current Management

List of authors:
Aaron Rubinstein\(^1\), Jeffrey Chen\(^1\), Michael Vosbikian\(^1\), Irfan Ahmed\(^1\)
\(^1\) Rutgers University- NJMS (Newark)

Objectives / Interrogation: Management of fifth metacarpal neck fractures lacks consensus and is highly variable throughout the available literature. Our study aims to examine patterns and trends in nonoperative treatment, surgical indications, and surgical techniques for fifth metacarpal neck fractures amongst hand surgeons of different demographic backgrounds within the US.

Methods: A survey consisting of 18 questions was hosted online and distributed to the members of the American Society for Surgery of the Hand (ASSH) via email. Questions sought to determine the demographics of the surgeon, preferred initial treatment for metacarpal fractures of varying degrees of angulation, preferred immobilization technique, factors leading to surgical intervention, and preferred technique for surgical intervention. Responses were analyzed for significant patterns and trends.

Results and Conclusions: A total of 581 responses were received (17% response rate). The majority of respondents utilize intramedullary lines on lateral radiographs to measure fracture angulation, prefer splinting in the intrinsic-plus position for fracture immobilization, and prefer closed reduction and percutaneous pinning for surgical management. Average measurements to indicate patients for surgery were 9.2° of rotation, 41.6° of sagittal malalignment, 20.2° of coronal malalignment, or 6.1 mm of shortening. On average, orthopaedic surgeons tolerated greater degrees of volar angulation (43.8°) than general surgeons (30.7°) or plastic surgeons (27.9°).

Our study reveals several significant differences regarding the management of fifth metacarpal neck fractures between hand surgeons with different residency backgrounds, variable years of experience, and in different practice settings. Geographic region of practice and primary consultant were less impactful. Ultimately, management decisions appear to be a result of patient-specific factors as well as surgeon preference.

Intraneural hemangioma of a digital nerve: a case report

List of authors:
MASAO OKAMOTO*1
1 OSAKA MISHIMA EMERGENCY MEDICAL CENTER (TAKATSUKI)

Objectives / Interrogation: We report a very rare case of intraneural hemangioma of a digital nerve reconstructed using a collagen artificial nerve conduit after segmental nerve resection of hemangioma because complete excision was considered difficult without sacrificing the nerve fascicles, even with microsurgical technique.

Methods: A healthy 30-year-old right-handed male presented with a palpable mass on the radial side of his left index finger noticed a few years ago. His medical history was unremarkable with no previous trauma. The mass was red, bean-sized, mobile, and independent of the adjoining tendons. Although tenderness was positive, Tinel's sign was negative, and no sensory deficits were detected. An ultrasound examination revealed a well-defined, oval, hypoechoic subcutaneous lesion in continuity with the digital artery and digital nerve. Magnetic resonance imaging revealed a subcutaneous small lesion that was nonspecific hypointense on T1-weighted images and heterogeneous hyperintense internally. After administration of an intravenous contrast agent, the lesion showed no enhancement.

Results and Conclusions: Exploration revealed a dark blue tumor originating from the radial digital nerve. Because the tumor was strongly adhesive to fascicles, it could not be resected without sacrificing a nerve segment. The tumor with the involved part of the digital nerve was resected, and the 15-mm nerve defect was bridged by a collagen artificial nerve conduit. Histopathological examination revealed thin-walled dilated capillaries embedded in the fibroadipose stroma with peripheral nerve fibers, consistent with the hemangioma and intraneural extension. Postoperatively, sensibility of the radial aspect of the index finger could be completely restored, as confirmed by normal Semmes-Weinstein test results. Notably, there was no recurrence of the lesion during the 1-year follow-up.

Some reports have stated that intraneural hemangioma can be excised microsurgically, but complete excision of lesions is not always possible, and incomplete resection carries a high risk of recurrence. In such cases, an artificial nerve conduit can provide an alternative to an autologous nerve for treatment of peripheral nerve defects. Although the collagen artificial nerve conduit is considered to have some limitations for application, it facilitated a shorter surgical time and showed no unfavorable donor site morbidity, no uncomfortable feeling even in the fingers, no painful neuroma and good sensory recovery.

**hand burns in Austere environment**

**List of authors:**
yousef Alloun*
1 Damascus university (Idleb_atmeh)

**Objectives / Interrogation:** Abstract:
Hand burns in austere environment can cause contractures, joint dislocations, deformities and loss of the function of fingers.

**Introduction:**
Deep hand burns (including 3rd degree and deep 2nd degree) might lead to loss of function of the hand, unless these burns are treated properly. Early identification of the burn degree, correct dressings in functional position, early debridement of deep burns and covering the defect with flaps or skin graft followed by physiotherapy are necessary to promote early healing, reduce infections, shorten hospitalization, prevent contractures and maintain hand function. Inadequate treatment of deep hand burns may end with infections, dislocated joints and contracture of the fingers and may lead to amputations of parts of the hand.

**Objective:**
In austere environment with limited access to trained hand surgeons we could prevent hand contractures, deformities and preserve hand function by proper treatment of deep burn followed by physiotherapy.

**Methods:** Methods:
Case report of 5 cases of deep hand burns in austere environment context.

**Discussion:**
In order to obtain better results, the degree of the burn should be determined early. It is essential that burn debridement is performed early, dressings are done regularly and physiotherapy should be provided for a long period. If the treatment is not started early, the fibrosis will occur in the site of the burn and contractures will be formed, dislocation of the joints and adhesions of the fingers may happen. The end result will be loss of function of the hand.

**Results and Conclusions:** Results:
One patient with incorrect initial treatment of hand burns ended with amputation of fingers.
Two patients have received early skin grafting with physiotherapy, followed up for two months and have got good results.
Two cases had contractures in the hands and fingers, although there have been good initial treatment, but had no physiotherapy follow-up.

**Conclusion:**
In spite of lack of advanced medical equipment, unavailability of hand surgeon, and lack of specialized physiotherapy proper treatment at early phase after the hand burns followed by physiotherapy could maintain hand function and prevent contractures or deformities of the hand.

Management of scaphoid fractures in the skeletally immature age 10: Case series and literature review test

**List of authors:**
Rachana Tataria*1, Cynthia de Courcey1, Jeannette Ting1, Tatiana Yoko1, Sarbjit Kaur1, Andrea Jester1, Sami Al-ani3, Karl Johnson1, Kerstin Oestreich1

1 Birmingham Children's Hospital (Birmingham)

**Objectives / Interrogation:** Scaphoid fractures are relatively uncommon in children, even more so in children in the first decade. The average age group for the ossification of the scaphoid bone to start is 4-6 years which goes through until 13-15 years of age. Due to the ongoing ossification of the carpal bones, diagnosing scaphoid fractures is challenging. The aim of our study was to report our experience with managing scaphoid fracture from a tertiary paediatric hand and upper limb trauma centre comprising of age group till ten years.

**Methods:** An analysis of prospectively collected data was done. The cases of scaphoid fractures in children up to the age of 10 years, treated in our hospital from January 2014 to June 2018 were included in the study. Parameters studied were patient demographics, clinical presentation, mechanism of injury, investigations, type of fracture, associated injuries, treatment offered, outcomes and complications if any were documented.

**Results and Conclusions:** RESULTS: Total 24 patients with documented scaphoid fractures in children up to the age of 10 years were included. The mean age was 9.79 years, with female preponderance. The most common cause of injury was accidental fall on outstretched hand, followed by sport activities and road traffic accidents. The most common location of fracture was the distal pole (10 patients) and waist (9 patients). Four patients had associated injury of capitate bone. None of the patients needed surgery; all of them were managed conservatively. No major complications noticed. The patients had to make an average of 4.33 visits for consultation and review before discharge. The average time of immobilisation was 6.67 weeks (Range: 4-10 weeks).

CONCLUSION: The incidence of scaphoid fractures in the skeletally immature age is relatively low however it is increasing due to active contact sport activities in children. The early detection and low threshold of high resolution of imaging makes detection of these fractures easier. In the very young age group of up to 10 years, when the cartilaginous portion of the scaphoid dominates, majority fractures healed well with plain immobilisation with minimal to no complications. Surgery is rarely required.

Unidirectional porous beta-tricalcium phosphate: a new bone filling substitute for treatment of distal radius fracture in the elderly population

List of authors:
Keiichi Muramatsu*, Ryuta Iwanaga
1 Dept. Orthopedic Surgery, Nagato General Hospital, Yamaguchi University (Ube)
2 Yamaguchi University (Ube)

Objectives / Interrogation: The distal radius is the most common fracture site in the upper extremity, especially in elderly patients. Dorsally displaced fractures are often treated by open reduction and internal fixation using the volar approach. The bony defect can be filled with bone graft substitute in order to increase the mechanical strength of the subchondral bone. A new beta-tricalcium phosphate with unidirectional pore structure (UDPTCP), Affinos® (Kurray, Okayama, Japan), has been in clinical use since 2015. To date, there have been only a few clinical studies using this material. We report here the first clinical study for distal radial fracture in the elderly population treated with UDPTCP.

Methods: Consecutive patients aged 65 years or older with dorsally displaced unstable fracture of the distal radius (n=36) were treated operatively in our department. Following reduction of the fracture site, a 7 mm size cube of UDPTCP was placed in the gap of the bony defect and the fracture stabilized with mono-axial or poly-axial type locking plates and screws. The evaluation of all cases was based on clinical examination at the final follow up as well as serial radiography. Resorption and remodeling of UDPTCP were assessed radiologically by measuring the area of filled UDPTCP and the density at their center.

Results and Conclusions: The clinical outcome in all cases was excellent. No serious complications were observed in the post-operative period. Significant correction loss of radial alignment was seen in patients stabilized with poly-axial locking plate. The area of filled UDPTCP and the density at their center was significantly reduced at 2 months after surgery. These results indicate that resorption and remodeling of UDPTCP starts peripherally and centrally at the same time. The resorption of UDPTCP and the formation of new bone were well balanced in our patient cohort.

Conclusion: Block UDPTCP is a safe and convenient material for the treatment of distal radius fracture and is replaced within a suitable time period after grafting into the fracture site. Additional stability can be expected by using block UDPTCP as a bone filler. UDPTCP and stable internal fixation is therefore a reliable strategy for restoring and preserving anatomical position, especially in the elderly population.

A Study of Impact of Prolonged Repetitive Training on Microsurgical Skills of Residents in a Laboratory Setting

List of authors:
Wendy Teo¹, Amitabha Lahiri¹, Alphonsus Chong¹
¹ National University Hospital (Singapore)

Objectives / Interrogation: Microsurgery is an intricate surgical skill that requires fine movements with a high level of hand-eye coordination. Residents in hand surgery must successfully acquire microsurgical skills via repeated practice in order to attain skills that will enable them to achieve vascular patency in patients. As residents, few have the opportunity during their training duration to perform microsurgery in patients on a regular basis as a primary surgeon. There is hence a need for residents to practice in a non-clinical setting in order to improve their skills. However, there is scarce literature that objectively tracks a resident’s improvement in microsurgical skills with practice outside a clinical setting. Our hypothesis is that the microsurgical skills of residents will improve with regular practice over time, in terms of ability to place sutures accurately, consistency of suturing and duration taken.

Methods: 4 residents at different stages of training in the Hand Surgery Residency Program at National University Hospital participated in the study, which spanned across 18 sessions with the residents being evaluated in each session. The task set in each session was to place 9 sutures in a prefabricated 4mm elastic strip under the microscope. A previously validated computer program from Digital Surgicals was used to objectively assess the strips - the spacing between the sutures placed (band score); and the spacing between each suture and wound (deviation score) were measured to give a total score out of 35. The duration taken to place 9 sutures in each strip was also recorded.

Results and Conclusions: Not only did all residents demonstrated improvement in their total scores over 18 sessions, their scores also showed increased consistency, reduced variability and the residents all took a shorter duration to carry out the same task at the end of the 18 sessions. Residents who are more advanced in their training, with more years of microsurgical exposure, attained higher mean scores with reduced variability.

This study is the first of its kind to objectively track improvements of microsurgical skills in residents at regular intervals over a prolonged period of time, with the use of a validated computer program. The findings of this study hence justifies the need for regular microsurgical practice outside of a clinical setting.

Arthroscopic Treatment of Scaphoid Non-union: A Case Report

List of authors:
Gino Francis Baylon*, John Hubert Pua

* University of Santo Tomas Hospital (sampaloc)

Objectives / Interrogation: Scaphoid fractures are one of the most common carpal bone fractures, with a higher incidence occurring in young men. Due to its tenuous blood supply, the scaphoid is at risk for avascular necrosis after a fracture. The primary risk factor for scaphoid non-union is fracture displacement; other risk factors are delayed diagnosis, inadequate immobilization, fracture location, and poor blood supply. The open approach using corticocancellous bone grafts, either vascularized or non-vascularized, has been the gold standard in the treatment of scaphoid non-union. The arthroscopic technique for the treatment of scaphoid non-unions is challenging, and requires extensive experience. However, the advantage of the arthroscopic technique as a minimally invasive technique continues to evolve. The goal of arthroscopic-assisted surgery of scaphoid fractures is to reduce displaced fractures without an open incision and to allow stable fixation for early range of motion until union is achieved.

Methods: This is a case of a 22-year-old male, right-handed, collegiate basketball varsity player who had a history of fall on his outstretched left hand that resulted to a fracture of the proximal pole of the scaphoid. The patient was advised surgery but was lost to follow-up until 3 years after when he presented with chronic wrist pain due to non-union of the scaphoid fracture.

Results and Conclusions: To the authors' knowledge, this is the first case of scaphoid non-union managed arthroscopically in the Philippines. The summary of the results showed radiographic union at day 50 post-surgery and 0-65 degrees range of motion for both wrist flexion and extension with grip strength at 24 kilograms force.

Immediate controlled active motion following Zone 5-7 Extensor Tendon Repair

List of authors:
Rudolf Rosenauer¹, Christoph Pezzei², Stefan Quadlbauer², Thomas Hausner², Martin Leixnering²
¹ Trauma Hospital Lorenz Böhler, Millesi Center (Vienna)
² Trauma Hospital Lorenz Böhler (Vienna)

Objectives / Interrogation: Recent literature suggests dynamic follow-up treatment after extensor-tendon repair. In these patients improved range of motion is reported especially in the first three months after the accident. Additionally, no increased risk of adverse events or secondary tendon rupture is reported. We started using an immediate controlled active motion orthosis (Yoke Orthosis) after extensor-tendon repair in the Zones 5 to 7. The aim of this study is to evaluate the results of this follow-up treatment.

Methods: We reviewed 42 patients who had an extensor tendon repair from 2016 to 2018. A modified Zechner suture und a running epitendinous suture was performed within 6 hours after the accident. The controlled active motion orthosis was applied the first day after surgery for 3 weeks day and night and another 3 weeks during heavy manual activities. Range of motion was measured 3 weeks after the tendon suture in the MCP, PIP and DIP joint.

Results and Conclusions: In total 29 patients were male and in 22 cases the right side was affected. The mean age was 33 ± 14 years, mean follow-up was 38 ± 20 days, mean sick leave was 37 ± 11 days. In 24 cases the middle finger was affected in 5, 7 and 6 cases the index, ring, and small finger, respectively. 37 injuries were in Zone 5 and 5 in Zone 6. After 3 weeks 40 patients (95,2%) showed full range of motion in the MCP, PIP and DIP joint. One patient (2,4%) presented with a 20°, and one patient (2,4%) with a 10° extension deficit in the MCP joint. No flexion deficit was reported. No adverse events were noticed.
In conclusion, a controlled active motion orthosis provides excellent results 3 weeks after the accident. No increased risk of secondary tendon rupture is observed.

Deltoid to triceps transfer in tetraplegic patients: The Stoke Mandeville experience

List of authors:
Marie Song*, Rebecca Shirley¹, Anthony Heywood¹
¹ Stoke Mandeville Hospital (Aylesbury)

Objectives / Interrogation: More than 50% of spinal cord injuries occur at the cervical level, leading to tetraplegia. Surgical restoration of upper limb function has the ability to improve patient autonomy and self-esteem[1]. However, these operations are underutilised in the United Kingdom and elsewhere. The authors describe a 15-year experience of deltoid to triceps transfer - using different types of interconnecting grafts - to restore elbow extension, one of the key functions to improve reaching capability and hand function.

Methods: A retrospective review of all tetraplegic patients who were considered for deltoid to triceps transfer between the years 2003 to 2017 was performed using clinical records. Pre-operative evaluation included sensory and motor testing for ICSHT (International Classification for Surgery of the Hand in Tetraplegia) grading. Patients who were offered deltoid to triceps transfer but declined the procedure were noted, with their reasons for declining where recorded.

Operation notes and follow-up records were reviewed to determine the types of grafts used, and the outcome, including early and late complications, and elbow extension power.

Results and Conclusions: We identified 26 patients who underwent deltoid to triceps transfer, 21 male and 5 female, with a mean age at the time of operation of 37 years (range 21 - 66). A total of 32 reconstructions were carried out, 20 unilateral and 6 bilateral (not simultaneous), with one late revision procedure to shorten a graft that had stretched. Thirteen were performed with the sole aim of restoring elbow extension, and 19 were combined with additional tendon transfer procedures to restore grip.

During our 15-year experience, the graft types changed from synthetic to fascia lata and most recently to tibialis anterior, respectively 18, 5, and 9 grafts, and the reasons for these changes are discussed. Early complications included haematoma, seroma, and superficial wound infection, and late problems included 2 suture granulomas and one case of graft stretching. There were no ruptures.

All but two patients achieved useful and measurable elbow extension power of MRC 3/5 or better. The two failures were both due to insufficient strength in the donor deltoid muscle, although one of the two patients felt that he had better control of his upper limb.

Herbert ulnar head implant arthroplasty: 47 cases; mean follow-up 6.5 years

List of authors:
Peter Axelsson*, Allan Ibsen-Sörensen, Christer Sollerman
1 Dept. of Hand Surgery, Institute of clinical sciences, Sahlgrenska Academy, University of Gothenburg (Göteborg)

Objectives / Interrogation: To report clinical and radiographic outcomes for the Herbert Ulnar head prosthesis.

Methods: We reviewed all Herbert ulnar head arthroplasties performed at our department between March 2000 and September 2017. Fifty-one arthroplasties were performed in 50 patients. 47 cases had a minimum follow-up of one year. Five patients were lost to follow-up; two deceased unrelated to the operation, one due to unrelated illness and two implants were revised. The 42 remaining implants had a mean follow-up of 6.5 years (range 1-17 years). The rationale for the procedure were; Rheumatoid arthritis (n=12), Osteoarthritis (10), secondary Osteoarthritis (11), painful instability after previous resection arthroplasty (8) and failed implant arthroplasty (1). Assessment included Disability of the Arm, Shoulder and Hand (DASH) and Patient Rated Wrist Evaluation (PRWE) questionnaires, 100 mm Visual analogue scales (VAS) for pain and satisfaction, measurements of range of motion, grip, lifting, and forearm rotational strength. For 17 of the cases full preoperative assessments, including strength measurements were available. The change in preoperative and last follow-up measurements for these patients was analyzed with Wilcoxon sign rank test.

Results and Conclusions: Data for patient reported outcomes and strength measurements at final follow-up visits are summarized in table 1.

Table 1. Patient reported outcomes and Strength measurements at latest follow-up, 42 patients.

For the subgroup with full preoperative assessment there were significant improvements in DASH, PRWE, VAS for pain with activity and strength for grip and lifting with neutral forearm rotation. We did not detect radiographic signs of implant loosening except for one patient whose implant was revised. Another patient had the implant removed due to recalcitrant pain and one patient underwent successful secondary surgery due to persistent painful DRUJ instability.

In a selected group of patients the Herbert implant produced favorable outcome with a low complication rate.

Impact of Plate Design on Contact Force Between Flexor Tendons and Distal Radius Volar Plates

List of authors:
Ido Volk*, Katharine M Hinchcliff², Xenia Ivanova², Sandra Taylor², Robert M Szabo²
¹ Hadassah Medical Center (Jerusalem)
² UC Davis Medical Center (SACRAMENTO)

Objectives / Interrogation: The purpose of this study is to determine whether the design of distal radius volar plates impact the amount of force exerted on the flexor digitorum profundus (FDP) and flexor pollicis longus (FPL) tendons when the plates are placed proximal and distal to the watershed line.

Methods: Three commercially available plates were applied to ten fresh, matched-pair upper extremity specimens. External cyclical loading was applied to the tendons, and the force generated between tendon and plate was measured. Linear mixed effect models were used to evaluate differences in log-transformed values of maximum and mean force by plate position, plate design and the interaction between position and design.

Results and Conclusions: Results: The forces on the tendons differed significantly by position, as measured by Soong grade, but were not significantly different for plate design. For the FPL tendon, the average maximum force with a plate in Soong 2 was 4.50 [95% CI: 2.8, 7.3] times higher than when the plate was in a Soong 0 placement, and 4.63 [95% CI: 2.82, 7.61] times higher for the FDP tendon. While not statistically significant, lower observed force values with thinner plates when plates were placed distal to the watershed line suggest that plate thickness could also be a critical plate characteristic for distally placed plates.

Conclusions: Despite differences in plate design, the main determinant of plate prominence and therefore flexor tendon injury potential is placement in relation to the watershed line. This study may help guide surgeon implant selection and volar plate design.

Effect of proximal interphalangeal (PIP) joint fusion on grip force and load distribution of the hand

List of authors:
Angela Reger*, Marion Mühldorfer-Fodor¹, Karl-Josef Prommersberger¹, Jörg van Schoonhoven²
¹ Rhön-Klinikum AG, Klinik für Handchirurgie (Bad Neustadt)
² Klinik für Handchirurgie, Rhön-Klinikum AG (Bad Neustadt)

Objectives / Interrogation: This study investigates in vivo if an isolated fusion of a single PIP joint influences the grip force and the load distribution of the hand when gripping a cylindrical object.

Methods: Ten patients, who had one single PIP joint fused due to posttraumatic joint destruction (4 x index, 4 x middle, 2 x ring finger), but without other structural lesions of the hands were included in this study. On average 59 (17-121) months p.o., patients returned for a manugraphy analysis. Patients performed grip force tests, using three cylinders (100mm, 150mm and 200mm circumference) covered with a pressure sensor matrix to measure the total grip force and load distribution pattern of both hands. Grip force and the load applied by each of the four fingers were compared for the affected and the healthy hand. The fusion-angle was determined by x-ray, which also confirmed the bony healing of the fusion. Due to the small number of patients, only descriptive statistics were provided.

Results and Conclusions: Results: The total grip force of the affected compared to the healthy hand was reduced after PIP-joint fusion of middle- and ring finger for all cylinder sizes (PIP III 56%/88%/91%, PIP IV 76%/105%/91%). After PIP-joint fusion of the index finger grip force was only reduced at the smallest cylinder (91%), while it was increased to 120% at the middle and 139% at the large cylinder. Compared to the opposite side, the load applied exclusively by each affected finger was always reduced, except for the large cylinder, where even the fused index-fingers exerted more strength than the healthy side. The loss of strength by the fused finger was partially compensated through a gain of strength of the other fingers of the affected hand. So, 5/10 patients showed a higher grip strength than the opposite side using the middle cylinder, 6/10 using the large cylinder.

Conclusion: After PIP-joint-fusion grip force is severely impaired when gripping small cylindrical objects, but less affected when gripping larger objects. The load applied by the fused finger is always reduced, but for the total grip force this can often be compensated by the other fingers of the affected hand, especially while gripping large objects.

Title: Wide awake local anaesthesia no tourniquet technique (WALANT) for hand surgery: an observational study for patient agreement

List of authors: olivier mares*, pascal kouyoumdjian¹, Philippe Cuvillon¹, helene dietrich¹, remy coulomb¹
¹ CHU Nimes (Nimes)

Objectives / Interrogation: Hand surgery with Walant becomes more popular for surgeon and a new strategy for hospital. Few data are available for patient agreement and comfort.

Methods: After IRB approval, patients scheduled for Walant hand surgery were prospectively enrolled and evaluated. Surgery was performed in the ambulatory unit using a standard Walant surgery without premedication, monitoring nor intravenous line. Before surgery, evaluations were performed using APAIS score (pre operative anxiety) and Likert scale (for comfort and stress). After surgery, perioperative procedure quality (primary end point) was evaluated using EVAN G scores (at discharge) by an independent evaluator. Times and pain scores (0-10) at each time were recorded (0 to 10). Statistical analyses using SAS software.

Results and Conclusions: Results : 31 patients (12 males, 62±15 years, 56±6 kg, ASA 2±1) were prospectively included. Before procedure, pain score at surgical site was 4±3 with an APAIS score at 9±5 (=very low stress level). Only one patients reported personal high stress level. Pain at infiltration was 2±1. At incision, only 1 patient required more infiltration and 1 patient required a general anesthesia due to surgical complication: WALANT success without anaesthesit rescue was 97 %. Duration of surgery was 11±10 min, no adverse effect was recorded in PACU. Total intra hospital (including infiltration and surgery) stay was 63±29 min. At discharge, EVAN score (median, IQ) for global satisfaction (1 scale: 0-5) was 5 (5-5), comfort (3 scales:0-15) was 15 (12-15), adverse event (10 scales :10-50) was 10 (10-14), pain (scales 7 :7-35) was 7 ( 7-9) No side effect was recorded at discharge, with a mean pain score at 0 (no nausea or vomiting). Chung score at discharge was 12/12 for all patients.

Conclusion

This study demonstrated a very high level of agreement and satisfaction for Walant surgery for the patient (primary end point) and high benefit for the surgeon and hospital, regarding time per procedure.

Training in microsurgery.

List of authors:
KONSTANTINOS TOLIS*1, Sarantis Spyridonos2, Ioannis Triantafyllopoulos2, Antonios Galanos2, Emmanouil Fandridis1, Filippis Giannoulis1, Panagiotis Kanellos1, Ismene Dontas2
1 GENERAL HOSPITAL KAT (ATHENS)
2 Medical School of Athens (ATHENS)

Objectives / Interrogation: Microsurgery is defined as the type of surgical operation performed with the assistance of microscope. It has been proven that training in microsurgical techniques can improve the abilities of the residents mostly, after the attendance of at least 8 weeks intense seminars, in such a way that it has affection even at macrosurgical skills.

Methods: At the Laboratory of Research of the Musculoskeletal System a 3 - month training seminar in microsurgical techniques regarding the repair of arteries, veins and nerves is provided for 30 years continuously. The seminar includes 5 gradual stages of training in latex frames, rabbits and rats.

We performed a prospective study regarding the surgical abilities of participants during the years of 2017 and 2018, at the end of every training session. Also the research analyzed the correlation of success at every session to speciality, gender, year of residency and previous experience.

Results and Conclusions: Results: During a period of two years 40 persons (30 men, 10 women) participated, 30 of whom were orthopedic residents with a mean age of 33 years old. With only two specialists taking the microsurgery seminar, the rest were residents at their fourth (15 residents, 37,5%), fifth (9 residents, 22,5%) and second (8 residents, 20%) year of residency, while other 6 residents (15%) cover the rest. Previous experience on microsurgery had only 3 participants (7,5%). There was significant relationship between gender and successful suturing and functionality of a small vein in rats(p value=0,042), as well as the year of residency in the total number of sutures performed in 15 minutes on a latex frame (p value=0,007).

Conclusions: The microsurgery seminar provides the participant surgeons with the ability to better understand the shape and structure of tissues, while gaining a gentle approach across them. It contributes in improving surgical skills, strengthening coordination between brain and hands, as well as sight on three dimensions. Lastly it increases concentration in very narrow surgical fields.

nterosseous SL Reconstruction for Chronic Scapholunate Dissociation augmented DIC stabilized by RASL vs SwiveLock as internal splint

List of authors:
Keiji Fujio
1 Orthopaedics, Kansai Electric Power Hospital (Osaka)

Objectives / Interrogation: Staged 3 or 4 of Scapholunate (= SL) dissociation according to 5 questions by Garcia is good candidate for reconstruction. How long should we need to keep K-wire after any ligament reconstruction? When can we achieve successful engraftment? Internal splint such as RASL or SwiveLock fixation would be hypothesized to maintain SL reduction and achieve engraftment and analyzed their results.

Methods: Berger’s approach was applied for all cases. Partial DIC was transferred to dorsal portion of SL ligament. 12 patients of SL were fixed by RASL using double thread screw, and 6 patients were fixed using fiber tape with SwiveLock system as internal fixation. 12 cases of RASL were analyzed averaged followed up for 32.4 months. 6 cases of SwiveLock system were analyzed averaged followed up for 15 months. The three dimensional kinematic analysis was performed after operation for each methods.

Results and Conclusions: 10/12 of RASL patients returned to previous occupation. 2 cases were converted to SwiveLock system because of screw loosening. Breakage of double thread screw was occurred in 1 case. Postoperatively SL angle is reduced from 69 degrees to 40 degrees. SL gap is also reduced from 4.1 to 1.8 mm. There was no carpal collapse or progression to SLAC. 6/6 of SwiveLock system patients returned to previous occupation. There was no progression of SL gap except for 1 case. Result showed almost normal motion during flexion and extension. Postoperatively SL angle is reduced from 72 degrees to 40 degrees. SL gap is also reduced from 5.3 to 1.2 mm. According to 3D analysis, normal scaphoid motion center axis is dorsal scaphoid. Distance between scaphoid apex and motion axis are different among normal, RASL, SwiveLock system. Kinematics of SwiveLock system was closer to that of normal compared to RASL. (fig 1) Fiber tape with SwiveLock system was closer to normal compared to RASL, and better clinical results were obtained compared to RASL as internal splint.

Treatment of osteoarthritis of the carpometacarpal joint of the thumb with trapeziectomy and tendon allograft interposition.

List of authors:
Nadine Hollevoet*, Camille Thys¹, Lieselot Vekens¹
¹ Ghent University Hospital (Ghent)

Objectives / Interrogation: One of the surgical treatment options for osteoarthritis of the carpometacarpal (CMC) joint of the thumb is tendon interposition after partial or total trapeziectomy, with or without ligament reconstruction. Usually a tendon autograft is used. The advantage of a tendon allograft is shorter operation time. The aim of the study was to evaluate patients who were treated with tendon allografts.

Methods: Forty-eight patients (56 hands) were operated on between 2006 and 2015 with tendon allografts for osteoarthritis of the CMC joint of the thumb. Thirty-four patients (41 hands) were included in the study. Ten patients were male and 20 female. Mean age was 59 years. In 11 hands partial trapeziectomy with tendon interposition was done, in 20 partial trapeziectomy with tendon interposition and ligament reconstruction, in 1 total trapeziectomy with tendon interposition and in 9 total trapeziectomy with tendon interposition and ligament reconstruction. Patients were evaluated with the disabilities of hand and shoulder (DASH) and visual analogue scale (VAS) for pain. Patients were also asked if they were satisfied. In 23 patients (29 hands) clinical evaluation was done (Kapandji score, thumb abduction, key pinch). Eleven patients (12 hands) could not come to the hospital and the questionnaires were sent to their homes. Mean follow-up was 57 months (range: 15-124).

Results and Conclusions: Mean DASH score was 19 and mean VAS for pain 1.3. Eighty-three percent of patients were satisfied. Mean Kapandji score was 9.3, mean abduction measured 56° and mean key pinch 5.1 kg. Four patients needed a surgical revision procedure (9.8%). In one the tendon graft was removed because of infection, in another a partial trapeziectomy was converted into a total trapeziectomy, one had an additional interposition of the scaphotrapezoidal joint and in another patient with spasticity an arthrodesis was performed because of adduction contracture of the thumb.

Conclusion and discussion: Trapeziectomy with donor tendon interposition is one of the treatment options for CMC joint osteoarthritis of the thumb. Good results can be obtained in about 80% of patients which is similar to other treatment options such as total joint arthroplasty.

Spread of hand infections: A Retrospective trial single center study

List of authors:
Khaled Dastagir¹, Sören Könneker¹, Peter M. Vogt²
¹ Hannover Medical School (Hannover)
² PÄHW (Hannover)

Objectives / Interrogation: Owing to its function, the hand is predisposed to be injured or infected in daily work in many different ways. Hand infections present due to the complex anatomy of the hand, various causes and broad germ spectrum as heterogeneous and complex diseases. They can lead to severe disabilities and reduce drastically the quality of life. Early diagnosis and therapy prevent severe morbidities. Specific knowledge of trauma mechanism, pathogens and especially the spread of hand infection are necessary for adequate and early treatments.

The aim of this study was to evaluate systematically the spread of hand infections according to injury mechanism, pathogens and its entry area.

Methods: Retrospectively, all data of 519 patients with hand infections, who admitted from 2007 to 2014 our department of Hand Surgery, were generated from electronic hospital information system (SAP) and medical records. Patient's demographics and clinical data were recorded and analyzed for age, gender, pre-existing illnesses, course of treatment, the microbiology, C-RP, leukocyte number, the pathogen entry area and spread of infection.

Results and Conclusions: Our study revealed that, compared to other known factors for the spread and severity of hand infections such as germ spectrum, cause and individual risk, the localization of the portal of entry on the hand has a significant influence on the tendency to spread and the risk of a correspondingly severe infection.

Due to the different spread of infections depending on the localization of infection entry, finger infections in particular should not be trivialized, but should be judiciously closely assessed and treated by hand surgeons.

Impact of delayed presentation of patients with hand infections to hand surgeons: A retrospective study with 379 patients

List of authors:
Khaled Dastagir¹, Peter M. Vogt², Sören Könneker¹
¹ Hannover Medical School (Hannover)
² PÄHW (Hannover)

Objectives / Interrogation: Due to the special anatomy of the hand, hand infections present as heterogeneous and complex clinical illness. An early and professional treatment is essential to avoid complications. The aim of our study was to investigate the impact of the presentation time of patients with hand infections to hand surgeons on hospital stay and the frequency of necessary operations.

Methods: Retrospectively, 379 Patients with hand infections, who were treated in our clinic were evaluated for a time of presentation to hand surgeon, time of trauma, length of stay, and frequency of necessary operations.

Results and Conclusions: On average, more than one-day delayed surgical presentation led to a longer hospital stay of 1.22 days (KHVD) (95% CI: 1.20-1.25, p <0.001). Also, the odds of being operated every day increased by 13.59% (95% CI 4.01%-25.43%, p <0.001). KHVD also increased by a factor of 1.09 (95% CI: 1.03-1.15, p <0.001) with delayed antibiotic challenge. However, the time of antibiotics did not correlate with the decision to undergo surgery (yes / no) (p = 0.11).

The present retrospective study shows that a late presentation of patients with hand infections leads to a longer inpatient length of stay as well as to a higher number of necessary surgeries. An early surgical presentation of hand infections to an experienced hand surgeon is important to avoid complicated patient pathways that add costs to the healthcare system.

Dynamic Carpal Tunnel. Association of the incursion of the lumbrical muscles in the carpal tunnel as an etiological factor

List of authors:
Ramon de Bedout*
1 H san Ignacio (bogota)

Objectives / Interrogation: The carpal tunnel syndrome is the most common peripheral nerve entrapment pathology. But there is a group of patients where, at the time of the examination, their clinical signs are not clear enough for diagnosis and the tests and exams cannot confirm it. patients can be part of the group of manual workers of repetitive activities. The worker is sent to medical control, usually with temporary suspension of their routine activities. This means that when assessed by the doctor, there will be no clear signs of compression of the median nerve. Is there any relation to the incursion of the lumbrical muscles in the carpal tunnel as a dynamic etiological effect of this?

Methods: A study, using ultrasound, was made in workers between 20 and 60 years of age, and had no previous pathologies. The workers consulted a carpal tunnel clinic and were evaluated by the clinical signs.

They underwent an ultrasound examination (Siemens, sonoline-versa with a 10Mhz transducer) in three planes like this:
1 level of the carpal radio joint
2 transverse plane on the body of the lunate
3 transverse plane at the level of the hook of the Hamate

And each of these was taken at two different times:
A-Carpal tunnel with neutral wrist and extended fingers
B-Carpal tunnel with neutral wrist and fingers in forced flexion

Results and Conclusions: Findings: A study was made of 118 wrists into two groups: first group of 59 wrists with carpal tunnel symptoms and a second group of 59 wrists in workers without carpal tunnel symptoms. The ultrasonography study was done to each one of them in three levels and in two positions and it was reported as negative positive in each level of the observation.

In the first group: level I all negative, level II 22 positive (37.28%), level III 38 positive (64.4%).
In the second group: level I all negative, Level II 5 positive (8.47%), level III 15 positive (25.4%)

Discussion: the low insertion of the lumbrical muscles, which can be the etiological factor for a dynamic carpal tunnel. We recommend a study with ultrasound in those patients who have an evident symptomatology but is not clearly verifiable by conventional methods. The study with ultrasound should be of great importance.

Acquired hemophilia A as a rare cause of nontraumatic compartment syndrome and hematoma formation

List of authors:
Daniel Walder*, Flavien Mauler, Claudia Meuli, Thuan Ly
1 Kantionsspital Aarau (Aarau)

Objectives / Interrogation: Acquired factor VIII inhibitor (hemophilia A) is a very rare, often idiopathic disease that can lead to diffuse bleeding, with a high rate of morbidity and mortality. We present two patients with first-time diagnosed acquired hemophilia A who were treated at our clinic within 2 months.

Methods: The first patient was an 83-year-old woman who presented with atraumatic compartment syndrome of the right hand which required fasciotomy. The compartment syndrome was due to spontaneous bleeding. Only after several revision surgeries and a complicated course, the resulting defects could be closed by secondary sutures and skin grafting. The second patient was an 85-year-old man who was admitted with multiple hematomas on both upper extremities, which were treated nonoperatively. The two patients received interdisciplinary care, involving early initiation of clotting factor replacement and immunosuppressive therapy, which were necessary to control the bleeding.

Results and Conclusions: Acquired hemophilia A must be considered as a very rare but important life-threatening differential diagnosis in multiple hematomas, especially in atraumatic compartment syndrome. Early diagnosis with immediate start of replacement therapy to correct coagulation and initialization of immunosuppressive therapy are crucial for successful treatment.

Volar plate buttress on bended Kirschner wire fixation for the displaced volar rim fragment of distal radius comminuted fracture

List of authors:
Ko Temporin*1, Keiichiro Oura1, Kozo Shimada1
1JCHO Osaka Hospital (Osaka)

Objectives / Interrogation: Volar rim fragment of distal radius fracture supports the carpal bones and is challenging for the rigid fixation. We investigated the outcome of volar plate buttress on the bended Kirschner wire fixation for the displaced volar rim fragment of distal radius comminuted fracture.

Methods: 2 cases with the volar rim fragment of distal radius fracture, which displaced after the initial surgery, were enrolled in this study.
Case 1 was 51-year-old woman and sustained volar Barton fracture. 6 months after the initial surgery with volar locking plate, she had the plate removal. However, the fragment got displaced. Case 2 was 73-year-old woman and had comminuted Smith fracture. 1 week after the initial surgeries with volar locking plate, Plain radiography showed displaced volar rim fragment (Figure 1).
In the surgery, the volar rim fragment was reduced and fixed with titanium Kirschner wires. The wires were bended to fit the volar cortex of the radius. Volar locking plate applied on the wires and was fixed with screws to buttress the wires and the fragment (Figure 2).
**Results and Conclusions:** At the final follow-up, they had no pain. Flexion/extension recovered into 50/60 and 40/50 respectively. Bone union of the fragment was confirmed by plain radiography and CT. This method used the standard instrument without special plate and complex technique. The volar rim fragment could be fixed rigidly by buttressing the wires with the plate, and favorable outcome was obtained. Thus, this method is an option for the fixation of the volar rim fragment.

Is there a correlation between duration of scaphoid fracture non-union and degenerative changes of the wrist?

List of authors:
Joseph Dias¹, Amin Kheiran*¹, Donald Ngo², Randy Bindra², Clare Wildin¹, Aamer Ullah¹, Bhaskar Bhowal¹
¹ University Hospitals of Leicester (UHL) (Leicester)
² Gold Coast University Hospitals (Southport)

Objectives / Interrogation: The primary aim of this study was to identify the rate of osteoarthritis in scaphoid fracture non-union. The secondary objectives were to investigate whether the incidence of degenerative changes correlates with the duration of non-union(interval) and the site of fracture,and to identify the variables that influence the primary outcome.

Methods: We conducted a retrospective review of 273 consecutive cases with scaphoid fracture non-union presenting to our hand surgery unit from 2007-2016. Data included patient demographics, the duration of non-union (interval), anatomical location of fracture (distal, middle, and proximal), anatomical area of scaphoid non-union advanced collapse (SNAC areas 1-3), and the presence of dorsal intercalated segmental deformity (DISI). Overall health-related quality of life were assessed using EuroQol five-dimensional questionnaire (EQ-5D). Data was retrieved from case notes, Patient Archiving and Communication System (PACS), postal and telephone follow-up using a designated case report form. Patients were divided into two groups (SNAC vs. Non-SNAC). Group differences were analysed by the Mann-Whitney U test and association between scales with Pearson’s correlations. A two-sided p-value of <0.05 was assumed as significant.

Results and Conclusions: We identified 273 cases with scaphoid fracture non-union confirmed on CT scans (n=250) and plain radiographs (n=23). The subjects consisted of 33 males and 240 females with the mean age of 34.3 years (SD, 13.2). Degenerative changes occurred in 49% (n=135) of non-unions (SNAC group), and 51% (n=141) had no degenerative changes (non-SNAC group). In overall, the average interval was 3.1 years (range, 0-45 years) in those with known date of initial injury (n=221). The fracture location in SNAC group included 3.3% of distal 20%, 41% of middle 60% (distal to ridge), 29% of middle 60% (at ridge), 88% of middle 60% (proximal to ridge), and 100% of proximal 20% fracture non-unions. Of these, 67% had SNAC 1, 14% with SNAC 2, and 21% presented with SNAC 3. The mean interval in the SNAC 1, 2, and 3 were 4.3, 4.9, and 5.5 years, respectively. An overall incidence of DISI deformity of the wrist was 86%. The average summary index between SNAC and non-SNAC groups was 0.803 and 0.819, respectively. Our results demonstrate that advanced osteoarthritis was seen more in the proximal fracture non-unions (P<0.05). There was no clear correlation between the interval and the progression of osteoarthritis. SNAC occurred in fractures aged 4 years or older.

Rupture rate, functional outcome and patient satisfaction after primary flexor tendon repair using the Arthrex FiberLoop® and Tsuge suture technique with early active motion rehabilitation

List of authors:
Stephanie Köhler*, Florian Neubrech¹, Michael Sauerbier¹
¹Berufsgenossenschaftliche Unfallklinik (Frankfurt am Main)

Objectives / Interrogation: While the current literature in flexor tendon repair primarily supports a 4-strand locking core suture and epitendinous repair, the optimal suture material remains unclear. Identifying the ideal suture material could help provide sufficient stability for early dynamic splint therapy and thus improve total active motion (TAM), grip strength and daily activities. We hypothesize the rupture rate after flexor tendon repair with the Arthrex FiberLoop® (Arthrex, Munich, Germany) is lower than other suture materials and functional outcome and patient satisfaction are superior compared to the current literature.

Methods: A 2-stage retrospective, randomized follow-up study of 143 patients treated with the Arthrex FiberLoop® after flexor tendon injury in zones 2 or 3 from May 2013 - May 2017 was performed. In the 1st stage, the rupture rate in all patients was assessed after a follow-up of >1 year to exclude revision surgery. In the 2nd stage, 20% patients (29 patients) were randomly clinically examined. Functional parameters, such as finger and wrist mobility measured with a goniometer, grip strength measured with a Jamar dynamometer, patient satisfaction measured using school grades (1-6), pain-levels measured using visual analogue scales (0-10), and DASH-score were assessed. The Buck-Gramcko and Strickland scores were calculated to compare our results to the current literature.

Results and Conclusions: A rupture rate of 2.1% was recorded. A postoperative complication was reduced TAM. 29 patients (20% of all patients) were examined at a mean of 34 ± 7.5 months postoperatively. 10.3% of these patients had an incomplete fingertip palmar distance. Postoperative grip strength was on average 24 ± 3.1 kg. 93.0% of these patients were very satisfied with treatment. No patient complained of pain postoperatively. The mean postoperative DASH score was 6.7 ± 2.8 points. The mean Buck-Gramcko score was 14 ± 0.2 points. According to the Strickland score, 93.0% patients had excellent and 6.99% good results. Patients returned to work at a mean of 4 ± 0.7 months postoperatively.

Phalangeal neck fractures with volar displacement: description of the injury, and open reduction and internal fixation with interfragmentary screws

List of authors:
Ricardo Kaempf*, Márcio Aita², Bernardo Vaz Peres Alves¹, Antônio Tufi Neder³, Paulo Henrique Ruschel⁴, Pedro J Delgado⁵
¹ Hospital Santa Casa de Porto Alegre (Porto Alegre)
² Faculdade de Medicina do ABC (São Paulo)
³ Hospital Lifecenter (Belo Horizonte)
⁴ Hospital Santa Casa de Porto Alegre (Porto Alegre - RS)
⁵ Hospital Universitário Montepríncipe (Madrid)

Objectives / Interrogation: Phalangeal fractures are among the most frequent fractures of the skeleton. Lesions at the proximal phalanx are considered challenging because of the complexity of the anatomy in the region. The extensor tendon is a delicate structure that at the distal portion of the proximal phalanx spreads like a sheet, surrounding the bone surface with close contact. Commonly seen in children and seldom in adults, fractures of the phalangeal neck occur mostly at the proximal phalanx of the thumb and at the medial phalanx of the long fingers in adult patients. In nearly all cases described, the fracture shows dorsal displacement and is treated with K-wires fixation.

In the only study that specifically described proximal phalangeal neck fractures, Al Qattan reported on ten patients treated with non-displaced or dorsally-displaced fractures. In addition, that author employed the same classification to differentiate phalangeal fractures in adults and children, but it has neither mention of soft-tissue injury (extensor tendon injury) nor direction of fracture displacement.

There are no previous publications describing the treatment of choice for proximal phalangeal neck fractures with volar displacement.

Methods: We described the lesion and the treatment of two patients with proximal phalangeal neck fractures and severe volar displacement. We highlight that this type of deformity can cause a boutonniere-like lesion of the extensor tendon, with the distal stump of the central extensor tendon trapped at the fracture site.

Results and Conclusions: We propose to add a division in the classification of Al Qattan for type II fractures in adults (displaced and with bone contact), in which IIA fractures show dorsal displacement (more common), and IIB fractures have palmar displacement (rarer and unstable).

3 Pontifícia Universidade Católica de Campinas (Campinas)
4 Irmandade da Santa Casa de Misericórdia de São Paulo (São Paulo - SP)
5 Hospital Universitário Montepríncipe (Madrid)

Objectives / Interrogation: Radial neck fractures in children (RNFC) are rare; represent approximately 1% of all pediatric fractures, and 10% of elbow fractures in childhood. Jeffery et al. described in 1950 the most common mechanism of RNFC as a fall onto an outstretched hand with valgus force, causing compression of the radial head against the capitellum. This laterally angulated radial head fracture was called a type I lesion. The type II lesion, which is rarer, occurs in association with posterior elbow dislocation. In these cases, either with spontaneous or provoked closed reduction of the dislocation, there is an impaction fracture of the anterior lip of the radial head caused by the capitellum, which gets trapped between the proximal radial metaphysis and the head fragment, that is rotated in 90°.
Open reduction has always been the treatment of choice. Furthermore, closed reduction was believed to be impossible and was classically contra-indicated due to the risk of fracture displacement and vascular compromise of the proximal radial epiphysis. There are less than 30 cases of type II Jeffery fractures described in literature, and only Chotel et al. had percutaneously treated those lesions, by means of a varus lateral space opening, manipulation of the fracture, conveying an easier reduction of the radial head to its anatomic site.

Methods: We describe a closed reduction technique of type II Jeffery fracture with the use of two K-wires, being the first inserted at the fracture site and working as guide and fulcrum to the fragment, so that it pushes the head towards its anatomic position.
Method for closed reduction Jeffery type II radial neck fracture.

Results and Conclusions: We reckon this maneuver to be effective, reproducible, and less aggressive, thus decreasing the risk of iatrogenic chondral and ligament injuries. We also highlight that there is a risk of displacement and fragmentation of the head fragment after multiple attempts of reduction; therefore, we recommend proceeding to an open reduction after initial failure of the closed method.

Nerve transfer for recovery of protective sensitivity in the radial aspect of the hand.

List of authors:
aida garcia*
1 Militar Hospital (bogota)

Objectives / Interrogation: In the management of the sequelae of the brachial plexus lesions, motor and sensory recovery is sought, in order to preserve the greatest possible functionality and to reduce the complications derived from anesthetic zones, thus sensitive transfers have gained greater importance within the surgical techniques. The objective of the study is the identification of the innervation patterns of the first interdigital space, as well as to propose a surgical technique for the sensitive recovery of the radial edge of the hand in the first and second ray. For this purpose, the dissection of 20 cadaverous specimens was performed, seeking to describe the anatomical variants of the branch of the sensitive branch of the median and carry out the nerve transfer in the palm of the hand or in the distal third of the forearm.

Methods: descriptive study, dissection in cadaveres

Results and Conclusions: Regarding the anatomical variants, it was found that the sensory branch of the median nerve branches within the carpal tunnel in 40% of the specimens, distally in 40% and proximally in 20%. With these findings, it is proposed to perform two sensitive transfers (terminal-terminal techniques): 1. of the digital nerve of the 4 finger and of the radial digital nerve of the 5 finger to the trunk of the sensory nerve of the first space or one to the common digital nerve of the thumb and the other to the radial sensory nerve of the second finger; 2. the proximal sensory transfer of the dorso-ulnar sensory branch of the ulnar nerve to the common sensory trunk for the first space, in this technique a carpal tunnel approach is necessary, since the sensory branch of the ulnar nerve is not of sufficient length as to make a distal transfer to this and therefore it is necessary to identify the receiver trunk distal to the tunnel and dissect it to the distal forearm to perform the transfer. This last technique would require a greater surgical exposure, greater dissection and manipulation of the receptor nerve without improving the expected results, for which reason the transfer at the level of the palm of the hand is recommended.

Keywords:
radial nerve
Nerve transfer for recovery of protective sensitivity in the ulnar aspect of the hand.

List of authors:
aida garcia*
1 Militar Hospital (bogota)

Objectives / Interrogation: Preserving the distal sensitivity of the upper limb is one of the fundamental objectives that should be sought when focusing and managing a patient who has a brachial plexus or peripheral nerve lesion; since this type of alteration increases the morbidity and the risk of suffering injuries such as burns, cuts, compression ischemia among others. Sensory transfers have become more important in the current management of brachial plexus injuries as they positively impact functional scales. The objective of the study is the identification of the innervation patterns of the ulnar ridge of the fifth finger and the digital ulnar sensory branch of the 3 finger, as well as surgical techniques for the sensitive recovery of the ulnar border of the hand.

Methods: descriptive study, dissection in cadaveres

Results and Conclusions: For this purpose, 20 cadaverous specimens were dissected and two techniques (end-terminal) are described: 1. the ulnar sensory branch of the third finger is taken as a donor and is transferred by subcutaneous tunnel to the recipient in the ulnar sensory branch of the 5 finger in the palm of the hand. 2. The ulnar sensory branch of the 5 finger is identified before the Guyon canal and the cutaneous palmar branch or the sensory branch for the third space is used as a donor at the proximal level. The cutaneous palmar was inconsistent in 50% of the components and in those that it was found, it had a caliber 50% lower than that of the receptor nerve. Given this finding, it was preferred to use the branch of the common digital nerve of the third space in the transfer at the level of the distal third of the forearm, but for this purpose it is necessary to identify it distal to the carpal tunnel and dissect it proximal to the wrist crease. to transfer it to the recipient, this second technique involves a greater dissection, longer surgical time and greater manipulation of the donor nerve, which is why we recommend carrying out the transfer at the level of the palm of the hand which has lower morbidity and meets the same objectives as the proximal transfer in terms of the expected results.

**Functional muscle transfer of the low trapezius portion for paralytic shoulder, ipsilateral and contralateral**

**List of authors:**
aida garcía*

1 Militar Hospital (bogota)

**Objectives / Interrogation:** Functional muscle transfers (FMT) are an option for the management of the paralytic shoulder in brachial plexus lesions that are not candidates for nerve transfers. FMT can be associated with other muscle or nerve transfers in the upper limb to improve the overall function of the upper extremity. Given that in different biomechanical studies the theoretical advantage of the lower trapezius muscle has been demonstrated with respect to the latissimus dorsi as a donor, the objective of this work is to know the surgical anatomy of the dynamic transfer of the ipsilateral and contralateral lower trapezius, and to identify advantages and disadvantages of these two techniques.

**Methods:** Descriptive study, dissection in cadaveres

**Results and Conclusions:** A descriptive anatomical study was performed on 20 cadaveric specimens with the transfer of the lower trapezius to the contralateral shoulder (10 specimens) and ipsilateral (10 specimens). The contralateral transfer is indicated when there is paralysis of the ipsilateral trapezius muscle in the paralyzed shoulder or when the function or power of the ipsilateral trapezius it’s not enough to be transfer, in the other hand the ipsilateral transfer does not compromise the healthy upper limb of the patient. It was found that in the ipsilateral FMT the spinal accessory nerve should always be visualized and protected during the procedure; as well as performing augmentation with allograft of the Achilles tendon to reach the necessary length when performing posterior or posterosuperior tenodesis to the rotator cuff, this is not necessary in the contralateral technique, since with the extension towards the lumbar fascia that is performed in the dissection as described in the art, sufficient length is achieved to perform the tenodesis. Both techniques allow transfer at the posterior (infraspinatus) or posterosuperior (between supraspinatus and infraspinatus) level of the shoulder. During the dissections, infraspinatus and supraspinatus tendons were always found to perform tenodesis, however in vivo, given the atrophy that the rotator cuff may have, we recommend having anchoring sutures at hand to reinsert the donor tendon directly to the humeral head in case of be necessary. It becomes very important to achieve an adequate tension and tenodesis effect, the position of the shoulder in external rotation and abduction.

Midcarpal instability after hemitrapeziectomy, total trapeziectomy and distal resection of the scaphoid pole

List of authors:
Luzian Haug¹, Leo Paeffgen², Tom Adler³, Esther Vögelin⁴
¹ Inselstipial (Bern)
² Inselspital Bern, University Hospital (Bern)
³ Orthoklinik Dornach (Dornach)
⁴ Inselspital, Universität Bern (Bern)

Objectives / Interrogation: Non-dissociative carpal instability (CIND) is a challenging pathology that can lead to severe functional impairment of the wrist. Removal of the distal scaphoid pole or trapeziectomy in patients with advanced osteoarthritis of the thumb were identified as possible causes of midcarpal instability and even symptomatic carpal collapse. Destabilization of the scapho-trapezial-trapezoidal (STT) ligament complex seems to lead to a CIND in certain circumstances. In a biomechanical study, the behaviour of the carpus after trapeziectomy and resection of distal scaphoid pole will be investigated for a better understanding of the importance of the involved ligaments.

Methods: 16 cadaver arms were randomly divided into two groups. In the first group distal scaphoid pole was resected with the adjacent ligaments, in the other group hemitrapeziectomy was performed followed by total trapeziectomy. Before and after the resection, a CT scan was performed in wrist extension, flexion, fist, radial and ulnar deviation with standardized load from 5 to 10kg. The three series were then reconstructed using a 3D model and the positional changes of scaphoid, lunate and capitate were measured in comparison to the non-operated wrists.

Results and Conclusions: After trapeziectomy the scaphoid, lunate and capitate rotate dorsally in wrist extension (capitate: -2.9° ±0.7), at fist closure (-17.9° ±9.9) and during radial deviation (-3.0° ±1.4). In wrist flexion, the proximal carpal row remains unchanged, while the distal row tilts palmarly (2.7° ±1.0). In ulnar deviation, both the proximal and distal row experience a palmar torque. Dissociation of the rows is most obvious at fist closure (capitolunar angle: 12.9° ±4.9).

Conclusion
Destabilization of the STT ligament complex by total trapeziectomy or scaphoid pole resection leads in this cadaver model to dissociation of the proximal and distal carpal row during fist closure and wrist flexion, but without instability within the proximal or distal row corresponding to a CIND.

The clearest destabilization of the carpus is seen at fist closure, with the highest axial load. Scaphoid pole resection may have some influence on SL instability.

Quantitative Analysis of Surface Contouring with bipolar Radiofrequency on chondromalacic cartilage

List of authors:
Michaela Huber*1
1 Klinik und Poliklinik für Unfallchirurgie (Regensburg)

Objectives / Interrogation: Over the last years treatment of cartilage degeneration with radiofrequency energy (RFE) has been still a controversy. Many experimental studies have been shown, that using RFE can lead to a severe damage to chondrocytes, which may be critical in the wrist and MCP-Joints, where the cartilage layer is extremely thin compared to other joints. The goal and the positive effect using RFE instead of a mechanical debriding is the so called "sealing effect" of the cartilage layer, which has been proved histological and morphological to stabilize the damaged cartilage.

Methods: This experiment was conducted on fresh osteochondral sections from the tibia plateau of slaughtered 6 month old pigs, where the thickness of the cartilage is similar to the wrist. An area of 1 cm² was first treated with emery paper to simulate the chondromalacic cartilage. Than the treatment with RFE followed in 6 different pattern. The osteochondral section were post processed with Live/Dead staining, caspase staining and a quantitative analysis by confocal laser scanning microscopy (CLSM). For quantitative characterization of the surfaces various roughness parameters were measured using the Olympus LEXT OLS 4000 3D CLSM. To describe the roughness the Root-Mean-Square parameter Sq was registered.

Results and Conclusions: Results
A smoothing effect of the cartilage surface was detectable
The smoothing effect was depended of the number passes of the RFE over the cartilage surface. The better the smoothing effect was, it was unfortunately correlated with an increasing rate of death chondrocytes up to 99%.

Conclusion
Using RFE treatment in arthroscopy in small joints like the wrist or MCP joints should be only used under great care, especially when a chondroplasty is performed.
There is a likely high chance to destroy the joint.

The ageement rate and accuracy of classification of distal radius fracture by plain roentgenography.

List of authors:
Hiroaki Ogihara¹, Takao Omura², Kaori Sugiura², Midhio Sano³
¹ Orthopaedic Surgery, Japanese Red Cross Hamamatsu Hospital (Hamamatsu)
² Orthopaedic Surgery, Hamamatsu University School of Medicine (Hamamatsu)
³ Orthopaedic Surgery, Shizuoka City Shizuoka Hospital (Shizuoka)

Objectives / Interrogation: Plain roentgenography is primarily used to classify fracture types of distal radius fractures. Although the AO classification is also frequently used to classify distal radius fractures, many reports have pointed out that the AO classification is not reproducible. We examined the following two points regarding distal radius fractures: how far the results of plain roentgenography diverge from those of CT scan, and how similar the interpretations of plain roentgenography are among doctors.

Methods: We examined 113 patients with distal radius fractures (115 wrists) who had visited our hospital and undergone both plain roentgenography and CT scan between 2012 and 2014. Three orthopedic surgeons interpreted biplanar plain X-ray images and evaluated them by the AO classification. Classification methods for the CT images were discussed by the concerned doctors to standardize the results. The agreement rates among the doctors who had classified the plain X-ray images were calculated using the Kappa coefficient between every two doctors.

Results and Conclusions: The correct answer rates of plain X-ray diagnoses according to the AO classification when considering CT diagnoses as correct answers were as follows: The correct answer rates according to the Type classification (A, B, and C) were high (66%-75%). The correct answer rates according to the Group classification (A2, A3, B1, B3, C1, C2, and C3) were lower (33%-52%). The correct answer rates according to the subgroup classification were very low (24%-38%). When analyzing the correct answer rates of each group, we found out that those of the type C Subgroups were lower and that those of C1 and C2 were especially low (27% and 25% respectively). In particular, 25% of the fractures diagnosed as type C by CT scan were misclassified as Type A by plain roentgenography. The agreement rates between the examiners using the Kappa coefficient were moderate for the type classification and poor for the Group classification.

Many reports have pointed out that the agreement rates of X-ray diagnoses among examiners are low. Our investigation also revealed that the agreement rates among the doctors who had classified the plain X-ray images were low. In addition, 25% of the type C fractures were misclassified as type A, resulting in overlooks of intraarticular fractures. We thus concluded that combined adoption of CT scan and roentgenography is desirable when deciding on treatment methods for distal radius fractures.

Our experience of surgical treatment of old instability of finger joints

List of authors:
Anton Ivanov*, Maria Skvortsova¹, Karen Egiazaryan¹, Alexander Sushkov¹, Fyodor Dolgov¹
¹ Pirogov Russian National Research Medical University (Moscow)

Objectives / Interrogation: Old instability of finger joints is a common problem in trauma region due to the diagnostic and treatment tactic problems. Examination and treatment results of 17 patients with lateral instability of metacarpal-phalanx thumb joint and 1 patient with front-back instability of proximal interphalangeal joint of index finger were presented. The indication to operation and technique of surgical intervention in dependence on the terms from injury moment, presence or absence of instability, value of passive lateral deviation angle were detected. Surgical technique for the treatment of complete tears of collateral ligaments of metacarpal-phalanx thumb joint was perfected.

Methods: Surgical technique for the treatment of complete tears of collateral ligaments of metacarpal-phalanx thumb joint was perfected. We performed intraosseal reinsertion with anchor and screw fixation, ligament reconstruction with palmaris muscle tendon free grafts. We used additional transarticular fixation by single K-wire in cases with lateral instability.

Results and Conclusions: Follow up period ranged from 6 to 12 months. Excellent results were achieved in 3 (11,1%), good - in 14 (51,9%), satisfactory - in 10 (37%) patients.

**Prognostic Factors Affecting Clinical Outcomes of Arthroscopic Assisted Reduction and Volar Plating Through Pronator Quadratus Preservation for Intra-Articular Distal Radius Fracture**

**List of authors:**
Jong-Pil Kim¹, Ja Hea Gu¹, Ji-Won Kim¹, Jae-Uk Jung*¹
¹ Dankook University (Cheonan)

**Objectives / Interrogation:**
The purpose of this study was to evaluate the clinical and radiological outcomes of arthroscopic reduction and volar plating (AR-VP) through pronator quadratus (PQ) preservation for the treatment of intra-articular distal radius fracture (DRF) and to assess prognostic factors that affect its functional outcomes.

**Methods:**
Between March 2014 to February 2017, a total of 54 patients who had intra-articular DRF (AO/OTA classification C-type), and underwent AR-VP through PQ preservation technique, and completed 1-year follow-up were enrolled. They were 23 males and 31 females with an average of 50.9 years old (ranges, 17 to 73 years). Clinical outcome data including visual analogue scale (VAS) score, disabilities of arm, shoulder, and hand (DASH) questionnaire, Patient-Rated Wrist Evaluation (PRWE) questionnaire, range of motion, grip strength, and radiographic parameters were collected at 3, 6, and 12 months after surgery. We conducted a simple and multiple linear regression analysis to identify clinical and radiologic factors affecting clinical outcomes based on the modified Mayo wrist scoring system (MMWS) at 1-year follow-up: satisfactory group (excellent and good results) versus unsatisfactory group (fair and poor results).

**Results and Conclusions:**
All clinical outcome measures significantly improved at 12 month follow-ups. The MMWS were 10 excellent, 22 good, 14 fair, and 8 poor. According to univariate analysis, all radiographic parameters at injury, sex, and a presence of intra-articular comminution show a significant difference between the groups (p < 0.05). In the multivariate analysis, female gender, a presence of intra-articular comminution, and the difference of dorsal or palmar tilt more than 20.1º compared to uninjured wrist at initial injury were considered as significant poor prognostic factors of functional outcome.

In conclusion, AR-VP through PQ preservation for intra-articular DRF provides reliable clinical and radiological outcomes. However, female gender, a presence of intra-articular comminution, and the difference of palmar or dorsal tilt more than 20.1º compared to uninjured wrist at initial injury are considered as poor prognostic factors of AR-VP through PQ preservation for intra-articular DRF.

Association between radiological results and functional long-term (6.8 years) outcome in conservatively treated AO Type-C distal radius fractures

List of authors:
Leena Raudasoja*, Samuli Aspinen¹, Heidi Vastamäki²
¹Helsinki University Hospital (Helsinki)
²Hospital Mehiläinen-Neo (Turku)

Objectives / Interrogation: Objective: Our aim was to explore association between the radiological result and functional long-term outcome of conservatively treated distal radius fractures (AO type-C).

Methods: Methods: Sixty-three consecutive AO type-C distal radius fractures treated with reduction and cast immobilization were retrospectively collected from the trauma hospital database. Thirty-nine patients (mean age 53, 59% female) came for the clinical and radiological control visit mean 6.8 years after the treatment. Mean immobilization time was 5 weeks. The QDash-score and PRWE (Patient Rated Wrist Evaluation) served as functional outcome measures. Radius shortening, possible step-off in radius articular surface, and the dorsal tilt of distal radius were measured. The data was analyzed with Mann-Whitney U-test.

Results and Conclusions: Results: In all wrists, the primary reduction result was considered acceptable according to the National Current Care Guidelines. After mean 6.8 years, exact anatomical result was only seen in 7 wrists (18%). According to the National guidelines in 24 wrists (62 %). Radius shortening of 2mm or more was found in 19 wrists with no association to PRWE (7.3 vs 4.8, p= 0.92) or QDash (11.4 vs 4.9, p =0.65). Only 3 patients had step-off on joint surface. Twelve wrists had dorsal tilt of 10° or more (one volar tilt of 24°) with no effect on PRWE or QDash (6.8 vs 5.6, p=0.63 and 11.4 vs 6.6, p=0.89). Together patients with dorsal tilt, step-off or shortening had worse PRWE compared to those with none (PRWE 6.3 vs 1.2, p=0.040), but no difference on QDash (8.4 vs 6.1, P= 0.157). Six complications emerged: four medianus entrapments, one EPL rupture, and one very stiff and painful wrist. These complications together showed no difference to PRWE (11.7 vs 4.6, p=0.64) or QDash (11.9 vs 6.7, p= 0.66). Neither did a fracture of ulnar styloid.

Conclusions: Most of the AO type-C distal radius fractures lost once gained posture during conservative treatment. Still in long-term follow up mere dorsal tilt or shortening of radius showed no association to functional outcome. Overall worsening of radiological parameters associated with worse PRWE but not QDASH. We acknowledge the small population size sets limitations and recommend further, larger controlled trials.

Effect of discontinuous low dose FK506 administration on motor recovery after cryopreserved nerve allograft

List of authors:
Jong-Pil Kim¹, Ja Hea Gu¹, Jae-Uk Jung¹, Ji-Won Kim¹
¹ Dankook University (Cheonan)

Objectives / Interrogation: Cryopreservation and controlled freezing of the allograft nerve can decrease the immune response and graft rejection. Nerve allografts following discontinuous immunosuppression with FK506 also induced successful neuroregeneration with motor recovery following slight rejection and functional loss.
The purpose of this study was to evaluate efficacy of discontinuous FK506 administration on the axonal regeneration in a rat model after sciatic nerve reconstruction with allograft nerve pretreated with a cryopreservation.

Methods: Forty-eight Sprague-Dawledy rats were randomized into four groups (twelve rats per each group). In each group, had a unilateral 10-mm sciatic nerve gap repaired with an ipsilateral autologous graft (group I) and a cryo-preserved nerve allograft from 18 Lewis rat in the other three groups followed with low dose (0.1mg/kg) FK506 administration for 4 weeks (group II), 8 weeks (group III), and until sacrifice (group IV). At 12 weeks, motor nerve regeneration was evaluated on the basis of the ankle contracture, compound muscle action potential (CMAP), maximal isometric tetanic force (MITF), wet muscle weight of the tibialis anterior (TA) as well as histomorphometry and immunohistochemistry of the allograft nerve.

Results and Conclusions: MITF showed significantly lower functional recovery in Groups II and III treated with discontinuous FK506 administration after cryo-preserved nerve allograft compared Group I: 52.3 ± 10.3% for Group I, 31.7 ± 9.6% for Group II, 35.6 ± 8.6% for Group III, and 41.7 ± 6.7% for Group IV compared to the contralateral side. Groups II and III were inferior to Group I regarding CMAP and the TA muscle weight (p < 0.05). There was no significant difference between the Group I and IV in terms of MITF and TA weight (p > 0.05). Histomorphometric analysis revealed that Groups II and III were inferior to Group I regarding Axon area, axon number, nerve fiber density (p < 0.05) and to Group IV regarding axon number (p = 0.001) (Table 2). Immunohistochemistry demonstrated that the morphology and distribution patterns of the axons in Group II and III showed less densely packed and little disorganized than Group I and IV.
In conclusion, withdrawal of immunosuppression resulted in graft rejection, a marked deterioration in function, and loss of generating fibers. A using cryo-preserved allograft nerves from cadaveric donors requires permanent immunomodulation for a valid surgical strategy to restore motor function of the damaged peripheral nerve.

**Very distal sensory nerve transfers in high median nerve lesions**

**List of authors:**
Chuanjun Yi\(^1\), Yin Zhu\(^1\), Chunmei Hou\(^1\)
\(^1\) Department of Hand Surgery, Beijing Jishuitan Hospital (Beijing)

**Objectives / Interrogation:** We report the results of reconstruction of fingertip sensation of thumb and index by modified distal sensory nerve transfer of superficial branch of radial nerve or dorsal branch of ulnar nerve in 6 patients with high median nerve lesions.

**Methods:** The 6 patients in this group are those with high median nerve lesions which could not repaired directly for some reasons. All had surgery during 7-14 months of trauma. For isolated nerve lesions, branches of the radial nerve on the proximal phalanx of the index and thumb were sutured to the ulnar proper digital nerve of thumb and radial proper digital nerve of the index finger in 3 patients. Whereas part of dorsal cutaneous ulnar nerve is transferred to fascicular group of median nerve including the radial digital nerve of index and both sides digital nerves of thumb at the wrist in those 3 patients with concomitant radial nerve palsy. Patients were followed up for at least 12 mouths.

**Results and Conclusions:** Either sensory nerve transfer restored protective or better sensation to the fingertips in all patients. Better locognosia was acquired in all thumbs whatever the transfer is. Good results were observed in patients who had undergone surgery later than 12 months after injury. Little paraesthesia of corresponding area of donor nerve is presented without trouble in either transfer. Fingertip sensation of thumb and index finger could be effectively restored by sensory transfer of either radial nerve branches to palmar nerves at the level of the proximal phalanx or partial ulnar dorsal cutaneous branches to fascicular group of median nerve at wrist in high median nerve lesions. These two transfer maybe also be suitable for chronic low median nerve lesions or lesions in older patients, as a adjunct to nerve grafting.

A Single Score as a Comprehensive Outcome Measure for the Wrist

List of authors:
Esther Vögelin¹, Ronit Wollstein², Sarah G Ewald³
¹ Handchirurgie und Chirurgie der peripheren Nerven (Bern)
² Orthopaedic Surgery (New York)
³ City Hand Therapy (Zurich)

Objectives / Interrogation: There has been an effort in medicine in general, and in hand surgery specifically to focus on a unified approach to outcome measures. The ability to analytically evaluate outcomes in hand surgery is critical for the understanding and sharing of results. It is fundamental to improvement and optimal tailoring of treatment regimens, personalizing treatment and ultimately to the advancement of the field. Despite its evident importance, the ability to do so has remained incomplete. This is due to the complexity of hand and wrist anatomy, mechanics, function, and individual functional requirements and expectations as well as a range of treatment options including conservative and surgical options.

Methods: Currently utilized evaluations are constrained in their ability to determine exact function, and thus have limited capacity to identify specific functional deficits and personal needs. The availability of multiple functional tests, each addressing a specific function and rarely standardized, further complicates outcomes evaluation. Existing measures allow us to evaluate and compare a specific outcome such as grip strength, motion, or the patient's perception of his or her function, but a global picture of the outcome that combines these factors and incorporates a functional measure remains elusive.

Results and Conclusions: We are in the process of utilizing a multidisciplinary approach that includes hand surgeons, hand therapists and clinical trial specialists to determine predefined outcome measures that can be combined and weighted into a single score for the evaluation of wrist conditions. An international forum of experts in this field has been assembled and will meet on the 21st of November 2018 in Switzerland with the aim of establishing a comprehensive single scoring system for wrist outcomes. Further plans include clinical trials utilizing this "consensus tool" and refinement of the tool as we accumulate experience with it. Ultimately, it is our aim to have a tool that will allow comparison of outcomes for both surgical procedures and therapeutic interventions for wrist conditions. We believe it is important to promote awareness of the challenge in creating and implementing consistent evaluation measures and the efforts to address it in our respective societies (hand surgeons and hand therapists).

Radial longitudinal deficiency. Analysis of clinical and radiological results

List of authors:
Enrique Vergara-Amador*, Laura Lopez, Sebastian Herrera-Rodriguez
1 Universidad Nacional de Colombia, Hospital universitario Nacional de Colombia (Bogota DC)
2 Universidad Nacional de Colombia, Hospital Universitario Nacional de Colombia (Bogota, D.C)

Objectives / Interrogation: Radial longitudinal deficiency (RLD) includes bone, musculotendinous and neurovascular abnormalities of multifactorial etiology of the radial side of the upper extremity. Treatment includes improving the length of the limb, the appearance and functioning of the hand. The aim of the work is to show the experience in a series of patients attended in the last 15 years and describe clinical and radiological results.

Methods: Retrospective study of patients with RLD between 2000 and 2016. Variables were analyzed and age associations were identified at the time of surgery, sex, laterality, type of deformity according to the modified Bayne-Klug classification, surgical technique, physis damage, associated diseases, functional and radiological results with degree of satisfaction, clinical position and radiological hand forearm angle.

Results and Conclusions: Results: 47 cases of 65 met the inclusion criteria. The average age of surgery was 19 months, 61% female, 64% right hand. According to classification, type IV was 60%, type III 19%, type 0 in 17% and type I in 4%. 11% VACTERL association. The intervention performed was centralization 72.3%, radialization 8.5% and one case of lengthening. Ulna osteotomy was performed in 55.3%. There was damage of the physis in 31%. The postoperative radiological position was neutral in 48.9%. Conclusions: In patients with centralization at 1 year, a good clinical and radiological correction were observed, however the result worsened in some patients with longer follow-up.
Radial longitudinal deficiency. Preoperative, one and five years follow-up

The management of soft tissues prior to centralization is believed to give better results. The use of intramedullary nail from the ulna to the carpus could be associated with damage of the distal ulna.

Long-term Patient Reported Functional Outcomes following Bennett’s Fracture Repair

List of authors:
Benjamin Langridge, Michelle Griffin, Mo Akhavani, Peter Butler
1 Department of Plastic and Reconstructive Surgery, Royal Free London NHS Foundation Trust (London)

Objectives / Interrogation: Optimal management of Bennett’s fractures of the thumb are important for long term hand function. The current evidence base on the management of Bennett’s fractures is limited due to the infrequency of this fracture. We present an 11-year retrospective analysis of Bennett’s fracture fixation and patient reported outcome measures to identify long term functional outcomes and risk factors for suboptimal recovery.

Methods: We conducted a retrospective analysis of our centre’s trauma database over an 11-year period to identify all patients with a Bennett’s fracture who underwent surgical intervention. Electronic medical records were analysed to extract mechanism of injury, smoking status, comorbidities, complications, time to surgery, surgical fixation method and post-operative hand function. Patients were invited to complete a Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire to assess long term functional outcomes. Descriptive statistics were applied to characterise the patient cohort. Statistical analyses were conducted to identify risk factors for suboptimal functional recovery.

Results and Conclusions: A total 79 patients were identified over a 11-year period with a mean age of 31.7 years at time of injury (13 to 74), 18 were excluded. Mechanisms of injury reported were: sports injuries (31.1%), violence (24.6%), falls (18%), road traffic accidents (16.4%), occupational (4.9%) and other accidents (4.9%).

Of the 61 patients, 71% returned to unrestricted range of movement during hand therapy. 95% of cases were managed with K-wire insertion. 85% of cases were closed reduction. The post-operative complication rate was 14%. Of the 61 patients asked to complete a DASH questionnaire, 21 patients did not respond and 40 patients responded. The mean time since injury was 5.1 years (0.8 to 11.6 years). Of the 40 responders, the mean DASH score was 9.1 (1.7 to 69.2).

Long term patient reported functional outcomes in patients with Bennett’s fractures requiring K-wire fixation are excellent. Post-operative complication rates are low and wound infections are uncommon. Age at time of fracture, smoking status and open fixation were not associated with inferior long term patient reported outcomes.

Arthroscopic reconstruction of chronic unstable scaphoid nonunion

List of authors:
Pedro J. Delgado*, Belen Garcia-Medrano, Fernando Polo, Marcio Aita, Ricardo Kaempfl
1 HM Monteprincipe (Boadilla del Monte)
2 Faculdade de Medicina do ABC (São Paulo)
3 Hospital Santa Casa de Porto Alegre (Porto Alegre)

Objectives / Interrogation: To present our experience of arthroscopic assisted reconstruction in patients with unstable scaphoid non-union using cancellous non-structural graft and internal fixation with headless screw.

Methods: A case series of patients with chronic unstable scaphoid non-union treated with dry arthroscopic reconstruction using two midcarpal portals. DISI was corrected with a temporary Kw through the dorsal radius. Scaphoid defect was packed with cancellous bone graft from the distal radius across the radial-midcarpal portal. Internal fixation was performed using a mini-Acutrak or HCS headless screw. Fusion rates, radiographic and clinical evaluation was performed, with a mean prospective follow-up of 16.8 (12-36) months. All patients were treated by the same surgeon.

Results and Conclusions: 32 patients with 26 (18-45) years mean age were treated. All cases showed “humpback deformity” in preoperative radiological/TC scan study. Consolidation rate was 95% (30/32) at mean 7 (4-10) weeks. Range of flexo-extension arc improved after surgery, from 138.4º to 165º. Scapholunate angle (SLA) and radio-lunate angle (RLA) was significantly improved: SLA 67.7º to 47º; RLA 30.8º to 4º. Functional postoperative evaluation: mean DASH-questionnaire was 8 and VAS (0-10) 0.7. Two cases were reoperated due to non-union: 1 case using arthroscopic cancellous bone graft again and the other patient using a 1,2 ICSRA vascularised bone graft. All cases consolidated and no reoperations was needed after the second surgical technique.

Conclusions: Arthroscopic reconstruction can be a useful alternative for chronic unstable scaphoid nonunion. In our experience presents good clinical and radiological results in scaphoid non-union with humpback deformity using a non-structural bone graft. Probably is limited for restoration of the normal carpal alignment but has positive effects on clinical wrist function recovery with comparable results to open techniques

**Treatment of scapholunate dissociation with arthroscopic ligamentoplasty reconstruction**

**List of authors:**
Pedro J. Delgado*1, Fernando Polo1, Belen Garcia-Medrano3, Marcio Aita2, Ricardo Kaempf3

1 HM Monteprincipe (Boadilla del Monte)
2 Faculdade de Medicina do ABC (São Paulo)
3 Hospital Santa Casa de Porto Alegre (Porto Alegre)

**Objectives / Interrogation:** To evaluate the results of the arthroscopic reconstruction for the treatment of the scapholunate instability of the wrist

**Methods:** 31 patients were treated, with a mean age of 39.9 (22-51) years old. The mean time of symptoms before surgery was 6.9 (1-18) months. All patients were operated using the arthroscopic ligamentoplasty technique according to Corella. Only the dorsal escafolunate ligament was reconstructed. Kirschner wires fixation was not used. The wrist was immobilized for 2 weeks, followed by a progressive rehabilitation protocol. Preoperative and postoperative clinical and radiological parameters were evaluated. The mean follow-up was 16.2 (8-24) months.

**Results and Conclusions:** 4 patients had an Outbridge grade IV chondral lesion greater than 5 mm and the reconstruction was not performed. The ligamentoplasty was performed in 27 cases. 6 patients (22.2%) had associated lesions: 3 TFCC lesions and 2 LT instability. The range of flexo-extension was 141.6° before surgery and 127.4° in the post-operative period. Watson test was positive in 93% pre-operative period and only in 8% at the end of FU. Pain (EVA 0-10) decreased from 5.5 (3-7) to 1.9 (0-8). Scapholunate angle decreased from 73.8° (60-90°) to 64° (35-90°), DISI deformity was present in 100% before surgery and only in 46% at the end of FU. The Scapholunate gap decreased from 3.8 to 2.3 mm. All patients returned to their previous sports activity. There were no reoperations. 2 patients has complications at the end of FU: 1 median nerve injury by the volar approach and 1 persistent ulnar border pain.

Conclusion: The treatment of scapholunate instability with arthroscopic assisted repair presents good clinical and radiological results with a short period of recovery.

Clinical Outcomes of Zone 1 Flexor Tendon Injuries Treated With Bone Anchor

List of authors:
RaviKanth Mallina¹, Rajive Jose¹
¹ Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Objectives
Surgical repair of Zone 1 flexor tendon injuries is associated with significant complications depending on the fixation methods. Some studies have reported a complication rate as high as 65% and there is no consensus on optimal fixation technique. We report our results of treating Zone 1 FDP injuries at tertiary referral Hand Unit.

Methods: All Zone 1 FDP injuries between January 2012 to December 2017 were retrieved from our in-house bespoke electronic database, the eHands. Relevant patient demographics, mechanism of injury, type of injury classified according to Leddy and Packer classification, intra-operative findings, rehabilitation protocol and functional assessment as per modified Strickland criteria were recorded.

Results and Conclusions: Results
A total of 68 Zone 1 FDP injuries with a mean follow-up of 72 months (range 9-56m) were included in the study. The average age of the patients was 21y (range 18-54), majority being men(n=41). Time from injury to surgery was at a mean of 5 days (range 3-8d). Contact sports were the major cause of the injury(n=21). Majority of the injuries were Leddy Parker type 2(n=18) and type 1(n=32). Only 3 patients had type 4 injury and the remaining patients has type 4 injury. A significant proportion of Zone 1 injuries were treated by Mitek micro bone anchor (DePuy Mitek Inc., MA, USA): n=48. All patients underwent rehabilitation as per the Belfast controlled active movement (CAM) regime. 6 patients underwent surgery for subsequent complications, two directly related to the failure of the bone anchor. According to the modified Strickland criteria 18 patients had excellent, 13 had fair and the remaining had poor outcome.

Conclusions
The current study is the largest series reporting the use of bone anchors in Zone 1 FDP tendon injuries. These injuries when treated with bone anchors although have a low complication rate, are not necessarily associated with excellent outcomes.

Comparison between supercharged ulnar nerve repair by anterior interosseous nerve transfer and isolated ulnar nerve repair in proximal ulnar nerve injuries: A pilot study

List of authors:
Islam Koriem*, Ahmed Naeem Atiyya¹, Ramy Diab¹, Mohammed El Mahy¹
¹ Ain Shams University (Cairo)

Objectives / Interrogation: To compare combined ulnar nerve repair with supercharged end to side anterior interosseous nerve to ulnar motor nerve transfer (UR+SETS) to conventional isolated ulnar repair (IUR) techniques in proximal ulnar nerve transection

Methods: A comparative randomized trial was conducted prospectively on 30 patients with proximal ulnar nerve transection injury. Fifteen patients were managed by UR+SETS. Fifteen patients were managed by IUR. The level of injury was classified into 1-3 according to Post et al.[1]

Results and Conclusions:
Results: Only 13 patients in both groups completed their 18 months follow up. At the 3-month follow up, the results showed no statistically significant difference in outcomes between the two groups. At the 6-month follow up, the Birch's score was statistically insignificant. The Brand's score was better in the UR+SETS group, possibly indicating early return of function. At 12-18 months, there was a statistically significant difference in the outcomes in favour of UR+SETS group. On comparing the outcome according to the level of injury: At level 1 injuries, UR+SETS group showed statistically significant higher Birch and Brand's scores. Although the sample size was small to be statistically analysed, the UR+SETS group showed better results than the IUR group in level 2 injuries. The preliminary results indicate that the 2 groups were comparable in level 3 injuries indicating that UR+SETS transfer may be of no value at that level of injury.

Conclusions: At the short term, UR+SETS transfer results in better intrinsic muscle re-innervation and clawing deformity correction following proximal ulna nerve transection injury

Post-traumatic deformities around wrist: two-stage treatment

List of authors:
Alexander Zolotov*
1 Far Eastern Federal University (Vladivostok)

Objectives / Interrogation: Treatment of bone and joint deformities is a challenge for surgeons. Correction of old deformities is associated with the risk of damage of peripheral nerves and blood vessels with subsequent ischemic disorders. In case of severe deformity two-stage treatment with slow distraction using external fixator on the first stage can be an available alternative to acute deformity's elimination.

The purpose of study - to analyze the efficacy and safety of two-stage treatment for the correction of post-traumatic deformities around the wrist with the aid of external fixator at the first stage.

Methods: We analyzed the treatment of 10 patients (from 24 to 42 years) Two-stage treatment was applied for correction of chronic perilunate dislocation (3) and chronic trans-scaphoid perilunate fracture-dislocation (3). Two-stage treatment was applied for correction of severe deformities after distal radius fracture (malunion - 1 patient, nonunion - 3 patients) with ulna head dislocation. Period of time following after trauma varied from 1,5 months to 4 years. Ilizarov apparatus was used at the first stage in all cases. Standard Ilizarov frame with 130-140 mm in diameter rings was used. The rate of distraction was 1 mm per day. Distraction period continued for 3-4 weeks. The second stage surgery procedures included: open reduction of perilunate dislocation (6), screw fixation and bone grafting of scaphoid (3); ORIF and bone grafting of radius (4).

Results and Conclusions: In all cases, severe deformities were corrected with the aid of distraction. Slow distraction provided a gradual lengthening of the skin, muscle, joint capsule, nerves and blood vessels without ischemic and neurological destruction. After the second stage of surgery, perilunate dislocations were reduced in all cases, bone deformities were eliminated in all cases, and bone healing was achieved in all cases. Function was improved in 9 cases, and recovered fully in 1 case. There was a complication after osteosynthesis in one case - K-wire's broken and loosening. Previous "stage I" surgical procedure facilitated the ability to perform "stage II" surgical procedure significantly.

Conclusion. Two-stage treatment of severe post-traumatic deformities around wrist is effective and safe. Pre distraction at the first stage makes it easier to do the second stage surgical procedure.

Efficiency, setup, impact and distribution of the procedures in a wide-awake surgical theater built within the department ward: a review of surgical procedures in a year period

List of authors:
shuguo xing1, Tian Mao1, Guheng Wang1, Jinbo Tang1
1 Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Objectives The wide-awake hand operations have not typically performed in a minor procedure room in our hospital. This study is to report the surgical procedures that were performed in the wide-awake surgical theater inside the department ward over a year period and its impact to surgeons' efficiency and quality of life.

Methods: Methods In our unit, a wide-awake hand surgery theater was built outside of the main operating rooms of the hospital, but inside a hand surgery ward, which is entirely managed by the Department of Hand Surgery without anesthesiologists involved. It is very close to surgeons' offices within 5-20 meters. The regulations of this wide-awake theater of the department are less stringent than those for hospital operating rooms because the operations are only for appropriate hand related patients without complex reconstruction. The surgeons have no restriction in deciding the time of surgery. Any surgery, whether outpatient or inpatient, can be performed whenever the room is available. Inside the operating room, patients usually enjoy watching movies or listening to music stored in hard drives or iPads with earphones during surgery. Questionnaires were sent to surgeons to assess the efficiency of workflow and improvement of quality of life of surgeons by this new setting.

Results and Conclusions: Results This operating room provides easy access and simplified workflow for both patients and surgeons and a more pleasant patient experience. From September 2017 to August 2018, a variety of wide-awake surgical procedures were performed in 613 patients in this theater. The number of patients underwent surgery include excision of soft tissue 143, carpal tunnel release 73, trigger finger release 76, hand fracture internal fixation/removal 62, flap transfer 50, tendon repair 25, tenolysis 8, cubital tunnel release 9, nerve repair 5, tendon transfer 4, collateral ligament repair of joints 5, release of finger joint contracture 4, wound debridement, skin graft, foreign body removal in 149 patients. There was no waiting time for these patients and questionnaire sent to surgeons indicate very favorable response from surgeons who all reported improvement of work efficiency and improvement of quality of life of surgeons.

Conclusions Our experience indicates that such a specialized operating room improves efficiency in hand surgeons' workflow, improves quality of life of the surgeons, and decreases waiting time for the patients and surgeons.

Correction of Radially Deviated Wassel Type III Thumb Polydactyly using Modified Open-Wedge Osteotomy vs Conventional Closed-Wedge Osteotomy in 51 Children

List of authors:
Xiaofei Tian*
1 Children’s Hospital of Chongqing Medical University (Chongqing)

Objectives / Interrogation: To report a novel modified technique used to correct radially deviated Wassel type III thumb polydactyly by using open-wedge osteotomy (OWO) to restore the normal length of the thumb and to compare the technique with the conventional closed-wedge osteotomy (CWO).

Methods: 30 children suffered unilaterally from radially deviated Wassel type III polydactyly and the radial deviation of the interphalangeal joint of unlar main thumbs ranged from 15° to 45°. After removal of the radial hypoplastic thumb, the ulnar thumb was corrected by modified OWO. The wedge-shaped bone defect was reconstructed with a bone graft taken from the resected thumb, and the soft tissue flap of the resected thumb was merged to preserved thumb. The length of the thumb, radial deviation and range of motion of the interphalangeal (IP) joint were assessed. For comparison, we also retrospectively collected another group of 21 children treated with conventional CWO. Significant difference was set at p<0.05.

Results and Conclusions: The average age at surgery was 1.5 years (range, 1-2.3 years). At the final follow-up of 3.4 years (range, 2-5.4 years), the mean length of the affected thumbs reached 96% (range, 92%-100%) of the opposite thumbs. The mean radial deviation of IP joints was 6° (range, 0°-15°). The average functional point was 12 points (range, 10-14 points), and the mean cosmetic score was 3.7 (range, 3-4 points). In comparison group, The average age at surgery was 1.7 years (range, 1-2.8 years). At the final follow-up of 4.6 years (range, 3-5.2 years), the mean length of the affected thumbs reached 83% (range, 75%-92%) of the opposite thumbs. The mean radial deviation of IP joints was 7° (range, 0°-14°). The average functional point was 10 points (range, 9-12 points), and the mean cosmetic score was 2.4 (range, 2-3 points). Bone healing was achieved in both groups, and slightly small nails were deemed acceptable. Stability of IP joint was archived in all children, and no revision surgery was required. There were significant differences with regard to the length of thumb, functional and cosmetic scores (p<0.05). For the correction of radially deviated Wassel Type III thumb polydactyly, the modified OWO can more effectively restore the normal length of thumb comparing with the conventional CWO, and the rebalance of the flexor pollicis longus could prevent radial deviation recurring and the flap transfer could achieve better contour of the thumb.

Implementation of a finger stump database after traumatic finger amputation - Concept evaluation and clinical consequences

List of authors:
Arne Böcker¹, Anne-Sophie Rasner¹, Berthold Bickert¹, Leila Harhaus¹, Ulrich Kneser¹
¹ BG Klinik, Klinik für Hand, Plastische und Rekonstruktive Chirurgie, -Schwerbrandverletztenzentrum- (Ludwigshafen)

Objectives / Interrogation: Aim of the current study is to evaluate risk factors, treatment strategies and outcome evaluation after traumatic finger amputation

Replantation is still the gold standard for treatment of traumatic finder amputation. However, if replantation is not feasible or not preferable, generation of a stabile and sensible stump is mandatory. Although this is a straight-forward procedure, clinical outcome is not always predictable and neuroma and chronic pain pose significant challenges for patients, physicians and therapists. Still today, a precise analysis of the treatment and outcome after finger stump amputation is lacking.

Methods: In our retrospective analysis, we performed a chart review of finger stump amputation in 2007-2017. During this period, 1187 patients have been admitted to the study. Patients comorbidities, operation techniques, and especially postoperative treatment strategies, as well as the need for long-term rehabilitation, are reviewed and analyzed.

Results and Conclusions: Benefits and the potential of the implementation of a finger stump database for clinical usage will be considered. Furthermore, the resulting clinical adjustments following the implementation of the database are presented and discussed. Focussing on the short- and long-term complications, the kind of trauma, anatomical localization and the operative treatment applied are related. Moreover, comorbidities and social factors have an impact on rehabilitation time and functional outcome after traumatic finger amputation. Adjusted treatment plans and algorithm will be presented based on the data gathered in the study.

Functional impairment and rehabilitation times are influenced by multiple factors considering the applied operative treatment, comorbidities of the patient and the kind of trauma. The collected experience can be used for standardized treatment protocol after traumatic finger amputation.

Traumatic Subluxation of Extensor Carpi Ulnaris System

List of authors:
Fabio Curini-Galletti*¹
¹ Clinica Mater Dei (Roma)

Objectives / Interrogation: Extensor carpi ulnaris (ECU) subluxation at the wrist joint can be a disabling condition. We present our experience with this problem.

Methods: From 2012 to 2017, we evaluated 21 patients with a diagnosis of ECU as subluxation, tenosynovitis and longitudinal fissuring. The cohort included 8 women and 13 men (average age 32 years). Timing of presentation: 11 acute trauma and 10 chronic post traumatic (from 6 months to 2 years post trauma). None of the patients had pain or instability of the distal radioulnar joint; 7 patients (33%) play tennis golf or sport activity with bats.

All patients underwent splinting and physiotherapy. Patients who failed conservative treatment were indicated for surgical stabilization of the ECU tendon. Post-operatively patients were placed in a sugar tongue splint day and night for 6 weeks and then a forearm splint at night for an additional 2 months. Return to sports and heavy work was allowed at 6 months.

Results and Conclusions: All patients with an acute trauma had resolution of symptoms with therapy and splinting and returned to work and sports uneventfully. All patients with a chronic injury ended up requiring surgery. In 8 patients we performed a Graham ulnar retinacular flap with augmentation on the 4/5 septum; in 2 patients we performed a Garcia Elias ulnar retinacular flap, capsular flap and periosteum flap. After the Graham flap 6 patients had a good result with regard to return to work and/or return to sports; 1 patient had continued symptoms that subsequently resolved at the 1 year mark; and the final patient (tennis player) had persistent pain and recurrent tenosynovitis after the surgery but actually after PRP injection she is getting better. In 2 patients operated with Garcia Elias technique we had good results with regard to return to sports and work. No statistically significant differences as result between sport and labour patients. No more ECU subluxation/luxation in all patients operated. No pain (except one patient); complete wrist range of motion in all patients; no complications during and after surgery.

A careful evaluation for ECU subluxation should be performed when dealing with ulnar-sided wrist pain.

All-Inside Arthroscopic Dermal Allograft Reconstruction of Massive TFCC Tears

List of authors:
Felix Riano*, Christopher R. Adams
1 Naples Hand Arth (Naples)
2 Naples Community Hospital (Naples)

Objectives / Interrogation: The TFCC stabilizes the DRUJ, provides a cushion between the ulnar head and the lunate with axial loading and ulnar deviation of the wrist, and it is an efficient ulnar-side restrain to the carpus. Extensive radial side tears and combined massive radial and central tears without DRUJ instability are still a challenge to treat. We describe an all-inside arthroscopic dermal allograft reconstruction that restores the radial insertion, the central disk (meniscus homologue) while enhancing the support for the dorsal and volar radioulnar ligaments.

Methods: The concept of this technique is based on the optimal results obtained with the SCR (Superior Capsular Reconstruction) for massive rotator cuff substance loss in the shoulder. Biomechanical and prospective clinical studies have demonstrated the benefits of this reconstruction in the subacromial space. We used the standard 3-4, 4-5 and 6R portals for this reconstruction. The massive radial and central tears with significant substance loss are debrided, and DRUJ stability is assessed. A knotless reconstruction is then accomplished by inserting FiberWire (Arthrex, Inc. - Naples, FL) preloaded SutureTak anchors (Arthrex, Inc. - Naples, FL) on the dorsal and volar corners of the radial wall. Intra-articular measures are taken from volar to dorsal and from radial to ulnar to determine the perfect size for the allograft. The allograft is tagged and brought inside the joint. A tight knotless radial fixation is completed, the new meniscus homologue covers the ulnar head and peripheral fixation is finalized via a standard ulnar tunnel foveal technique. The specimens were tested for axial load, ulnar deviation, and forearm pronation.

Results and Conclusions: This is the first study looking into an all-arthroscopic allograft TFCC reconstruction. The dermal allograft did not get displaced or got torn when the wrist was taken from radial to ulnar deviation, forearm rotation, or when axial load was applied from the carpus down to the ulna. This type of reconstruction could also be combined with an arthroscopic wafer when ulnocarpal abutment is present. The combination of these two procedures might expedite the recovery time and return to previous activities when compared to an ulnar shortening osteotomy. The results of the on-going high repetition cyclic load will be presented as well. We believe this is a minimally and very reproducible technique, which might extend the bridge between reconstructive and salvage wrist procedures.

The effect of articular tilt on carpal alignment in acute distal radius fractures

List of authors:
Rachel Dias*, nick johnson, joseph dias
1 kings college (london)
2 University hospitals of leicester (leicester)

Objectives / Interrogation: Carpal malalignment is thought to be an important influence on functional outcome following distal radius fracture. The aim of this study was to investigate the relationship between tilt of the articular surface of the radius and measures of carpal malalignment in patients with an acute distal radius fracture.

Methods: Radiographs of 249 consecutive distal radius fractures were prospectively analysed. Distal radius articular tilt, scapholunate angle, radiolunate angle, capitolunate angle and capitate shift were measured. Patient demographics, wrist position, radiograph quality and fracture type were recorded. 184 patients underwent manipulation under anaesthetic and all measurements were repeated after manipulation. One independent observer carried out all measurements which were then checked by the senior author. Linear regression modelling was used to investigate the relationship between tilt and the carpal parameters. Models were tested using forward selection to identify if other parameters affected the association.

Results and Conclusions: A significant, linear relationship was seen between scapholunate angle (p<0.005, R²=0.20), radiolunate angle (p<0.005, R²=0.35), capitolunate angle (p<0.005, R²=0.33), capitate shift (p<0.005, R²=0.82) and tilt. This relationship was consistent irrespective of whether the fracture was displaced volarly or dorsally. A similar, proportionate change in alignment was seen with reduction of the fracture. Initial malalignment increases with age. Capitate shift occurs independently of wrist position.

Carpal malalignment frequently occurs following distal radius fracture. Reduction of the fracture will reliably reduce the malalignment. Capitate shift appears to be the most useful measurement of carpal malalignment as it is not affected by the position of the wrist when the radiograph is taken. We would recommend capitate shift is routinely measured by clinicians on initial radiographs, following manipulation and during long term follow up.

Tetraplegic and Spastic Posterior deltoid to triceps transfer to restore active elbow extension in tetraplegic patients

List of authors:
Manuel Mendez¹, Marcia Carrasco², Catalina Parot², Elias Concha², Alejandra Alvarez²
¹ Teleton Santiago, Clinica Las Condes (Santiago)
² Instituto Teleton Santiago (Santiago)

Objectives / Interrogation: Evaluate functional results, after a surgical reconstruction of elbow extension with deltoid to triceps transfer.

Methods: Prospective cohort study of 10 tetraplegic patients (11 elbows). 6 men and 4 women, between 17 and 29 years of age, 1 patient from group 1 of ICSHT, 8 from group 2 and 1 from group 3. The patients were evaluated by a multidisciplinary team. To restore the active elbow extension we used the posterior deltoid to triceps transfer whit anterior tibial tendon graft. Elbow extension strength was measured according to BMRC 1-5. Performance and satisfaction was assessed by the Canadian Occupational Personal Measure (COPM), which rates patient individual goals, and activities of daily living with the WeeFIM scale. Follow up was performed at 6 and 12 months postoperatively. Surgeries were carried out between May 2013 and July 2017. Reconstruction of elbow extension was done with posterior deltoid to triceps transfer using anterior tibialis tendon graft. Patients were discharged home the day after surgery, and entered a rehabilitation protocol that included immobilization in elbow extension and shoulder abduction for 3 weeks, and then progressive elbow flexion was encouraged but protected with an articulated elbow brace. After 3 month free elbow motion was allowed.
The statistical analysis was performed using SPSS v17.0 software, summary measures were calculated and the comparison was made through nonparametric Friedman and Wilcoxon statistics, all with p <0.05.

Results and Conclusions: All patients improve elbow extension strength from a median of M2 strength to M3 at 6 months and M4 at 12 months (p 0,0004) . There was a significant improvement in each individual goals measured by the COMP from a median of 2 points of performance at preoperative assessment to 4 points at 6 months and 7 points at 12 months after surgery. Satisfaction improved from a median of 2 points to 5 points at 6 months and 8 points at 12 months after surgery (p 0.033). WeeFIM scale improved in many activities such as self-care (p 0.034) bathing (p 0.033), dressing (p 0,02), self- catheterization (p 0.042), and use of wheelchair (p 0.08). There was one early postoperative complication consisting of pain that required hospitalization in 3 patients.

Conclusion
Restoration of elbow extension with deltoid to triceps transfer in patients with tetraplegia results in a significant improvement in their own perception of gain in activities that are meaningful in their daily living.

Outcomes of Endoscopic release for Patients with de Quervain’s Tenosynovitis: Retrospective Review of 181 cases

List of authors:
Won-Taek Oh*, Ho-Jung Kang1, Il-Hyun Koh1, Jung-Jun Hong1, Jin-Chul Oh1, Yun-Rak Choi1

1 Yonsei University College of Medicine, Severance Hospital (Seoul)

Objectives / Interrogation: De Quervain's tenosynovitis is one of the common causes of radial wrist pain resulting from thickening of the fibro-osseous sheath of the first extensor compartment. Surgical release of the compartment is indicated when non-operative treatment fails. We have reported earlier improvement and less complications after endoscopic release of the compartment in patients with de Quervain's disease, when compared with open release. However, there are lack of evidences of benefits and risks of the endoscopic technique for de Quervain's disease over the open technique. Thus, we have retrospectively reviewed patients who underwent endoscopic release for de Quervain's disease with minimum follow-up of 12 months.

Methods: Between Apr 2009 and Jan 2017, this retrospective study enrolled consecutive patients with de Quervain's tenosynovitis who underwent endoscopic release of first extensor compartment and followed-up minimum of 1 year. Patients fulfilling the following criteria were excluded: (1) concomitant osteoarthritis of TM joint or STT joint, (2) concomitant Wartenberg syndrome, (3) underlying chronic inflammatory disease like rheumatoid arthritis or gouty arthritis, and (4) inadequate follow-up. For clinical assessment, VAS pain score, pinch strength and DASH score were assessed preoperatively and postoperatively, and VAS satisfaction score for postoperative scar was also evaluated. Complications were reviewed such as neurovascular injury, postoperative infection, unrelieved pain, and redo surgery.

Results and Conclusions: One hundred sixty eight patients (181 wrists) were included and their mean age was 49.2±14.3 years. Among them, 96.4%(162 patients) were female. Dominant wrist was involved in 67.4%(122 wrists). The mean follow-up period after surgery was 17.6 months. The mean VAS pain score and DASH score improved from 7.1±1.7 to 1.2±1.3 and from 52.4±21.5 to 5.6±4.7. The mean pinch strength improved from 5.0±2.4 kg to 6.6±2.5 kg. The mean VAS satisfaction score for postoperative scar was 8.2±1.2(higher score representing greater satisfaction). Twelve patients had transient superficial radial nerve symptom(5.49%) postoperatively and resolved spontaneously within 6 weeks in all patients. One patient underwent open tenolysis due to unrelieved pain after endoscopic release.

This study showed that the endoscopic release for the first extensor compartment seems to be effective and safe procedure for patients with de Quervain's tenosynovitis when conservative treatment fails.

Wide-Awake versus General Anesthesia Results in Patients with Dupuytren's Disease Surgery: Preliminary Results

List of authors:
Zeynep Tuna*, Ali Nazmican Güröz2, Egemen Ayhan3
1 Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation (Ankara)
2 University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology (Ankara)
3 University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology - Hand Surgery (Ankara)

Objectives / Interrogation: Wide-awake local anesthesia with no tourniquet (WALANT) has an increasing popularity in Dupuytren's disease surgery as it eliminates adverse effects of general anesthesia and the need for hospitalization. Moreover, in Dupuytren's surgery, controlling active movement during the surgery is the foremost advantage of WALANT besides providing a bloodless area for the fine surgical intervention. For this reason, we hypothesized that the WALANT technique would improve the clinical outcomes in patients that were operated for Dupuytren's contracture. Therefore, the aim of this study was to present our preliminary results in patients who underwent open partial fasciectomy under WALANT and compare their results with those that had GA.

Methods: Nineteen patients were called up who were operated between January 2017- June 2018 and 12 of them were reached. One patient was excluded due to cardiac surgery during follow-up. Five patients were operated under WALANT and 6 of them had GA. Range of total active flexion motion and residual extension deficit were measured and pain, satisfaction level, post-operative analgesic use, follow-up period since surgery and any recurrence were recorded. Results of the patients in the WALANT and GA groups were compared.

Results and Conclusions: The mean age of the patients were 60 years in GA and 67 years in WALANT group. Patients were operated on their 4th or 5th digits. Mean follow-up was 13 months in the GA group and 6 months in the WALANT group (p>0.05). Total range of active flexion motion was 264±13° in the WALANT group and 252±32° in the GA group. Moreover, no residual extension deficit was seen in the WALANT group while it was 8±11° in the GA group. However, the differences were not statistically significant. Pain level, post-operative analgesic use and patient satisfaction were similar across the groups.

In this preliminary study, although not being statistically significant, WALANT technique seems to provide improvements in the total active motion and residual extension deficit in patients who underwent surgery for Dupuytren's contracture. However, as a limitation, we have to declare that present extension deficit in GA group may result from mild recurrence due to longer follow-up period. Studies with large samples and long-term follow-up will provide evidence for clinical outcomes and especially recurrence rates.

Long-term Outcomes of Surgically Treated Metacarpal Fractures Using Bioabsorbable Plates.

List of authors:
Kenji Kosugi¹, Yukichi Zenke¹, Toshihisa Oshige², Kunitaka Menuki¹, Yoshiaki Yamanaka³, Takaumi Tajima¹, Akinori Sakai¹
¹ Department of orthopaedic surgery, University of Occupational and Environmental Health, Japan (Kitakyushu, Fukuoka)
² Department of orthopaedic surgery, Tobata Kyoritsu Hospital (Kitakyushu, Fukuoka)

Objectives / Interrogation: Osteosynthetic bone fixation implants made from composites of unsintered hydroxyapatite (u-HA) and Poly-L-lactide (PLLA) with bioabsorbability and osteoconductive properties are widely used in orthopaedic surgery. In oral and maxillofacial surgery, it has been reported that the plate was absorbed in about 6 years after surgery, but in our orthopaedic fields, long-term outcomes have not been reported yet. We report long-term outcomes of 8 fingers of 6 patients surgically treated metacarpal fractures using bioabsorbable plates (Super-Fixsorb® & #65038; MX40 mesh) for more than 5 years after surgery in our hospital.

Methods: This study included 8 fingers of 6 patients surgically treated metacarpal fractures with bioabsorbable plates (Super-Fixsorb® & #65038; MX40 mesh) for more than 5 years after surgery in our hospital between March 2009 and September 2017. The average age at the injury was 29.5 years (16-54 years), and the average follow-up period was 6 years and 9 months (5 years and 8 months-8 years and 5 months). Open reduction was performed, and the fracture was temporarily fixed with 1.0 mm-diameter Kirschner wires. We used surgical scissors to cut the bioabsorbable mesh sheet appropriately shape for fixation of the metacarpal fracture and then bent it in hot water bath (68 degrees) to make a one-third or semi-tubular plate. It was placed on the metacarpal bone surface and was fixed with eight to sten bioabsorbable 2.0 mm-diameter cortical screws totally. Clinical endpoints were range of motion for wrist and forearm, grip strength ratio (percentage of the unaffected side), Quick-Disabilities of the Arm, Shoulder, and Hand (Q-DASH) score, bone union on plain X-ray, and resorption status on plain CT.

Results and Conclusions: In all cases, bone unions were achieved without displacement. There were no complications such as infections and aseptic swelling and necrosis in all cases. Q-DASH scores were almost good except for two cases because of the limitation of the range of motion and poor recovery of the grip strength ratio. The plate and screws still remained in 7 years and 2 months after surgery, but, in 8 years and 5 months after surgery, the plate was completely absorbed, and the screws slightly remained in the bone. This study suggests that the process of bioabsorption in metacarpal fractures may take at least about 8 years after surgery, and the absorption rates in the bone may differ from outside the bone.

Arthroscopic-assisted capsuloplasty in scapholunate tears: The role of the dorsal capsulo-scapholunate septum

List of authors:
Adrian Pleßmann*, Max Haerle¹, Nicole Schmelzer-Schmied², Tobias Del Gaudio³
¹ Orthopädische Klinik Markgröningen (Markgröningen)
² Orthopädie Rosenberg AG (St Gallen)
³ Kliniken Villingen-Schwenningen (Villingen-Schwenningen)

Objectives / Interrogation: Carpal instabilities and in particular the complex consequences of scapholunate (SL-) dissociation are still subject to investigation. Recent biomechanical findings (Elsaidi et al., 2004) suggest that a new found anatomical structure - the Dorsal Capsulo-Scapholunate Septum (DCSS) - stabilizes the scapholunate complex and thus makes an important contribution to this already complex biomechanical system (Overstraeten et al., 2013). In the past, suture of the SL-ligament with an open approach showed mediocre results as well as soft tissue procedures, which were insufficient due to a SL-ligament avulsion. To address the Dorsal Capsulo-Scapholunate Septum and to avoid soft-tissue problems we refined the arthroscopic technique: by using diverging needles instead of converging needles, we attempt to suture the remaining attachments of the Dorsal Capsulo-Scapholunate Septum.

Methods: Our prospective follow-up study was carried out as a bicenter study. Patients were stratified into groups of acute and chronic SL-lesions, dynamic or static SL instabilities and according to Messina-EWAS classification. Between 2009 and 2015 we performed 63 arthroscopically assisted dorsal SL-capsuloplasties. The clinical follow-up included an assessment to pain level, range of motion (ROM) and grip-strength. The radiographic follow-up was performed in terms of SL gap and SL angle.

Results and Conclusions: The radiographic 3.5-year mean follow-up showed a significant decreased SL-gap in the group of dynamic instabilities regardless of whether they were acute or chronic. Even for Messina-EWAS IIIB and IIIC stages we could show a significant decreased SL-gap. We found no significant impairment for range of motion. VAS at rest declined by 90%, under load by 70%. Regarding the Mayo Wrist Score the result were good with an average score of 83 points. Regarding the DASH score we achieved a mean of 12.7 points.

Our modified arthroscopic assisted SL-capsuloplasty is an effective and due to its nature as an minimal invasive approach less traumatic technique to stabilize the scapholunate complex. The results were better in dynamic than in static SL-lesions regardless if they have a acute or chronic entity. The DCSS seems to heal regardless of the lesions age but longer follow-up is necessary.

Wide-Awake Local Anesthesia No Tourniquet (WALANT) Versus Local or Intravenous Regional Anesthesia with Tourniquet in Elective Hand Surgeries: A Systematic Review And Meta-Analysis

List of authors:
Ted Matthew P. Evangelista*, John Hubert C. Pua1, Mara Therese E. Huber2
1 University of Santo Tomas Hospital (Manila)
2 Levana Dermatology Clinic (Quezon City)

Objectives / Interrogation: The WALANT technique is gaining popularity over the use of tourniquets in elective orthopaedic hand surgeries as it eliminates the complications associated with general or intravenous regional anaesthesia and the discomfort associated with tourniquets.

The objective of this study is to compare the efficacy, safety and patient satisfaction of the WALANT procedure versus local or intravenous regional anaesthesia with tourniquet in atraumatic hand surgeries.

Methods: We conducted a comprehensive literature search using PubMed, MEDLINE, Embase, and the Cochrane Library from inception to October 2018. All randomized or quasi-randomized trials and cohort studies comparing WALANT procedure versus local anaesthesia or intravenous regional anaesthesia with tourniquet among atraumatic, elective hand surgeries such as carpal tunnel release, tendon sheath incision, and excision of baker’s cyst were included. Methodological quality, risk of bias, and GRADE of the eligible studies were assessed by three independent reviewers. The random effects model was used due to both statistical and clinical heterogeneity of the studies.

Results and Conclusions: The search yielded 70 records, of which 9 studies were included in the systematic review. In our interim analysis, we were able to pool findings for operative time, post-operative pain scores, patient satisfaction, and complication rates. On the average, the WALANT group had longer operative times by 2.06 minutes (pooled mean difference, random effects, 95% CI 0.46 to 3.67 mins, p = 0.01, I² 0%, p = 0.66). The post-operative pain scores were lower in the WALANT group by an average of two VAS points (random effects, pooled mean difference -2.40, 95% CI -3.41 to -1.38, p < 0.00001; I² 0% p = 0.99). We had insufficient evidence to demonstrate a difference in terms of patient satisfaction (random effects, pooled RR 0.98, 95% CI 0.93 to 1.03, p = 0.36, I² 0%, p = 0.64) and complication rates (random effects, pooled RR 0.40, 95% CI 0.07 to 2.18, p = 0.29, I² 60% p = 0.08) between WALANT versus conventional methods.

The WALANT group reported lower post-operative pain scores, but had slightly longer operative times. There are no significant differences between WALANT and conventional methods in terms of patient satisfaction and complication rates.

New method for operative treatment of bony mallet fractures without transfixation of the distal interphalangeal joint - a biomechanical study

List of authors:
Peter Schwendinger*1, Lukas Horling2, Rohit Arora2, Werner Schmölz2, Romed Hörmann3
1 Unfallchirurgie LKH Feldkirch, Unfallchirurgie Universitätsklinik Innsbruck (Feldkirch)
2 Department of Trauma Surgery University Hospital Innsbruck (Innsbruck)
3 Sektion für klinisch funktionelle Anatomie (Innsbruck)

Objectives / Interrogation: Several surgical methods are described for the treatment of the mallet fracture. Most closed techniques use a K-wire fixation through the distal interphalangeal (DIP) joint for temporary transfixation. Multiple tries to achieve an acceptable K-wire position may cause cartilage damage and increase the risk of a joint infection. Based on the Ishiguru technique, we describe a new method, using a single K-wire, without transfixation of the DIP joint. The purpose of the study is a biomechanical comparison of the new surgical technique to the proven technique according to Ishiguru.

Methods: 32 fingers (Digit 2-5) from 4 freshly frozen hand pairs were disarticulated at the PIP joint and fixed in PMMA. Exclusion criteria were previous soft tissue injuries, fractures and loose fingernails. The hands were randomized to have a donor’s hand in each group. The fractures were created with a flat chisel under fluoroscopic control. Including criteria were fractures up to 30% of the articular surface and subluxation of the distal phalanx. One group was treated using the Ishiguru method and the other group using the new fixation method. We use single K-wire which enables indirect fracture fragment fixation, as described in the original Ishiguru technique. The same K-wire is bent distally over the fingernail and is fixed with a special device without intra-articular K-wire transfixation of the DIP joint. The fingers underwent a cyclic load test consisting of 2000 cycles with a load between 1N and 7N. After this cyclic test, a load to failure test was performed. The load applicator was applied to the finger nail. X-rays were taken every 500 cycles, and again after the load to check the reduction and the plastic deformation.

Results and Conclusions: So far, 14 fingers have been tested. All fingers in the fixator group were superior in both maximum load and stiffness (max. load mean 29N and 19N, p=0.0014, stiffness mean 4N/mm and 8N/mm, p=0.0086). There was no significant difference in the plastic deformation and loss of reduction after the cyclic load test. The first fingers were tested with a force of 10N. The Ishiguru group failed immediately in the first cycles; therefore the cycling load was reduced to 7N. The remaining test results are pending. The initial biomechanical test results demonstrated superiority to an already established method. We could demonstrate higher biomechanical stiffness without intra-articular K-wire placement avoiding cartilage damage. Further applications are being tested.

Objectives / Interrogation: Upper limb amputations can strongly limit the quality of life of a person. The most advanced dexterous prosthetic hands have remarkable mechanical features. However, in most cases, the costs are often prohibitive for most patients and the control systems are often rudimental. 3D printing and open source software can allow to solve this problem in the future. Publicly available 3D models of hand prostheses are increasingly being released, as well as open source control algorithms, that can strongly improve the state of the art. This paper aims at testing current state of the art in this revolutionary field, by testing in real life settings one of the most advanced 3D printed robotic hand prostheses, which is used in combination with a low cost myoelectric armband.

Methods: Several subjects with transradial amputation wore the Thalmic Labs Myo armband and an adaptive socket that was connected to an HANDi Hand. The control of the hand was multi function and involved four different hand and wrist movements. The subjects tested the system in real time while grasping several objects, performing movements that were selected according the usefulness for activities of daily living. The time required to complete the movement and movement performance were evaluated.

Results and Conclusions: The 3D printed prosthetic hand was successfully controlled by the classifier provided with the low-cost Myo armband and used for daily life activities by 2 subjects with hand amputation. The gesture recognition approach implemented in the control system used in this study allowed the automatic identification of the desired grasp quickly. The system allowing the subjects to control up to 3 hand grasps in addition to the gesture used to open the prosthetic hand. Factors like the level of the amputation, neuromuscular fatigue and mechanical limitations of the 3D printed hand prosthesis can influence the performance of the setup. Furthermore, practical aspects still need to be improved to reach performances that can be applied to real life settings. The results show that multi-function control of dexterous 3D printed hand prostheses can be performed, also using low-cost setups. Future assistive and rehabilitative devices will probably be revolutionized by publicly available software, additive manufacturing and low cost sensors. Scientific research in this innovative field can allow patients to benefit of such change and surgeons to develop surgical procedures that can integrate better with such innovative approaches.

4 Universitätsspital Basel, Klinik für Mund-, Kiefer- und Gesichtschirurgie (Basel)

Objectives / Interrogation: Additive Manufacturing (AM) is rapidly gaining acceptance in the healthcare sector. Three-dimensional (3D) virtual surgical planning, fabrication of anatomical models and patient specific implants (PSI) are well-established processes in the surgical fields. Poly-ether-ether-ketone (PEEK) has been used, mainly in reconstructive surgeries as a reliable alternative to other alloplastic materials for the fabrication of PSI. Recently, it has become possible to fabricate PEEK PSI with Fused Filament Fabrication (FFF) technology. 3D printing of PEEK using FFF allows construction of almost any complex design geometries in a cost-effective manner, within a short time-frame, even in an in-house 3D printing setup.

Methods: The FFF 3D printer used in our research is a prototype of the Apium P220 (Apium Additive Technologies GmbH, Karlsruhe, Germany). Patient's data in DICOM format is processed in a medical modeling software program and a virtual 3D anatomical model is created. With further processing & designing, the PSI is constructed and exported as an STL file which is sent to the 3D printer for fabrication of PSI.

Results and Conclusions: 3D printed PEEK PSI have a smooth finish and were without any irregularities. No black-specks formation nor discoloration (improper crystallization) were detected in the test parts. All of the 3D printed parts passed a certified sterilization test without any deformation. The preliminary tests confirmed the feasibility of fabricating 3D printed PEEK PSI by FFF.

Long Term Results of First Major Upper Extremity Replantations In Turkey: A Replantation Under Direct Vision of 42 Years versus Another With Microsurgery of 37 Years

List of authors:
Turker ÖZKAN*, Ayhan Nedim KARA
1 Dr. Türker ÖZKAN (Nisantasi-ISTANBUL)

Objectives / Interrogation: The long term results of major upper extremity replantations are evaluated with the functionality of the extremity and the occupational and biopsychosocial status of the patient. In this study, we aimed to compare the long term functionality of a case with replantation under direct vision with another case with replantation by microsurgery.

Methods: Two seventeen year old male patients were referred with above elbow, clean cut amputations at their non-dominant left hands. The pressman (#1) had a guillotine type accident whereas the carpenter (#2) had a saw trauma. The ischemia times were less than 5 hours for both patients. The radial and ulnar arteries of the #1 was operated under direct vision whereas standard microsurgical anastamoses were performed for the #2. The bones were stabilized with intramedullary nailing for both cases. The median and ulnar nerves were coapted in both cases. In the #1, the nerves were repaired with non-absorbable 6/0 sutures epineurally whereas they were repaired with non-absorbable 9/0 sutures epiperineurally in the #2. Both of the patients received standard hand physiotherapy.

The following tests and evaluations were done for 37 and 42 years: Semmes - Weinstein monofilament test, vibration test, 2 point discrimination test, localisation test, grip and pinch strength measurements, motor evaluation, Chen criteria, DASH and ADL.

Results and Conclusions: During the early postoperative period, distal necrosis was seen at the tip of the fourth finger of the #1, requiring a revision amputation. Early complications were not seen in the #2. Total osseous union was achieved in both patients. Both patients returned to their occupations two years after the surgery, and the #2 completed his military service four years after the surgery. The Semmes - Weinstein test was 2.83 for both of the patients and two point discrimination at all the fingers were 4 millimeters for the #1 and 3 millimeters for the #2. In both patients, the grip and pinch strengths were comparable with the unaffected dominant hand. The thenar and intrinsic muscle functions were satisfactory in both cases. The recovery of both patients were found to be Chen Class I. The cases have the longest followup period after major upper extremity replantations with satisfactory function in Turkey.

Basic operative informations in three main aetiological causes which necessitate tendon transfers in upper extremity

List of authors:
Fatih Aydin¹, Ender Gümüşoğlu², Kadir Uzel², Metin Manouchehr Eskandari²
¹ University of Mersin, School of Medicine, Department of Orthopaedics and Traumatology (Mersin)
² University of Mersin, School of Medicine, Department of Orthopaedics and Traumatology, Division of Hand Surgery (Mersin)

Objectives / Interrogation: Tendon transfers (TTs) are the last treatment options indicated in patients with three main aetiologies. These are peripheral nerve palsies (PNP), local loss of muscle-tendon units without nerve injuries (LLMTU) and muscle imbalances due to central nervous system dysfunctions (MICNSD). In this study we aimed to analyse timing, number of transferred tendons and need of additional surgical procedures (ASPs) in patients who underwent TTs on the base of their aetiologies.

Methods: Digital archive of the university hospital between May 2007 and September 2018 was searched. Informative data required by the aims of the study were compiled.

Results and Conclusions: There were 112, 53 and 24 patients in each group of PNP, LLMTU and MICNSD, respectively. The most frequent diagnosis, transferred tendon and additional procedure in PNP was Brachial plexus palsy(n=39), PL-EPL(n=29) and nerve release(n=12); in LLMTU was Closed EPL rupture(n=19), EIP-EPL(n=19) and Tendon release or plication(n=4); and in MICNSD was Cerebral palsy(n=20), PT rerouting and FCU-EDC(n=6 in each) and Muscle-tendon fractional release(n=16), orderly and respectively. Other findings are given below. Findings in each line are belonging to PNP, LLMTU and MICNSD groups respectively. Time data is given as "mean(min,max)". PNPs include both neonatal and adult type brachial plexus palsies.

Gender(men/Women): 87/25, 37/16, 15/9
Age at 1.surgery(year): 26(3-70), 37(8-74), 19(7-44)
Onset-1.surgery interval(month): 58(1-300), 24(1-228), 202(24-444)
Total n of TTs: 193, 68, 46
n of TTs/patient: (1,7), (1,3), (1,9)
n of operations/patient: (1,1), (1,05), (1,08)
Field of the most frequent ASP and its n:
ASP-Nerve: 32, 0, 0
ASP-Muscle-tendon-pulley: 35, 4, 17
ASP-Bone-joint: 8, 2, 2
ASP-Skin (1.webplasty): 3, 2, 3
Total ASPs & n/patient: 78(0,7), 8(0,15), 22(0,92)

Conclusions: Tendon transfers can be successful when it is well-planned on the base of patient's physical resources, goals, and expectations. For these aims, patients should be adequately informed about the timing, probability of additional procedures, necessity for further operation sessions and possible complications. We think that informations provided by this study can be useful while informing patients on the base of their three main etiological problems.

Keywords:
tendon transfer, aethiology, timing, need of additional procedures
Bilateral idiopathic radioulnar synostosis

List of authors:
Sten Deschuyffeleer¹, Frédéric De Schrijver²
¹ University Hospitals Leuven (Leuven)
² AZ Herentals (Herentals)

Objectives / Interrogation: We would like to report on a 31-year-old otherwise healthy male with a limitation of rotation to the left forearm. He complained of increasing pain at night and progressively decreasing range of motion for one year. There was no previous trauma to the limb. Radiographs showed bridging bone formation. Contralateral radiographs were obtained and showed a similar process, although less pronounced. A resection of the bony mass without interposition of soft tissues was performed. Histological examination confirmed the resected specimen to be made up of bony tissue without cellular abnormalities.

Methods: A resection of the bony mass without interposition of soft tissues was performed. Histological examination confirmed the resected specimen to be made up of bony tissue without cellular abnormalities. Postoperatively there was a restored range of motion, which remained stable 6 months later. Preoperative pain also disappeared.

Results and Conclusions: Radioulnar synostosis has traditionally been classified into 2 groups: congenital and post-traumatic. The congenital form is thought to be a developmental error occurring in utero, when the proximal ends of the radius and ulna are covered by a common perichondrium. Only proximal congenital fusions have been reported. The diagnosis is usually made between 2.5 and 6 years of age, as patients usually have little complaints. Secondely, posttraumatic radioulnar synostosis is described as a complication occurring following osteosynthesis of fractures of one or both forearm bones. It has also been reported after stab wounds and other soft-tissue injuries. The synostosis may develop anywhere along the intraosseous membrane.

This case does not seem to fit in to either of these categories. The patient presented because of progressively decreasing pro-supination, previously having symmetrical motion. Also, the location of the synostosis was not proximal. Both arguments favour against a congenital synostosis. On the other hand, there is no recollection of any trauma, and the contralateral forearm showed a similar problem, excluding a posttraumatic synostosis.

Review of the literature yielded one case report documenting an 18-year-old man with progressively decreasing motion, without previous trauma. Radiographs showed a distal synostosis, which was resected with good results. The authors termed this condition 'idiopathic radioulnar synostosis'. This is, to the best of our knowledge, the first report of a diaphyseal, bilateral idiopathic radioulnar synostosis.

Use of giant-sized flow-through venous flap for simultaneous reconstruction of dual or multiple major arteries in salvage therapy for complex upper limb traumatic injury

List of authors:
Hui Zhu*
1 Xuzhou Renci Hospital (Xuzhou)

Objectives / Interrogation: Salvage repair after complex upper limb traumatic injury is surgically challenging due to underlying major arterial impairment with complicating a large-sized soft tissue defect. The purpose of this study was to evaluate the effectiveness and safety of using a giant-sized (larger than 100 cm²) flow through venous flap for reconstruction of dual or multiple forearm, metacarpal, or digital arteries after complex upper limb traumatic injury.

Methods: Seven patients were consecutively hospitalized for emergency salvage repair after complex upper limb traumatic injury between March 2012 and May 2014. The forearm and palmar artery defects were repaired using the calf great saphenous vein flap and the volar forearm venous flap, respectively.

Results and Conclusions: The flow-through venous flap ranged from 9.5 cm × 12.0 cm to 12.0 cm × 20.0 cm (mean, 158.4 cm²) in size. The flaps and affected limbs survived uneventfully in five patients, with one patient experiencing distal flap marginal necrosis and a second patient requiring amputation of the affected limb. Computed tomography angiography showed patent vessels in all patients. The mean total active motion of the repaired fingers was 199.5° versus 258.8° for the contralateral counterpart (77.1%). The sensory return was determined to be S2 in 2 patients, S3 in 3 patients and S3+ in 1 patient. The disability scores for the arm, shoulder, and hand ranged from 4.6-18.2 (mean, 11.3), and the mean Michigan hand outcomes questionnaire score was 7.8 ± 0.9.

The flow-through venous flap is an effective and safe treatment alternative for salvage therapy of a larger than 100 cm² complex upper limb traumatic injury with dual or multiple major arterial impairment. This technique allows simultaneous reconstruction of dual or multiple artery injuries and an extensive soft tissue defect. Serious surgical site infection remains a major safety concern and necessitates radical debridement in complicating cases.

Trigger finger at the distal A2 pulley with extension locking of proximal interphalangeal joint: category of the idiopathic trigger finger

List of authors:
Chul-Hyung Lee¹, Cheol-U Kim*¹
¹ Daejeon Sun Hospital (Daejeon)

Objectives / Interrogation: Trigger fingers are known to be caused by volume mismatching of the A1 pulley and flexor tendon. We experienced a A2 trigger finger with extension locking of the proximal interphalangeal joint.

Methods: A 44 year old man came to our hand clinic because of the triggering of the right ring finger, which began five years ago. Except triggering, the patient could not fully extension of the proximal interphalangeal joint, and flexion contracture of about five degrees was observed. On physical examination, the nodule was not obvious on the A1 pulley, but there was tenderness. We planned A1 pulley release. After axillary brachial plexus block, a tourniquet was applied and a 2 cm longitudinal skin incision was made on the A1 pulley area. Degenerative changes and abnormal findings of the A1 pulley, abnormal findings of the flexor tendon like nodule were not evident. Despite performing A1 pulley release, the flexion contracture was still observed. Full extension was possible only after giving excessive force, and it was kept locked in a state of hyperextension of two to three degrees of the proximal interphalangeal joint. When compressing the musculotendinous junction of the forearm, other fingers were naturally flexed, but the metacarpophalangeal joint of ring finger was flexed with locking on the proximal interphalangeal joint. In the hyperextension state, the proximal interphalangeal joint was manually flexed, and locking was released with snapping at about 90 degrees. Hyperextension locking was reproduced without improvement. In the operating room, we found a nodule like lesion moving along the flexor tendon during flexion-extension on the A2 pulley area. We explained to the patient that there may be a cause other than A1 pulley like A2 pulley or proximal interphalangeal joint problems. Additional incision was performed on the proximal interphalangeal joint area. When passive flexion of hyperextended finger was performed, the flexor digitorum profundus did not glide into the pulley at distal part of the A2 pulley and became bulged. We concluded that the triggering occur between the both slips of flexor digitorum superficialis and the flexor digitorum profundus exiting the Camper's chiasm at the distal part of the A2 pulley.

Results and Conclusions:
The hyperextension locking of proximal interphalangeal joint was disappeared after releasing distal 4mm of A2 pulley. There were no significant enlargement of flexor tendons and inflammatory findings around A2 pulley.

Use of a Distal Ulnar Artery Perforator-Based Bilobed Free Flap for Repairing Complex Digital Defects

List of authors:
Dawei Zheng*
1 Xuzhou Renci Hospital (Xuzhou)

Objectives / Interrogation: To retrospectively evaluate the effectiveness and safety of using a distal ulnar artery perforator (DUAP)-based bilobed free flap (BFF) for the repair of complex digital defects in the hand.

Methods: We retrospectively studied 15 patients who sustained traumatic digital defects with complicating tendon and phalanx exposure and were hospitalized for repair using a DUAP-based BFF. Main outcome measures included patients’ self-assessed physical appearance, total active motion, and 2-point discrimination.

Results and Conclusions: The flaps survived and the wounds healed with primary intention in all patients except one who experienced partial necrosis of the distal margin and required treatment with a second skin graft. Patients were observed for a mean of 13 months. The physical appearance and texture of the repaired fingers were assessed as good with minimal scarring. Total active motion and 2-point discrimination were 113° to 255° (contralateral, 255° to 275°) and 6 to 11 mm (contralateral, 5 to 8 mm), respectively.

Use of the DUAP-based BFF is a feasible, effective, and safe treatment alternative for repairing complex digital defects with favorable aesthetic and sensorimotor outcomes.

Posteromedial dislocation of the elbow with lateral humeral condyle fracture in children; Arthrography is useful for distinguishing between dislocation or epiphyseal separation

List of authors:
Kayo Tsuzawa*1, Keikichi Kawasaki1, Katsunori Inagaki1
1 Showa University School of Medicine (Shinagawa Ward, Tokyo)

Objectives / Interrogation: Posteromedial dislocation of the elbow with lateral humeral condyle fracture is rare in pediatric elbow injury. It is often difficult to distinguish between elbow dislocation with lateral condyle fracture and epiphyseal separation of the distal humerus, especially in younger infants whose ossification centers are not yet apparent. We report 6 cases of the posteromedial shift of the forearm with the distal humeral fractures and discuss the importance of the diagnosis of the fracture patterns.

Methods: Retrospective data were collected for the cases of distal humeral fractures with posteromedial shift of the forearm treated at our hospital.

Results and Conclusions: There were six cases of these fractures, which five were boys and one was a girl. Mean age at the injury was 7.5 years, ranging from 0 to 12 years. Four cases were elbow dislocation with lateral humeral condyle fracture and two were epiphyseal separation of the distal humerus. All four cases of lateral humeral condyle fractures had an appearance of an ossification center of the lateral condyle, hence were easily diagnosed. However, trochlear of these three cases hadn't been fully ossified and were difficult to categorize according to Milch's classification. Three cases were treated by fixation with tension band wiring (TBW), and one was with TBW and K-wire. Two of the epiphyseal separation of the distal humerus were diagnosed by arthrography because their ossification centers didn't appear. One case underwent surgical treatment by pinning and one was treated by closed reduction and casting. One postoperative patient had painless flexion of elbow motion to 120 degree, but others had no clinical symptom after all.

The epiphyseal separation of the distal humerus is difficult to diagnose when the ossification center is not yet apparent and is radiographically assessed by the alignment of the radial axis and the capitulum of the humerus. The injury is likely to be an elbow dislocation with lateral condyle fracture if the reduction position is kept, but we should confirm the fracture pattern by arthrography before the treatment. The lateral condyle fracture is Salter-Harris type 4 epiphyseal separation and some report shows the importance of the Milch’s classification. One of our cases needed arthrography for the assessment of elbow joint at the removal of wires. We should evaluate the posteromedial shift with the humeral fracture by arthrography at the time of reduction or before the operation.

Bizarre Parosteal Osteochondromatous Proliferation: a serie of cases.

List of authors:
Bruno Crepaldi*, Peter Maloney¹, Owen Ou Yang¹, Anthony Berger¹, James Thomas¹
¹ St Vincent's Hospital Melbourne , VHSA (Melbourne)

Objectives / Interrogation: We report on a serie of cases of Bizarre Parosteal Osteochondromatous Proliferation (BPOP).

Methods: Case 1:
A 63-year-old woman presented with right thumb pain since November 2017. Radiographs and an ultrasound demonstrated findings suggestive of osteomyelitis.
MRI Findings remained suggestive for terminal tuft right thumb osteomyelitis and small palmar phlegmon/collection.
Surgical excision was performed and no evidence of necrotic, inflammatory or infective tissue was found.
BPOP was reported by the pathology department.

Case 2:
A 76-year-old, right-handed man presented with a growing solid lump over the last 8 months on his right ring finger.
MRI scan reported an osteochondroma with features suspicious for sarcomatous degeneration to chondrosarcoma.
CT guided biopsy followed by surgical excision were consistent with BPOP.

Case 3:
55 year-old, female, presented with a reasonably painful lump in her right wrist with constant growth in the last 2 years and ulnar nerve symptoms.
CT scan reported bony exostosis from the volar and radial aspect of the distal ulna (20 x 16 x 15mm).
Surgical excision was performed with ulnar nerve release and the specimen reported as BPOP.

Results and Conclusions: Bizarre parosteal osteochondromatous proliferation was first described by Nora et al. in 1983. It is an extremely rare lesion (less than 200 cases reported in the literature), with reported age onset as being anywhere between 5 months to 74 years old, absolutely benign and without sex predilection.
Clinically, presents as a slowly growing hard protuberance, painless in most cases, unless due to mass effect.
The classical radiographic pattern consisted of a pedunculated or broad-based osseous protuberance along the cortical surface of the bone, mostly seen in tubular small bones metaphysis.
Typical MRI features of BPOP are low signal intensity on T1-weighted sequences, high signal intensity on fast spinecho T2-weighted and short inversion time inversion recovery sequences with a normal cortex, medullary cavity, and adjacent soft tissues.
Histologically, BPOP presents as a cartilage-capped exostosis. The cap is cellular with focal atypia. The subchondral area is composed of fibrovascular tissue. The presence of calcified cartilage that stains blue on hematoxylin and eosin (H & E) stain is characteristic.
Generally, BPOP does not induce metastatic lesions and the most effective and safe treatment is radical excision surgery, including the fibrous pseudo-capsule and part of the compromised cortical bone.

Effects of hand amputation surgery procedures on phantom limb sensation

List of authors:
Franco Bassetto*, Cesare Tiengo1, Peter Brugger2, Gianluca Saetta2, Manfredo Atzori3, Matteo Cognolato4, Diego Faccio3, Marco Coppola1, Barbara Caputo5, Henning Müller3

1 UOC Chirurgia Plastica, Università degli studi di Padova (Padova)

3 University of Applied Sciences Western Switzerland (Sierre)
4 University of Applied Sciences Western Switzerland, Department of Health Sciences and Technology, ETH Zürich (Sierre)
5 Dep. of Automatics and Informatics, Politecnico di Torino (Torino)

Objectives / Interrogation: Phantom limb syndrome refers to afferent and efferent sensations and perceptions of a missing limb following its amputation. Non-painful phantom limb sensations (nPPLS) and phantom limb pain (PLP) are distinguished in literature. The theories proposed to explain the etiopathogenetic mechanisms show the importance of both peripheral and central phenomena. The presence of neuromas, high levels of amputation and psychological factors contribute to the onset of the syndrome. The objective of this study is to search for relationships between different surgical techniques used in the amputation surgery and phantom limb sensation phenomena.

Methods: 11 patients who had undergone a transradial amputation of the hand between 1999 and 2017 were included in the study. Phenomenal characteristics of individual phantom limb sensations are quantitatively assessed by structured interviews such as the interview on phantom sensations (RAM SIPS) and the phantom and stump phenomena interview. The surgical procedures performed on the patients (such as cutaneous flaps, nerve treatment and amputation packing techniques) are assessed from the surgical reports. The statistical techniques used for data analysis are the Mann-Whitney test for the comparison between two groups of independent samples and the descriptive analysis of the graphs (box plots).

Results and Conclusions: Mean values for nPPLS are lower in patients in whom cutaneous flaps have been used. The stratification of patients according to demographic, clinical and biometric criteria seems to show how the techniques applied on the severed nerve ends have a greater weight in determining the sensations of phantom limb. The techniques for packing the amputation abutment appear to be also important for phantom limb sensations. The study allows to infer how the transradial amputation intervention must be performed: from the correct approach to nerve injury to the appropriate choice and realization of soft tissue covering techniques and remodeling of the extremity. The different surgical procedures considered in this study can be important for the characteristics of the phantom limb syndrome. Despite the limits of the retrospective study and the low number of population, the study is innovative and useful to prevent the development of PLP. The study is currently being improved by taking into consideration the most innovative and recent surgical techniques, increasing the number of subjects and reducing confounding factors.

Effects of hand amputation surgery procedures on sEMG activity to control robotic hand prostheses

List of authors:
Franco Bassetto*, Cesare Tiengo1, Manfredo Atzori2, Arjan Gijsberts3, Barbara Caputo4, Matteo Cognolato5, Diego Faccio1, Gianluca Saetta6, Peter Brugger6, Henning Müller2
1 UOC Chirurgia Plastica, Università degli studi di Padova (Padova)
2 University of Applied Sciences Western Switzerland (Sierre)
3 Italian Institute of Technology (Milano)
4 Dep. of Automatics and Informatics, Politecnico di Torino (Torino)
5 University of Applied Sciences Western Switzerland, Department of Health Sciences and Technology, ETH Zürich (Sierre)
6 Department of Neurology, University Hospital of Zurich (Zurich)

Objectives / Interrogation: Amputation is both an ablative and reconstructive surgical procedure. It consists in the partial or complete removal of the limb. Currently amputations are aimed at creating stable stumps for prosthetic sockets, but they are quickly evolving to functional procedures that can allow amputees to better control robotic dexterous prosthetic hands with electromyography. This technique promises a high capacity for movement but require high patient compliance. At the moment there are no appropriate studies that have tried to identify the relationship between surgical techniques used in the amputation surgery, control of prosthetic movements and phantom phenomena. The purpose of the study is thus to analyze the effects that different surgical procedures have on the control of myoelectric prostheses.

Methods: 11 patients who had undergone a transradial amputation of the hand between 1999 and 2017 were included in the study. Muscular activity is measured using 12 double differential sEMG electrodes (Delsys Trigno Wireless System). The subjects were asked to imitate hand movement movies with the missing limb as naturally as possible. Machine Learning and Artificial Intelligence techniques were used to understand the muscular movements performed by patients through recorded data. The surgical procedures performed on the patients (such as cutaneous flaps, nerve treatment and amputation packing techniques) were assessed from the surgical reports. The statistical techniques used for data analysis are the Mann-Whitney test for the comparison between two groups of independent samples and the descriptive analysis of the graphs.

Results and Conclusions: The techniques for packing the amputation abutment appear to have a similar weight on prosthetic control and phantom limb sensations. Among patients less than 40 years old, it appears that the use of the fasciocutaneous flap is better compared to skin grafts. The use of myocutaneous flap and lipofilling shows lower values of classification accuracy of the movements. Despite the limits of the retrospective study and the low number of population, the study is certainly innovative and useful to define optimal amputation strategies. All the different surgical procedures taken into consideration can have a determining role for the control of myoelectric prosthesis. Currently, the surgeon goal should include patient's future need to use functional prostheses. This must be done taking into consideration even the most innovative and recent surgical techniques.

Surgical technique to improve the reduction of fractures of distal radius by "Screw Post". Technique and patient follow-up

List of authors:
julio sandoval**, camilo Romero², camilo Estrada³
¹ Fundacion Cardioinfantil (Bogota)
² Fundacion Cardioinfantil (Bogota)
³ Fundacion Cardioinfantil (Bogota)

Objectives / Interrogation: The reduction of the fractures of the distal radius are of great importance to the evolution of this type of fracture, once the decision to make a surgical management is made, our goal is to achieve a reduction as anatomical as possible. In some cases, this reduction is not achieved in an appropriate form and that is when the surgical technique of the post screw is applied.

Methods: Through a geometric quantification the reduction of the fracture can be improved by using a screw locked in the same plate. The screw is placed and its length is decided according to the pre-established table and depending on the reduction deficit. The corresponding hole is also made according to the table. The screws of the distal branch are fixed first to the epiphysis then the post screw is removed. The correction of the missing angle on the radio's face is made by bringing the proximal branch of the plate to the surface of the radio.

The formula - Ang Tang (a / b) = Alpha
Where it is known, a = known leg (length of the screw), b = known leg (length on plate) and angle a / b known = 90 °
A calculation can be made and recorded in an Excel table to make the correction of the missing angle in each case according to the intra-operative and / or pre-operative images. Through a follow-up of 31 patients with the post screw technique their radiological and clinical studies are monitored, obtaining very good results.

Results and Conclusions: Discussion: we recommend the application of the post screw technique. The safety of the procedure, the correction achieved by this technique, and the advantage of not needing another device other than the same plate and its screw system, gives a good result and does not increase the costs.

Keywords:
Cosmetic appearance of congenital upper extremity anomalies

List of authors:
Noora Nietosvaara*1, Antti Sommarhem1, Jani Puhakka1, Ruth Tan2, Johannes Schalamon3, Yrjänä Nietosvaara1
1 New Children's Hospital (Helsinki)
2 National University Hospital (Singapore)
3 University Hospital Graz (Graz)

Objectives / Interrogation: Cosmetic disability of congenital hand anomalies is unknown. The purpose of this study was to determine the general opinion about how different congenitally malformed hands look.

Methods: We developed a questionnaire in a game format to evaluate the appearance of different hands. Altogether 1450 (954 females) 4-84-year-old residents (296 children) of two European and one Asian (n=102) country were asked to rate the appearance of hands on a 1-5 scale using emoticons. Standardized photographs of the dorsal aspect of 17 different congenitally malformed hands and a normal hand were presented to respondents. All 18 photographs were shown twice in a random order. For intrarater reliability ICC (A,1) and for interrater reliability ICC (C,1) estimates and their 95% CI were calculated. Significance of age, gender and nationality of the respondents was assessed using Mann-Whitney U test. Hands were divided into three subgroups according to the respondent's evaluations using Latent profile analysis.

Results and Conclusions: The normal hand and clinodactyly were perceived to have the best appearance. Symbrachydactyly and radial club hand received the lowest scores. Intrarater reliability was good (ICC=0.862, 95% CI 0.859-0.865, p<0.001) and interrater was moderate (ICC=0.621, 95% CI 0.479-0.786, p<0.001). Adults rated the appearance of all hands higher than children (p<0.05 in 14/18 hands), females regarded all hands better looking than men (p<0.05 in 15/18 hands) and Europeans gave higher scores (p<0.05 in 4/18) to all hands compared to Asians, with one exception. Europeans rated four-finger hand (mean=3.21, SD=1.18) better looking than six-finger hand (mean=2.92, SD=1.18), p<0.005), whereas Asians scored six-finger hand (mean=2.66, SD=1.26) higher than four-finger hand (mean=2.51, SD=1.14). The respondents' ranking order of the hands was consistent, except in the intermediate group (Table 1).

Despite age, gender and nationality the appearance of different congenital upper limb anomalies is rated very similarly. Asians prefer an additional digit to a four-finger hand.

The Cone Beam Computed Tomography: An alternative imaging modality for the hand surgery

List of authors:
Horst Zajonc*1, Nico Leibig1, Jan Thiele1, Jakob Neubauer2, Sebastian Goerke3, Bjoern Stark1
1 Clinic for Plastic and Hand Surgery, University of Freiburg (Freiburg)
2 Department of Radiology, University clinic Freiburg (Freiburg)
3 Institute of Radiology, Ortenau clinic, Offenburg-Gengenbach (Offenburg)

Objectives / Interrogation: Objectives/Interrogation
The Cone Beam Computed Tomography (CBCT) is already an established standard procedure in imaging of head and neck. In comparison with Multidetector Computed Tomography (MDCT), the CBCT seems to have a lower radiation dose. Since 5 years we use the CBCT routinely for handsurgical questions in our clinic.

We compared the diagnostic accuracy of CBCT with MDCT pictures in protocols and radiation dose, which are equivalent to the projection radiography in two layers. In addition we compared in a phantom study the diagnostic accuracy of both section diagram methods (CBCT and MDCT) at the identification of fractures, cortical defects and material of osteosynthesis.

Methods: Methods
As study subjects we obtained 10 cadaveric human hands from body donors. Distal radius, distal ulna and carpal bones (n = 100) were artificially fractured in random order in a controlled experimental setting.

We performed radiation dose equivalent radiography (settings as in standard clinical care), MDCT in a 320 row with single shot mode and CBCT in a device dedicated to musculoskeletal imaging.

The results of fractures and the level of confidence for each finding were evaluated by three raters independendly. Gold standard was evaluated by consensus reading of a high-dose MDCT.

In addition 18 feet of European roe deer were fractured in a universal testing machine. Another 3 feet were prepared with cortical defects and screws, or both combined.

Six observers rated the scans according to number of fragments, size of defects, size of defects opposite orthopedic screws, and the length of different screws. The image quality regarding depiction of the cortical bone was assessed. The gold standard (real number of fragments) was evaluated by autopsy.

Results and Conclusions: Results
On the cadaveric human hands, the section diagram methods showed at same radiation dose better sensitivity in fracture detectionning compared to radiography.
(MDCT: 0.89; CBCT: 0.81; projection radiography: 0.54 [P = < ,004])

Between both section diagram methods there was no significant difference.

In the phantom study of European deer feet both modalities proved to be comparable regarding the visualisation.

Conclusions
Clinical and experimental experience showed that CBCT has he potential to replace the convential radiography in different areas. Most beneficial is the high quality of imaging with excellent spatial resolution and the minor radiation dose.

Volar Locking Plate for AO Classification Type C Distal radius Fracture in the Elderly

List of authors:
Jinrok Oh*
1Dept. Orthopedic Surgery, Wonju Severance Hospital (Wonju-si, Gangwon-do)

Objectives / Interrogation: Even though the conservative treatment for distal radius fracture in the elderly is relatively common, but which is hardly accepted in AO Type C. We treated AO type C distal radius fractures with volar locking plate and checked up clinical outcomes with considering patients daily motion returning time.

Methods: We treated total 118 cases of AO type C distal radius fractures with distal radius locking plates from 2011 to 2017. Among those patients, 73 cases could be followed up more than 4 months; 12 cases of C1, 32 cases of C2, 29 case of C3. All patients treated with volar locking plate, and ulnar side fractures treated with fixation for only ulnar head and neck fracture, and ulnar distal shaft fracture. After surgical treatment, short arm splint period didn't exceed more than 3 weeks. The clinical results evaluated by radiologic profiles, VAS, and functional evaluation criteria.

Results and Conclusions: Ulnar side involvement rate, including styloid process fracture, head and neck fracture, and distal shaft fracture is 33.3% in C1, 72.3% in C2, 75% in C3. The functionally excellent results are 91.6% in C1, 96.8% in C2, 68.9% in C3. The radiologic profile changes rate is 41.6% in C1, 28.1% in C2, 58.6% in C3, but the radiologic change rate reaching to malunion criteria is 0% in C1, 3.1% in C2, 13.8% in C3. The rate of daily motion returning within 6 weeks is 100% C1, 100% C2, and 86.2% in C3. The early firm fixation method is beneficial for AO type C distal radius fractures in Elderly in viewpoints of early returning daily motion.

Technique for Intramedullary Stabilization of Ulnar Neck Fractures with Headless Compression Screw

List of authors:
Jinrok Oh*  
1 Dept. Orthopedic Surgery, Wonju Severance Hospital (Wonju-si, Gangwon-do)

Objectives / Interrogation: Distal ulnar neck fracture is commonly accompanied with distal radius fractures, and there are multiple treatment options like splinting, percutaneous pinning, intramedullary pinning, and plating. Each method of above mentioned treatment options is useful according to the fracture condition of ulnar neck and patients. We present a new percutaneous intramedullary fixation method for the ulnar neck fracture in concomitant with distal radius fracture.

Methods: We underwent percutaneous intramedullary fixation with Depuy-Synthes 4.5mm headless compression screw for distal ulnar neck fractures of ten cases. A focal stab skin incision is made on dorsal side near ulnar head with wrist flexion. A guide pin is inserted from ulnar head crossing ulnar neck fracture to distal ulnar shaft. And the intramedullary canal is drilled with 4.0 mm cannulated drill bit. Then we decide optimal 4.5 mm headless screw. The selected headless screw is inserted to ulnar intramedullary space following guide pin. We maintained splint short arm splint 2 weeks and then permitted active wrist motion with discarding the splint.

Results and Conclusions: We followed the 10 cases patients after fixation with above mentioned method for more than 4 months. All ten cases showed more than good results in radiologic and functional evaluation without special ulnar side problems. This technique uses minimal invasive approach, it is very simple and reliable to produce constant results for ulnar neck fracture in concomitant with distal radius fracture.

A new type of silicone implant for the thumb CMC joint osteoarthritis in grade III and IV. Four years follow-up.

List of authors:
Alena Schmoranzova*, Tomas Hellmuth¹, Jiri Paroulek¹, Radek Kebrel¹, Daniela Horackova¹, Lucie Smrckova¹
¹Hand and Plastic Institute (Vysoké nad Jizerou)

Objectives / Interrogation: PURPOSE:
To investigate the short-term functional outcomes of arthroplasty for osteoarthritis of the basal joint of the thumb using our new type of silicone prosthesis. The indications were osteoarthritis in grade III and IV, unsuccessful conservative treatment, elderly patient, and no requirements for manual work.

Methods: METHODS:
We observed 82 patients, operated in the years 2014-2016 who received basal joint resection arthroplasty with our new type of silicone replacement. Subjective outcome measures included patient satisfaction scores, and Disabilities of the Arm, Shoulder and Hand (DASH) scores.

Results and Conclusions: RESULTS:
At an average follow-up of 4 years, majority of the patients subjectively scored the procedure as good or excellent and reported improvement in activities of daily living. No intraoperative complications were reported. Only 7 early postoperative complications were reported for incorrect indication.
CONCLUSIONS:
Basal joint arthroplasty using our new type of silicon implant provides very good short-term results for carpometacarpal thumb osteoarthritis. The procedure is safe, with a low complication rate. Evaluation of the results after four years with measured by patient satisfaction and functional outcome is encouraging.

Satisfaction with collagenase for Dupuytren contracture disease: A patient related outcome analysis

List of authors:
Fernando Dávila*, David Ferreño-Marquez¹, Jorge Ruiz-Zafra³, david gil-ruiz¹, Homid Fahandezh-Saddi³
¹ Hospital Universitario Fundación de Alcorcón (Alcorcón)

Objectives / Interrogation: Collagenase of clostridium histolyticum (CCH) is a therapeutic alternative for Dupuytren disease. Although his efficacy and safety are well established, few data exist about patient satisfaction.

Objectives
Stabilize patient satisfaction with CCH treatment.
Compare patient satisfaction with efficacy and complications appeared.

Methods: Prospective nonrandomized single center cohort study.
Inclusion criteria: passive extension deficit at metacarpophalangeal (MCP) joint > 20º or proximal interphalangeal (PIP) joint > 15º treated with CCH between 2012 and 2017.
Extension deficit and complications were registered at manipulation day, 1st month, 3-6 months, 12 months and discharge. Satisfaction was evaluated using the Southampton Dupuytren scoring scheme at the end of follow up.
Clinical success when flexion contracture was < 5º in day 30 post injection.
Clinically acceptable when passive extension was less than 20º in MCP joint or 10º of the PIP joint in day 30 post injection.
Recurrence when global contracture was > 20º after clinical success.
P values below 0.05 were considered significant.

Results and Conclusions: 159 collagenase injections performed in 137 patients.
For joints, baseline extension deficit at MCP affected joints (40,9%) was 37,6º(SD±17,7), at PIP joints (17%) was 56,9º(SD±25,5) and at MCP+PIP joints (42.1%) was 75,3º(DS±36,1).
5th finger was the most common affected in 48,4% cases.
Globally mean total extension deficit decreased 90% after manipulation.
Global Clinical success was achieved at 68.02 % of cases.
Global Clinically acceptable results were achieved at 7.54 % of cases.
Global Recurrence at 12 months appeared in 9.4% of cases.
After asking the patients about CCH treatment, 69.6% declared to be satisfied.
76.1% of patients reported to have had problems with the treatment, but 72.4% of them, referred none or minor concerns when complications appeared.
The satisfaction analysis revealed that when success was achieved, satisfaction was higher (74% vs 40% satisfied) p=0.02 and patients would repeat treatment (70.7% vs 16.2%) p=0.04.
There were no significant differences in global satisfaction related to occurrence of complications (73.9% vs 68.5% satisfied) p=0.695.
When recurrence appeared 57.1% vs 78.5% of patients declared to be satisfied/very satisfied. P=0.1 but only 52.4 vs 75.6 % would repeat treatment with CCH. p= 0.007

Conclusion
Patient satisfaction with Collagenase injection procedure is high.
Complications appeared with the treatment does not change patient satisfaction.

Comfortable Cast to restrict pronation and supination. Is it possible?

List of authors:
Christian Kindler*1, Bernhard Lukas1
1 Schoen Klinik Muenchen-Harlaching (München)

Objectives / Interrogation: After TFCC Refixation limitation of pronation and supination (P/S) is necessary. About 7 years ago we switched from the upper arm splint or cast to the muenster cast. In this time we did 207 TFCC refixations, afterwards a muenster cast was applied. The exact application of this cast is not clearly described or varies in the literature. We optimized this cast concerning stability and comfort over the years. The aim of this study was to compare "our" muenster cast (MUC) with the upper arm cast (UAC) and upper arm splint (UAS).

Methods: 12 healthy volunteers were enrolled in the study. Each person obtained an upper arm cast, upper arm splint and a muenster cast. They had to wear the cast for one hour, doing activities of daily life and afterwards evaluate the cast with a questionnaire, which included: cast comfort, adaption to the cast, weight, keyboard use, drinking/eating, personal hygiene, overall satisfaction. Range of motion of elbow, wrist and forarm was measured before and with all of the three casts.

Results and Conclusions: On average test persons ranked the muenster cast first (23,8 points out of 35), the upper arm brace second (23,3 points) and the upper arm cast third (20,1 points). Advantage of the upper arm cast was adaption to the cast, the upper arm splint was best rated in weight, keyboard use, the muenster cast in drinking/eating, overall satisfaction. Measurement of range of motion showed, that the upper arm cast limits P/S slightly better than the muenster cast (27,78° SD 6,71 versus 36,11° SD 6,57). The upper arm splint does not limit P/S sufficient (98,89° SD 14,49). Elbow flexion is limited in the UAC to 17,78° (SD 6,28), in the UAS to 40,00° (SD 15,09) and in the MUC it is little limited, range of motion was measured with 99,44° (SD 11,65). Wrist extension and flexion results were: UAC 5,56° (SD 6,85), UAS 41,67° (SD 10,8), MUC 12,78° (SD 6,29). The main technique of our muenster cast is to reinforce the cast at some important spots, this can be explained in demonstrating a video. If the cast has to be split, the split has to be stabilized with a special plaster technique. Overall "our" muenster cast offers a very good patient comfort an satisfaction and limits P/S to a satisfying amount compared to the other cast or splints. The main advantage is the elbow extension and flexion which is nearly not compromised by this cast.

Medial femoral condyle to reconstruct the scaphoid: Did we improve in 8 years of experience? Comparison of our first and last 20 cases

List of authors:
Christian Kindler*, Moritz Schoeneich¹, Bernhard Lukas¹
¹ Schoen Klinik Muenchen-Harlaching (München)

Objectives / Interrogation: Since 2009 we are using the technique of reconstruction of the scaphoid bone with a vascularized bone graft of the medial femoral condyle. The aim of this study was to compare the results of the first 20 (n1) and the last 20 (n2) cases. We wanted to figure out, if results of the last ones are better than the first ones, in detail if we improved over the years.

Methods: In our prospective study of scaphoid non-union the patients numbers 1-20 and 94-113 were selected. We compared the results concerning healing rate, complication rate, revision surgeries, donor side morbidity, pain, range of motion, grip strength, krimmer score and surgery time. All surgeons (3) were interviewed to emphasize their tips and tricks and experience.

Results and Conclusions: We could not find any statistic differences in healing rate, range of motion, grip strength, pain reduction and krimmer score. Complication rate was significant lower in the second group (n1=5 versus n2=0), also number of unplanned revision surgery (n1=8 versus n2=1). Donor site morbidity is equal in both groups, only the amount of sensibility disorder was reduced in the second group (n1=13, n2=8). Mean surgery time was 3:22 hours in the first group and 2:44 hours in the second group.

As tips and tricks we revealed:
- take the most possible distal donor site at the femur,
- reduce the transplant size by maintaining the periosteum,
- more resection of scaphoid and a bigger transplant makes surgery easier,
- dorsal and volar approach for osteochondral transplants ist the securest option to receive an accurate proximal pol reconstruction,
- use of linscheid wire/maneuer,
- use two different incisions (one for scaphoid, one for the anastomosis).

In our institution we invented this procedure about 8 years ago and we could optimize the surgery technique, to minimize surgery time, complication rate and rate of revision surgery. One must take care of the infrapatellar nerve, but still nerve disorders are common. Data of patient's outcome did not significantly improve over the years, but this also relies to the small number of patients and divergent data. Healing rate stays at a high level of more than 85% in both groups.

8 Plastic Surgery, University of Catania, Italy (CATANIA)  
9 Plastic Surgery, University of Palermo, Italy (Palermo)  
10 Plastic surgery, University of Modena, Italy (Modena)

Objectives / Interrogation: A number of techniques have been proposed for treatment of painful neuromas, but the results still remain poor in up to 67-75 percent of cases. Fat grafting has proven to effectively contrast post-traumatic adherences and painful scars. In this multicentric Italian study, the efficacy of fat grafting in treatment of painful upper limb neuromas is presented.

Methods: Since 2012 to 2018, 37 (20 female and 17 male, mean age 49 y) patients were treated in Messina, Milan, Ancona, Turin, Modena, Padua, Palermo and Catania. The affected nerves were 6 sensate radial, 1 medial antebrachial cutaneous, 6 median, 5 ulnar, 2 digital common trunks, 18 digital collateral nerves. Terminal neuromas or neuromas in continuity causing persistent pain, unresponsive to conservative and surgical treatments, were ruled in. Before surgery, the nerve was assessed by clinical examination. Preoperatively, the patient gave an evaluation of pain at rest about the neuroma with a visual acuity scale. Limb functionality was evaluated with the "Disabilities of the Arm, Shoulder, and Hand" score. The same variables were collected at day 30, 60, 90; 1, 2 and 6 years after surgery. At surgery, proper skin incisions were placed to minimize adherences and scar tissue near the nerve. Both neuroma and nerve trunk were exposed, with a complete visualization of neuroma and an accurate proximal dissection, to find healthy proximal nerve. The neuroma was resected and the adipose tissue harvested from the abdominal region with tumescent technique. The adipose tissue was injected with fine-gauge cannulas around the proximal nerve stump. Depending on the involved segment, an early gentle range of motion was allowed.

Results and Conclusions: DASH score recorded a mean decrease of 10.7 points, from 48.3 to 37.6 (22.2% of the initial value), whereas VAS decreased from 7.6 to 5.2 (31.5%). Analgesic medications were stopped.

The positive effect of fat on painful neuromas can be explained as a gliding soft fat envelope isolating the stump, allowing a normal excursion and modulating inflammatory response, creating neoangiogenesis and paracrine production of signals, interrupting local triggering for pain (1). Fat grafting is easy to perform, does not require infusion of local anesthetic nor immobilization, is repeatable without reduction of effectiveness, and can be applied virtually for every nerve. The Authors recommend its use to treat painful neuromas of the upper limb, even if further biological and instrumental/functional studies are needed.

Volar fracture subluxation of PIP joint: A rare injury with a novel technique for treatment

List of authors:
1 Ain Shams University (Cairo)

Objectives / Interrogation: The volar fracture-dislocations of the proximal phalangeal joint (PIP) of the fingers, the so-called "central slip fractures", are both rare and challenging. They are treated operatively by using either k wires, mini - screws, miniplates, external fixators or anchors. Sometimes open reduction and fixation is technically demanding because of the small size of the fragment or due to its comminuted nature. We introduce a novel technique in treating volar fracture subluxation/dislocation of the PIP joints. We used a 2mm mini-plate as a blocking plate to wedge the central avulsion fragment back to its position till union. We hypothesized that this technique would simplify the surgery and yield favorable functional and radiographic results.

Methods: We present a prospective case series comprised of 8 patients (5 females and 3 males) with volar fracture dislocation/subluxation of the PIP joint. The patients were managed by the index technique within an average of 15.4 days following the injury (range, 1-27 days). Clinical outcome measurements included assessment of pain (visual analog score) and range of motion. Radiographic outcome measurements included reduction of subluxation/dislocation, articular congruity, and occurrence of arthritic changes.

Results and Conclusions: Results:

The length of the follow up averaged 15 months (range, 8-24 months). Union was obtained in all cases in an average of 4.2 weeks (range, 3-5 weeks). The visual analog score was 1.6 (range, 0-3). Postoperative proximal interphalangeal motion averaged 74 degrees (range, 55-90 degrees). Reduction of the subluxation/dislocation was obtained in all cases. There was articular incongruity in one patient. No arthritic changes were noticed during the whole follow up period. Complications included superficial infection of the wound (one case), limited flexion of distal interphalangeal joint (DIP) (3 cases), and mild extension lag of DIP (10-20 degrees) was noticed in 6 patients.

Conclusion:
The index technique yields satisfactory outcome at the short term. The technique is simple and straightforward. It can be an addition in treating these challenging cases.

Delayed nerve repair: experimental treatment with chitosan tubes enriched by fresh skeletal muscle fibers

List of authors:
Alessandro Crosio¹, Benedetta Elena Fornasari¹, Stefano Geuna¹, Bruno Battiston², Giulia Ronchi¹, Pierluigi Tos³
¹ University of Turin, Department of Clinical and biological scince (Orbassano)
² AOU City of Health and Science, CTO Hospital (Turin)
³ ASST Gaetano Pini CTO (Milan)

Objectives / Interrogation: Nerve regeneration after delayed nerve repair is often unsuccessful. Indeed, the expression of genes associated with regeneration, including neurotrophic and gliotrophic factors, is drastically reduced in the distal stump of chronically transected nerves; moreover, Schwann cells undergo atrophy, losing their ability to sustain regeneration. In the present study, to provide a three-dimensional environment and trophic factors supporting Schwann cell activity and axon re-growth, we combined the use of an effective conduit (a chitosan made tube) with a promising intraluminal structure (fresh longitudinal skeletal muscle fibers). In particular in this study was evaluated the efficacy of muscle in tube as a support of nerve regeneration after a delayed surgical nerve reconstruction (secondary repair).

Methods: 15 female adult Wistar rats were used. The first surgical procedure consisted in denervation of median nerve (10mm) for 3 months. Afterwards the nerve was reconstructed with a) empty chitosan tube b) enriched conduit c) autograft. The nerve gap was of 10mm. Functional and morphometrical analyses were performed 4 months after nerve repair.

Results and Conclusions: Our data show that the enriched chitosan conduit is as effective as the hollow chitosan conduit in promoting nerve regeneration, and its efficacy is not statistically different from the autograft, that is the "gold standard" technique for nerve reconstruction. We hypothesize that the use of fresh muscle fibers to fill the chitosan conduits could be a promising strategy to repair longer gaps because fresh muscle fibers release factors inducing nerve regeneration especially within the first few days. Moreover muscle fibers create a favorable three-dimensional environment provided by their basal lamina useful for Schwann cell migration and axonal regrowth.

Knife Crime-related Injuries: Clinical, Operational and Financial Impact

List of authors:
Rizwana Imran¹, Cynthia De Courcey¹, Kwang Lee¹, Beau Munoz¹, Darren Chester¹, Mark Foster¹
¹ University Hospital Birmingham (Birmingham)

Objectives / Interrogation:
Knife assaults in England and Wales have risen by 16% according to latest figures this year. This study aims to evaluate the incidence of knife-related assault injuries, their clinical outcomes and operational and financial impact.

Methods:
A retrospective analysis of knife assault injuries admitted with subsequent surgical episode in a single major trauma center between May 2015 and April 2018 was performed. Data was collected on demographics, injury patterns, treatment, complications, as well as operational and financial outcomes.

Results and Conclusions:
Results:
A total of 228 patients were identified in the study period. Of these, 140 (60%) required plastic surgery input. The majority of patients were young (mean age 27.7 years; 71% of patients aged <30 years) and male (Male to female ratio 12:1). 42% of these patients sustained injuries in multiple anatomical regions, the upper limb being the most commonly injured site (72%). 30% (n=42) of patients required input from other specialties, especially Orthopedics (10%). Structures most commonly requiring repair were tendons (178 repairs in 52 cases), followed by muscle (73 repairs/51 cases) and nerves (70 repairs in 55 cases). 21 patients required vessel repairs with 4 requiring vein grafts. Mean operating time was 192 minutes and mean hospital stay was 3.5 days. The most common complications were neurological: 21% sensation deficit, 9% nerve palsy with an infection rate of 2%. Tariffs for the 140 cases totaled £732,136.

Conclusion:
This study represents the first series from a major trauma center in West Midlands, United Kingdom. Knife-related violence and the resulted injury is not only a significant operational and financial burden to the NHS but can also have long-term functional consequences for patients.

MANAGEMENT OF ANTERIOR CONMINUTION OF A DISTAL RADIO FRACTURE WITH A SCREW BAR FOR PALMAR FIXING: A CASE REPORT

List of authors:
julio sandoval*¹, camilo Romero², Viviana Vela³
¹ fundacion cardioinfantil (bogota)
² fundacion cardioinfantil (Bogota)
³ Fundacion cardioinfantil (Bogota)

Objectives / Interrogation: INTRODUCTION: Distal radius fractures, occasionally present with comminution in the palmar side and are a challenge for the hand surgeon. Some fractures have an important anterior comminution that makes it difficult to have sufficient bone contact with the plate. Fixation can be made with a "bar" support screw. It is a screw placed from radial to ulnar in a transversal way and over the metaphysis of the distal radius. This will generate a support to the entire distal row of the plate, functioning as a transverse bar and the palmar plate have anti-shear support and not only depend on the locked screws. In addition, it will also close the joint gap by making compression.

Methods: OBJECTIVE: technique of osteosynthesis the application of a screw as a substitute anterior cortical metaphyseal anti-shear, when it is not possible to perform a fixation with the palmar plate of the radius given the comminution of the fracture.

METHODOLOGY: clinical case of a male patient, a 50 years old, with a Fernández V ,type fracture with anterior comminution, an intraarticular involvement in two planes and a metaphyseal fracture line with impaction and loss of radial height and carpal subluxation. The "bar" screw technique was used to control shear and achieve anterior cortical augmentation of the fixation to decrease the risk of failure.

Results and Conclusions: RESULTS: Patient with follow-up at 6 months with complete mobility arches, with restitution of the articular surface, with QuickDASH of 6.81%, analogous visual scale of pain of 1. Postoperative radiographs with consolidation without failure of osteosynthesis material. With return to work activity within the month of the procedure.

CONCLUSION: When the traces of comminution are multiple and small, and there is no space to place the fixation screws through the holes in the plate because the screws have an insufficient bone segment for their fixation or because the screw is directed through the vertical line of the fracture, the “bar screw” gives the transverse support so that, with the plate support effect, it is possible to contain in its place the palmar edge distal of the fracture of the radius. In clinical cases where palmar comminution is severe and does not allow an adequate fixation of the plate, a screw can be used as a “bar” or support in the distal metaphyseal part so that it allows to control the shearing forces.

TENSIL RESISTANCE IN A TENORRHAPHY OF FLEXORS OF THE HAND ACCORDING TO THE DISTANCE OF THE GRIP: Pilot study in pigs

List of authors:
julio sandoval*, Nestor A Camacho
1 fundacion cardioinfantil (bogota)

Objectives / Interrogation: When reviewing the literature on the flexor tenorrhaphy techniques, it is not easy to determine in the study the distance of the fixation strand from the central point of each suture. We considered that this distance can be determined by the diameter of the tendon

The purpose of this study is to make a quantification based on the diameter of each tendon
Experimental question: What is the ideal length of the core suture purchase in the surgical repair of flexor tendon, in an experimental test carried out on the tendons of pigs?

Methods: 40 tendons of the front limb of adult pigs (Yorshire) were taken. Four groups were taken to perform in a controlled manner. The cuts, measurement and sutures were made by the researchers.
The variable in distance of the locking loop depending on the diameter of each tendon of the study was determined as follows:

I-Fixation of the point at ¼ of the diameter
II-Fixation of the point a ½ of the diameter
III-Fixation of the point to a 1 diameter
IV-Fixation of the point at 1 1/2 of the diameter

The tenorrhaphy was done with a Prolene 4-0 AT 957 suture, and the distance was quantified with a gauge. Then, the resistance was measured until failure in an Instrom 3367 machine and associated software from CITEC (Technological Research Center from the University of the Andes)

Results and Conclusions: In group I, the load at the moment of failure is at a maximum of 25,419N, with a standard deviation of 7,151N; in group II, the load at the time of failure is a maximum of 41.762 N, with a standard deviation of 8.525N; in group III, the load at the time of failure is a maximum of 43,699N, with a standard deviation of 7,835N; in group IV the load at the maximum moment of failure is 46,497N, with a standard deviation of 4,943N.

Discussion: With this experimental study, it can be determined that the longer the length of the core suture purchase (distance between locking loop and lesion), the greater the resistance to the suture tension. However, in the experiment it was observed that when it is done at a distance of 1 ½ of the diameter when making the adjustment of the knot, the tendon widens by the traction of the fixed segment and this considerably increases the diameter of the repaired area, which would be an inconvenience for the good sliding of the tendon in its flexor sheath. For this reason we can recommend that the site of better resistance behavior and conservation of the anatomical feature be a diameter from the tendon.

tendon, core suture, diameter, tenorrhaphy
Comparing Functional Outcomes of Endoscopic and Open Carpal Tunnel Release from the Patient's Perspective

List of authors:
Suleen Low*¹, Mark CH Tan², Pei Yein Tong², Vaikunthan Rajaratnam²
¹ NUS Yong Loo Lin School of Medicine (Singapore)
² Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: Endoscopic carpal tunnel release (CTR) is an established and popular treatment for carpal tunnel syndrome (CTS), however there remains little patient reported experience comparing the post-operative outcome of the endoscopic approach with that of the open approach. Based on patient-reported data within 2 to 4 years post-CTR, this study investigated the hypothesis that endoscopic CTR would result in better functional outcome and patient-reported experience as compared to open CTR.

Methods: All patients fulfilling the following criteria at one urban hospital were included in the study: i) documented physician's diagnosis of CTS with NCS validation; ii) underwent unilateral CTR from the period of 2014 to 2016 with at least 2 years of post surgery review. Data collection was through review of medical records and telephone interview of patients: the patients' post-operative function was assessed using a validated questionnaire, which consisted of 28 questions pertaining to the following categories - demography, occupational history, subjective symptoms and patient satisfaction.[01] The QuickDASH tool was also used to evaluate the patient's physical function and symptoms of musculoskeletal disorders of the upper limb. Comparisons made between patients who underwent endoscopic and open surgery within the same year were analysed with chi square calculations to determine statistical significance.

Results and Conclusions: Two hundred and thirty-two patients were identified for data collection (79 males, 153 females), of which 51 (22.0%) underwent endoscopic CTR and 181 (78.0%) underwent open CTR. The proportion of patients opting for endoscopic CTR increased from 17.1% (2014) to 26.4% (2016), indicating an increasing preference for endoscopic CTR over open CTR. Right hand CTR was slightly more common than the left (92 versus 89 open cases and 43 versus 27 endoscopic cases respectively), and the average age of the patients was 57.8 (SD = 10.8). Details of the results and multi-variate analysis will be presented.

Conclusion: Endoscopic CTR has superior functional outcome from the patient's perspective as compared to open carpal tunnel release, using post-operative pain and rate of return to pre-morbid function as key indicators of recovery. Overall patient satisfaction and experience with CTR was good, and there was no significant superiority of the endoscopic approach over open surgery in terms of patient experience measures.

FIBULO SCAPHO LUNATE ARTHRODESIS: an option in case of important loss of substance of the distal radius.

List of authors:
simona odella*, davide ciclamini², alessandro crosio³, stefano bastoni¹, primo daolio¹, bruno battiston², pierluigi tos¹
¹ asst pini cto (milano)  
² CTO (TORINO)

Objectives / Interrogation: In case of radius trauma, infection or tumour resection, free micro-vascular fibula transfer is considered the established method for the reconstruction. There are different possibilities to reconstruct the radius defect: arthrodesis, this solution provides a good strength and stability but even a complete loss of motion; an alternative could be harvesting the head of the fibula to restore articular surface of the RC joint, this technique is more demanding and it's not able to restore joint stability; the objective is to evaluate the fibula scapho-lunate arthrodesis to understand if it could be a good solution to restore stability and a partial range of motion.

Methods: we used this technique in one case of forearm osteosarcoma, and in three cases of giant cell-tumors showed Campanacci grade 3 lesions, in all patients the fibular graft was based on peroneal artery and vein, the average length was 14,3 cm.  
In all cases before positioning the locking plate, we stabilised the scaphoid and the lunate in a correct position compared to the capitate surface using a k-wire, a slot has been created to allow the placement of the fibula between the two carpal bones. After surgery patients were protected in a cast including elbow for 6 weeks and for 2 weeks in a palmar forearm cast.
An x-ray has been performed at 40 days from surgery and after 2 months and 6 months. We evaluated the radiological healing and the ROM at 1 year follow-up.

Results and Conclusions: In literature are reported 16 cases, of these 14 TGC and 2 sarcoma, the mean length of the fibula is 10 cm, the mean ROM is 70 degrees flexion-extension; 130 prono-supination, 6 months to obtain healing at x-ray.
In our patients at 1 year follow-up the mean range of motion was 65° in flexion extension and 120° in prono-supination, the time of healing at x-ray was 6 months from surgery, the mean length of the fibula is 14 cm.
No case of instability. Our results are similar to the one referred in literature. The goal of the treatment in case of tumour reconstruction is a one stage procedure that provides secure bony consolidation and allows early physical therapy and further adjuvant therapeutic procedures. We think that the vascularized fibula scapho lunate arthrodesis is a good solution to give stability to the wrist avoiding the complete loss of range of motion. In our experience this procedure is able to restore an adequate function for daily activities, with a high stability associated to a radical wide resection in order to prevent recurrence.

Ulnar carpometacarpal dislocations and fracture-dislocations. Surgery may not be always required.

List of authors:
Isidro Jiménez*1, Juan Sánchez-Hernández1, Dimosthenis Kiimetoglou1, Gustavo Muratore1, Jonathan Caballero1, José Medina1, Alberto Marcos-García1
1 Hospital Universitario Insular de Gran Canaria (Las Palmas de Gran Canaria)

Objectives / Interrogation: Carpometacarpal (CMC) joint dislocations and fracture-dislocations are uncommon injuries and, initially, they may be often overlooked because of the diffuse hand swelling and misinterpretation of subtle radiographic features as normal. Surgical stabilization is recommended by most authors in order to prevent a secondary dislocation assuming that these injuries are inherently unstable. We hypothesized that when the diagnosis is early and a closed concentric and initially stable reduction is achieved, the surgical treatment may be unnecessary.

Methods: Prospective series of five consecutive cases. In all cases, a closed reduction was performed by traction after an ulnar nerve block of the wrist at the level of the patient. Joint stability was assessed by active motion of the wrist and metacarpophalangeal joints by the patient. An ulnar splint leaving the MP joint free + buddy-tape was placed in 3 cases and a cast + buddy-tape was used in two. Demographic data, immobilization time, time until reincorporation to previous activities, range of motion, pain and DASH questionnaire were registered.

Results and Conclusions: Five males. Average age of 24 (range, 20-28) years. Minimum follow-up was 12 months. Pure CMC joint dislocation of 4th and 5th radius in 2 cases and fracture-dislocations in 3. In all cases a concentric and stable reduction was achieved. Splint was maintained for 4 weeks and active motion started immediately. No physical therapy was required in any case. Time to reincorporation to previous activities was 11 (range 8-13) weeks. At final follow-up the ROM was complete with pulp-to-palm distance of 0mm in all cases; VAS for pain was 0 at rest, 0 in daily-life activities and 1.6 in physical effort activities; and DASH score was 2.27 (range 0-4.5) points.

We believe that, if the diagnosis of CMC joint dislocation is early and a closed, concentric and stable reduction is initially achieved, the conservative treatment may be a good choice obtaining good functional results and a quick recovery.

NERVE DECELLULARIZATION: LOOKING FOR THE MORE RELIABLE METHOD

List of authors:
simona odella*, stefania raimondo, arianna lovati, alessandro crosio, francesco locatelli, stefano geuna, pierluigi tos
1 asst pini cto (milano)
2 San Luigi Gonzaga Hospital (orbassano)
3 IRCCS Isituto Galeazzi (milano)

Objectives / Interrogation: In the case of large defects, end to end suture is not possible and conduit is not enough to obtain good results, thus the gold standard is the autograft, however this solution presents disadvantages: donor site morbility and longer surgery time. Allograft could be another alternative but nerves from donors frequently cause immunogenic response. Starting from 1980, several authors are looking for the correct way to decellularize nerves preserving both the extracellular matrix and basal lamina to improve nerve regeneration. In Italy, a recent law prohibits to commercialize human tissue for profit, thus the use of marketed human-derived devices is forbidden in the case of nerve injuries that need a graft. The purpose of this study is to find an easy, cost effective, standardized and reliable protocol for the allogeneic nerve decellularization to be stored in a nerve bank.

Methods: From a literature review, we concluded that the best method to eliminate cells and to remove cell debris is the chemical one. This method is able to maintain preserved basal lamina and collagen that are indispensable for nerve regeneration. In our study, we propose two chemical-based protocols for the nerve decellularization: one chemical (TritonX100 + sodium dodecyl sulphate- SDS- detergent) in association to sonication cycles, the other also chemical (phosphate-buffered saline- TBP-detergent) in association to a DNase. According to these protocols, we decellularized human (median and ulnar) and rat (sciatic) nerves. We processed and evaluated samples by means of histology and electron microscopy compared to commercial decellularized allografts.

Results and Conclusions: The results showed that both of them could remove immunogenic components maintaining the basal lamina to improve nerve regeneration. nerves decellularized with the chemical and sonication protocol showed a good tissue organization with oriented and intact collagen, but still present axons within the extracellular matrix. The best results were obtained by the chemical and DNase protocol in which a rich matched connective matrix was maintained and no integral axons were present. The purpose of this study is to identify an accessible method of decellularization that is also cost-effective, standardized and permits to obtain a complete removal of immunogenic elements maintaining an intact basal lamina to help axon regeneration.

Keywords:
The outcome of bone graft surgery for non-union of fractures of the scaphoid

List of authors:
Michael Elvey*, Tim Davis, BSSH Scaphoid Non-Union Group
1 Hand and Wrist Unit, London Northwest University Healthcare NHS Trust (London)
2 Nottingham University Hospitals (Nottingham)
3 British Society for Surgery of the Hand, Royal College of Surgeons of England (London)

Objectives / Interrogation: Previous studies have suggested that outcomes following scaphoid non-union surgery are affected by factors including smoking, fracture location or chronicity, and graft donor site or vascularity. These studies are limited by low numbers, differing definitions of non-union, and variable follow up. This study investigates the outcome of scaphoid non-union surgery with bone graft across 19 United Kingdom centres.

Methods: This study was defined as a multicentre retrospective evaluation of service. Non-union was defined as a failure to unite within 12 weeks of acute injury. The minimal interval between surgery and data collection was 2 years with a minimum of 12 weeks radiological follow up following non-union surgery. The outcome of the "non-union" surgery was union status. Descriptive statistics are provided as frequencies with percentages (%). Proportional differences were examined using the Chi squared or Fisher’s exact tests as appropriate. Logistic regression was used to estimate the odds ratio (OR) and 95% CI for persistent non-union following surgery. To adjust for known confounders, multivariable logistic regression was used with pre-selected co-variables.

Results and Conclusions: Results
Data was collected for 806 individuals (n=462 following exclusions). 93% of patients were male with a mean age of 27yr (SD 10). Overall union rate was 69%. The choice of bone graft differed significantly depending on the fracture site (p<0.001). Smoking at the time of surgery doubled the odds of non-union (adjusted OR 1.8, 95% CI 1.0, 3.1). Separate analysis of proximal pole and waist fractures suggested that smoking may particularly affect the outcome of proximal pole fracture non-unions (union rates for non-smokers v smokers = 77% v 43%; p=0.01); Surgical delay of 1 or 2 years was independently associated with 40% (adjusted OR 1.4 (0.7, 2.8)) and 140% (2.4 (1.2, 4.8)) higher odds of non-union respectively. Age, graft vascularity, and fixation method had no association with outcome. Comparison of assessments of union by the treating surgical team and the investigators showed excellent agreement (90%, k=0.8, p< 0.001).

Conclusions
This study suggests that in the United Kingdom healing rates following surgery are less than previously published ( >80%). Our findings support the hypotheses that smoking and the time interval between acute fracture and non-union surgery influence the outcome of bone graft surgery.

Toe to hand transfer for five digit hand reconstruction in congenital thumb's hypoplasia

List of authors:
Dzintars Ozols*, Janis Zarins¹, Aigars Petersons²
¹ Microsurgery Centre of Latvia, Riga Stradins University (Riga)
² Riga Stradins University (Riga)

Objectives / Interrogation: A stable 1st CMCJ has been considered a mandatory factor for a successful toe to hand transplantation. The base of metacarpal bone is absent for hypoplasia type IIb - V, therefore, toe to hand transplantation is not recommended. Tan and Tu 2013 described a technique for toe-to hand transplantation for thumb hypoplasia patients IIb-V but overall results were not better than pollicization. The aim of this study is to describe a new technique for thumb reconstruction with a second toe transfer with metatarsophalangeal joint arthrodesis, which can provide a 5-digit hand and restore the functionality of the thumb for thumb hypoplasia IIb - V.

Methods: A total of five patients with thumb hypoplasia stage IIb V were included in study. All patients underwent long-term (3-5 years) follow-up evaluation. VAS was used for an aesthetic evaluation, patients and their parents were asked to give a score from 1 to 10 (more is better) points to two questions, "Does the transplanted toe look like a thumb?" and "Does the transplanted toe work like a thumb?". To establish functionality patients were asked to complete the DASH survey, objectively ROM in 3 thumb's joints, the strength of the grasp and pinch grip were measured, and two-point discrimination test was performed. To find out overall population's perspective on aesthetic outcomes between a 4-digit hand after the pollicization and a 5-digit hand with a transplanted thumb internet survey was created. The survey to evaluate aesthetical outcome for transplantation method and pollicization method was completed by 290 respondents. Statistical evaluation was performed using the Student's t-test and Wilcoxon-Mann-Whitney test.

Results and Conclusions: Patients with toe-to hand transplantation scored average DASH 9,35 (8,0-10,7) points. Patients who had pollicization procedure gave average DASH 19,8 (6-26,7) points. The aesthetical survey was completed by 290 respondents. VAS for the toe transplantation was 7,04 (3-10), whereas for the pollicization - 5,84 (1-10).
Stable and long 1st metacarpal bone created using MTPJ arthrodesis is an option provided by our technique. Then PIPJ and DIPJ of transplanted toe becomes IPJ and MCPJ of new thumb what works similar to pollicization technique. Overall population rates transplantation's aesthetic outcomes higher than pollicization's (the scores is statistically significant (p<0.0001).

Progressive palmar contracture of Dupuytren in a 6-year-old boy.

List of authors:
Isidro Jiménez*, Luis Bahillo¹, Ariadna Santana-Betancort¹, Jonathan Caballero¹, Gustavo Muratore¹, Alberto Marcos-García¹, José Medina¹
¹Hospital Universitario Insular de Gran Canaria (Las Palmas de Gran Canaria)

Objectives / Interrogation: Dupuytren's disease is a benign fibromatosis of the palmar and digital fascia of the hand. It is well known in adults with an overall incidence of 3-6%. To the best of our known, there are only 13 cases documented in the English bibliography in children under 13 and only seven cases histologically confirmed in children under 10 years. Our goal is to present the case report of a 6-year-old boy with histologically confirmed Dupuytren's disease.

Methods: 6 years-old male referred to our consultation by retraction of his fourth finger in his left hand. When he was 14 months, a longitudinal congenital cutaneous scar was operated on the ulnar side of his fifth finger and, at 3 years-old, a zeta-plasty was performed also on his fifth finger. Currently he presents a nodule and a palmar and ulnar cord in his fourth finger that conditions an irreducible flexion of DIP joint in 80° and a clinodactyly of 15° towards ulnar. His mother reports that this deformity began two years ago (when he was 4 years old) as a bulge and it has been subsequently retracting the finger.

Surgery was performed on an outpatient basis. A palmar-ulnar hemi-Bruner incision was made on the fourth finger, identifying a subcutaneous scar that did not invade the skin and that was extended from the PIP joint, displacing the digital neurovascular bundle, to the ulnar side of the DIP joint where it was attached to the ulnar collateral ligament and the joint capsule. A complete resection of the flange was achieved with a complete intraoperative range of motion and correcting clinodactyly. A proximal advance-rotation flap and a V-Y cutaneous plasty for cutaneous closure were performed. A splint was place to keep the interphalangeal joints in extension for 3 weeks.

Results and Conclusions: The wounds healed without incident. At 5 weeks, ROM was complete and the child had been returned to his daily-activities. One year after surgery there were no signs of recurrence or involvement in another location.

Dupuytren's disease in the child is exceptional. The differential diagnosis should include camptodactyly, sequelae of burn, extraperitoneal fibromatosis, epithelioid sarcoma, giant cell tumor or fibrous hamartoma among others. Therefore, the surgical treatment is not only functional but it also must confirm the diagnosis histologically. The risk of recurrence of the disease in the pediatric age and the optimal time for surgery are still uncertain due to the limited bibliography available.

Which are the Limits Nowadays for Indication to Replantation?

List of authors:
Tos Pierluigi*, Davide Ciclamini2, Alessandro Crosio1, Simonetta Odella3, Bruno Battiston2
1 G Pini Milan, Hand Surgery and Reconstructive Microsurgery, ASST Gaetano Pini CTO, Milan University (Milano)
2 CTO Hospital, Turin, Italy (Torino)
3 G Pini Milan, Hand Surgery and Reconstructive Microsurgery, ASST Gaetano Pini CTO, Milan University (Milano)

Objectives / Interrogation: Over the years upper limb replantation of small and large segments has experienced a progressive widening of indications because of the improvements in reconstructive techniques. While there are clear indications for replantation or amputation (general and local conditions of the patient and of the amputated segment, timing, etc.), there is on the other hand a "gray area" in which indications tend to depend on the skill, experience and creativity of the surgeon. This is true in the emergency setting, and for patients undergoing secondary reconstructive surgery.

Methods: Over the past 10 years we have collected 17 cases of consecutive cases of "borderline indications" that in the past would not have been considered for replantation: double level reimplantations, avulsion injuries, patients over 75 years of age, significant degloving injuries, longer than suggested revascularization time, etc. The minimum follow-up was 1 year and each case has been analyzed using Chen's criteria for assessment of residual function. All secondary procedures are pointed out. Failures are also reported.

Results and Conclusions: RESULTS
In all the cases presented, the replanted segment survived. There were no major complications in the survived segment. Reoperation was necessary in 20% of cases (tendon transfer, tenolysis, etc.). All patients said they were satisfied with the treatment.

CONCLUSIONS
This case series suggests how to deal with special cases and will stimulate the use of imagination in this kind of surgery in extreme conditions. The goal of reconstruction should be restoration of function that is better than prosthetic replacement. It is clear that this type of surgery can only be performed as long as the patient's life is not in danger.

“Spare parts surgery” - functional saving for long segmental defects. A ten years long follow up study for the cross hand replantation.

List of authors:
Dzintars Ozols*, Janis Zarins¹
¹ Microsurgery Centre of Latvia, Riga Stradins University (Riga)

Objectives / Interrogation: “Spare parts surgery” is well-described in the plastic surgery literature. In the setting of trauma, otherwise discarded parts can be utilized for reconstruction resulting in a superior functional and aesthetic outcome for the patient.

Methods: Cross arm replantation was done for 26 years of age patient in 2008 who had train injury. Patient has both hand damages - right hand damage distally to wrist joint and left hand damage at level of the elbow joint. Left elbow joint and right palm were not be able to reconstruct. Therefore left hand (at distal forearm level) was transplanted to right forearm in mirror shape. ALT flap was used to cover soft tissue defect and late wrist arthrodesis was done to improve functional outcome. Functional evaluation as DASH and ROM scores were calculated in the ten year's long term follow up study.

Results and Conclusions: Cross hand replant get good sensation and good grasp and he use hand more than left prosthetic hand. Patient use replanted hand in daily activities and has no complains about thumb's mirror like position. Train injuries are becoming less common in Latvia. But is very hard to manage as patients usually have shock, all extremities had sever damaged tissues. Very important is to evaluate amputated segment and usually you can find replantable part but as these patients are critically ill you have to work and think very fast therefore short-time replantation can be done. Hand allotransplantation can be as an alternative method but patient have to use immunosuppression for all life. The prosthetic hand has been other option to reconstruct functionality for the hand but it is hard to manage sensation therefore replantation or as this cross hand replantation still have a place in era of modern microsurgery.

Median-to-radial nerve transfer - our experiences

List of authors: Chuanjun Yi*, Yin Zhu1, Chunmei Hou1
1 Department of Hand Surgery, Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To provide New modality for radial nerve palsy, we provide our experience on median-to-radial nerve transfer, especial the indication, choice of donor motor branch, technique tips.

Methods: We choose the patients of severe radial nerve palsy as the candidates for median-to-radial nerve transfer, including 1) proximal injury; 2) long nerve defect more than 8~10cm; 3) severe soft tissue injury. We treated 6 patients during 2008 to 2017, two proximal injuries and 4 long nerve defect. We transfered branch of Pronator teres (PR) to branch of extensor carpi radialis brevis (ECRB) and branch of flexor digitorum superficialis (FDS) of middle or ring finger to posterior interosseous nerve (PIN) in the first case, then changed the strategy into FDS-to-ECRB and flexor carpi radialis (FCR)-to-PIN. In operation, after identifying the main trunk and branches of median and radial nerve, the donor and receipt branches were indentified and freed as long as possible. Confirming again, the PIN and ECRB nerves were divided well proximally and FDS and FDS or PR as distal as possible, then coapted ends without tension. Positive exercises of joints were initiated 3 days postoperatively. Synergic exercises were started 3 mouths later. Once synergic movements achieved, independent movements were started.

Results and Conclusions: 2 patients reported numb in index and middle fingers and resolved within 4 weeks. The strength of FPS of middle or/and ring fingers were 4- in 3 patients and recovered to normal within 12 w. The strength of FCR decreased to 2 in 5 patients, 4- in 1 patient, which recovered to normal in 3 patients, and 4 degree in 1 patient within 6 m, and no recovery in 1 patient. The extensors regained their strength 3~6 m gradually, and achieved biggest strength 12~18 m. The strength of recovered muscles are 3+~5. The patients orderly regained their movements. The patients can extend their thumb, index and little fingers independently. The excursion of wrist and fingers were comparable to contralateral side, to gain full excursion, 3 patients had to finish the movement along with the corresponding donor movement. In conclusion, median-to-radial transfer is an effective to restore the motor function of radial nerve. We recommend using the synergic motor nerve for transfer. It will take long to achieve these functions and need effective rehabilitation to finish the cortical plasticity, but the patients can gain more independent and flexible movement and larger excursion compared to tendon transfer.

Bilateral bipartite carpal scaphoid: a case report and comparison with bilateral scaphoid nonunion found on incidental radiography.

List of authors:

JUNGEUN LEE*

1 Gachon University College of Medicine, Department of orthopedic surgery, Gil Medical Center (Incheon)

Objectives / Interrogation: Bipartite carpal scaphoid is a rare congenital anomaly of carpal bones. The scaphoid usually has one ossification center. We present a case of bilateral division of the carpal scaphoid in a 57-year-old man.

Methods: He presented to our outpatient clinic with acute pain and swelling in his right wrist without a history of trauma. Physical examination showed tenderness, heating sense, and mild redness in the dorsum of the entire wrist. The patient had an elevated white blood cell (WBC) count with left shift, an erythrocyte sedimentation rate (ESR) and a C-reactive protein (CRP). A diagnosis of cellulitis was made. Plain radiographs of bilateral wrist were obtained for routine evaluation, and incidentally noted the scaphoid bone composed of two ossicles separated at the waist with smooth margins in his bilateral wrist. He had no previous history of wrist trauma and a normal developmental history. Magnetic resonance imaging (MRI) revealed bilateral bipartite scaphoids with cartilaginous tissue evident between the two ossicles. The symptom resolved after intravenous antibiotic therapy.

Congenital bipartite carpal scaphoid was first described by Gruber in 1877, and Bunnel and Boys proposed the criteria of bipartite scaphoid in 1970. Several factors were considered to be supportive of the diagnosis of congenital bipartite scaphoid rather than traumatic non-union in this patient. These included bilateral scaphoid bipartition, clear space between the two components with smooth edges at the joint surfaces, equal size and density of each part, and no history or signs of wrist injury. In this case, there were a few degenerative changes in the articulation between the distal ossicle and the radial styloid. However, several reports suggest that degenerative change developed due to abnormally biomechanics incurred by a bipartite scaphoid. The authors concluded that the case presented is bilateral bipartite carpal scaphoid and the patient discharged without further treatment. After our first experience, a 51-year-old man with a distal radio-ulnar fracture presented to the emergency department and unrecognized bilateral scaphoid fracture nonunion was found on radiography. This patient did not fulfill the five established criteria.

Results and Conclusions: Differential diagnosis of bipartite carpal scaphoid and non-union is difficult, but knowledge of congenital bipartite scaphoid is important to avoid unnecessary treatment.

Carpal scaphoid; Bipartite; Non-union
A TRIAL COMPARING PAIN DURING LOCAL TUMESCENT INJECTION IN FINGERS USING DIFFERENT SYRINGE-NEEDLE COMBINATIONS

List of authors:
Teddy O.H. Prasetyono1, Mohamad Rachadian Ramadan1*
1 Division of Plastic, Reconstructive and Aesthetic Surgery, Faculty of Medicine University of Indonesia, Ciptomangunkusumo National Hospital (Jakarta)

Objectives / Interrogation: This study aims to obtain the most favorable syringe and needle combination, which causes the least pain during local anesthesia tumescent injection in the simulation of fully awake hand surgery.

Methods: A randomized single-blinded controlled trial is designed for 30 adult male healthy subjects to compare the pain from injection using syringe and needle combination i.e. 1) 1 cc syringe with 26G needle, 2) 3 cc syringe with 26 G needle, and 3) 5 cc needle with 26 G needle. The injection will be performed in any of at the second, third and fourth fingers of either subject’s hand randomly. The injection will be SIMPLE block technique using 1 cc of NaCl 0.9% solution under the injection speed of 30 seconds/cc. Subjects are required to rate three check-point of VAS at the timing of needle puncture, initial tumescent solution injection and just right after the completion of the infiltration. Upon the completion of each finger, the subject is also asked to give a response to a series of questions regarding the procedures. At the end of all injections, the subject is asked to rate his preference of syringe and needle combination.

Results and Conclusions: 90 fingers were randomized, we assume no differences between all finger that were tested. No adverse events were noted. The mean VAS score at the timing of needle puncture for 1 cc syringe with 26G needle, 3 cc syringe with 26 G needle, and 5 cc needle with 26 G needle are 0.76, 0.72 and 0.63 respectively. The mean VAS score at the initial tumescent solution injection for 1 cc syringe with 26G needle, 3 cc syringe with 26 G needle, and 5 cc needle with 26 G needle are 0.88, 0.75 and 0.74 respectively. The mean VAS score right after the completion of the infiltration or 1 cc syringe with 26G needle, 3 cc syringe with 26 G needle, and 5 cc needle with 26 G needle are 0.85, 0.87 and 0.71 respectively. We found no correlation between syringe-needle combinations to VAS Score at three different checkpoints and patient preferences (p<0.05). In our knowledge, this the first study to translate the variance in Initial Force and Maintenance Force of a syringe-needle combination into a subjective perceptible pain in the clinical setting. We postulate that the difference of forces among combinations in this study is too small to be recognized by VAS Score. The findings in this study have promoted the equal safety, usability and comfort of either 1, 3 and 5 cc syringe with 26 G needle combinations for local tumescent injection in fully awake hand surgery.

Treatment of length discrepancy after posttraumatic radial growth arrest

List of authors:
Florian Goehtz¹, Hermann Krimmer², Jörg van Schoonhoven¹, Wiebke Hüsemann³
¹ Klinik für Handchirurgie (Bad Neustadt)
² Zentrum für Handchirurgie (Ravensburg)
³ Wilhelmstift Hamburg (Hamburg)

Objectives / Interrogation: Posttraumatic growth disturbances after radial physeal fractures occur in about 4%. Depending on the children's age a partial or complete growth arrest of the distal radial physis leads to progressive shortening of the radius with radioulnar length discrepancy and/or deformation of the distal radius with functional limitation, disturbance of the DRUJ, pain and cosmetic impairment. A variety of different procedures are performed for correction: callus distraction of the radius, osteotomy of the radius with or without bone graft, ulna shortening osteotomy, ulnar physiodesis. Factors influencing treatment and results are children's age at trauma, amount of radius shortening/radioulnar length discrepancy, uniplanar or two-dimensional deformity of the distal radius, and remaining growth potential. It is not proven which correction at which age ends up with the best functional results.

Methods: Retrospectively we analysed the demographic data and x-rays of 13 cases treated in 3 hand centers with distraction of the radius for:
- age at trauma (mean age at trauma 9.3 yrs; range 4-14 yrs.)
- age at 1st operative correction of length discrepancy (mean age at 1st operative correction 14.5 yrs, range 9-18 yrs.)
- amount of radius shortening at the 1st operative intervention (mean 19.3 mm, range 9-30 mm)
- performed operative technique: callus distraction radius 5, distraction radius with secondary internal plate fixation: without bone graft 4 - with iliac bone graft 4
- additional correction of the ulna: in no case an additional intervention of the ulna was performed at the 1st operative correction.
- recurrence of length discrepancy with need of second intervention: 2 cases (1 treated with callus distraction, 1 case with ulna-shortening).
- secondary operative intervention due to complications: 3 cases (2 non-union in the group with plating with iliac bone graft, 1 pin-site-infection of the distraction fixator)

Results and Conclusions: Collected data show different approaches of adjusting the radioulnar length discrepancy by lengthening the radius. In younger patients the remaining growth potential of the distal ulna may lead to recurrence of length discrepancy after correction. Therefore an additional physiodesis of the distal ulna may be advisable in the growing child. A comparing further study at the end of growth is planned to compare functional results, final forearm length and radioulnar position and satisfaction of patients to decide about the best treatment age and technique.

Isolated dorsal radiocarpal dislocation with volar opening treated with external fixator and percutaneous pinning

List of authors:
Petra Jurina*1
1 University Hospital Centre "Sestre milosrdnice", Department for traumatology (Zagreb)

Objectives / Interrogation: Dislocations of radiocarpal joint represent rare, high-energy injuries that make up to 0.2% of all dislocations. Usually, dislocations are associated with serious soft tissue lesions, open fractures with volar or dorsal destruction and possible vascular or neurologic deficit.

Methods: Authors report a case of isolated dorsal radiocarpal dislocation (Dumontier type I, Moneim type I) with volar opening (Gustillo II) and partial lesion of muscle tissue of flexor digitorum muscles of the 4th and 5th finger, of the right, dominant arm, in an adult, after fall from a height. The treatment consisted of open reduction and temporary arthrodesis with bridging external fixator and two parallel K wires placed percutaneously in a radiocarpal direction. After 8 and half weeks external fixator and K wires were removed and active rehabilitation was started. The rehabilitation lasted for 3 months.

Results and Conclusions: Early results after 6 months showed the range of motion (dorsal flexion 30°, palmar flexion 45°, radial abduction 15°, ulnar abduction 20°). Also, at the same time VAS score measured 1.4/10 and Quick DASH Score 56.81/100. Radiocarpal dislocations are demanding injuries since residual radiocarpal instability, pain, stiffness and early posttraumatic wrist degeneration are common outcomes.

Deep Lipomas of the Elbow

List of authors:
Koichiro Ihara*1
1 Kanmon Medical Center (Shimonoseki)

Objectives / Interrogation: Lipoma is the most common soft tissue tumor occurring anywhere in the body, and is generally regarded harmless. Most of them arise superficially, and deep lipomas are far rare. Lipoma seldom affects peripheral nerve function, but deep lipoma arising in the elbow may cause disturbances due to its proximity to radial nerve. We have experienced four cases of lipoma around the elbow, and here we reported the results with thorough literature review.

Methods: All four patients were middle-aged females, and their age ranged from 57 to 68 years. All tumors located at radial side of the elbow, and were deep-seated. One patient did not complain any symptom other than soft tissue mass. In the remaining three patients, one complained of inability to extend her left ring and little fingers, and the other two noticed pain or numbness. All tumors were pathologically confirmed as benign lipoma after surgical resection.

Postoperative follow-up period ranged from one to 12 months.

Results and Conclusions: The patient with posterior interosseous nerve palsy, complete recovery was obtained 6 months after surgery. In three patients with or without symptoms, superficial branch of radial nerve run over the tumor, attaching the capsule, and posterior interosseous nerve was involved by the tumor in one of them. Meticulous dissection was undertaken during surgery.

During resection of lipoma in the upper extremity, peripheral nerves sometimes exist besides the tumor. White & Hanna reported a series of lipomata arising in the upper extremity, half of which were called as “troublesome lipoma”, presenting with nerve palsy, pain or discomfort. Typical troublesome lipoma is the case arising around the radial neck with posterior interosseous nerve palsy, approximately 30 cases of which have been reported. It is important to carefully evaluate patients with lipoma in the elbow region, and atraumatic dissection is required to avoid postoperative nerve complication.

Distal radius decompression osteotomy for ulnar impingement syndrome

List of authors:
Katrin Koch*, Roman Wolters¹, Hermann Krimmer²
¹ Zentrum f. Handchirurgie (Ravensburg)  
² Zentrum f Handchirurgie Ravensburg (Ravensburg)

Objectives / Interrogation: Severe ulna minus variance caused by congenital ulna minus variance can lead to a painful DRUJ. Clinically compression at the DRUJ leads to increasing pain at forearm rotation. Radiologically incongruence at the DRUJ with malformation is noticed

Methods: Based on the clinical experience in a young female athlete where painful ulnar minus variance of about 5mm following excessive ulnar shortening was solved by correction osteotomy with shortening and radial shift of the radius we treated meanwhile 32 patients with congenital ulnar minus and painful DRUJ in the same way. Depending on the amount of malformation an oblique closing wedge osteotomy is performed. It is important that the distal part of the osteotomy is done at the proximal border of the sigmoid notch and the proximal part beneath the joint surface of the ulnar head. The amount of shortening depends on the preoperative situation. The distal part is shifted radially and fixation is done with a fixed angle plate. Due to the wedge osteotomy the increased angle of the sigmoid notch is reduced leading to reshaping of the DRUJ.

Results and Conclusions: All osteotomies showed primary healing. 30 patients reported significant pain relief and no restriction of forearm rotation. One patient who was satisfied on his right side suffered continuous pain after correction on the opposite side and was converted into hemiresection of the ulna head. The second patient got instability of the DRUJ after correction where ligamentous reconstruction with distally attached brachioradialis tendon was done. By corrective osteotomy with shortening of the radius and radial shift reshaping of the DRUJ can be observed. The key point of this procedure seems the decompression at the DRUJ by reducing the tension of the distal interosseous membrane which is gained by radius shortening and additional ulnar shift of the radius shaft. Preoperative instability at the DRUJ should be respected as contraindication for this procedure.

Keywords: DRUJ, Ulnar minus, Impingement, corrective osteotomy
A rare cause for distal bone resorption of the fingers and drumstick deformity. The Hajdu-Cheney syndrome.

List of authors:
Isidro Jiménez*, Gustavo Muratore³, Jonathan Caballero¹, Jesús A. Rodríguez-Socorro¹, Eduardo Morales-Mata¹, Alberto Marcos-García², José Medina²
¹Hospital Universitario Insular de Gran Canaria (Las Palmas de Gran Canaria)

Objectives / Interrogation: Hajdu-Cheney syndrome is an extremely rare hereditary connective tissue disease described in 1948. It is characterized by craniofacial deformities, dental deformity, hyperlaxity, osteoporosis, and acro-osteolysis. The importance from the Orthopedic and Hand Surgeon view lies in the fact that the main cause of consultation usually is a progressive digital shortening, so that the knowledge of the disease can help to avoid complications derived from osteoporosis and to adequately refer the patient for treatment of other systemic injuries that may be present. We report a family in which three members of three successive generations are affected by the disease.

Methods: A 64-year-old woman was referred for consultation due to progressive shortening of the fingers and wrinkling of the skin. She measures 139 cm and weighs 43 kg. She has a widened face, micrognathia, thin lips, low set ears and a short neck. Her fingers are short, with drumstick appearance and there seems to be skin left over mainly on the dorsum. X-rays showed normal metacarpals, normal proximal phalanges in long fingers but with osteolytic lesions in the thumbs, middle phalanges reduced to the proximal third (except in the fourth finger of her left hand) and distal phalanges reduced to a small distal bone stump. Her 35-year-old daughter presents distal bone resorption in the distal phalanx of all the long fingers and the distal phalanx of the thumbs. And the 6-year-old grandson already has a mild bone resorption of distal phalanges of all the fingers.

Results and Conclusions: In this case, a decrease in bone mass was confirmed by bone densitometry and antiresorptive treatment was established with adequate evolution. In conclusion, Hajdu-Cheney syndrome does not seem to diminish life expectancy, although it is associated with renal, cardiac and neurological complications. Preventive treatment of bone lesions is not known and its treatment is symptomatic trying to avoid the complications derived from the loss of bone mass. We believe that knowing the disease may be useful for the differential diagnosis of acro-osteoysis and for its multidisciplinary approach.

Corrective osteotomy at the distal radius without bone graft for Madelung deformity

List of authors:
Sabine Smieja¹, Roman Wolters¹, Rne Schandl¹, Hermann Krimmer*²
¹ Zentrum f. Handchirurgie (Ravensburg)
² Zentrum f Handchirurgie Ravensburg (Ravensburg)

Objectives / Interrogation: The malformation of the wrist joint in case of Madelung deformity is characterized by shortening of the ulnar part of the radius with increased palmar shift and angulation leading to increased radial inclination and incongruency at the DRUJ with dorsal displacement of the ulnar head. Usually the patients if symptomatic are seen in young age with painful restricted forearm rotation. Indication for correction is based on complaints of the patient and the goal to prevent rapid osteoarthritic changes. Additionally the deformed wrist joint with the prominent ulnar head should be corrected from patients point of view for aesthetic reasons.

Methods: Corrective osteotomy was performed in 24 patients by an oblique open wedge osteotomy at the ulnar side. An open book technique was used leaving the radial cortex intact. The ulnar part was lifted to the level of the ulnar head. By bending a fixed angle corrective plate straight the palmar shift was corrected by plate fixation. The osteotomy gap was left open. In 2 cases due to significant bending of the radius shaft double osteotomy was done distal and at the radius shaft.

Results and Conclusions: All osteotomies showed primary healing without loss of reduction. 22 patients would have the procedure again. Significant pain relief was seen in 18 patients. ROM showed no significant change. From aesthetic point of view 23 patients were satisfied and felt real improvement. One patient where due to severe malformation a second correction was done remained still unhappy with the result.

Corrective osteotomy at the distal radius lead to improvement of the malformed wrist joint in Madelung deformity. With fixed angele plates there is no more need for bonegraft. If arthritic changes can be decreased or even prevented will be examined by longtime follow-up.

Volar approach of "On-Top Plasty" for reconstruction of radial polydactyly

List of authors:
Bin Wang*¹
¹ Shanghai 9th People's Hospital, Shanghai Jiaotong University (Shanghai)

Objectives / Interrogation: To report our volar approach of "on-top plasty" technique in reconstruction of radial polydactyly.

Methods: We evaluated 20 thumbs in 20 patients who underwent radial polydactyly reconstruction using the "on-top plasty" technique between 2009 and 2016. This technique was used when neither thumb possessed adequate proximal and distal structures to provide a functional and aesthetic thumb. The average age at time of surgery was 1.2 years and the mean follow-up time was 4.5 years. Subjective patient evaluation, objective outcomes values, and validated patient-oriented outcome measures were obtained.

Results and Conclusions: There was no soft tissue loss and union was achieved in all thumbs. Mean flexion-extension arc for the metacarpophalangeal joint was 62 degrees (range, 5 degrees extension to 72 degrees flexion) and at the interphalangeal joint was 18 degrees (range, 20 degrees extension to 30 degrees flexion). Mean percentage of age-matched norms for lateral, tripod, and tip pinch were 51%, 45%, and 49%, respectively. Mean grip strength was 56% of age-matched norm. The mean Pediatric Quality of Life Inventory (PedsQL) score for parent questionnaires was 92 and for teen/child questionnaires was 85. In conclusion, for patients with radial polydactyly in which neither thumb possesses adequate distal and proximal components, volar approach of "on-top plasty" is a reliable method which can reconstruct nice web and relatively lengthen the digit.

radial polydactyly, thumb duplication, reconstruction, outcome
A comparison of functional outcomes of conservatively and surgically treated metacarpal neck fractures with angulation greater than 50 degrees

List of authors:
Patricia Martin Playa*, Sandeep Jacob Sebastin Muttath¹, Aiswarya Ajith¹
¹ National University Hospital (Singapore)

Objectives / Interrogation: Metacarpal neck fractures are frequent injuries in the young male working population and controversy between surgical and conservative management exists for severely angulated fractures. The aim of this retrospective case series is to compare the functional outcomes of conservative and surgical treatment of closed metacarpal neck fractures with more than 50 degree angulation.

Methods: We reviewed 135 consecutive metacarpal neck fractures that were managed at our center over a 2-year period (2016-2017). 28 closed fractures showing more than 50 degree angulation in oblique x-ray view were retrospectively reviewed. A demographic and clinical comparison was made between fractures managed conservatively (group A) vs surgically (group B). Clinical outcome was determined measuring grip strength and metacarpophalangeal joint active range of motion.

Results and Conclusions: Results: Of the 28 fractures reviewed, 3 were work related injuries, of which 1 was high energy impact, 27 patients were male with mean age of 34.5 years. Most common metacarpal bone affected was 5th (25 fractures) followed by 4th (3 fractures). Patients were classified into two groups: group A was treated with splint (ulnar gutter splint) or cast immobilization and group B was managed surgically with percutaneous pinning (4 fractures) or ORIF (6 fractures). Mean difference between grip strength for group A was 10.7kg and 7.8kg for group B. Range of motion in group A was 0-69 degrees and 0-65 degrees for group B. Only one complication was noted in conservative group (nonunion).

Conclusion: Conservative management in terms of splinting of metacarpal neck fractures with angulation greater than 50 degrees has a functional outcome comparable to those managed surgically with a low rate of complications.

metacarpal neck fracture conservative
Functioning lymphatics transfer for treatment of severe upperarm lymphedema

List of authors:
Hirofumi Imai*, Isao Koshima¹, Shuhei Yoshida¹
¹ International Center for Lymphedema, Hiroshima University (Hiroshima)

Objectives / Interrogation: Lymphaticovenular anastomosis (LVA) can reduce compression therapy, the incidence of cellulitis and end with a mild infection. However, there are cases in which progression after LVA in the long term and cases where exacerbation cannot be suppressed in severe cases. Since 2004, we have been attempting to transfer of lymphatic vessels with reflux function from normal parts with vascular pedicle and simultaneous multiple LVA (combined surgical treatment) on affected limbs. In this report, the progress so far will be presented.

Methods: We have performed LVA for about 300 upper limb lymphedema since 1990, but we undertook joint surgical treatment for 14 cases of severe (LVA ineffective) upper limb edema after 2013. The breakdown was 46 to 76 (average 61.4) years old, male 1, female 13 cases, right 6, left 8 cases. Edema progressed or unchanged despite compression therapy and LVA before and after surgery between 2 months and 20 years after edema occurred. Radiotherapy 8 cases, cellulitis 4 cases occurred. Combined surgical treatment was done from 4 months to 5 years and 3 months after the initial LVA. The donors of the flaps were taken from the first web space with the first dorsal metatarsal artery perforator (4 cases). Alternatively, lymphatic channels with SCIP were collected from the groin (11 cases), and divided into 1-2 (5 cases) pieces, transplanted into single or multiple parts in the arm, and vascular anastomosis (& LVA) was performed.

Results and Conclusions: In 13 cases, postoperative follow-up observation was possible. The period was from 2 months to 3 years 2 months (average 11.3 months). The results after surgery at the present time were: compression unnecessary 1, improvement 11, invariant 1, exacerbation 1 case. From the searches so far, there are individual differences in the effect of LVA, and it is presumed that degeneration / regeneration of smooth muscle cells within lymph vessel affect the postoperative course. Combined surgical treatment using LVA and functional lymphatics transfer requires supermicrosurgical dissection of the lymphatic system, but severe cases of upper and lower limbs where improvement could not be obtained with LVA seems to be indicated. In cases where postoperative compression became unnecessary, we believe that functional recovery of the transplanted lymphatic channels is occurring.

Arthroscopic distal scaphoid resection for STT arthritis

List of authors:
Riccardo Luchetti¹, Andrea Atzei², Roberto Cozzolino¹
¹ Rimini Hand Centre, Via Pietro da Rimini, 4 (Rimini)
² Fenice Hand Surgery & Rehabilitation Team, Treviso (Treviso)

Objectives / Interrogation: To describe the technique of the arthroscopic resection of the head of the scaphoid and evaluate the clinical and radiographic results of scapho-trapezium-trapezoid osteoarthritis cases.

Methods: Seventeen cases (13 males and 4 females) with a mean age of 57 years old (24-74 years old) were operated from 2002 to 2015. Inclusion criteria were non-traumatic radial wrist side pain without improvement after 4 months of conservative treatment and positive x-ray images to osteoarthritis. All cases were evaluated preoperatively and postoperatively with pain level, wrist ROM, grip strength and work status (Mayo Wrist Score). DASH and PRWE questionnaires were also given. The technique consisted in the 3-4 mm rounded shape arthroscopic resection of the head of the scaphoid preserving the scapho-trapezial and scapho-capitate ligaments insertion.

Results and Conclusions: At an average follow-up of 24 months all the patients were satisfied. The results showed significant statistical improvement for pain at rest (p=0.001), under maximal load (p=0.0001) and Mayo Wrist Score (p=0.0001). Wrist ROM, grip strength, DASH and PRWE showed an improvement without reaching statistical significance. At x-ray the preoperative mean radio-lunate (RL) angle was 17° (-10° to 35°). The postoperative mean value was 25° (0° to 45°). In the preoperative x-ray evaluation the “critical” RL angle of 15° exceeded in 11 cases. At follow-up, the RL angle increased in 10 cases, unchanged in 7 cases. No one of these cases became symptomatic. Transitory neuroapraxia of the DSBRN was observed in one case. Damage of the DBRA was immediately tied.
Conclusion: The technique of the arthroscopic resection of the distal part of the scaphoid for the STT osteoarthritis demonstrated to be effective and safe with less complications than open surgery.

Dorsal hand coverage. Aesthetic and functional outcome.

List of authors:
Roberto Adani¹, Giovanna Petrella³, Mario Lando¹, Andrea Leti Acciaro¹, Norman Della Rosa¹
¹Hand and Microsurgery Department, Modena, Italy, Policlinico di Modena (Modena)

Objectives / Interrogation: The dorsum of the hand is a specialized region with thin and fragile skin characterized by poor subcutaneous tissue. The dorsal aspect of the hand is frequently prone to different types of injuries that result in exposed tendon and bone. The treatment of cutaneous defects may be achieved with local pedicle flaps, distant pedicle flaps, or free flaps. The purpose of this study is to review the patients with dorsal soft tissue defects treated with different pedicle flap or free tissue transfer and to determine the best flap for dorsal hand coverage in terms of aesthetic appearance and donor site morbidity and to define an algorithm of treatment of this type of injury.

Methods: A retrospective study of all flaps used for dorsal hand coverage was done. Between 1990-2016, 67 patients (mean age, 37 years; range 16 to 79 years) were treated for large soft tissue defects located on the dorsum of the hand. 22 patients with composite tissue loss of tendon and skin on the dorsum of the hand were treated employing a completely vascularized single-stage reconstruction (the cutaneo tendinous dorsalis pedis and the radial tendinous island flap were used). In 4 cases ALT and Gracilis Flap were employed in conjunction with tendon grafts. The management of pure cutaneous defects (41 cases) includes different type of pedicle fascial cutaneous flaps (radial forearm flap with different modifications, posterior interosseous flap and groin flap), or using a free tissue transfer (LAF, ALT).

Results and Conclusions: Results
All flaps survived completely. Tendon-cutaneous flap required tenolysis in two cases. Fasciocutaneous flap required debulking procedures in 7 cases. Fascio-cutaneous flaps had the highest need for skin grafting at the donor site.

Conclusions
The approach to the patient with a dorsal hand injury requires the surgeon to be aware of a variety of treatment options. Techniques that most closely replace that which has been injured are the most successfully. Flap selection must be individualized to the specific patient and defect. Cutaneous and fascial flap showed good functional and aesthetic results, donor site was better in fascial flaps. The replacement of combined loss of skin and tendons in only one stage gives the best opportunity for functional recovery, and can allows patients a relatively rapid return to a productive life. The dorsalis pedis flap and radial forearm flap are less often used now because of the donor site morbidity. The ALT represents a good choice in case of extensive defect.

Arthroscopic assisted tendon reconstruction for TFCC irreparable tears

List of authors:
Riccardo Luchetti¹, Andrea Atzei², Roberto Cozzolino¹
¹ Rimini Hand Centre, Via Pietro da Rimini, 4 (Rimini)
² Fenice Hand Surgery & Rehabilitation Team, Treviso (Treviso)

Objectives / Interrogation: To report our 11-year experience performing arthroscopically assisted anatomical TFCC reconstruction in the treatment of chronic DRUJ instability resulting from irreparable TFCC injuries.

Methods: Eleven patients were submitted to reconstruction. Three skin incisions were made in order to create a radial and ulna tunnel for passage of the graft which is used to reconstruct the dorsal and palmar radio-ulnar ligament under fluoroscopic and arthroscopic guidance.

Results and Conclusions: Seven patients were affected by severe chronic DRUJ instability following distal radius fracture, 3 cases of DRUJ instability due to simple wrist sprain and one patient had instability due to TFCC wear following chronic calcium deposits. The ulnar styloid was un-united in two patients. All patients were classified arthroscopically as Palmer Type 1B, Atzei class 4; in two cases the avulsion was not reducible and in the other cases the patients had poor TFCC quality and poor healing potential. Two cases had instability recurrence after TFCC bone repair. One patient had associated luno-triquetral instability. Pre-operative evaluation demonstrated that prono-supination ROM was almost complete in all patients but one (this patient had supination limited at 60°), all patients had evident and painful DRUJ instability, and grip strength was half of the contralateral side.

All patients (6 females and 5 male) with mean age 37 years, were evaluated at a mean follow-up of 68 months (range from 9 to 120 months).
At follow-up, DRUJ stability was restored in all but one patient, who was re-operated on using the Moritomo technique of open palmar tendon graft reconstruction. Pain decreased from 4 to 2 at rest and from 9 to 4 under stress according with the 0 to 10-points Visual Analogue Scale. Wrist ROM did not demonstrate significant modifications, but only a minimal decrease for pronation, flexion and extension. Grip strength increased from 54% to 96%. Modified Mayo Wrist Score was excellent in 4 patients and good in 5. Eight patients were satisfied with the results of the procedure: DASH and PRWHE scores improved (Table 2). Eight patients resumed previous manual activities (1 student), 3 patients changed work due to unrelated reasons.

Conclusions: Arthroscopic assisted approach for TFCC reconstruction is safe and produces comparable results as the standard technique.

TFCC reconstruction, Arthroscopic TFCC reconstruction, Anatomical TFCC reconstruction, Arthroscopically anatomic TFCC reconstruction
ARPE-prosthesis: Clinical and radiographic relevance of intra-operative fluoroscopy guided orientation of the cup. Comparison to retrospective data with a minimal follow-up of ten years.

List of authors:
Loïc Vercruysse*1, Sanne Vanstockstraeten1, Arne Decramer1
1 AZ Delta (Roeselare)

Objectives / Interrogation: It is known that cup placement is considered important to minimize the risk of complications. Up until now, it was based on experience. A study of Duerinckx et al, suggested that there is a fixed relationship between the centre of range of motion and the proximal articular surface of the trapezium (PAST-line).

Primary endpoint in this study is comparing cup inclination and positioning with respect to the PAST-line with and without the PAST-technique. Secondary endpoint in this study is to evaluate clinical outcomes and complications of prostheses with a minimal follow-up of ten years (without the PAST-technique) and compare it to the results of recently placed prostheses (with the PAST-technique) with a follow-up of 12 months.

Methods: We looked for patients meeting the inclusion criteria with trapeziometacarpal arthritis that underwent primary arthroplasty with an ARPE-prosthesis for the retrospective part and the prospective part, between 2002 and 2007 and between 2016 and 2017 respectively. For the retrospective part, the PAST-technique was not used in contrast to the prospective part where intra-operative fluoroscopy for cup placement was used. The same inclusion- and exclusion criteria for both parts of the study were used. Patients got a PA and a lateral Kapandji view postoperatively.

Patients were assessed at follow-up for clinical outcome parameters.

Results and Conclusions: Between 2002 and 2007, 89 patients were enrolled in the study and eventually 37 patients remained for retrospective data collection. Furthermore, prospective data collection occurred for 25 patients, operated on with the use of the PAST-technique.

We intend to obtain demographic data as well as pre- and postoperative mean strength, ROM, Kapandji-, DASH- and VAS scores. Radiographic parameters regarding cup placement such as inclination and the centre of the cup were measured. Finally complications will be notified for the group with a follow-up of more than 10 years which will help us to get insight long-term survival rates.

The survivorship rate of these prostheses is proven in various studies. The clinical results of our patients regarding strength, pain relief and range of motion are promising. Cup placement is of utmost importance to minimize complications such as dislocation and wear but further studies and a longer follow-up with a larger group of patients are needed to detect significant changes regarding the usage of the PAST-technique.

Reinsertion of distal biceps tendon through a mini invasive anterior approach: our experience

List of authors:
Massimo Massarella†, Eleonora Piccirilli*1
1 Villa Stuart Sport Clinic (Rome)

Objectives / Interrogation: Distal ruptures of the biceps often occur in men during eccentric contraction of the biceps or after overload with flexed elbow. Usually, surgical treatment is the best choice. The aim of our work is to evaluate the mid term results of a mini invasive anterior approach for the reinsertion of distal biceps tendon using a reabsorbable anchor.

Methods: A retrospective analysis was performed on prospectively collected data from 15 patients treated for total distal biceps tendon rupture in 15 months from 2017 to 2018. We included all male patients, mean age 40 years (35-55) who underwent distal biceps tendon rupture after sport injuries. Clinical and radiological diagnosis was made through Magnetic Resonance performed a few days after the trauma. The tendon was anatomically repaired through a single anterior mini open approach (2.5 cm incision) using a reabsorbable anchor (2.9mm) inserted into the biceps radial tuberosity.
After the surgical procedure, elbow brace set at 90° flexion was maintained for two weeks, then rehabilitation started. The average follow-up of our study was 12 months.

**Results and Conclusions:** 12 months after the surgical procedure, patients satisfaction was good. The mini invasive anterior approach has a minimal aesthetic impact and it allows a good functional outcome, without nerve damage or infections. We reported a single case of fibrotic scar. On a functional point of view, the anchored tendon allows the complete range of motion of the elbow after five weeks. In four months patients were completely back to their previous sport activities. In our experience, this surgical procedure is a valid option with a very low rate of complications.

distal biceps tendon, mini invasive approach, reinsertion, anchor
The postoperative dressing regime in congenital hand surgery - Is frequent dressing change necessary?

List of authors:
Christanne van Nieuwenhoven*, Cornelia Nooteboom¹, Steven Hovius¹, Lisebette Burger¹
¹ Erasmus MC (Rotterdam)

Objectives / Interrogation: In hand surgery, efficient and effective wound management is important, because rapid wound healing results in fast remobilization of the hand, which is significant for effective rehabilitation of the hand function. Factors that can influence wound healing are postoperative wound infections and ineffective immobilization of the hand. In pediatric hand surgery, creating a safe healing environment is even more challenging, because children are more active and therefore the dressing is easily damaged. To avoid pain and stress of the child and parents during wound care and to optimize the postoperative care in congenital hand surgery, we changed the wound management at our institution to a regime where the post-operative dressing stays six weeks in place before removing. We hypothesized that frequent dressing changes are unnecessary and wound inspections after two or three weeks will not prevent wound infections.

Methods: Patients between the age of 0 and 18 years old that received elective hand surgery for their congenital hand malformation were enrolled in this retrospective study. Patients that received desyndactylisation, correction osteotomy, pollicisation, opposition plasty, ray amputation, or chondrodesis/arthrodesis surgery, or a combination of these, were included. The total amount of adverse events and post-operative hospital visits between the dressing regimes were compared with the use of a Chi-square test or Fisher's exact test.

Results and Conclusions: A total of 551 hands were included with 272 hands for the long term and 279 hands in the short term group. Significantly more hand infections were reported in the short term group (42 vs 1) treated with antibiotics. Problems with the dressing were comparable for both (40 versus 43). The same amount of unplanned hospital visits were reported (12.3% vs 12.7%).

In our opinion, frequent dressing changes in elective congenital hand surgery is often unnecessary and asks a lot of effort from children and their parents. Furthermore, infection might be overdiagnosed with an increase in the prescription of antibiotics. Subgroup analyses of patients with syndactyly and Apert syndrome, showed more infections in the short term group. Considering our results, it seems that when using a FTG, it is also safe to use a long term dressing. Therefore, this study shows that long term dressing in elective congenital hand surgery is safe, without increased risk on adverse events.

Surgical Treatment of congenital camptodactyly, multicenter study

List of authors:
Mattia Giardini*, Massimo Corain¹, Roberto Adani², Mario Lando²
¹ AOUI Verona, Hand surgery departement (Verona)
² Modena University Hospital, Hand Surgery Department (Verona)

Objectives / Interrogation: Camptodactyly is a congenital deformity that appears as a contracture in flexion of the proximal interphalangeal (PIP) joint. Mostly involves the lesser fingers, mono or bilateral. There isn't any consensus about the pathogenesis but the literature reports specific modifications in the soft tissues that bring to an impairment of flexion and extension strength acting on PIP joint. These imbalances cause also a deformity of the bony shape of the PIP. The contracture worsts during the growth sprout periods. Surgical treatment is for patients with a contracture over 40° who conservative treatment failed. In this presentation will be described the pathologic steps, the author’s preferred surgical procedure and long term results.

Methods: From 2010 to 2018, 45 patients have been surgically treated; 56% male and 44% female, for 52 fingers at all. The mostly involved fingers are the ulnar (84%), 27% bilateral. Almost The 70% of the patients started with a contracture over 60°. Every patient has been studied with a preoperative AP an LL Xray and a clinical examination of the degree of contracture and PROM. Only the patient with a mild or moderate bone degeneration have been included. All the patients have been approached through a Malek surgical technique, consisting in a volar incision on the PIP, the detachment of FSD distal insertion, the release of the volar plate, skin graft from the volar wrist crease and arthrorisis in extention for 4 weeks, after surgery the same splinting and rehabilitation protocol. We have recently checked 45 patients with a AP and LL Xray view and a clinical evaluation of the residual contracture and the PROM using the Siegert scale, with an average follow up of 52 months (97-6).

Results and Conclusions: About postoperative results 60.7% are Excellent (complete extention, < 15° loss of flexion), 28.5% are Good (gain of extention >40°, loss of flexion < 20°), 11.8% are Fairy (gain of extention >20°, loss of flexion <45°). No case of a Poor result have been detected. No progression of the bone deformity at the postoperative Xray check has been observed. Camptodactyly is a common (1% of population) congenital pathology. Surgical treatment is considered for patients for whom the conservative treatment failed or for those with a real severe contracture. About our casistic almost 90% of the patient have a Excellent or Good result after surgery (sec. Siegert). The radiological pattern of the PIP bones shows no progression of the deformity from the preoperative stage.

Keywords: camptodactyly
**Secondary dislocation after osteosynthesis of first metacarpal fractures - A retrospective analysis**

**List of authors:**
Susanne Langen\(^1\), Carsten Surke\(^1\), Stefanie Hirsiger\(^1\), Esther Vögelin*\(^1\)
\(^1\)Handchirurgie und Chirurgie der peripheren Nerven (Bern)

**Objectives / Interrogation:** In order to restore the anatomy after a fracture and ensure complete biomechanical functionality of the thumb, osteosynthesis (ORIF) of the fractured first metacarpal bone is advised. Nonetheless, secondary displacement regularly occurs despite the use of variable angle locking plates, screws and k-wires. The objective of this retrospective study was to assess the anatomical and functional outcome of secondary displaced fractures after ORIF.

**Methods:** Between January 2013 and December 2017 65 patients were diagnosed with a fracture of the first metacarpal bone which was subsequently reduced and fixed with locking plates, screws or k-wires in our clinic. 12 (18%) of 65 patients developed a secondary displacement. We analysed the radiological and clinical records in terms of malpositioning, treatment and functional outcome.

**Results and Conclusions:** The majority (10/12) of malpositions included a volar dislocation (mean 34.4°) after using a T-shaped locking plate (TLP). One patient of the TLP-group (1/10) had to undergo revision with a corrective osteotomy and a change to a double-row locking plate. Additional six patients from the entire cohort (8/12 or 66%) underwent metal removal after a healed fracture. For the other 6 patients no metal removal was performed. Range of motion (ROM) and pinch strength (PS) was comparable to the contralateral side in all analysed patients. Secondary displacement of ORIF of first metacarpal fractures is probably more frequent than desired despite variable angle locking plates. Despite secondary displacement of fractures of the first metacarpal bone, there was no significant impairment of the ROM and PS. However, we suspect that using TLPs might bear an increased risk for secondary displacements especially in intraarticular fractures of the first metacarpal bone. Depending on the type of fracture grid plates or double plating, bone graft and adjustment screws should be considered.

secondary dislocation, Metacarpal I fracture
Vascularized versus non-vascularized bone grafts for scaphoid non-union: evidence and new findings

List of authors:
Gernot Schmidle*, Rohit Arora¹, Tobias Kastenberger¹, Markus Gabl¹
¹ Department of Trauma Surgery, Medical University Innsbruck (Innsbruck)

Objectives / Interrogation: The main risk factors for a scaphoid non-union (SNU) are fracture displacement, location and vascular supply. The treatment with vascularized (VBGs) or non-vascularized bone grafts (NVGBs) is a debated issue. In clinical practice VBGs are indicated in cases of avascular necrosis (AVN) of the proximal pole and when previous surgery has failed. However, there is no high-level evidence, the role of vascularity as indicator for SNU healing is unclear and little is known about the biology of bone healing.

Methods: Based on a literature review we analyzed evidence of VBG versus NVBG treatment. Union rates were compared and the quality of evidence was evaluated.
In a study with 68 patients (42 fractures, 26 SNUs) we compared how well the different imaging modalities can display fracture patterns, stability and vitality.
In a second study we assessed the bone healing capacity (BHC) of SNUs in 33 patients by histological analyses. We compared these results to CT parameters of fracture location and bone structure.

Results and Conclusions: Most of the studies found are case series with retrospective, non-randomized designs and a high risk of bias. Higher union rates are usually obtained in the absence of AVN, however the use of a wide range of definitions and assessment methods make a valid comparison difficult and the role of vascularity in SNU healing unclear.
Our study regarding imaging modalities showed that the 3D analysis provides complementary information in comparison to two-dimensional imaging. Fracture location and extension of fracture lines can be best analyzed by 3D imaging and give important information about stability and potential vascularity.
The second study showed a correlation of bone healing capacity and 2D CT parameters, with higher BHC in cases with normal trabecular structure and lower BHC in cases with fragmentation. The 3D CT fracture location showed lower BHC in completely intraarticular proximal pole non-unions.
The choice of bone grafting cannot be based on evidence and further studies are necessary to determine and precise the indications of VBG treatment.
CT parameters of bone structure and fracture location can predict bone healing and are helpful to choose the appropriate SNU treatment in clinical practice.

Proximal phalangeal fractures - Is it worth fixing them?

List of authors:
Sunil Parthiban*, Manish Gupta1
1 Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Management of proximal phalanx fractures has been a subject of debate for a long time. Conservative methods are popular as they obviate the risk of interference with the delicate soft tissue balance around the bone. However, internal fixation methods can provide skeletal rigidity, thereby allowing immediate mobilisation. Recent systematic reviews published by the European Hand Society (2017) show no clear evidence of the superiority of any one treatment method. However, it has been noted that there is a paucity of published literature on this very commonly treated injury. The purpose of this study was to review the results of open reduction and internal fixation of proximal phalangeal fractures at our Unit.

Methods: We reviewed outcomes of patients that underwent internal fixation of proximal phalangeal fractures at our Unit between October 2016 and March 2018. The information was collected retrospectively from case notes. K wire fixation and simple manipulations were excluded for the purpose of this review. Information collected included patient and injury demographics, method of internal fixation, union rates, range of movement, functional recovery, complications and secondary procedures, if any.

Results and Conclusions: We found that 102 patients underwent internal fixation with plates and/or screws. The mean age of patients was 38 years old with a fairly even split between left (52) and right (50) hand injuries. All fractures healed with no incidence of nonunion. One patient, with severe crush injury and composite tissue loss, developed infection that required metalwork removal. One patient required metalwork removal due to breakage of implant. 13 other patients required metalwork removal and tenolysis due to tendon adhesions and stiffness. There was a significantly increased correlation between joint stiffness and severity of injury. The remaining patients had excellent recovery and returned to full functional activity.

We present one of the largest series in the literature regarding outcomes of surgical fixation of proximal phalanx fractures. Unlike previous reports, our experience shows good outcomes with few complications. Internal fixation provides rigid stabilization, thereby improving rehabilitation without cumbersome splintage. Comparison with conservative methods is difficult due to the inherent bias in the severity of injury chosen for this treatment modality. Internal fixation remains the method of choice for severe, comminuted and open injuries of the proximal phalanx of hand.

Decellularized vascularized nerve scaffolds for the reconstruction of large peripheral nerve defects

List of authors:
Radu Olariu¹, Jérôme Duisit², Ioana Lese*¹, Esther Voegelin³, Benoît Lengele², Robert Rieben⁴, Adriano Taddeo⁴
¹ Hand and Plastic Surgery (Bern)
² Cliniques Universitaires Saint-Luc, Department of Plastic and Reconstructive Surgery (Brussels)
³ Handchirurgie und Chirurgie der peripheren Nerven (Bern)
⁴ Department of clinical research (Bern)

Objectives / Interrogation: Peripheral nerve injuries are devastating, life-altering injuries. Decellularized scaffolds, which act as guide-conduits for the regenerating nerves, represent a promising approach to increase availability of nerve grafts and effective nerve reconstruction when used as vascularized grafts. Here we report the development of a vascularized nerve scaffold in which the preserved vascular tree can be used for perfusion and recellularization in order to improve cell engraftment, supply of nutrient and, thus, regeneration and functional recovery.

Methods: Seven vascularized porcine sciatic nerve scaffolds (VPNS) were retrieved and perfusion-decellularization was applied using a SDS/Triton X detergent protocol. Decellularized VPNS were characterized analyzing cell and DNA content and preservation of extracellular matrix (ECM), vascular tree and cytokine content. Reendothelialization of decellularized scaffolds was conducted with porcine-aorta endothelial cells (PAEC) in a perfusion-bioreactor.

Results and Conclusions: Scaffold vascularization was confirmed by angiography before and after decellularization. Morphologic examination of decellularized VPNS and analysis of the DNA content demonstrated cell and antigen clearance. ECM content and structures of the nerve fascicles were preserved. Detailed 3D characterization of the VPNS’s vasculature was conducted using micro-computed tomography (microCT)-based imaging approach and showed optimal vasculature preservation down to the capillary level. Cytokines quantification demonstrated a strong preservation of growth factors and reduced preservation of pro-inflammatory cytokines. Reendothelialization experiments showed PAEC viability and engraftment with repopulation of the scaffold’s vessels.

This study shows that perfusion-decellularization can be used to generate vascularized nerve scaffolds with preserved ECM structure and a functional vascular tree, which can be reendothelialized in vitro. As compared to non-vascularized conduits, vascularized engineered nerve scaffolds may represent an ideal approach for promoting better nerve regeneration in larger nerve defect reconstructions.

Triangular fibrocartilage complex repair in pediatric patients

List of authors:
Alex Balboa¹, Kendra Eckstein¹, Kevin Little*¹
¹ Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine (Cincinnati)

Objectives / Interrogation: Introduction: Triangular fibrocartilage complex (TFCC) injury is a common cause of ulnar-sided wrist pain in pediatric patients and can be difficult to identify. In the pediatric population, patients often present with TFCC pathology secondary to acute trauma, physeal arrest, or chronic, repetitive damage. Although some patients respond to conservative therapy, TFCC repair (arthroscopic or open) can be definitive treatment for those with persistent pain and functional limitations.

Objective: To report the outcomes following surgical TFCC repair in pediatric patients.

Methods: Methods: Medical records of pediatric patients who underwent TFCC repair at an academic pediatric hospital between 2004-2018 were reviewed for demographics, operative reports, clinical/occupational therapy notes and imaging reports. Inclusion criteria included 1 month minimum follow-up and confirmed TFCC injury. Patient outcomes were analyzed according to Palmer classification, ROM, grip strength, and PODCI scores.

Results and Conclusions: Results: 89 patients (40:49, 14.6(9.5-28.7); M:F, age(range)) diagnosed with TFCC injury and underwent 88 arthroscopic and 7 open surgical operations. The mean follow-up time was 16.5 months (1-68 months). 38 children (43%) had distal radius and/or ulna fractures prior to diagnosis of TFCC injury. The most common cause of injury was sport (31%). 82 patients (92%) had diagnostic MRI prior to surgery with 75 patients having positive pathologic imaging findings confirmed by arthroscopy, while 7 patients (8.5%) had false negative MRI findings with pathology later identified at time of arthroscopy. Palmer classification 1B (67%) and 1D (11%) were most commonly seen on arthroscopy. 32 patients (36%) were simultaneously treated for ulnar impaction/abutment and/or distal radial growth arrest at the time of TFCC repair. Following surgery, mean grip strength increased 21.2 kg on average (p<0.05). 74 patients (83%) recovered full ROM. Patients with available goniometric data, wrist flexion improved 13.92% (p<0.05). PODCI Upper Extremity function & pain scores increased 30 and 42 points following surgery, respectively (p<0.05).

Conclusion: MRI imaging was a useful diagnostic tool in identifying TFCC pathology (91.4% sensitivity). Palmer Classification 1B (67%) and 1D (11%) were the most common TFCC injuries encountered. Surgical TFCC treatment (arthroscopic and/or open) led to significant increases in PODCI function & pain scores, ROM, and grip strength.

Pain as the main predictor of the one-year outcome in distal radius fractures

List of authors:
Magnus Tagil*, Sara Zakrisson Andersson1, Antonio Abramo3, Marcus Landgren1
1 Department of Orthopedics (Lund)

Objectives / Interrogation: For most patients with distal radial fracture (DRF), the outcome is good but 15-20 % have suboptimal subjective results one year after the injury (Landgren 2018). Previous long term studies have focused mainly on radiographic appearances as predictors of inferior subjective outcome but personal factors like pain coping strategies and pain behaviour may play a similar or even larger role. The aim of this study was to identify such factors which may predict poor outcome, thereby providing us with instruments to identify and treat complications before they become manifest.

Methods: 1045 patients, 18-65 years with a distal radius fracture 2003-2012 were sent a "yellow flags" questionnaire regarding general health, socioeconomic background, previous pain experience and coping of the present injury. One year after the injury, quick-DASH, a validated subjective outcome questionnaire was distributed. The two questionnaires were merged and analyzed using Matlab and SPSS. Linear regression was used to evaluate correlation between the information from the initial treatment and the qDASH-evaluated outcome. The included cases were then analyzed using SPSS automatic linear modeling to identify the most important predictors of a patient's one-year qDASH outcome.

Results and Conclusions: 645 patients had full data from both the early yellow flags questionnaire and the 12-month DASH. Using the automated linear model, approximately 30 % of the 12-month DASH outcome was explained by the first week yellow flags predictors. The self-evaluated pain level at the time of injury was by far the single best predictor of the one-year qDASH outcome. Other factors such as comorbidities and education level had minor impact on the outcome.

Conclusion: The level of pain as experienced by the patient during the first weeks after the fracture seems to be the most important factor to predict a high one year qDASH-score. Increased efforts to help the patient control/cope with the initial pain after the fracture are therefore important and controlled, prospective preferably randomized studies necessary. With the present tragic opioid crisis in mind, it is important not only to focus on pharmacological treatment. We must carefully identify other factors causing excessive pain experience, like, massive edema, inability to adhere to rehab protocol, fear of movement or suboptimal coping mechanisms.

Carpal tunnel syndrome: Recurrence Assessment SCORE (RASc)

List of authors:
Daniel Georg Gmainer*, Petra Brinskelle, Saskia Kotschar, Birgit Michelitsch, Lars-Peter Kamolz, David Benjamin Lumenta
1 Division of Plastic, Aesthetic and Reconstructive Surgery, Department of Surgery, Medical University Graz, Research, Unit Tissue Regeneration, Repair & Reconstruction, Austria (Graz)
2 Division of Plastic, Aesthetic and Reconstructive Surgery, Department of Surgery, Medical University Graz, Austria (Graz)

Objectives / Interrogation: The current literature of carpal tunnel syndrome lacks appropriate distinction or definition of persistence (e.g., due to incomplete release) vs. recurrence following a primary surgical intervention of carpal tunnel release. The aim of our work is to propose a novel methodology to clearly define recurrence based on parameters from a literature review and own clinical data.

Methods: Following ethical board approval, we analysed the medical literature (Medline, Embase) for definitions of recurrence, and reviewed our own retrospective cohort from 2005 to 2015. To objectify clinical decision making, we summarized parameters of symptoms, signs, neurophysiological- and imaging studies in a combined point-based score. A 50 percent reuptake of symptoms following a three-month symptom-free interval was defined as recurrence.

Results and Conclusions: In our cohort of 1094 carpal tunnel syndrome patients, 67 interventions were documented in operative reports as recurrence. Following review of these, we excluded 10 incorrectly classified cases, and patients with comorbidities related to the cervical spine nerve roots. 35 of 57 cases presented without a symptom free interval in the mean 10.1 month follow-up and were classified as persistent carpal tunnel syndrome. Using the above SCORE requirements, 16 cases fit the criteria for recurrence, of which 13 were previously operated on in other hospitals. Intraoperative documentation revealed residual scar tethering in proximity to the median nerve in 15 cases and incomplete release in one.

On mean 7.8 month follow-up of the recurrent cases, 2 cases were entirely free of symptoms, in 10 cases, symptoms had improved and one case worsened, and received additional surgery. 2 cases were lost to follow-up.

While carpal tunnel syndrome recurrence is rare, differences in characteristics of symptoms, signs and electrophysiological studies may explain its causes and should be differentiated from persistent carpal tunnel syndrome following surgery. Our suggested score is quick and easily applicable in daily practice for future use in clinical research focusing on recurrent carpal tunnel syndrome.

The role of arthroscopy in the treatment of a fracture of the body of the hamate

List of authors:
Paulo Gil Ribeiro*, José Alexandre Marques1, João Marques1, António Alves2
1 Centro Hospitalar e Universitário de Coimbra (Coimbra)
2 Hospital Amato Lusitano (Castelo Branco)

Objectives / Interrogation: Fractures of the body of the hamate are rare and difficult to diagnose and treat surgically. The radiographic evaluation of the hamate-metacarpal joint is difficult, making its evaluation with a CT Scan necessary. In this kind of fractures it is necessary to reconstruct the articular surface of the joint to minimize the post-traumatic complications like painful posttraumatic osteoarthritis.

Methods: The authors present a clinical case of a fracture of the body of the hamate treated surgically with an arthroscopic approach.

Results and Conclusions: Case report:
We present a case of a 36 year-old male with a complex fracture of the body of the hamate (Type II of Milch's classification) after a high energy fall. The articular CT Scan revealed an impacted osteochondral fragment and one dorsal fragment. According to the characteristics of the fracture (that presented a split depression fragment) we opted to do the fracture fixation with an arthroscopic approach. We used the vertical traction tower and two dorsal arthroscopic portals that allowed the elevation of the osteochondral fragment with the arthroscopic probe. We opted to stabilize the small dimension fragments with two percutaneous K wires with the aid of fluoroscopy. The patient used a splint for 5 weeks and was then assigned a specific physical rehabilitation program. At this moment, 6 months after surgery, the patient is completely recovered, having no limitations in its physical activity. He has a Visual Analogue Scale score of 0 and recovered is grip strength completely.

Conclusion:
The arthroscopic approach in this complex fracture of the body of the hamate was an excellent option to avoid the surgical aggression and the complications of an open procedure while allowing a good reduction of the osteochondral fragment with a magnified view.

All-through 6R single portal repair of superficial TFCC tear

List of authors:
Mostafa Mahmoud*
1 Cairo University  (Cairo)

Objectives / Interrogation: Many repair techniques were described for the traumatic superficial peripheral TFCC tear (Palmer type 1B or European Wrist Arthroscopy Society (EWAS) Atzei type 1). Most outside in techniques report 6U or DRUJ portal in addition to the 6R portal as working portals to achieve a secure repair. We used the 6R as a single portal for repairing such tears and evaluated the results of this technique in 28 patients.

Methods: We repaired the TFCC in 28 patients following arthroscopic confirmation of the tear using two or three vertical mattress 2/0 PDS sutures tied through 6R portal after its hypodermic insertion 1 cm proximal to it. We included patients with traumatic ulnar side wrist pain with positive foveal sign who failed conservative management and rehabilitation for at least three months. We excluded patients with previous distal radius fracture, DRUJ instability, radiographic ulna plus variance, arthroscopic diffuse synovitis, cartilage degeneration or complex TFCC tear. The mean age of the patients was 32y (range from 18 to 45). They were 26 males and 2 females. Dominant side was affected in 19 patients. Sixteen patients only reported traumatic event with acute pain due to twisting injury (n=6) or a fall on a pronated hand (n=10) while the other 12 reported gradual onset of the pain with no considerable trauma.

Results and Conclusions: The mean follow up period was 39 months (16-66). There was statistically significant (p < 0.05) improvement of the mean post-operative VAS for pain from 4.8 (3.5-6) to 1.3 (0-4.5) and QDASH from 31.5 (27.3-40.9) to 9.2(6.8-15.9). Twenty-six patients returned to their pre injury level of activity, one patient needed revision surgery after 12 months pain free period and found to have complex tear and the last patient stopped his recreational activity because of post activity pain. No irritation of superficial nerves reported and we did not need to remove the PDS stitches in any patient.

In conclusion: Single 6R portal repair of the traumatic superficial TFCC tear is possible and effective method of management.

10-year-follow-up after implantation of a custom made wrist prosthesis in a patient with giant cell tumor of the distal radius

List of authors:
Hans-Georg Damert*, Melanie Kober
1 Plastic, Aesthetic and Handsurgery, HELIOS Bördeklinik (Oschersleben/Neindorf)

Objectives / Interrogation: In contrast to implants of large joints, there is no standardized procedure for wrist implants in hand surgery, with the method being considerably newer. Over the years, the design of the implants has been changed due to the problems observed during their use. In case of total destruction of the wrist, complete arthrodesis usually is the method of choice. However, patients’ desire to preserve at least residual motion is becoming more and more crucial. Although long-term results for current wrist implants are still missing, a wrist implant is an alternative option to arthrodesis in the opinion of the authors. The case presented describes the use of a tumor wrist prosthesis based on the “Universal2©” model (KMI) in a patient with tumor destruction of the distal radius by a giant cell tumor.

Methods: After resection of the tumor there was a defect of the distal radius over a length of more than 6.5 cm. The 36 year old patient urgently demanded to preserve function and refused free fibular graft and arthrodesis whenever possible. Due to the good results experienced with the Uni2 implant, the idea to design a tumor prosthesis based on this device was born. The tumor implant was manufactured according to the patient’s x-ray images in cooperation with ArgoMedical Company. After cost approval by the patient’s health insurance a custom made device could be manufactured and implanted. So we could do the implantation in April 2009. The patient has returned to work after 6 months.

At the international congress we will present the ten year follow-up of this case. At the moment there is still good function with extension/flexion 30-0-20, ulnar/radial abduction 10-0-5 and pronation/supination of 80-0-80. During this time the patient don't need a second surgery and there was no complication. The patient still works and have hobbies like fishing and motorbiking.

Results and Conclusions: In our opinion the tumor wrist prosthesis may be an alternative or an option compared to a free fibula transplantation for the treatment of larger defects. You don’t have a donor side morbidity, the operation is not so complex and was doing in 2 ours with less collateral damage. This patient have still a good live quality and would take this treatment once again.

giant cell tumor, distal radius, custom made wrist prosthesis
The musicians' hand - A survey focusing on the challenges in diagnostics and therapy

List of authors:
Sabrina Holzer*, Bernhard Riebl, Matthias Bertsch, Gerhild Thalhammer, Irena Krusche-Mandl
1 General Hospital of Vienna, Department of orthopedic and trauma surgery, Division of Trauma Surgery (Vienna)
2 Krankenanstalt Rudolfstiftung, Institute of physical medicine and rehabilitation (Vienna)
3 University of Music and Performing Arts Vienna, Department of Music Physiology (Vienna)

Objectives / Interrogation: Professional musicians challenge their bodies to perform up to 25 notes per second. Manual handicaps combined with an inadequate therapy can be fatal for a professionals' career. In order to efficiently understand a musicians' impairment, additional knowledge about instrument-related requirements are needed.

Methods: A questionnaire was sent to professional musical institutions in Austria focusing on musicians having medical problems considering their hands. General demographic data, data about the entity of their symptoms, the instrument, different therapies and their rehabilitation time was collected. In order to obtain a better comparability, a score was established emphasizing on the level of impairment.

Results and Conclusions: We found a predominance of female musicians and an average age of 28 (range 16-65). Most common impairments included tendinitis, hypermobility, nerve entrapment syndromes and rheumatoid diseases. Mean duration of symptoms was 7.5 months.

The main risk factor for the development of symptoms were extended practice times (p<0.5).
Loss of fine motor skills, loss of strength and pain were leading symptoms. 9.8% were offered a surgical option, but only 3% admitted to the procedure, mostly being skeptical of the doctors' real understanding of their problem. In the surgically treated group, the procedure offered a good option with a favorable functional outcome.

In the treatment of musicians with problems in the hand, treatment should be adapted to the specific needs of each musician. Further examination with the instrument can be helpful to understand the nature of their problems. If surgery is needed, early intervention can be beneficial to the patient. Additional ergotherapy, retraining of their technique and psychological help can quicken the process of healing.

Free vascularized osteocartilagineous and osteoperiosteal medial femoral condyle graft for recalcitrant scaphoid non-union - Clinical and radiological outcome

List of authors:
Marco Keller*, Gernot Schmidle, Tobias Kastenberger, Markus Gabl, Rohit Arora
1 Universitätsklinik für Unfallchirurgie (Innsbruck)

Objectives / Interrogation: We present our experience with the use of a free vascularized bone graft from the medial femoral condyle (MFC) in the treatment of long-standing scaphoid non-union.

Methods: We report the clinical and radiological outcome of 38 treated scaphoid non-unions in 37 patients. Due to a fragmentented, unstable or avascular proximal pole or failed previous antegrade screw fixation 9 patients out of 37 were treated with an osteocartilagineous graft (proximal pole replacement). The other patients were treated with an osteoperiosteal graft. The mean age at the time of the procedure was 26 years (range 17-42 years). 15 (39,5%) patients underwent previous surgery with persistent non-union. 36 (97%) of the patients were male and one (3%) was female.

Preoperative gadolinium enhanced MRI scans were available for 31 (84%) patients and showed a compromised perfusion or avascularity of the proximal scaphoid pole in all cases. The mean time of persisting non-union until surgery using MFC graft was 51 months (range 6-184 months). The mean post-operative follow-up time was 16 months (range 6-53 months).

Results and Conclusions: Bone union was achieved in 9 out of 9 (100%) cases treated with a osteocartilaginous MFC graft and in 25 out of 29 (86%) cases treated with a osteoperiosteal MFC graft. Overall union rate was 89,5%. We saw a decreased union rate associated with previous screw fixation and with a combined volar and dorsal surgical approach. We observed no major donor site morbidity and all minor donor site symptoms wore off within one year. In terms of the clinical outcome we saw an improvement of the average grip strength (preoperative mean value 34kg, final follow up 44kg). The scapholunate and radiolunate angle improved as well (SL average 6° improvement, RL average 10° improvement). The range of motion of the wrist at final follow-up remained about the same. Within one year after the surgery 31 (83,7%) of the patients reported complete pain relief. The mean preoperative DASH score was 58,6 points and decreased to 18,8 points at final follow-up. The mean PRWE score decreased from 62,4 points before surgery to 29,6 points at final follow-up.

We see the advantages of this method in the possibility of a proximal pole replacement with an osteocartilagineous graft, the high union rate, the moderate donor site morbidity, the consistant vascular anatomy in the MFC area with a long pedicle, the possibility of harvesting a rather big graft and the comparably easy shaping since its a free vascularized graft.

Pyoderma gangrenosum of the Hand. Case Report

List of authors:
Jarema Kowalski*

1 Helios Kliniken Schwerin, Klinik für Handchirurgie, Wismarsche Straße 393-397 D-19049 Schwerin (Schwerin)

Objectives / Interrogation: Pyoderma gangrenosum (PG) is a rare inflammatory skin disorder. It is typically associated with chronic systemic inflammatory or neoplastic diseases, but may also arise secondary to the injury or surgery (pathergy). PG is difficult to be diagnosed. Currently it is a "diagnosis of exclusion". We present a case of postinjury PG of the little finger.

Methods: Case Report

Results and Conclusions: 69-year-old female was admitted to our clinic with suspicion of finger cellulitis. She reported to injured her left little finger 5 days before. Since then she is complaining about increasing redness, swelling and functio laesa. Despite operative debridement of the wound, the local findings became worse. The patient was consulted by our dermatologist. The diagnosis of pyoderma gangrenosum can only be made from clinical and histological findings according to the Mayo criteria. Based on this we evaluated the major and criteria. Under the prednisolone administration, there was a significant improvement. After completion of the diagnosis, therapy with ciclosporin and prednisolone was initiated. After a week of systematic therapy, the skin defect on the little finger was covered with split skin from the left elbow. After the week, the patient was discharged home. The control after two months continues to show good results without recurrence signs.

Pathways to Nonunion of a Scaphoid Fracture

List of authors:
Stephanie Spence1, Tim Davis2, Scaphoid Non Union Group Scaphoid Non Union Group2
1 Glasgow Royal Infirmary (Glasgow)
2 Nottingham University Hospital (Nottingham)

Objectives / Interrogation: To investigate the causation of scaphoid fracture nonunions which underwent bone graft surgery at 20 centres within the UK.

Methods: Data was collected from the hospital records of 796 patients undergoing scaphoid fracture nonunion surgery. This was completely by a collaboration of clinicians who were part of the scaphoid non union group.

Results and Conclusions: Results: 306 and 346 of patients presented to the NHS within 2 and 4 weeks respectively of the acute scaphoid fracture. 305 and 223 presented over 4 weeks and 12 weeks respectively of their fracture (incomplete data in 145 instances).

Of the 306 who presented within 2 weeks, appropriate treatment for the acute fracture was started within 2 and 4 weeks respectively in 172 and 188 cases. 74 of these 306 had no treatment during the first 13 weeks post-injury.

Patients who sought medical advice within 2 weeks but did not commence any treatment until after 4 weeks attended 1-4 different health resources before their fracture was diagnosed. Data from 121 of these cases showed first attendances with an Emergency Department (79), GP (10), Minor Injuries unit (20), Therapist (2), Walk-In Centre (5) and Fracture/Hand Clinic (2). Of the 79 who first attended an Emergency Department, 66 required attendances with 2-4 further health resources before their fracture was diagnosed.

Conclusion: This data show the present mechanisms for managing acute scaphoid fractures are failing, and causing the majority of scaphoid fracture nonunions. The problem is probably multifactorial with issues regarding patient awareness of the possibility of a fracture and compliance with treatment, and difficulties with the diagnosis of scaphoid fractures by health professionals. Efforts should be concentrated on addressing these issues, and also improving the success rate of surgery to treat scaphoid fracture nonunions.

Effectiveness of operative treatment in chronic long-lasting carpal tunnel cases

List of authors:
Marta Twardowska*, Marta Jokiel, Ewa Breborowicz, Piotr Czarnecki, Leszek Romanowski
1 Poznan University of Medical Sciences, Traumatology, Orthopaedics and Hand Surgery Department (Poznan)

Objectives / Interrogation: Carpal tunnel syndrome (CTS) is the most common peripheral neuropathy. CTS diagnosis is usually based on physical examination. Tinel’s and Phalen’s tests are proved as high sensitive and specific. In the literature it is unclear what results can be expected and achieved in chronic cases. There is a doubt how much improvement the patients can get in cases with accompanying muscle atrophy and sensation deficits. The aim of the study was to assess patients clinical condition after operative treatment of chronic long-lasting carpal tunnel syndrome.

Methods: We examined 114 patients (93W, 21 M) average age 57 y.o. after long-lasting carpal tunnel syndrome (mean: 8 years) operative treatment were examined with Biometric grip strength dynamometer, 2PD test. Grip strength was examined with electronic Biometric dynamometer. Patients underwent clinical examination with basic tests confirming clinical condition (Tinel’s and Phalen’s tests). We used DASH, PRWE and BCTQ Questionnaire to assess patients condition.

Results and Conclusions: There was a significant difference (p<0,0001) between DASH results before and after surgery. DASH result before was decreased from 44,6 ± 18,9 to 16,1 ± 20,4 . The PRWE result decreased significantly (p<0,0001) from 67,4 ± 38,2 to 10,9 ± 26,2. There were also significant increase (p=0,0002) of global grip strength from 15,9 ± 8,1 kg to 25,8 ± 9,6 kg. After surgery in BCTQ patients assess night wrist pain to 0,4 ± 0,8 and wrist pain during everyday living activities to 1,7 ± 1,2. There were no significant difference between 2PD test. Before surgery patients result was 6,2 ± 3,4 mm and after 5,4 ± 0,8. Long lasting carpal tunnel syndrome influence patients everyday living activities and diminish hand function. The prolonged time of disease leads to a small decrease of fingers two-point discrimination and a significant decrease of grip strength.

Relationship between ulnar variance and shape of the midcarpal joint.

List of authors:
Hanne Vandevivere*, Marc Garcia-Elias, Jeroen Vanhaecke, Marleen Dezillie, Frederik Vanrietvelde, Filip Stockmans
1 AZ Groeninge Kortrijk (Kortrijk)
2 Kaplan Institute (Barcelona)

Objectives / Interrogation: In 1993, Viegas et al. investigated the incidence and distribution of intracarpal arthrosis in 393 dissected cadaver wrists: 45% had cartilage damage at the proximal pole of the hamate, and 36% degenerative tears of the TFCC. The two conditions were rarely found in the same wrist. Indeed, a TFCC tear tends to be associated with positive ulnar variance, and this tends to coexist with a lunate type I. A luno-hamate impingement is expected to coexist with a type II lunate. We hypothesized that a long hamate, associated with a lunate type II, tends to have a negative UV, while a short hamate, associated with a lunate type I, tends to have a positive UV. Hence we investigated whether there exists a relationship between the midcarpal inclination (MI) angle, type of lunate and the ulnar variance (UV) in the general population and patients with proven ulnar impaction syndrome.

Methods: A retrospective, quantitative, population based analysis (asymptomatic patients taken from the hospital data base) was performed assessing 342 postero-anterior radiographs of normal wrists taken in pronated position with the arm in 90° abduction and 40 postero-anterior radiographs of patients with ulnar impaction syndrome. We estimated the type of lunate and measured the midcarpal inclination angle (MI) angle and UV. A statistical analysis was performed to assess the relationship between these parameters.

Results and Conclusions: We found a weak correlation between the MI angle and ulnar variance in the general population. Type II lunate wrists have a greater MI angle than those with Type I lunate (p<0.05).
In patients with ulnar impaction syndrome who have lunate type II, a smaller positive ulnar variance is symptomatic compared to those who have lunate type I. In this ulnar impaction population there is an inverse linear correlation between ulnar variance and MI angle ($R^2$ 0.15).
In the general asymptomatic population we could not confirm our hypothesis of a negative relation between the MI angle and ulnar variance. In the symptomatic ulnar impaction population we do see a negative correlation between MI angle and ulnar variance. The clinical relevance is that positive ulnar variance is better tolerated by the type I lunate wrist compared to the type II lunate wrist who has a higher risk to develop and ulnar impaction syndrome even with slight ulnar positive variance.

Keywords: ulnar variance, mid carpal inclination angle, ulnar impaction syndrome, type of lunate
carpal tunnel and median nerve volumes changes before and after carpal tunnel surgery (Comparison of endoscopic and mini open technique)

List of authors:
NAZMI BULENT ALP*1
1 BURSA ULUDAG UNIVERSITY, ORTHOPEDICS AND TRAUMATOLOGY DEPT, HAND SURGERY DIVISION (BURSA)

Objectives / Interrogation: To compare carpal tunnel volume and n.medianus volume changes in preoperative and postoperative MRI of patients who were operated with 2 different techniques.

Methods: In Bahçelevler State Hospital/ISTANBUL, 17 wrists of 13 patients who were diagnosed with carpal syndrome were included to our study.

In open technique, the transverse carpal ligament was cut by inserting a 1 cm longitudinal incision 1 cm distal to the distal wrist crease. It was noted that the incision tunnel passed through the middle of the 4th finger.

Microaire Smart release system was used for endoscopic surgery. In a single portal, incision, 1 cm transverse incision was made between palmaris longus and flexor carpi ulnaris tendons over most detectable proximal wrist crease. The direction of the blade was again aimed at the 4th finger center. Transverse carpal ligament was cut distal to proximal and inferior to superior direction.

Median nerve volume and carpal tunnel volume were measured in T2 fat-printed images. The distal and proximal borders of the carpal tunnel (pisiform bone and hook of hamatum) were identified on the coronal plane. (1)

The cross-sectional widths varied between 2 mm / 3 mm according to the MRI. Depending on the length of the carpal tunnel, 4 to 11 axial sections were taken from the MRI. The image was enlarged and the area of the median nerve and carpal tunnel was marked to find the axial cross-sectional area (mm2). Each section was measured 3 times and the average of 3 numerical values was taken (mean axial area mm2). Each mean axial carpal tunnel and median nerve area was multiplied by the width to find the estimated volume. (OAA * Width)

Total of all gave us estimated carpal tunnel and median nerve volume.

Results and Conclusions: There was a significant difference between preoperative carpal tunnel volumes and median nerve volumes, postoperative carpal tunnel volumes and median nerve volumes. p<0,0001. When we compared the two methods in terms of volume increments, a significant difference was found.

When techniques are compared with each other, we can see significant difference between pre- and post-operative cts volumes or n. medianus volume.

In our study, we found that 2 different techniques succeeded in increasing the carpal tunnel and median nerve volumes, but they did not have any superiority to each other.

A new finger-preserving procedure as an alternative to amputation in recurrent severe Dupuytren’s contracture of the small finger

List of authors:
Isam Atroshi*, Ase Eiriksdottir
1 Lund University, Department of Orthopedics Hässleholm-Kristianstad (Kristianstad)
2 Department of Orthopedics (Kristianstad)

Objectives / Interrogation: Recurrent severe Dupuytren contracture of the small finger proximal interphalangeal (PIP) joint is a difficult problem. Further surgery and joint release carries high risk of neurovascular injuries and residual contracture. Other treatments like PIP arthrodesis or arthroplasty commonly yield poor results. Patients are often offered finger amputation. We have devised a novel surgical procedure consisting of middle phalanx monobloc resection and ligament reconstruction to create a new functional interphalangeal joint.

Methods: Two patients with severe small-finger PIP joint contracture after multiple treatments who requested finger amputation were offered and accepted this new procedure. Through a dorsal incision the extensor tendon is incised longitudinally exposing the middle phalanx and interphalangeal joints. The collateral ligaments of both IP joints are detached from the middle phalanx. The middle phalanx is dissected from soft tissues (including the flexor digitorum superficialis tendon) and removed. The distal phalanx is brought proximally and the ends of the collateral ligaments are sutured with non-absorbable sutures with the joint held in extension and congruency. The two patients were evaluated at 18 months and 15 months after surgery, respectively.

Results and Conclusions: Both patients regained good finger posture with almost full extension and had normal sensation and no pain. The first patient had 60 degrees active flexion in the newly fashioned joint and the second patient had 35 degrees. Both patients had full MCP flexion and extension, normal 2-point discrimination in the small finger and higher grip strength in the treated than the contralateral hand. Radiographs showed a congruent new IP joint. Both patients were very satisfied with the outcome.

In patients with Dupuytren disease and severe recurrent PIP joint contracture after multiple treatments, this novel procedure consisting of middle-phalanx excision and ligament reconstruction creating a new functioning interphalangeal joint has good short-term outcomes and is a favorable alternative to finger amputation. Longer follow-up will show whether these results are durable.

Is night pain the most disturbing symptom for patients with carpal tunnel syndrome?

List of authors:
Beata Bajdik*, Balazs Lenkei, Adrienn Lakatos
1 Handsurgeon Center Miskolc, Hungary (Miskolc)

Objectives / Interrogation: There are different factors influencing the postoperative results of carpal tunnel syndrome. Our hypothesis was that patients with preoperative night pain will be more satisfied after the neurolysis of the median nerve than those without night pain.

Methods: A retrospective study was performed based on a prospective data collection. In the period 2014 and 2018 467 patients were operated in our unit for carpal tunnel syndrome, 29 were excluded due to missing data. In all cases open carpal tunnel release was performed without synovectomy. Changes in daytime numbness, nighttime numbness, night pain, and satisfaction was registered. For the evaluation of the subjective findings, a Visual analogue scale of 1-10 (VAS) was used. The patients were selected into 3 groups according to the level of preoperative night pain. Group 1 had no night pain prior the operation, group 2 had mild night pain (2-5 VAS) and group 3 had severe night pain (6-10 VAS). Significance was evaluated using Z-test (p=0.05).

Results and Conclusions: Group 1 had 77 patients (17.6%), group 2 had 74 patients (16.9%) and group 3 had 287 patients (65.5%). The average of preoperative night pain was 4 VAS in group 2 and 8.86 VAS in group 3. Patients with severe night pain complained of significantly higher level of daytime and nighttime numbness (7.18 VAS and 8.8 VAS respectively) compared to the ones without night pain (5.58 VAS and 5.3 VAS respectively). The level of night pain decreased to a minimal level after 1 week in all groups (1.36 VAS in group 1, 1.69 VAS in group 2 and 1.72 VAS in group 3). By the third month the night pain practically disappeared in all groups (1.32 VAS in group 1, 1.31 VAS in group 2 and 1.67 VAS in group 3). 3.6 VAS daytime numbness remained for group 3 which was significantly higher than the other groups (1.69 VAS in group 1 and 2.23 VAS in group 2). The overall satisfaction by this time was 8.45 VAS in group 1, 8.8 VAS in group 2 and 8.66 VAS in group 3.

Discussion
Our hypothesis failed as no significant difference was found in the satisfaction levels of the patients with and without night pain before surgery.

Melorheostosis of the hand.

List of authors:
KONSTANTINOS TOLIS*, Nikolaos Papoulides1, Konstantinos Raptis1, Sarantis Spyridonos1
1 GENERAL HOSPITAL KAT (ATHENS)

Objectives / Interrogation: Melorheostosis is a rare mesenchymal dysplasia. It develops with a sclerotomal distribution, usually affecting one limb. On plain radiographs the irregular cortical hyperostosis occurring on one side of the affected bone is seen as the characteristic melting "candle wax" sign. We present two rare cases of melorheostosis of the hand.

Methods: The first case involves a 55 years old Greek woman presenting with melorheostosis of her left hand. The disease involved the lunate, the capitale, the metacarpal and the phalanges of the middle and index fingers. The patient complained for pain and dyskinesia due to bony spurs between the metacarpals, as well as the proximal and middle phalanges. At presentation flexion at the metacarpophalangeal (MCP) joint of the index finger was at 20o and at the proximal interphalangeal (PIP) joint was 0o. Although the difficulties of any surgical intervention were presented to the patient, she insisted on being operated. Under general anesthesia and tourniquet a straight incision was performed between the second and third metacarpal, while as a second straight incision at the radial site of the middle finger. Although extensive tenolysis of the extensor tendons successful, during the procedure to remove the marble-like bony spurs two saw blades were destroyed and any effort to continue stopped. A plaster cast was used for protection and rest and the patient was discharged from hospital the next day.

The second case involves a 36 years old Albanian woman who reported pain and mild stiffness at her left hand. The radiological studies revealed melorheostosis affecting the lunate, the capitate, the metacarpal bones of the middle and index finger, and the proximal and middle phalanx of the middle finger.

Results and Conclusions: Results: At three months postoperatively the first patient showed no improvement in relation to her previous condition. Also she denied any suggestion of ray amputation of any or both of the affected fingers. The second patient continues her professional as a hair stylist, without the need for any surgical intervention.

Conclusion: Literature lacks evidence considering effective surgical intervention for the cortical hyperplasia in cases of melorheostosis of the hand. Ray amputation seems as the only alternative in cases of extensive hand dysfunction, only after taking into consideration the special needs of the patient.

Surgical repair of dorsal capsulo-ligamentous complex for dislocation of the thumb carpometacarpal joint

List of authors:
Haruhiko Shimura¹, Tetsuya Sato², Yoshiaki Wakabayashi³, Akimoto Nimura⁴, Koji Fujita⁴, Shiro Suzuki⁴
¹ Tokyo Bay Urayasu-Ichikawa Medical center (Urayasu)
² Doai Memorial Hospital (Tokyo)
³ Yokohama City Minato Red Cross Hospital (Yokohama)
⁴ Tokyo Medical and Dental University (Tokyo)

Objectives / Interrogation: Acute dislocation of the thumb carpometacarpal (CMC) joint is a rare, high-energy injury because of the strong capsulo-ligamentous complex structure. There are a few reports of this injury in the literature, and its optimal treatment remains controversial. This study aimed to evaluate the clinical outcome after surgical repair of the dorsal capsulo-ligamentous complex.

Methods: Six patients with a mean age of 42.7 years (range, 30-56 years) treated for the thumb CMC joint were reviewed retrospectively. The ruptured dorsal capsulo-ligamentous complex was repaired using suture anchors in all patients, and the joint was immobilized with a Kirschner wire pinning and splint for 3 weeks. The clinical outcome was assessed by measuring the range of motion of the thumb CMC joint and the Japanese Society for Surgery of the Hand version of the Quick Disability of the Arm, Shoulder, and Hand (Q-DASH-JSSH) score.

Results and Conclusions: The mean radial abduction of the thumb CMC joint was 61°, and the volar abduction was 59°. The mean Q-DASH-JSSH score was 4.0 (range, 0-15.6). There were no cases of infection, nerve disturbance, or osteoarthritis. Anatomical reduction of the thumb CMC joint was observed in five patients at the final follow-up. However, in a rugby football player, we found subluxation of the thumb CMC joint at 12 months of follow-up due to reinjury while playing rugby. In this patient, anatomical reduction was observed at 6 months of follow-up. Surgical repair of the dorsal capsulo-ligamentous complex with suture anchors is a reliable and simple treatment for unstable dislocation of the thumb CMC joint.

**Arthroscopic Anatomic Allinside (3A) reconstruction of the TFCC**

**List of authors:**
Andrea Atzei*, Riccardo Luchetti², Felix Riano³, Thomas Aust⁴, Fabio Tandioy⁵
¹ Clinica Giovanni XXIII (Monastier di Treviso)
² Rimini Hand Centre (Rimini)
³ Naples Hand Arthroscopy (Naples, FL)
⁴ Arthrolab (München)
⁵ Clínica Las Américas (Medellín)

**Objectives / Interrogation:** To report the preliminary experience on a novel technique of arthroscopically assisted tendon graft reconstruction of the Triangular Fibrocartilage Complex (TFCC) in the treatment of Distal Radio-Ulnar Joint (DRUJ) instability resulting from irreparable tears.

**Methods:** The technique uses a 3mm strip of the ECRL tendon, which is introduced in a radial metaphyseal tunnel originating from the anatomical sites of insertion of the DRUJ ligaments at the edges of the sigmoid notch. The tunnel is created under arthroscopic control using a wrist drill guide. The ulnar tunnel accepting the extremities of the tendon graft is created with an in-out technique, under arthroscopic control, to allow for the intra-articular fixation of the graft, using an interference screw. Postoperative immobilization with restricted forearm rotation was discontinued at 5 weeks, then post-operative rehabilitation was started. This novel technique was used in 5 patients, that were reviewed at minimum follow-up of 18 months. The DRUJ stability, visual analog scale of pain (VAS), ability to return to work, Prono-Supination range, grip strength and the Mayo Wrist Score were used for evaluation.

**Results and Conclusions:** We had no intra-operative complications. All patients had a stable DRUJ at follow-up and returned to previous work. VAS was significantly reduced and Prono-Supination, grip strength, and Mayo Wrist Score increased post-operatively. Compared to the previously described techniques of tendon graft reconstruction of the TFCC, this novel technique shows the main advantage to replicate the anatomic location of the tendon graft on the radius, which is achieved totally under arthroscopic control, without the need of fluoroscopy, with limited periarticular surgical dissection.

Fingertip Amputation - Different Injuries, Different solutions

List of authors:   
Luís Mata Ribeiro*, Diogo Casal†  
‡Hospital São José, Centro Hospitalar Lisboa Central (Lisbon)

Objectives / Interrogation: The distal phalanx of fingers has a significant relevance in hand functionality and finger aesthetics. Therefore, it must be replanted in case of amputation. Microsurgical reimplantation is widely accepted as the technique which provides the best outcome. The main difficulties lie in the adequate anastomosis of the vessels due to the small calibre of the veins at this level and a high degree of vasospasm, especially in crush amputations.

Methods: PMO, male, 55 years old, suffered a serious traumatic injury to his left index and third fingers due to a crushing/cutting accident with a heavy metal sheet. The patient did not smoke and had a previous history of hypertension and angina pectoris (both were controlled with medication).

The index finger suffered a complete amputation at the level of the base of the nail plate and had bone exposition. The third finger suffered an incomplete amputation at the DIP joint level; nonetheless the deep flexor tendon was the only structure connected to the proximal portion of the finger. The fingertip was clearly ischemic.

The patient was quickly transferred to the operating room (8 hours of ischemia). In the index finger we proceeded with debridement, bone shaping and coverage with a volar advancement flap (Atasoy). In the third finger we opted to try to salvage the fingertip. First, we removed the remaining bone fragments and fused the middle and distal phalanx with 2 Kirshner wires. Then we repaired the extensor apparatus and the collateral nerves. After that we anastomosed the collateral ulnar artery and a central dorsal vein. At the end of the surgery, after tourniquet release, the fingertip was perfused. Finally, the skin was closed with few simple sutures and an occlusive dressing was applied.

Results and Conclusions: 6 months postoperatively the patient has complete range of motion in the MCP and PIP joints of the index and 3rd finger and a good sensitivity in both finger pulp (static 2-point discrimination of 4 and 5 mm, respectively). The patient is very happy with the functional and aesthetic result.

Conclusion
Fingertip traumatic amputations are always a difficult challenge to solve. Microsurgery reimplantation offers the best outcome possible. Two of the most important factors for its success seem to be the mechanism of injury and hot ischemia time. Prompt revascularization with a skilled microsurgical technique is the most effective treatment.

Modified Arthroscopic Resection Arthroplasty for isolated STT osteoarthritis

List of authors:
Claus Deglmann*, Nina Knie¹, Claas Pawelek¹, Vanja Celigoj¹, Bernhard Lukas³
¹ Centre of Handsurgery, Microsurgery and Plastic Surgery, Schoen-Klinik Muenchen Harlaching (Muenchen)

Objectives / Interrogation: Distal resection of the scaphoid is known as an arthroscopic treatment of isolated STT osteoarthritis as an alternative treatment to open procedures, like resection arthroplasties or STT Fusion. Due to the insertion of carpal ligaments on the distal scaphoid, which are promoting mediocarpal stability, we prefer the arthroscopic resection distally on the trapezoid and the trapezium (TT-RSA) without resection of the scaphoid. We are presenting the follow up of our modified procedure (n=20) with the objectives on pain reduction, functional scores and patient satisfaction.

Methods: N=24 arthroscopic TT-RSAs were included in the study after exclusion of 3 patients with the need of secondary procedures and exclusion of resection arthroplasties with simultaneous surgeries on the carpus or the wrist. Average follow up time was 16,7 months. Patient age was 58,8 years on average. We evaluated qDASH and pain score VAS (0-10) in rest and on exertion preoperatively, after 6 months and on follow up. Also grip strength, key and pulp pinch and patient satisfaction was evaluated.

Results and Conclusions: QDASH in the ongoing study is 51,2 ± 18,5(SD) preoperatively, 32,4 ± 22,3 six months postop and 12,7 ± 15,9 on follow up. Resting pain is reduced from 4,9 ± 3,0 VAS preoperatively to 1,2 ± 2,2 on follow up. Pain on exertion is reported with 8,0 ± 2,1 preoperatively and 3,3 ± 2,7 on follow up. Patients are largely pleased with the procedure and recommend it. Grip strength was 80% of the contralateral side, pulp and key pinch 90,5% and 95,2% respectively.

Conclusions: Arthroscopic resection arthroplasty of the trapezoid and the trapezium (TT-RSA) can be recommended as a minimal invasive procedure and shows a major pain reduction for isolated STT osteoarthritis, if a preexisting mediocarpal instability is ruled out as the leading cause for the STT osteoarthritis.

May be the arthroplasty with spacer the best solution of CMC arthrosis in under seventy patients.

List of authors:
Gaetano Carriere*¹
¹ Villa Erbosa Hospital (Bologna)

Objectives / Interrogation: Maintenance of high of trapezium-metacarpal joint should be the aim in the CMC arthrosis Eaton's stage 2-3 surgery in under-seventy patients.

Methods: I used two different spacers in in my personal series of 190 consecutive cases of: Arthroplasty in CMC arthrosis, stages 2°-3° Eaton classification.
One hundred forty  cases with Pirodisk (pirocarbon spacer, age thirty-eight to sixty-five, follow up from ten to one year ), fifty cases Reg Joint (poliLactid acid biosorbable spacer, age from 45 to eighty-one, follow up five to one years).
The same technique for the Reg Joint, created an hole with specific tools into the biosorbable spacer.
The terminal end of FRC split is used to reconstruct the CMC dorsal ligament, "reinforced" from ALP detached from the 1° metacarpal base.
One hundred-ten (eighteen bilateral), twenty man (two bilateral) in Pirodisk series, forty women (four bilateral) and six man in Reg-Joint series.

Results and Conclusions: All patients were evaluated clinically, at 15, 30, 60 e 90 days, only twenty rx control and three Tc were done in first five months for persistent wrist pain.
One hundred and sixty-five patients compiled the quick-D.A.S.H. (Short disability of Harm-Shoulder and Hand) questionnaire (the average value was 17.5 point (from 13 to 28).
Kapandy value 8-10, (average nine)
Pain: V.A.S. 1.8 average (range 1-4), was 5.5 before surgery.
Pinch 4.6 (was 3.4 before surgery because of pain) similar to the other hand.
Grip: average 18.5 Kg (was 13 before surgery), 22 kg the value of the other hand.
No statistically difference were find between two groups.
All patients reached their best range of motion and were able to restart the normal work related activities in 2 to 6 months (average 2.8 months).
Eight patients were treated for trigger thumb and six for Dequervain disease at four-eight month from first surgery in Pirodisk series, only two woman was re-operated after eighteen months, replacing with reg-joint spacer.
On conclusion 90% of very-good and good results, 9% fair, 1% bad (two cases in pirodisk serie).

CMC arthrosis, rizoarthrosis.

List of authors:
Claus Deglmann*, Sanae Zens¹, Calvin Johnson², Carina Deglmann¹
¹ Centre of Handsurgery, Microsurgery and Plastic Surgery, Schoen-Klinik Muenchen Harlaching (Muenchen)
² OT4 Orthopaedietechnik (Muenchen)

Objectives / Interrogation: In this study, we introduce an innovative and new approach to the production of 3D printed orthosis in hand surgery on the example of a mini orthosis for mallet finger.
Frequent problems in the therapy of mallet fingers are prefabricated finger orthoses, that lead to insufficient results. Since individualized thermoplastic orthosis are not available in every setting, a new approach is software assisted planning of individualized orthosis and 3D printing. We have developed a new design for a DIP orthosis and present a pilot study.

Methods: We treated 10 patients with fresh or old (<6 months) extensor tendon rupture (Zone 1) or after failed treatment in a prefabricated orthosis. Patients received a preliminary thermoplastic orthosis, that was individually fitted with the aim of a mild overextension in the DIP joint (-10°). A hand laser scan was performed of the affected digits. 3D mesh-software customization of the orthosis was performed according to the fingerscan and 3D printing with PA12 executed. A thermoplastic orthosis was kept by the patient as a backup. After 8 weeks and 12 weeks, ROM was measured and patient feedback for haptic, comfort and restrictions of daily use was inquired.

Results and Conclusions: After 8 weeks, all patients in the ongoing study reached an extension deficit of 0° to 10°. The haptic experience was graded 8.5 (1-10), comfort was graded 7(1-10). 3 patients complained of pressure problems which required the printing of new modified orthosis. In total patients wore 70% of the time the 3D print orthosis, but changed back to the thermoplastic orthosis for 30%. All patients would undergo the treatment with the 3D orthosis again. Patents with prior treatment with a confection orthosis graded the 3D orthosis as very superior to the prefabricated orthosis. When directly compared to the thermoplastic orthosis, patients rated the experience comparable.

Conclusions: We demonstrate the therapeutic ability of individualized 3D printed orthosis for Zone 1 extensor tendon injuries. Advantages are comfort, haptic experience, waterproofness and long-term stability of the orthosis. Treatment goals were achieved, even after unsuccessful treatment as a second line therapy. Patients reflected a comparable rating and feedback as thermoplastic orthosis from our specialized hand therapists. Therefore 3D printing could offer an individualized treatment, even if - as in many hospitals or practices - there is no specialized occupational therapy with a broad orthosis experience.

Pacinian neuromas and neurofibromas: an uncommon cause of pain in the hands and fingers. Literature review.

List of authors:
Isabella Fassola*1, Kay Krüger2, Lena Wenzke3, Wolfgang Ertel3, Senat Krasnici2

1 Plastic, Aesthetic, Hand and Reconstructive Micro Surgery, Klinikum Ernst von Bergmann GmbH (Potsdam)
2 Department of Trauma and Reconstructive Surgery, Johanniter Krankenhaus Genthin-Stendal GmbH (Stendal)
3 Department of Orthopedics, Trauma and Reconstructive Surgery, University Charité Medical School, Campus Benjamin Franklin (Berlin)

Objectives / Interrogation: The study’s aim was to review the literature regarding the epidemiological, clinical, radiological, and histological characteristics of the Pacinian corpuscle neuromas (hyperplasia) and neurofibromas in the hand and fingers, in order to support clinicians in managing tumors responsible of unclear symptomatology in the hands and fingers.

Methods: A search of PubMed, Medline, Embase, Cochrane, and Google Scholar databases was undertaken, without restriction on date, language or publication status. The mesh terms used were "pacinian" or "pacini", "tumor" or "corpuscle tumor" or "neuroma" or "hyperplasia" or "hypertrophy" or "pacinioma" or "neurofibroma", and "hand" or "finger". Of the 1050 articles found, 67 met the inclusion criteria. Among these, 55 articles referred to Pacinian tumors at the level of the hands and fingers, and 12 articles referred to anatomical, histopathological, radiological and immunohistochemical studies regarding the Pacinian corpuscles without reporting a specific clinical case. All the case reports and cases series included in our final selection were evaluated for quality assessment by the first and last authors.

Results and Conclusions: A total of 72 tumors affecting the Pacinian corpuscles of the hand and fingers were identified, among which 58 cases (80.6%) were labeled as Pacinian corpuscles neuroma or hyperplasia (PCNH) and 14 cases (19.4%) as Pacinian corpuscle neurofibroma (PCNF). To the best of our knowledge, this is the largest review published. We found statistically significant difference between PCNH and PCNF in terms of age of appearance (50.2 vs. 31.1 years, p = .001), presence of pain (84.6% vs. 40%, p = .002), of sensory changes (57.9% vs. 0%, p = .027), of a visible or palpable mass (48% vs. 85.7%, p = .012), and history of trauma (64.2% vs. 12.5%, p = .006). Furthermore, the recurrence rate is not insignificant (21.2% for PCNH and 50% for PCNF, p = .244).

In conclusion, PCNH and PCNF behave differently with respect to their epidemiological and clinical presentation. Imaging may support the differential diagnosis with other common painful lesions of the hand. These findings are in contrast with previous reports, which decried the value of clinical signs in favor of a diagnosis mostly based on the histological examination. Accurate anamnestic data collection and clinical examination are essential to differentiate these conditions, while pathology tests are important to confirm the diagnosis.

LONG-TERM RESULTS OF TREATMENT OF RADIO-SCAPHOID ARTHRITIS AND SNAC WRIST BY USE OF PYROCARBON IMPLANT (APSI)

List of authors:
Enrico Carità\textsuperscript{1}, Alberto Donadelli\textsuperscript{2}, Landino Cugola\textsuperscript{2}
\textsuperscript{1} Clínica San Francesco, Ospedale Volta Mantovana (Verona)
\textsuperscript{2} Clínica San Francesco (Verona)

Objectives / Interrogation: Adaptive proximal scaphoid implant (APSI), maintaining carpal height and replacing an articular surface, prevents the worsening of arthritis and carpal collapse. Good tolerance of Pirocarbon and conformation of the implant give good expectations when there are lesions of styloscaphoid articulation.

AIM: In this retrospective study the authors describe their experience with the use of a Pirocarbon implant for proximal scaphoid in styloscaphoid arthritis linked to SNAC and SLAC wrist.

Methods: From January of 1999 to January of 2018 93 wrists were treated (85 for SNAC wrist from scaphoid pseudoarthrosis grade 2 and 3; 8 for SLAC wrist from S-L lesion). All cases were evaluated pre and post-operatively with MMWS, PRWHE and DASH scores with an average follow-up of 96 months (min 6 - Max 208).

Results and Conclusions: All the patients reported relief from pain, small improvement in ROM and improvement strength. At the follow-up there was an average reduction of pain from 7,01 to 2,7 VAS. There was an improvement of grip and pinch force from 51% to 85% of controlateral side. 85% of the patients were satisfied with the results and were able to return to the precedent activities. Improvement of DASH from 89 to 29 and of PRWHE from 101 to 27,8. Radiographic controls revealed 6 cases of complication with 4 cases of dislocation of the implant, no reduction in carpal height nor worsening of radio-lunate angle.

Replacement of proximal pole of scaphoid with APSI can restore a functional range of motion free from pain in patients affected from styloscaphoid arthritis maintaining height of proximal carpal row and preventing subsequent deterioration or collapse.

APSI, pyrocarbon implant, proximal scaphoid
ARTHROSCOPIC TREATMENT OF DORSAL WRIST GANGLIA: INFLUENCE OF DORSAL CAPSULODESIS

List of authors:
Elisabete Ribeiro*1, Nuno Oliveira¹, Jóni Nunes¹, Raquel Rocha Afonso³, Pedro Varanda¹, Juvenália Ribeiro¹, Luis Filipe Rodrigues¹
¹Department of Orthopaedics, Hospital de Braga (HB) (Braga)

Objectives / Interrogation: Dorsal wrist ganglia have been associated to mucoid dysplasia and anatomically related to dorsal scapholunate ligament complex. Arthroscopic treatment has lead to faster recovery and allowed simultaneous treatment of concurrent lesions during wrist assessment. High recurrence rates are nevertheless a concern. Here, the authors compare clinical results after arthroscopic treatment of dorsal wrist ganglia using arthroscopic excision alone and arthroscopic excision combined with dorsal capsulodesis.

Methods: A retrospective study included 19 patients (3 male and 16 female) with dorsal wrist ganglia submitted to arthroscopic excision (Group A, n= 10) or arthroscopic excision and dorsal capsulodesis (Group B, n= 9), between January 2011 and December 2017. Clinical evaluation included wrist range of motion, power strength and grip strength measures. Visual Analogue Scale (VAS) for pain and Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire were applied. Statistical analysis was displayed with Graph Pad Prism 6 for Windows 10.

Results and Conclusions: After 42.27±17.74 months of follow-up (range 14.97±81.81), mean range of power strength, pinch strength and range of motion values were all above 80% of the contralateral side for both groups. Post-operative pain was significantly lower for both groups (Group A: VAS 6,88±2,03 vs 1,94±2,82; Group B: VAS 6,86±2,04 vs 1,81±1,94; p<0.05). Average DASH score was 3,50±7,84 for Group A and 2,87±3,64 for Group B. There were no significant statistical differences for functional parameters between Group A and B. Recurrence rate was 30% for Group A and 11% for Group B. There were no registered complications.

Arthroscopic treatment of dorsal wrist ganglia by excision allows good functional results and significant improvement of preoperative pain with no major associated complications. According to our data, when performing routine dorsal capsulodesis simultaneously, positive results are maintained. The association of ganglionectomy and dorsal capsulodesis in our series allowed a significant lowering in recurrence rates (11%) in a short-term follow-up. We believe that dorsal scapholunate ligament complex might play a role in dorsal ganglia pathogenesis and recurrence. However, prospective studies with randomization, larger samples and longer follow-up periods are needed to validate these results.

Should I stay or should I go - how safe is the routine removal of volar locking plates after healed fractures of the distal radius?

List of authors:
Senat Krasnici*, Kay Krüger1, Wolfgang Ertel2, Isabella Fassola3
1 Department of Trauma and Reconstructive Surgery, Johanniter Krankenhaus Genthen-Stendal GmbH (Stendal)
2 Department of Orthopedics, Trauma and Reconstructive Surgery, University Charité Medical School, Campus Benjamin Franklin (Berlin)
3 Plastic, Aesthetic, Hand and Reconstructive Micro Surgery, Klinikum Ernst von Bergmann GmbH (Potsdam)

Objectives / Interrogation: We present our experience with removal of locked volar distal radius plates and screws and note the different complication rates between medically indicated (MI) and non-medically indicated (NMI) hardware removal.

Methods: We retrospectively reviewed all distal radius fractures treated with volar locking plates at our institution from 2003 to 2018 (1,473 cases) and identified those who underwent hardware removal. Patients were divided into two groups (MI and NMI) according to their indication for implant removal.

Results and Conclusions: A total of 66 patients (42 women, 24 men) underwent hardware removal (incidence 4.5%). The average age was 53.3 years (min 19, max 87). The MI group consisted of 31 patients (47%) and the NMI group of 35 patients (53%). According to the AO classification, there were 18 type A (27.3%), 7 type B (10.6%), and 41 type C (62.1%) distal radius fractures. The average interval between initial trauma and primary osteosynthesis was 5.6 days (min 0, max 100). The most common indications for hardware removal in the MI group were limited range of motion (n = 14), post-traumatic CTS (n = 6), ulnar impaction syndrome (n = 4), mechanical problems (n = 3), pain with identifiable source (n = 3), and tenosynovitis (n = 1), while in the NMI group the indications were patient’s wish (n = 33) and pain without an identifiable source (n = 2). The mean length of implantation was 63.8 weeks (range, 9-557). Overall there were 5 complications (4 persistent pain, 1 hematoma requiring revision) (incidence 7.6%). All complications occurred in the MI group (16.1%) (p = .02). There were no statistically significant difference between the two groups in terms of age (p = .70), gender distribution (p = .89), type of AO fracture (p = .87), time interval between injury and initial osteosynthesis (p = .29), and time between osteosynthesis and hardware removal (p = .34). Conclusion: We found statistically significant difference in the rate of complication between medically and non-medically indicated hardware removal following volar locking plate fixation of distal radius fracture. Non-medically indicated hardware removal of a healed distal radius fracture treated with volar locking plate is a safe procedure.

LONG-TERM RESULTS OF TREATMENT OF SCAPHO-TRAPEZIUM-TRAPEZOID (STT) ARTHRITIS BY USE OF PYROCARBON IMPLANT (STPI)

List of authors:
Enrico Carità*, Alberto Donadelli, Landino Cugola
1 Clinica San Francesco, Ospedale Volta Mantovana (Verona)
2 Clinica San Francesco (Verona)

Objectives / Interrogation: Scapho-Trapezium-Trapezoid (STT) arthritis is commonly treated by isolated distal scaphoid resection or plus biologic interposition. Isolated distal scaphoid resection can reduce carpal height developing DISI deformity in long term follow up. Scapho trapezium pirocarbon implant (STPI) is used as a spacer to maintain carpal height and reduce long term DISI deformity. Good tolerance of Pirocarbon and profile of the implant give good life expectancy.

AIM: In this retrospective study the authors describe their experience with the use of a Pirocarbon implant for distal scaphoid in STT arthritis.

Methods: From January of 2007 to September of 2018 42 wrists (Viegas 1 and 2) of 36 patients were treated. All cases were evaluated pre and post-operatively with MMWS, PRWHE and DASH scores with an average follow-up of 72 months (min 3 - Max 138). 6 cases were treated bilaterally.

Results and Conclusions: There was an average relief from pain, no significant improvement in flexion extension ROM and significant improvement grip and pinch strength. At the follow-up there was an average reduction of pain from 7,01 to 1,7 VAS. There was an improvement of grip and pinch force from 51% to 88% of contralateral side. 85% of the patients were satisfied with the results and were able to return to the precedent activities. Improvement of DASH from 89 to 15,6 and of PRWHE from 101 to 19. Radiographic controls revealed 6 cases of complication with 1 case of dislocation of the implant, light reduction in carpal height in 4 pz and average radio-lunate angle passed from 11° pre-operatively to 14° post-operatively.

Replacement of distal pole of scaphoid with STPI can restore a good functionality of wrist and pinch, a complete range of motion free from pain in patients affected from STT arthritis maintaining carpal height and avoiding increase of capito-lunate angle or collapse.

Results of fascia lata interposition arthroplasty for elbow ankylosis

List of authors:
Tos Pierluigi¹, Alessandro Crosio¹, Federica Olivero¹, Simonetta Odella¹
¹ G Pini Milan, Hand Surgery and Reconstructive Microsurgery, ASST Gaetano Pini CTO, Milan University (Milano)

Objectives / Interrogation: Elbow ankylosis is a predictable complication in severe complex trauma of the distal humerus or the proximal end of the ulna in which, in addition to stiffness, there is an important joint compromise but no prosthetic replacement is indicated. In young and motivated patients the recovery of the articulation can be restored with the interposition arthroplasties with ition of fascia lata. The aim of the work is to report our experience of a series of five patients operated between the years 2009 and 2017 with this method.

Methods: Five patients were operated by means of elbow arthrolysis, posterior skin access with a deep medial access with epicondylar osteotomy and fascia lata interposition (age 35, 40, 50, and 45 years - 2 women 3 men). In two cases at the end of surgery and ligament reconstruction it was necessary to use the external fixator to protect the reconstruction permitting immediate active movement. In the remaining three cases the elbow had good residual stability and was not protected after surgery. The minimum follow-up was 2 year, the maximum of 9 years. Four times the operated side was the dominant side. Regarding the etiology there were four post-traumatic cases and one post-coma. Ankylosis was present at 90 ° in 3 patients and at 80 and 70 ° in the others. Patients were evaluated with the mayo Elbow Performance Score MEPS. Once the fascia was harvested from a patient's triceps in all the others from tissue bank. Every time the fascia was folded on itself and secured by holes to the distal humerus. The principles of technique are shown in the presentation.

Results and Conclusions: Results
The mean age was 43 years (range 36 to 59 years) at time of surgery. There were no major complications. In all patients a degree of satisfactory particularity was achieved without pain that allowed to bring the hand to the mouth in 4 cases and 5 cm from the face in the last case. There were no cases of secondary instability. The average extension deficit was 40 degrees (SD +/- 10). Two cases were classified as excellent (MEPS>80), two good (MEPS>60) and one fair (MEPS > 40).

Conclusion
Elbow interposition arthroplasty with fascia lata or tricipital fascia is a valid alternative in patients with severe functional limitation who have no indication for an elbow prosthesis (young, active patients). The addition of distraction and external fixation, in conjunction with ligament reconstruction, has addressed the instability problem and therefore improved results.

The United Kingdom experience of trainee led multicentre prospective studies in hand surgery

List of authors:
Matthew Gardiner*, Jeremy Rodrigues1, Abhilash Jain2
1 Kennedy Institute of Rheumatology, NDORMS, University of Oxford (Oxford)
2 Botnar Research Centre, NDORMS, University of Oxford (Oxford)

Objectives / Interrogation: The evidence base for hand surgery is low quality. Most evidence is level III or below and there are few randomised controlled trials. The Reconstructive Surgery Trials Network (RSTN) was founded in 2013. It is the UK clinical trials network for hand and plastic surgery and part of the Royal College of Surgeons Clinical Trials Initiative. It is supported by the BSSH and BAPRAS. The aim was to review the progress of the RSTN after 5 years.

Methods: The review assessed the hand surgery studies supported by the RSTN. It focused on the experiences of collaborators involved in the studies, the study outputs and subsequent impact.

The RSTN has developed its own systems involving the early adoption of a range of technical innovations to support its work. These were reviewed to identify successes and challenges that might benefit other groups.

Results and Conclusions: The RSTN has supported eight hand surgery projects. It is developing a core pathway for the workup of studies, typically including systematic reviews, clinician and patient surveys, and prospective cohort studies before randomised controlled trials. Topics include: nail bed repair, antibiotics in hand surgery, splinting in hand conditions, hand trauma, placebo arm studies, use of Kirschner wires and trigger finger.

A national network of local representatives has been recruited to stimulate involvement, and these reps and study collaborators have been managed using videoconferencing and mailing list management programs. Annual national trials days have become a focus for new study ideas and provided trial methodology to surgical trainees.

To date the studies have generated over 20 publications and presentations. Over 100 collaborators have been PubMed cited and €1M grant money raised. One RCT is recruiting and a further three are in the pipeline. Two studies have an international component. Successes have included the involvement of a large number of trainees, delivering projects on small budgets and impact of studies. Challenges have included geographical location, maintaining engagement and lack of resources.

Trainees are willing to engage in clinical research. They are capable of setting up multicentre studies that attract funding. More needs to be done to support high quality multicentre clinical research that will make a positive contribution to the evidence base in hand surgery. We present this on behalf of the RSTN committee and our collaborators.

Outcome of terrible triad injury of the elbow: do concomitant fractures make a difference?

List of authors:
Senat Krasnič, Kay Krüger, Flamur Zendeli, Wolfgang Ertel, Isabella Fassola

1 Department of Trauma and Reconstructive Surgery, Johanniter Krankenhaus Genthin-Stendal GmbH (Stendal)
2 University of Basel, Medical School (Basel)
3 Department of Orthopedics, Trauma and Reconstructive Surgery, University Charité Medical School, Campus Benjamin Franklin (Berlin)
4 Plastic, Aesthetic, Hand and Reconstructive Micro Surgery, Klinikum Ernst von Bergmann GmbH (Potsdam)

Objectives / Interrogation: Terrible triad injuries (TTI) of the elbow are challenging to treat. Aim of this study was to compare the clinical, functional and radiological results from the treatment of these complex fracture-dislocations with or without associated ipsilateral injuries of the upper extremity.

Methods: Twenty-one patients treated for terrible triad injuries of the elbow were retrospectively reviewed at an average follow-up of eighteen months. Group I (n = 9) included patients with isolated TTI and Group II (n = 12) patients with TTI in addition to fractures of the ipsilateral upper extremity. Initial treatment after closed reduction of the dislocation included splint immobilization or temporary external fixation. Treatment of the radial head and of the coronoid fracture was in the majority of cases surgical while both lateral ulnar and medial collateral ligament were managed mostly conservatively.

Results and Conclusions: Overall results were good, with VAS, DASH and MEPI measuring on average 1.5, 16.9 and 89.8, respectively. A high-energy trauma (p = .023) and the use of an external fixator as initial treatment (p = 0.19) were significantly more correlated to patients in Group II than in Group I. MEPI scores were significantly higher for patients in Group I than in Group II (p = 0.46), although both groups had scores corresponding to good and excellent functional results. No difference was found between the two groups in terms of complication rates or heterotopic ossification.

Conclusion: The presence of associated ipsilateral injuries of the upper extremity in patients suffering from terrible triad injuries of the elbow affects the initial treatment, whereas the overall clinical, functional and radiological results are similar to that of patients with isolated injuries of the elbow.

Use of Processed Human Nerve Allograft in Reconstruction of Brachial Plexus Birth Injuries

List of authors:
Aaron Berger*1, Herbert Valencia1, John Al Grossman1
1 The Brachial Plexus Program, Nicklaus Children's Hospital (Miami, FL)

Objectives / Interrogation: To describe our experience with the use of processed human nerve allograft in the reconstruction of brachial plexus birth injuries.

Although the standard approaches to reconstruction of defects in the brachial plexus include sensory nerve autografts and nerve transfers, the availability of processed decellularized nerve allograft presents another option, which may be used in lieu of, or in addition to nerve autografts and nerve transfers.

Methods: The study design consisted of a retrospective review of the medical records of patients who underwent brachial plexus reconstruction that involved the use of processed human nerve allograft at our hospital from April 2012 to October 2013. Thirteen patients met the inclusion criteria for the present study. All patients underwent nerve grafting using a processed nerve allograft. All operations were performed by the same surgeon (JAIG).

Results and Conclusions: Results:
The participants ranged in age from 6 to 12 months. Of the 13 patients, 7 were female (54%) and 6 were male (46%). 7 were affected on the left (54%) and 6 were affected on the right (46%). 9 patients sustained upper plexus (Erb's) injuries (69%); 2 patients sustained extended Erb's injuries (15%) and 2 patients sustained global injuries (15%). 7 patients underwent concomitant spinal accessory to suprascapular nerve transfer (54%). Concomitant autograft was used in 5 cases: sural nerve autograft was used for reconstruction in 4 cases (31%) and cervical plexus autograft was used in 1 case (8%).

The number of processed nerve allografts used in each case ranged from 1-2; two patients each received 2 grafts. The length of processed nerve allograft ranged from 3.0-4.7cm with average length of 4.2cm. The allograft was placed in an end-to-end fashion in 4 cases (31%) and end-to-side fashion in 9 cases (69%). The donor signal was obtained from the C5 and/or C6 nerve roots and the recipient sites included the suprascapular nerve, anterior and posterior divisions of the upper trunk and the middle trunk.

Conclusions:
Although the observed recovery in many of the patients cannot be exclusively attributed to the use of processed nerve allograft, the results of the present study suggest that processed nerve allografts may be used in a supplemental fashion in reconstruction of brachial plexus birth injuries.

Assessment of surgical treatment for carpal tunnel syndrome. Endoscopic vs Open release.

List of authors:
JHON FREDY CASTAÑEDA*, DIEGO FERNANDO RINCON, ALVARO ANTONIO KAFURY, JULIANA ANDREA ROJAS NEIRA
1 UNIVERSIDAD NACIONAL DE COLOMBIA (BOGOTA)
2 UNIVERSIDAD INDUSTRIAL DE SANTANDER (FLORIDABLANCA)
3 CENTRO MEDICO IMBANACO (FLORIDABLANCA)

Objectives / Interrogation: To compare the clinical and functional results of surgical treatment of carpal tunnel syndrome between endoscopic and open techniques release

Methods: Cases series study that included patients who underwent either open or endoscopic release. The open technique was performed using the conventional palmar approach and endoscopy was carried out using Agee's one-portal technique. Immediate complications and progress within the first month after surgery were assessed. Long-term assessment was conducted. This included assessment of functionality (DASH), strength (level II JAMAR dynamometer) and level of pain (VAS) Additionally, satisfaction with the outcome (improvement of symptoms) and procedure (recovery process) was evaluated

Results and Conclusions: 408 procedures (open 184, endoscopic 224) performed in 331 patients with a mean age of 56.3 ± 13.5 years were included, 85.5% being women. Axonal injury (7.1%) and thenar atrophy (24.3%) were similar between treatment groups (p>0.05). During the open procedure 22.8% of cases needed associate surgical procedures as compared with 1.8% in the endoscopic group (p<0.05) The most common associate procedures were flexor tenosynovectomy and trapeziectomy with tenosuspension, among other. No statistically significant differences were observed between either open or endoscopic techniques in relation to intraoperative complications or infection. Adequate improvement of symptoms was observed in 98.3% of patients and need of physical therapy was more common for the open technique. A higher incidence of pillar pain, wound pain and scar adhesions within the first month was found for the open technique (p<0.05)

A total of 78 patients was contacted to evaluate long-term outcomes, with a mean follow-up of 28 months. The DASH scale showed an average of 3.2 points. No differences in symptom relapse or long-term pain were observed (p<0.05) Grip and pinch strength was more than 80% on the non-compromised side in the majority of patients

Patients who underwent the endoscopic technique showed greater satisfaction in relation to the surgical procedure and initial recovery (open 70%, endoscopic 98%, p< 0.05) but there were no differences regarding satisfaction with respect to the final outcome of either technique (p >0.05).

Conclusions: Although long-term clinical and functional outcomes were similar, the endoscopic technique showed faster recovery, less complications within the first month, reduced need of physical therapy during recovery and greater level of patient satisfaction

PERILUNATE FRACTURE-DISLOCATIONS: CLINICAL AND RADIOLOGICAL RESULTS WITH A MINIMUM 2-YEAR OF FOLLOW-UP

List of authors:
Elisabete Ribeiro*1, Cecília Sá Barros1, Guiherme França1, Mário Batista1, Pedro Varanda1, Juvenália Ribeiro1, Luis Filipe Rodrigues1

1 Department of Orthopaedics, Hospital de Braga (HB) (Braga)

Objectives / Interrogation: Perilunate dislocations are complex wrist injuries. Despite optimal treatment, permanent partial loss of wrist motion and grip strength is expected. Due to its rarity, only few reports including treatment outcomes exist in the literature. Here, the authors describe clinical and radiological results after perilunate dislocations and fracture-dislocations.

Methods: Retrospective study including 12 patients that underwent surgery for closed perilunate dislocations and perilunate fracture-dislocations of the wrist, between January 2012 and December 2016. All patients were male and mean age was 34.54±11.96 years old (range 22-56). Clinical evaluation included wrist range of motion, power strength and grip strength measures. Visual Analogue Scale (VAS) for pain and Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire were applied. Radiological assessment was performed with plain radiographs. Statistical analysis was displayed with Graph Pad Prism 6 for Windows 10.

Results and Conclusions: After 49.94±16.47 months of follow-up (range 25.60±76.50), mean range of motion values (comparing to contralateral side) were: flexion 89.63±50.59%, extension 60.81±26.87%, radial deviation 72.84±34.48%, ulnar deviation 77.77±35.81%, pronation 101.97±11.97% and supination 79.57±31.92%. Mean power strength and pinch strength were 82.18±16.68% and 91.09±27.16%, respectively. Post-operative pain and DASH score were 2.58±2.93 and 10.77±12.37, respectively. The mean carpal height ratio was 1.54±0.08 (range 1.44-1.64) and the mean scapholunate angle was 50.73º±9.95º (range 32.00º-66.00º). Arthritic changes were found in 25% of the patients. Two patients had a scaphoid non-union. One patient developed scapholunate dissociation. DASH scores correlated with supination and power strength and pinch strength (p<0.05), but not with other motion parameters neither radiological results. Age significantly correlated with final degenerative changes (p<0.05).

Our data overlap current literature on what concerns functional results. Most of the parameters reach 80% of the contralateral side values. Lower extension values do not correlated with DASH scores, meaning those are still acceptable results for these patients. Carpal height ratio and scapholunate angles were preserved for the majority of the patients. We believe that the low rate of degenerative changes comparing to other papers could be explained by the shorter follow-up period. Age might pose as an important indicator for wrist arthritis.

EVALUATION AND MANAGEMENT OF TFCC INJURIES

OBJECTIVES / INTERROGATION: Our primary objective is to describe TFCC injuries that required treatment in three different clinical scenarios. Additionally, to correlate the physical exam and MRI with the arthroscopic findings.

METHODS: Retrospective study including 105 patients and 107 wrists with TFCC injuries treated arthroscopically between January 2015 and July 2018.

We included patients with DRUJ instability (69), ulnar impaction syndrome (25) and patients with arthroscopic indication different from TFCC injury (13). Only were included patients who required treatment. Patients with distal radius fracture were excluded.

TFCC injuries were classified according to Palmer and Atzei classifications.

All physical examinations and MRI results were compared with the arthroscopic findings.

No functional results were evaluated.

RESULTS AND CONCLUSIONS: From a total of 107 wrists, 63% presented type 1B injuries, 14% type 2A, 9% type 1C, 7% type 1A and 3% type 2C according to Palmer.

In the type 1B injuries group, 72% presented type 3 injuries and 27% type 2 according to Atzei.

In the DRUJ instability group 83% presented type 1B injuries. In the ulnar impaction syndrome group 40% presented type 1B injuries and 32% type 2A. In the miscellaneous group the findings were heterogeneous without trends.

In the main group 88% presented a positive fovea sign and 72% a positive ballottement test.

The DRUJ instability group and the ulnar impaction syndrome group they both presented a positive fovea sign in all cases. 97% of the DRUJ instability group and 40% of the ulnar impaction syndrome presented a positive ballottement test.

In the miscellaneous group those findings were not seen.

Only in three cases the MRI was entirely coincident with the arthroscopic findings.

The DRUJ instability appeared to be highly suggestive of proximal tear of the TFCC.

In patients with ulnar impaction syndrome we need to consider the existence both proximal and degenerative injuries.

The fovea sing seems to be highly sensitive for TFCC injuries, and the ballottement test highly specific for proximal tears.

The MRI not prove to be a useful tool to diagnose or rule out clinically relevant injuries of the TFCC.

KEYWORDS:
triangular fibrocartilage complex, arthroscopy, foveal tear, DRUJ instability, fovea sign, ballottement test.
RECONSTRUCTION OF THE DISTAL RADIOULNAR INSTABILITY BY USING THE EXTENSOR RETINACULUM

List of authors:
Samuel Ribak*, Alexandre Tietzmann¹, Tibério Vanomark Chaves Bezerra¹, Helton Hirata¹, Sérgio Gama¹
¹ Puc Campinas University (Cotia)

Objectives / Interrogation:
Disturbances of the distal radioulnar joint (ARUD) are relatively common and its instability presents a diagnostic and therapeutic challenge due to the biomechanical complexity of this joint.
In cases without arthrosis, where direct repair of CFCT is no longer possible, reconstructive techniques are the most indicated, but in general, they do not present satisfactory results.
Objective: to evaluate the effectiveness of extensor retinaculum in the treatment of chronic distal radioulnar joint (DRUJ) instability through clinical and radiographic results. Is it effective?

Methods: The casuistry consists of ten cases, three of which are female. The mean age was 41.75 years and the mean time between the trauma and the surgical procedure was 13 months. In the surgical technique, after the reduction and fixation of the (DRUJ), the extensor retinaculum is used, which is disinserted from its ulnar insertion, maintaining its support base in the third extensor compartment. Divided into two tapes that are traced and fixed to the ulna with metal anchors of 2.7mm under maximum tension. The kirschner wire and the immobilization are maintained for 6 weeks.

Results and Conclusions: Joint stability occurred in the postoperative period in 100% of the cases. There was improved DASH after surgery for all patients from 74.6 to 38.3. The EVA presented a mean decrease from 8.5 to 4.0, in the active postoperative period and 1.0 at rest. All joint movements evaluated were improved. There was a mean palmar grip strength gain from 13.5kgf to 19.0kgf. There was a statistically significant improvement of all these parameters, with the exception of joint range of motion. In the radiographic evaluation, in all cases, the DRUJ congruence was obtained in the immediate postoperative period.
Conclusion: the technique of using the extensor retinaculum to stabilize chronic lesions of the distal radioulnar joint is effective and obtains good clinical and radiographic results.

Radial Nerve Palsies Associated with Paediatric Supracondylar Humeral Fractures: A Caution in the Interpretation of Neurophysiological Studies

List of authors:
Roisin Dolan*, Aliabbas Moosa¹, Henk Giele¹
¹ Oxford University Hospital NHS Foundation Trust (Oxford)

Objectives / Interrogation: Traumatic and iatrogenic neurological complications associated with paediatric supracondylar humeral fractures are well recognised. The severity of the nerve injury associated with supracondylar humeral fractures can be difficult to assess clinically and relies upon clinical progression or absence of recovery and neurophysiology. It is accepted that complete nerve palsy with neurophysiological complete block and absence of clinical recovery after three months requires surgical exploration and reconstruction. However, we argue that even a partial nerve palsy that is failing to recover as expected by three months should be explored even when the neurophysiology suggests the nerve is in-continuity.

Methods: We report two cases of closed Gartland type III paediatric extension-type supracondylar humeral fractures treated with open reduction and internal fixation. Both children developed persistent post-operative radial nerve motor palsy. Neurophysiological studies sought prior to exploration indicated a degree of sensory nerve function in both cases, indicating a nerve in-continuity.

Subsequent surgical exploration revealed interfragmentary radial nerve compression at the fracture site at two levels in one case and at one level in the second case. The site of compression was excised and the nerve grafted. Excellent near normal radial nerve recovery was achieved except for the persistent loss of extensor carpi radialis function in the first child.

Results and Conclusions: We publish these findings to highlight the possibility of misinterpreting the incomplete nerve lesion and the neurophysiology of a nerve incontinuity, as a nerve that would spontaneously recover. At exploration, in these two cases, it was clear by the level of inter-fragmentary compression, that the nerve would not have recovered without surgical intervention. We discuss the short-comings in neurophysiology test interpretation that may lead to this synopsis.

We propose that the decision to explore a peripheral nerve should be based solely on clinical acumen. We recommend prompt referral and urgent surgical exploration of persistent peripheral neuropathy associated with supracondylar humeral fractures, even where the nerve palsy is partial and in the face of neurophysiological evidence of an intact nerve. Delays in referral vastly compromise nerve regenerative potential and increase the likelihood of secondary reconstructive procedures.

TRANSFER OF THE TRAPEZIUM MUSCLE FOR EXTERNAL SHOULDER ROTATION GAIN IN PATIENTS WITH BRACHIAL PLEXUS INJURIES

List of authors:
Samuel Ribak*, Alexandre Tietzmann¹, Helton Hirata¹, Gustavo Mohr¹, Mogar Dreon Gomes¹
¹ Puc Campinas University (Cotia)

Objectives / Interrogation: In brachial plexus injuries after complete neurological treatment (neurolysis, grafting, nerve transfers) and adequate physiotherapy, secondary surgery may still be required to improve shoulder stability and function. The external rotation of the shoulder is essential for daily functions, as it allows the patient to properly position the hand in the coronal plane of his body. The weakness of external rotation in the brachial plexus lesions keeps the upper limb in a vicious position of internal rotation and generates functional limitation in the simple daily activities.
Objective: to analyze the results of the surgical technique of transfer the trapezius muscle to obtain external rotation of the shoulder. It aims to evaluate the stability of the shoulder as an adjunct effect.

Methods: prospective study between June 2013 and December 2016. The technique of trapezius muscle transfer was performed in patients with brachial plexus injury, with deficit in stability and external rotation of the shoulder, with time lapse longer than 12 months of the accident or cases where there was no recovery (total or partial) after repair surgeries or nerve reconstruction. The casuistry consists of ten cases, all male, of traumatic origin, coming from motorcycle accidents. The mean age was 23.8 years (18 to 28), with average time between the accident and the muscle transfer of 20.8 months (13 to 30 months). Parameters such as shoulder movement arc, DASH score and degree of muscle strength were analyzed in the pre and postoperative periods.

Results and Conclusions: Results: The gain of the external rotation was on average 30°, with statistical significance (p <0.05%). In all cases there was improvement in shoulder stability, improvement of pain and satisfaction with the procedure. The DASH scores had an initial mean of 67 points and a final score of 36 points. Conclusion: In patients with chronic brachial plexus injury, the transfer of the trapezius muscle to obtain external rotation of the shoulder is effective and presents good clinical results. With this technique, good shoulder stability is obtained, providing an improvement in the quality of life of these patients.

BRAQUIAL PLEXUS: NEW ADULT AND CHILDREN DIAGRAM OF DIVISIONS AND CORDS.

List of authors:
junot neto*
1 universidade do Estado do Rio de Janeiro - UERJ (Rio de Janeiro)

Objectives / Interrogation: Demonstrate the positioning of the divisions and cords of the brachial plexus of the adult and the child.

Methods: The work consists of 10 brachial plexus of adult men dissected by the same team. The findings were compared with the literature through a review including articles of interest in the area.

Results and Conclusions: We find the same anatomy in the 10 dissected plexuses. Contrary to what most diagrams represent, we observe that all posterior divisions have superior and posterior positioning, whereas anterior divisions have inferior and anterior positioning. Reviewing articles published in the literature, we have identified conflicting results. In the articles involving dissection of adult, the results were similar to ours, we identified reports of 254 dissected brachial plexuses and all had the same anatomical position described previously. We observed different positioning when the articles used infantile brachial plexuses. 340 dissections were analyzed and all were different from the adult brachial plexus. In the infantile plexus, the posterior divisions of the upper and middle trunk had inferior and posterior positioning, while the posterior division of the inferior trunk had superior and posterior positioning. The anterior divisions of the upper and middle trunk had superior and anterior positioning, whereas the anterior division of the lower trunk had inferior and anterior positioning. The lateral cord was formed by the anterior divisions of the upper and middle trunk as well as in the adult, but it was the most cranial cord among all, while in the adult it was central. The posterior cord was formed by the fusion of all posterior divisions not differing from the adult, but it was situated in a central position, while in adult was the most superior of all. The medial cord is similar between the infantile and adult plexus, being formed by the continuation of the anterior division of the inferior trunk and still considered the lower cord of all. The differences between the anatomy of the brachial plexus for children and adults are evident. We know that the nerve roots in the child are more horizontal and that at the end of growth they end up positioning obliquely and posteriorly, however, it is clear that the modifications are not restricted only to the roots, but also to the positioning of the divisions and cords. Unifying the graphical representation of the brachial plexus of adults and children is a serious error because it does not represent reality.

Comparison of Hand Surgery Exposure in U.S. Plastic and Orthopaedic Residency Programs

List of authors:
Steven Koehler\textsuperscript{1}, Neil Shah\textsuperscript{1}, Kate Krucoff\textsuperscript{2}, Suhail Mithani\textsuperscript{2}
\textsuperscript{1} SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)
\textsuperscript{2} Duke University Medical Center, Department of Plastic and Reconstructive Surgery (Durham)

Objectives / Interrogation: Pursuit of hand surgery fellowship in the United States is primarily sought after by those with residency training in orthopaedic surgery or plastic surgery. Given these different pathways to reach fellowship, there currently remains uncertainty regarding the disparities in case volume or exposure which may exist between both these training pathways. This study sought to highlight the case volumes of residents over a 5-year period and identify any differences.

Methods: The Accreditation Council for Graduate Medical Education (ACGME) case logs between 2012 and 2016 were obtained for residents in orthopaedic surgery and plastic surgery programs. National mean number of procedures performed per resident were extracted and organized into one of 12 procedure categories. Chi-square analysis was employed to evaluate whether the distribution of cases varied across the study period for each training pathway.

Results and Conclusions: Procedures sharply differed between residents and fellows in plastic surgery and orthopaedic surgery.

Orthopaedic surgery trainees performed a lower proportion of the following procedures: incision/excision, repair/reconstruction, amputation, nerve repair/reconstruction, neuroplasty, primary closure, and skin graft. Conversely, plastic surgery trainees performed fewer intro/removal, open or closed fracture treatment, arthroscopy, and replant/revascularization procedures.
Overall disparities exist in case exposure between plastic surgery and orthopaedic surgery trainees. Overall, orthopaedic surgery trainees do not appear to be receiving a similar proportion of soft tissue and nerve procedure volume as do their plastic surgery counterparts prior to hand fellowship.

Early Active Vector Adjustable Skin Traction (EAVAST) for phalangeal fractures of the hand

List of authors:
Jason Lam*, Jason Fairclough¹, Jason Diab¹, Stephen Wood¹, Queenie Chan¹, Michael Dowd¹
¹ NSW Health, Sydney University (Sydney)

Objectives / Interrogation: The study aimed to determine the efficacy and outcomes of EAVAST in the treatment of middle and proximal phalangeal fractures in comparison with surgical management.

Methods: A retrospective cohort study has reviewed the outcomes of middle and proximal finger phalangeal fractures managed by EAVAST (n=54) compared to surgical cases (n=47) in a public hospital over a 3-year period. Age range was 13-77 years. Outcome measures utilized included total active motion (TAM), clinical outcome measures (Belsky criteria), and grip strength. Main method of treatment was used for analysis grouping.

Results and Conclusions: In finger fractures at eight weeks post fracture, a mean 230° TAM (95% CI range 90°-285°, SD 34.2) was achieved with traction (n=54) compared to mean 198° TAM (95% CI range 50°-286°, SD 54.8) for surgical cases (n=47). The results were statistically significant (p<0.001). In the traction group, results were excellent in 18%, good in 41% and poor in 33% cases by Belsky’s criteria. In the surgical group excellent results were present in 9%, good in 28% and poor in 50%. There were no significant differences in grip strength between the traction and surgical groups.

The groups were similar in age and handedness, the traction group received more comminuted fractures (61%) than the surgical group (43%). ANOVA regression analysis showed age to be statistically significant in effect on data variation (p=0.026). Intra-articular classification (p=0.08), comminution (p=0.91), and location of fracture (p=0.41) were not statistically significant.

The traction group had less complications (5%) than the surgical group (22%).

This study shows EAVAST may provide improved TAM and clinical outcomes compared to surgery with less complications and should be considered an effective option for the management of middle and proximal phalangeal fractures of the hand.

Anteromedial release for post-traumatic flexion pronation contracture of the wrist.

List of authors:
Inma Puig de la Bellacasa1, Marc Garcia-Elias2, Dirck Añaños Flores2, Richard Jamieson3
1 Hospital Universitari Mutua Terrassa (Terrassa)
2 Institut Kaplan Barcelona (Barcelona)
3 Royal Hobart Hospital (Hobart)

Objectives / Interrogation: To propose a novel surgical technique to treat patients with wrist stiffness due to a soft tissue contracture in flexion-pronation after injuries or cast immobilisation.

Methods: Lack of extension and radial deviation, presented as a form of wrist stiffness, is related to multiple entities and has its own pathomechanics (ligament injury, tendon injury, pronator quadratus muscle disruption, scar retraction) that originate in the volar-ulnar compartment of the wrist.

Indeed, no soft-tissue release will ever correct bone deformity or joint incongruity, which is the most common cause of pronosupination loss, and must be corrected prior to addressing soft tissue contractures.

Not infrequently, however, there is a concomitant soft-tissue contracture that causes pain which should not be underestimated, and this is the object of our technique.

Lee et al. classified wrist stiffness into intrinsic and extrinsic aetiology. Most intrinsic adhesions are best managed arthroscopically while multilevel extrinsic contractures are more complex and require an open approach. Once an extrinsic mechanism has been recognised the anteromedial release has been tested in some patients by our group and has been shown to safely improve range of motion without destabilising or denervating the joint.

It requires minimal postoperative immobilisation, permitting rehabilitation in two weeks with good results.
Results and Conclusions: We have observed that stiffness limiting extension and radial deviation comes from the volar-ulnar compartment. It is a rare occurrence after wrist injury but can result in significant disability if it persists despite conservative management. In these cases, surgery is indicated.

We propose a safe and predictable technique to access the volar-ulnar corner, not only the distal radioulnar but also the ulnocarpal and midcarpal Space of Poirier. This approach offers a good therapeutic option for this particular form of extrinsic stiffness of the wrist. It is important to protect the surrounding anatomy in order to avoid further injury.

Ulnar shortening osteotomy: using a novel compression technique

List of authors:
Abdel hakim hakim Massoud1, Ahmad Akar1, Tarek badr1, Amro Fouad1, Nash Naam2
1 Al Azhar Faculty of medicine (Cairo)
2 Southern Illiniois Hand Center, Southern Illinois University (Effingham)

Objectives / Interrogation: Positive ulnar variance is one of the problems that cause ulnar sided wrist pain. Ulnar shortening osteotomy may be recommend to decompress the ulnar carpus and TFCC.
A novel technique of ulnar shortening osteotomy using the AO axial compression principle in a reversed compression direction used to achieve fracture simultaneous compression and shortening.

Methods: A prospect case series study was conducted on 19 patient with positive ulnar variance, 8 of them had post traumatic radial shortening. The average age was 35.6 years, the dominant hand involved in 10 patients. The osteotomy was performed using power saw with 2 mm thick blade, 7-8 cm proximal to the DRUJ, if the desired amount of shortening is less than 3mm, a single cut was performed started at the medial border of the ulna and directed proximal and lateral. The distal fragment was fixed first with a small LC-DCP plate, then the plate was fixed tho the proximal fragment in eccentric position of the hole. The direction of the osteotomy and the axial compression of the fracture in a reversed way allow proximal slide of the distal fragment and fracture compression.

Results and Conclusions: After a mean follow up of 3.2 years, ulnar sided wrist pain improved on VAS from 6.3 to 1.9. The mean Mayo wrist score improved from 46 to 77 points and the Q-DASH score improve from 52 to 15. Non of our patient developed DRUJ instability or impingement. The technique used in this study is simple and effective in treatment of ulnar impaction syndrome specially when special instrument and expensive implant for ulnar shortening are unavailable.

Axillary Hidradenitis Suppurativa in Female: Excision and Reconstruction by Axillary Flap

List of authors:
Nurrunahar Begum*, Tanveer Ahmed1, Abul Kalam1
1 Dhaka Medical College (Dhaka)

Objectives / Interrogation: Hidradenitis suppurativa is a chronic, recurrent inflammatory condition of the apocrine sweat glands. It usually involves axilla and females are more prone to developed infection. Initially though it is confined to apocrine sweat glands but later through recurrent infections it involves other glands and subcutaneous tissue leading to extensive tissue destruction and fibrosis. This chronic debilitating disease had widespread functional and psychological implications. Patients face difficulty in maintaining personal hygiene; more prone to recurrent infection and also had a poor quality of life. There are different modalities of treatment ranging from conservative treatment to surgical excision and coverage of the defect by primary closure, skin graft and flap coverage. Axillary flap is a suitable option for coverage of the defects as it provides a reliable, effective and simple method of treatment.

Methods: A prospective, observational study was design to conduct in Burn & Plastic Surgery Unit, Dhaka Medical College Hospital over a period of 3 years from January, 2016 to till date. 15 axillary flaps were done for reconstruction of axillary defect after wide local excision of all hair bearing skin and subcutaneous tissue in 10 patients with hidradenitis suppurativa. Excised tissue was sent for histopathology in all cases. The patients were observed for one year postoperatively for functional and aesthetic result and for any complications or recurrence.

Results and Conclusions: All fifteen flaps were survived with excellent outcome. One patient developed recurrent lesion. Donor site was closed primarily in all cases. All operations were done under general anaesthesia. Histopathology report reveals granulomatous inflammation suggesting tuberculosis in 3 patients which was treated by anti tubercular hemotherapy. Mean hospital stay was 14 days. All are female with age range from 20 to 35 years. About 50% patients had bilateral lesion. On functional evaluation full range of movement of shoulder joint was preserved. Axillary flap is a functionally useful and aesthetically acceptable option for reconstruction of the axillary hidradenitis suppurativa.

Wide Awake and ultrasound guided release of the lacertus fibrosis for chronic exertional compartment syndrome of the forearm. A prospective study.

List of authors:
Gilles Candelier*, Yann Erwan Favennec¹, Thomas Apard¹
¹Hand and Ultrasound surgery center, Private Hospital St Martin (Caen cedex)

Objectives / Interrogation: Chronic exertional compartment syndrome is a common condition in athletes and motorcyclists. The purpose of this study was to confirm our hypothesis that exertional compartment syndrome was due to a pronator median nerve entrapment at the lacertus tunnel.

Methods: We conducted a prospective study from January 2016 to August 2017. All the patient who complains for an exertional compartment syndrome (ECS) were included. The diagnosis of ECS was based on the existence of a pain appearing with effort and disappearing at rest, a weakness (grip) during effort and an elevated compartment pressure (>50mmHg). All the patients have had a clinical exam including muscle testing, a scratch collapse test and the search of a Tinel sign at the elbow.

Surgical procedure:
Anesthesia: The patient is anesthetized 30 min preoperatively using 30-40 ml 1% lidocaine with epinephrine and buffered (sodium bicarbonate) solution. We performed an hydrodissection assisted with an ultrasound guidance. An ultrasound evaluation of the relative motion between the median nerve and pronator muscle was made to entrapment. A limited incision is done at the proximal edge of the lacertus fibosus. The release of the lacertus fibrosis was done from proximal to distal. A second ultrasound evaluation is made to confirm that the median nerve entrapment had disappeared. A muscle testing was made. All the patients were reviewed 6 months after surgery.

Results and Conclusions: Results: We included 7 patients (all men) with an average of 26 years (17-42). The group included 5 competition motorcyclists, 2 around the world sailors. Symptoms have lasted an average of 12 months. Both hands were involved. In all patient the muscle testing revealed a typical pattern of weakness attesting to a pronator median nerve entrapment. The scratch collapse test was positive. Immediately after the release, muscle testing was normalized. One week after surgery all patients were free of symptoms. Two patients have had a second compartment pressure evaluation. It was normalized. At the last follow up all the patients could resume normal exertional activity.

In conclusion, the study emphasizes that ultrasound guided lacertus fibrosus release is a safe method to treat chronic exertional compartment syndrome. The length of surgery, recovery time and scar sequelae are less significant. Furthermore, this study points out the claw effect of the lacertus fibrosus as an etiology of the exertional compartment syndrome.

Clinical outcomes in revision carpal tunnel decompression using the AxoGuard nerve protector

List of authors:
RaviKanth Mallina*, Pieter Jordaan¹, Dominic Power¹
¹ Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Carpal tunnel release is associated with revision rates of 5-9%. Recurrent symptoms may be associated with perineurial scar formation and impaired nerve glide during functional movement of the wrist and flexors. An extended exposure of the median nerve with revision decompression and neurolysis is the recommended treatment, however the outcome of surgery is less favourable than for primary decompression surgery. We report a single institution experience of using porcine submucosa extracellular matrix (AxoGuard® AxoGen Inc., Alachua FL) in revision carpal tunnel surgery.

Methods: All patients undergoing revision carpal tunnel decompression and wrapping with an AxoGuard nerve protector between 2013 and 2018 were identified from a database at a regional hand and peripheral nerve injury service. Data capture included patient demographics, pre-and post-operative pain scores, sensation, Tinel's sign, DASH score and patient satisfaction. assessed by DASH score were recorded.

Results and Conclusions: Results
Thirteen patients with recurrent carpal tunnel compressive neuropathy were treated with revision release and AxoGuard nerve protector wrapping during the study period. The mean age at revision surgery was 42 years (range 24 to 79 years) and the mean follow up period was 42 months (range 4-36 months). The indication for application of the AxoGuard nerve protector was severe epineural scarring which was noted in all patients. Post-operative pain levels on a visual analogue scale improved from 8 to 3 (p<0.05) and subjective sensory improvement was from of 4 pre-operatively to 7 post-operatively using a 10/10 scale. All but one patient with neurofibromatosis reached the minimum clinically important difference in DASH score. Following revision surgery, absence of Tinel's sign was noted in all patients. In the current series there were no complications associated with the use of porcine submucosa extracellular matrix as a nerve wrap.

Conclusions
The application of a porcine submucosa extracellular matrix wrap as an adjunct to revision decompression and neurolysis of the median nerve is an effective treatment for patients with severe epineural scar formation and adhesions. This pilot study has defined the treatment and assessment protocol. A large scale multi centre randomised controlled trial comparing simple decompression versus decompression and adjunctive wrapping in revision carpal tunnel surgery is required to evaluate the outcomes further.

Evaluation for fracture type of mallet finger

List of authors:
Kosuke Sasaki*, Yoshitaka Tanaka¹, Hiroyuki Gotani¹
¹ Osaka Ekisaikai Hospital, Japan Seafarers Relief Association (Osaka)

Objectives / Interrogation: The purpose of this study was to determine whether only one extension block Kirschner-wire was sufficient fixation for mallet finger fractures.

Methods: We reviewed 33 cases with a mallet fracture, involving more than one-third of the articular surface, with or without volar subluxation of the distal phalanx. There were 12 females and 21 males with a mean age of 35.4 years (15 to 62). A case injured his index finger, thirteen cases their middle finger, thirteen cases their ring finger, and six cases their little finger. We measured transverse diameter of the proximal fragment and whole distal phalanx in the axial view of computed tomography (CT), then ratio of proximal fragment size was calculated. The fragment deviation from center of distal phalanx was evaluated in the three dimensional reconstruction image of CT. The deviation defined the percentage which the length between fragment center and whole distal phalanx center divided by transverse diameter of the proximal fragment and whole distal phalanx.

Results and Conclusions: The mean joint surface involvement was 50.6% (33% to 71.7%) in sagittal view of CT. The average of transverse diameter and ratio of the proximal fragment was 7.4mm and 75.2%, respectively. There was the case whose proximal fragment was less than half of distal phalanx diameter. The mean deviation from center of distal phalanx was 3.1%. The largest deviation was 10.3%. The proximal fragment was broken into 2 pieces in the 2 cases. In conclusion, in the case of one part fragment, it was able to support the proximal fragment with the central extension block of distal phalanx. But in the case of two parts fragment, one part was supported with the extension block, whereas another part was not supported. And so, only one extension block may be insufficient. We evaluated the size and the deviation of the proximal fragment by CT. It was difficult to evaluate correctly them by plain radiograph, therefore the preoperative CT evaluation was useful. In the future, the injury mechanism should be solved for the case of two parts fragment.

Lipofibroma Hamartoma of the peripheral nerves of the upper extremity. Analysis of twelve cases.

List of authors:
Roberto Adani*, Tos Pierluigi, Stefano Colopi, Giovanna Petrella, Filippo Pantaleoni
1 Hand and Microsurgery Department, Modena, Italy, Policlinico di Modena (Modena)
2 Hand and Microsurgery Department CTO Gaetano Pini (Milano)
3 Radiology Department ASST Mantova ospedale Carlo Poma (Mantova)
4 Hand and Microsurgery Department, Policlinico di Modena (Modena)
5 Orthopedic Department, Modena, Italy, Policlinico di Modena (Modena)

Objectives / Interrogation: Lipofibromatous Hamartoma (LFH) is a rare condition that involves diffuse infiltration of peripheral nerves by normal appearing fibrous and adipose tissue. The epineurium and perineurium are enlarged and distorted by excess fatty and fibrous tissues that infiltrate between and around nerve boundaries. The cause of LFH remains obscure; the tumor is usually present at birth and may be associated with digital enlargement. In the upper extremity, the median nerve is the most commonly involved but also the radial nerve and branches, the ulnar nerve and branches and even the entire brachial plexus may be interested.

Methods: In the period between 1989 and 2017 twelve patients (7 men and 5 women) were observed. The mean age was 20.4 year (range 35 to 15 years). Three patients had associated macrodactyly. Child with macrodactyly under age of 14 years old were excluded from this study. All patients showed a palpable mass, with sensitive peripheral nerve signs in 10 cases; MR examination was done in all cases.

The median nerve and its branches were involved in 10 cases, the ulnar and radial nerves respectively in one case. Open carpal tunnel release was done in 5 cases with the aim to decrease motor and sensor impairments. Microsurgical intra-neural dissection with partial excision of the fibrofatty tissue of the neoplastic elements of the median nerve was performed in two cases. The median nerve was resected and grafted in one case.

Two cases involving the radial and ulnar nerves were treated with fascia decompression and epineurolysis. Two cases of LFH of the median nerve were under observation.

Results and Conclusions: Four patients had a regression of neurological symptoms after carpal tunnel decompression. Microsurgical dissection generated disappointing results in both cases treated. Poor sensory recovery was recorded when the entire median nerve was excised and reconstructed with sural nerve grafts. Any improved function was reported in the radial and ulnar nerves after fascia decompression and epineurolysis. MRI is a valid a valid support in the preoperative differential diagnosis. Biopsy is not routinely recommended owing to potential functional deficits; The role of microsurgical debulking procedure remains unclear. On the basis of our experience and after reviewing the literature, the treatment should be limited to decompression of the ligament or fascia over the involved nerve; an epineurolysis may be additionally performed.

Corrective osteotomies of the radius: Grafting or not?

List of authors:
Roberto Adani¹, Raffaele Mugnai², Debora Lana³, Luigi Tarallo³
¹ Hand and Microsurgery Department, Modena, Italy, Policlinico di Modena (Modena)
² Hand and Microsurgery Department, Policlinico di Modena (Modena)
³ Orthopedic Department, Modena, Italy, Policlinico di Modena (Modena)

Objectives / Interrogation: One of the most common complications following distal radial fractures is malunion, especially when treated with closed reduction and cast immobilization. The aim of this study is to review the current literature regarding corrective osteotomies to provide the best evidence of the rule of bone grafting.

Methods: Our MEDLINE literature search included 280 studies using the following key words "Malunited distal radius fracture" and 150 studies using key words "Corrective osteotomy of the distal radius". Inclusion criteria were: Malunited distal radial, extra-articular fracture, volar locking plate, use of iliac bone graft (cancellous or corticocancellous), non-use of bone graft. Twelve studies met the inclusion criteria.

Results and Conclusions: Seven of the 12 studies considered, described the use of a graft; the remaining five studies didn't use any graft. Type of malunion was dorsal in most of the studies. The healing time was comparable using the graft or not (mean 12.5 weeks), ranging from 7.5 to 16 weeks. The mean disabilities of the arm, shoulder and hand score improvement was 23 points both in the studies that used the graft and in those not using the graft. This review demonstrated that corrective osteotomy of extra-articular malunited fractures of the distal radius treated by volar locking plate does not necessarily require bone graft. Maintaining a volar cortical contact following corrective osteotomy is important to ensure the physiological transmission of the force vector through the synthesis, and, in this case, the use of bone graft is not necessarily required. Bone grafts however, remain a valuable support, especially to fill gaps when a large defect is created.

Advancement of Homodigital Neurovascular Island Flaps

List of authors:
Jin Xi Lim*, Alphonsus Khin Sze Chong¹, Sandeep Sebastian¹
¹ National University Health System (Singapore)

Objectives / Interrogation: Homodigital neurovascular island (NVI) flaps are used for reconstruction of pulp defects. Previous articles have reported up to 22mm of flap advancement, although it is not clear from these studies, how flap advancement was measured and if flexion of the digits were required and to what extent. In our practice, we have not been able to achieve this degree of advancement. The aim of this study is to determine the maximal advancement of a homodigital neurovascular island flap. We hypothesize that extent of flap advancement correlates to the extent of dissection and the length of digit.

Methods: 27 cadaveric digits were dissected. The distance from the fingertip to the flexion creases for the distal interphalangeal joint (DIPJ), proximal interphalangeal joint (PIPJ) and palmodigital crease (PDC) for the fingers and interphalangeal joint (IPJ) and PDC for the thumb were marked and measured. A 1x1cm flap was designed on the radial and ulnar aspect of the pulp and sequentially elevated till the proximal interphalangeal joint crease, PDC, and bifurcation of the common digital artery. The ulnar digital artery of the index, middle and ring finger were then sacrificed and the flap dissected till the superficial palmar arch. The advancement of the flap at each dissection point was recorded.

Results and Conclusions: Average advancement following dissection till the PIPJ crease, the palmo-digital crease, following division of adjacent digital artery and till the superficial arch were 8mm (SD 2.5), 12mm (SD 3.6), 16mm (SD 2.8) and 19mm (SD 4.6) respectively. When dissection was done till the palmodigital crease, it was found that advancement was 20% of the digit length. We found that the Homodigital NVI flap could be advanced for a maximum of 19mm when dissection was carried out till the superficial arch with the digit fully extended. In addition, the degree of advancement can be predicted based on the length of the finger and is approximately 20% of finger length. We suggest that in future studies of flap advancement, authors should specify the method of measurement and quantify, if any, the degree of flexion of the PIP joint and MPJ. This will allow us to have a more accurate indication of flap advancement.

The abduction system of the fifth finger. An anatomic and electromyographic study

List of authors:
Daniel Postan*, Luciano Poitevin

1 Buenos Aires Medical School (Capital Federal)
2 Buenos Aires University Hospital (Buenos Aires)

Objectives / Interrogation: The purpose of this research is to study the role of the EDQ and the hypothenar muscles in the abduction of the fifth finger in a cadaveric and electromyography study.

The abductor digiti quinti and flexor digiti quinti are both typically considered the prime abductors of the fifth finger. This movement can be impaired in clinical situations such as ulnar neuropathies and post-burn scars on the hypothenar region. The extensor digiti quinti (EDQ) has been used as a tendon transfer and there is evidence that its rerouting improves the abduction of the fifth finger.

However, the abduction ability of the EDQ compared to the hypothenar muscles, has not been studied so far, to our knowledge. Does the EDQ have an abduction action?

Methods: 10 cadaveric fresh frozen hands were studied. A 1.5 Newton traction was sequentially exerted on the abductor digiti quinti, flexor digiti quinti and EDQQ. The resultant angle between the fourth and fifth finger was measured.

5 volunteer healthy patients were studied by means of an electromyography protocol. While performing abduction of the fifth finger, the electric activity on the hypothenar eminence and the extensor digiti quinti was recorded.

Results and Conclusions: Results
The EDQ abducted the finger 32.4° in average (CI95% 28.62-35.38), the abductor digiti quinti 39.9° (CI95% 35.22-44.58), and the flexor digiti quinti 31.2° (CI95% 26.21-36.18). There are significative statistical differences (p>0.05) between the degrees abducted by the EDQ and the flexor and abductor digiti quinti. During abduction, the electromyography noted synergic activity between the hypothenar muscles and the EDQ.

Conclusions
The fifth finger abduction system is constituted by two components: a) intrinsic - the hypothenar muscles - and b) extrinsic - the EDQ -. Both elements act simulataneous and synergically. This fact may suggest that the extrinsic part may still be abducting the fifth finger even when the hypothenar component is absent. Even though the EDQ featured less abductor power than the abductor digiti quinti, the amount of angular variation in the cadaveric experiment suggest a significant abductor role of the EDQ in clinical situations.

Total Wrist Arthroplasty in Rheumatoid and Posttraumatic Arthritis: Highly different survival rates

List of authors:
Martin Chochole*
1 Herz Jesu Hospital Vienna (Vienna)

Objectives / Interrogation: Introduction: Total Wrist Arthroplasty (TWA) in painful panarthritis is to establish a stable, painfree wrist to cope with daily life. Even with newer designs the procedure's prognosis would remain uncertain. Numbers of implants in the US would not differ between 2008 and 2016. Progressively older patients preferably with rheumatoid arthritis are operated on. Aim of the study was the comparison of revision free post-OP time and total implant survival between the two entities.

Methods: Material and Method: Between 2002 and 2018 31 patients received UNI 2 total wrist arthroplasty KMI. 18 of these were included. 9 Cases in either group with rheumatoid or post traumatic arthritis. Rheumatoid patients: n=8 (1M,7F -1operated on both wrists) age at surgery 65,5 years, with Carpus Simmen Stadium 1+2, 6 with long lasting Cortisol. In the Group of posttraumatic patients: n=9 (6M,3F; mostly SLAC Wrist) age at index surgery was 64 years.

Results and Conclusions: Results: In the rheumatoid patients group first revision n=5 (Changing of polyethylene (PE) alone or together with carpal plate) was done at an average of 47 months. Arthrodesis either as immediate and final solution or as secondary or even tertiary revision was undertaken after 85 months n=6. In the post traumatic group revision meant exclusively changing of the polyethylene layer after a period of 112 months. None of the bony implants was loose. In only one female patient with demand of walking aids arising after index surgery arthrodesis was done 36 months after implantation. 4 other implants stay symptomless with a follow up of 75,5 months. The difference is statistically significant.

Early results of TWA were encouraging. Midterm results in mixed indications showed 90% survival rate. An own FU showed 50% failure rate in rheumatoid patients after 5 years. Initial symptoms of PE wear are reported to be carpal tunnel syndrome due to synovitis and metallosis later on. In the literature recommendation is given for TWA in older patients and rheumatoids although TWA and arthrodesis will not differ markedly in quality of life. Our data let entertain grave doubts about TWA in rheumatoid arthritic patients. We now prefer arthrodesis over TWA in this group. Numbers of implantation in post traumatic wrists growing in adverse.

Does pre-operative depression and anxiety affect outcome after trapeziectomy?

List of authors:
Flossie Carpenter¹, Thomas Fleming¹, Julia Blackburn¹, Rouin Amirfeyz¹
¹ Bristol Royal Infirmary (Bristol)

Objectives / Interrogation: Trapeziectomy is used to treat osteoarthritis of the carpo-metacarpal joint. Depression associated with osteoarthritis is a well-established phenomenon and dissatisfaction may be linked to the patient’s mood pre-operatively. The objective of this study is to explore the association of pre-operative anxiety and depression with functional outcome for thumb pain and function before and after trapeziectomy.

Methods: Twenty-two consecutive patients undergoing trapeziectomy completed pre-operative Hospital Anxiety and Depression Scale (HAD) and quickDASH (DASH) pre and post-operatively. Median results are reported. Non-parametric statistics were used to evaluate the relationship between variables.

Results and Conclusions: Results
Twenty-two patients, 18 female and 4 males, with a median age of 63 (IQR 57, 66) years were recruited to the study. Median follow up was 38 months. Fourteen right and 8 left trapeziectomies were performed. Median pre-operative DASH was 58 (IQR 43, 70) and 18.1 (IQR 4.5, 35) post-operatively (p < 0.001).

Fourteen participants showed evidence of anxiety or depression: 6 mild, 5 moderate and 3 severe.

DASH improved by 36 points with or without evidence of anxiety or depression. Pre-operative DASH increased with HAD (p = 0.02) and across HAD categories: none 52, mild 49, moderate 61 and severe 75.

Change in DASH increased with HAD category: none 36, mild 32, moderate 34, severe 49 but no statistically significant difference among groups was seen (p = 0.59).

Post-operative DASH tends to be worse if HAD is moderate or severe, 27 and 25, than none or mild, 19 and 17.

Conclusions
The difficulty of interpreting pre-operative anxiety or depression and outcome after trapeziectomy is establishing a causal relationship. Although the greater improvement is seen the more severe pre-operative anxiety or depression, absolute post-operative function tends to be worse. This study suggests that trapeziectomy offers equal functional improvement in the presence of POAC or without.

Keywords: trapeziectomy, anxiety and depression, osteoarthritis
Case Report: Lipofibromatous hamartoma of the digital branches of median nerve

List of authors:
Amal Sharaf*, David Mather
1 Mid Yorkshire Hospitals NHS Trust (Wakefield)

Objectives / Interrogation: Lipofibromatous hamartoma is a rare benign tumour which is characterised by diffuse infiltration of peripheral nerves by fibrous and adipose tissues.

In 2013, a comprehensive literature review by Tahiri et al. reported that there have been 180 known cases of lipofibromatous hamartoma of the median nerve published in literature; to the best of our knowledge there have been approximately 10 more cases published since that time.

We are reporting a case of lipofibromatous hamartoma of the median nerve in the hand and its digital branches.

Methods: Case Report:

A 39-year-old lady presented with gradually decreasing sensations along the ulnar border of her thumb for six months. She reported having a swelling affecting her thumb since birth. Examination revealed soft non-tender lump on the first web space and ulnar side of the thumb with some numbness and no motor deficit.

MRI scan showed thinly capsulated non-enhancing lobulated predominantly fatty lesion centred around the median nerve and its digital branches in the hand and wrist. The fat was noted to insinuate between the nerve fibers. The appearances were in keeping with lipofibromatous hamartoma.

Median nerve was explored, and its branches were identified. The ulnar digital nerve of thumb was totally taken over by disease and therefore excised. The radial digital nerve of the index was involved at flexor zone 2; the lesion was dissected without nerve interruption.

Microscopic examination showed multiple nerve bundles and Pacinian corpuscles surrounded large amounts of mature fibrofatty tissue. The nerve fascicles themselves were preserved and showed only perineural fibrosis. These features confirmed the diagnosis of lipofibromatous hamartoma.

Results and Conclusions: Lipofibromatous hamartoma is a rare and benign fibro-fatty tumour of unknown etiology. To date, there have been less than 200 cases reported in literature. Approximately one third of the cases had associated macrodactyly.

MRI scan is pathognomonic modality for Lipofibromatous hamartoma diagnosis. Treatment options range from observation of asymptomatic cases to prophylactic carpal tunnel release with or without neurolysis in symptomatic patients. A biopsy is recommended with carpal tunnel release to confirm diagnosis. Treatment of macrodactyly, if present, should be addressed separately.

Ultrasound-guided carpal tunnel release - a new technique by using a tissue-preserving cutting device

List of authors:
Sebastian Kluge*, Rainer Litz, Georg Feigl

1 Handchirurgie Seefeld, Klinik Impuls Wetzikon (Zürich)
2 Hessing Hospital, Departement of Anaesthesiology (Augsburg)
3 Medical University of Graz, Division of Macroscopic and Clinical Anatomy (Graz)

Objectives / Interrogation: Ultrasound-guided carpal tunnel release (UGCTR) is a new minimal-invasive treatment option for patients with carpal tunnel syndrome. Compared with an open procedure it has the advantage to place the incision outside the weight bearing zone and, therefore, to limit the risk of pillar pain. Related to an endoscopic treatment a continuous visualization of the nerve and its related structures is possible.

Methods: UGCTR was performed in twenty Thiel-embalmed cadaver extremities using a U-shaped cutting device with a cutting edge protected by its specific location inside the U. The individual anatomy was sonographically investigated to rule out anatomical abnormalities and to localize the course of the median nerve, the flexor retinaculum (FR) and the superficial palmar arch (SPA) prior to the treatment. A small incision along the distal wrist crease ulnar to the palmaris longus tendon was made, the distal forearm fascia was incised, and the flexor retinaculum was divided under permanent sonographic visualization, changing repeatedly from a longitudinal to a transverse view.

Results and Conclusions: The study was performed using a researcher-blinded protocol. UGCTR was performed by a hand surgeon followed by a dissection by an anatomist to proof the complete separation of the FR and the exclusion of any lacerations of relevant structures. The study results will be presented.

UGCTR allows a controlled dissection of the FR with an permanent visualisation of the median nerve and the SPA. The length of the surgical incision can be reduced and transferred to a non-weight bearing area to limit the risk of postoperative scar tissue pain. Therefore UGCTR seems to have some advantages over an endoscopic or open carpal tunnel release.

The avascular proximal pole nonunion treatment with NVBG from radius, open or arthroscopically: a role for core decompression and biophysics.

List of authors:
Pier Paolo Borelli*1, Alessandro Fagetti2
1 Casa di Cura San Camillo (Brescia)
2 SSD Microchirurgia e Chirurgia della Mano ASST Settelaghi (Varese)

Objectives / Interrogation: There is a general consensus about the indications of a VBG, but up to now there is no evidence for technique superiority between VBGs and NVBGs. There is still no consensus on definition of avascular necrosis of the PP: x-ray, CT scan, MRI, histology, or bleeding points at surgery.
Since some years, arthroscopy has been proposed for proximal pole nonunion, even with vascular impairment, using a spongious NVBG to fill the emptied PP.
It is well known that the metaphyseal core decompression of the distal radius can incite hyperaemia and, more recently underlined, can stimulate regional bone regeneration factors, the Bone Morphogenetic Protein-2 BMP-2 to accelerate revascularization of a necrotic lunate or even of a scaphoid avascular proximal pole non-union (APPN). Even the biophysical treatment has been recognized to be able to stimulate BMP-2.

Methods: 13 patients, between 18 and 30 years, with scaphoid APPN confirmed at surgery by the absence of bleeding points, with obvious need for volar grafting detected by CTCB, has been treated through a mini-invasive volar approach, characterized by:
- a volar NVBG, spongious or corticospongious only in case of shortening of the bone, harvested from distal radius, producing a metaphyseal core decompression.
- a stable fixation by means of an headless screw with a short leading thread, or 2 Kirschner wires, when the proximal pole, after debridment in nearly emptied, making impossible a volar screw fixation. Technical details of Kirchner wires stable application, are shown.
- an early biophysical treatment (CCEF) therapy, for at least 2 months.
Arthroscopic Bone Graft (2 pts.) is based on the same technical aspects, harvesting the spongious bone graft from the dorsal radius.

Results and Conclusions: Results
Radiological union was obtained in all patients with obvious proximal pole revascularization, detected by CBCT or MRI, with gadolinium when need. Optimal ROM recovery was observed, without any functional limitation, even when Kirschner wires are still in place after many years.

Conclusions
The technical aspects of this approach are similar to the increasingly popular Arthroscopic Bone Graft in APPNs, but performing a longstanding stable fixation is easier with open surgery. In practice, as long as the proximal pole is intact and the cartilage is good it is possible to have its revascularization even with a NVBG, open or arthroscopically. VBG still remains a correct indication after failed fixation with NVBG, but it is not an absolute indication.

Keywords:
The Effect of Radioscapholunate Fusion with and without Distal Scaphoid and Triquetrum Excision on Capitolunate Contact Pressure

List of authors:
Ido Volk*, Nasser Heyrani¹, Christopher O Bayne², Sean McNary²
¹ Hadassah Medical Center (Jerusalem)
² UC Davis Medical Center (SACRAMENTO)

Objectives / Interrogation: Radioscapholunate (RSL) arthrodesis has been demonstrated to be effective for patients with isolated radiocarpal arthritis. However, it has been associated with decreased ROM and midcarpal arthritis postoperatively. To improve ROM after RSL arthrodesis, distal scaphoid excision (DSE) and triquetrum excision (TE) may be performed. Capitolunate (CL) joint forces were measured to evaluate the effect of each of these motion-improving RSL fusion modifications on the midcarpal joint.

Methods: Ten wrist specimens were dissected of all superficial soft tissue. The carpus was exposed and RSL arthrodesis was performed using plates and screws. Contact area, pressure, and force were measured in the CL joint during application of uniaxial load, using pressure sensitive film. Measurements were obtained before RSL fusion, after RSL fusion, after RSL fusion with DSE, and after RSL fusion with DSE and TE. Statistical analyses were performed using a one-way ANOVA.

Results and Conclusions: Results: RSL fusion, with and without DSE, significantly increased contact forces (p < 0.03) in the CL joint from 5.05 ± 1.24 N to 7.59 ± 2.82 N and 6.87 ± 2.82 N, respectively. TE reduced CL contact forces to 6.26 ± 1.88 N. The CL contact pressures were similar between all groups (p = 0.42). Additionally, RSL fusion with or without DSE increased the CL contact area between 32% and 43%, while TE reduced CL contact area from RSL fusion to an intermediate level.

Conclusions: Motion increasing procedures performed at the time of RSL fusion may affect midcarpal joint contact force and area. These results showed that DSE increased contact forces resulting from RSL fusion, while the addition of TE reduced contact forces to an intermediate level. While the clinical significance of these findings is unknown, surgeons should take this information into consideration when counseling their patients on the possibility of developing adjacent joint arthritis in the future.

How can we avoid complications following ORIF of Distal Radius Fractures with a palmar locking plate?

List of authors:
Rohit Arora¹, Lukas Horling*, Kerstin Simon³, Tobias Kastenberger³, Gernot Schmidle³, Markus Gabl³
¹ University Hospital Innsbruck, Department of Trauma Surgery (Innsbruck)

Objectives / Interrogation: The increasing number of fixed-angle plate systems used to treat DRF carries with it the problem of determining the optimal fixation for unstable fractures. Our goal was to analyse the clinical and radiological outcomes of patients with displaced, unstable DRFs treated with a palmar locking plate.

Methods: Over a mean 15-month period, 141 consecutive patients were treated for an unstable dorsally displaced DRF. Objective and subjective functional results (active ROM; strength; DASH score; VAS; Green and O'Brien Score) and radiographic assessment (palmar tilt, radial inclination, ulnar variance, fracture union) were assessed. Potentials for complications were given special attention.

Results and Conclusions: 114 patients with a mean age of 57 years were treated. Fractures were classified as type A2 (n=39), A3 (n=16), C1 (n=24), C2 (n=30), or C3 (n=5). The modified Green and O'Brien Score revealed 31 excellent, 54 good, 23 fair and 6 poor results. Active wrist motion averaged 54° extension (82% of uninjured side), 46° flexion (72%), 81° pronation (95%), and 82° supination (95%). Mean grip strength was 70% of the uninjured side. 81 patients (71%) were pain free, 17 patients (15%) had mild pain, 10 patients (9%) had moderate pain and 6 patients (5%) severe pain. Mean DASH score was 13 points. Fracture union was achieved in all patients. A mean loss of palmar tilt of 3.4°, radial inclination of 0.4° and ulnar variance of 1.2 mm was measured. Overall complication rate was 27%. Most frequent problems were flexor and extensor tendon irritation (57% of the total number of complications). CTS was observed in 3 patients, CRPS in 5 patients. In 2 cases, loosening of a single screw and loss of palmar fragment was seen. Delayed union occurred in 3 patients and intraoperative intraarticular screw displacement was recognized in 1 patient. Neither clinical outcome nor complication rate were dependent on fracture type (intra- vs. extraarticular).

Very distal palmar plate position can interfere with the flexor tendon system, too long screws can penetrate the extensor compartments and distal screws in comminuted fracture patterns can cut through the subchondral bone and penetrate into the radiocarpal joint. We present our algorithm to avoid these complications using the intra-operative dorsal horizon view, pronator quadratus flap and fragment specific plate fixation.

Open palm vs closed technique for treatment of multiple digit involvement with Dupuytren's contracture: A prospective randomized study.

List of authors:
Nash Naam*, Abdel Hakim Massoud
1 Southern Illinois Hand Center, Southern Illinois University (Effingham)
2 Al Azhar University (Cairo Egypt)

Objectives / Interrogation: Introduction: Dupuytren's contracture is a fibroproliferative disease that affects the palmar aponeurosis resulting initially in nodule formation often with progression to cords with increasing contractures of affected digits. Contractures result in flexion deformities of the metacarpophalangeal (MP) and interphalangeal (PIP and DIP). Frequently multiple digits are involved. The use of collagenase injections has reduced the number of patients in need of surgical intervention. Still some patients would require surgical treatment especially if there is multiple digit involvement. Open palm technique has been shown to improve the functional outcome especially when used for multiple digit involvement.

Methods: Between 2002 and 2017 a prospective randomized study was conducted comparing the functional outcome of treating multiple digit involvement of Dupuytren's contracture using either open palm technique (Group I) vs. closed technique (Group II). Patients were assigned randomly to either group. There were 27 patients in group I vs 25 in group II. Both groups were very similar in age, gender, and number of digits involved. The average flexion deformities of MP and PIP joints in group I was 56 and 34 degrees respectfully compared to 62 and 27 in group II. 12 patients in group I (45%) and 17 patients in group II (68%) had excision of the check-rein ligaments of the PIP joints. Follow up ranged from 14 months to 178 months for both groups with an average of 42 months.

Results and Conclusions: Results: There were 3 complications in group I (transient paresthesia in 2 and digit wound dehiscence in 1) vs. 9 complications in group II (3 CRPS, 2 hematoma formation, 3 wound dehiscence and one nerve injury) (P=0.001) Average post-operative flexion deformities of the MP and PIP joints at final evaluation were 12 and 7 degrees respectively in group I vs 18 and 12 in group II. Recurrence was seen in 5 patients (19%) in group I vs. 12 patients (48%) in group II (P=0.002). Recurrence was more in patients who were treated earlier in the study. There were no infections in either group.

Conclusions: When compared to closed technique, open palm technique for multiple digit involvement in Dupuytren's contractures, provides better functional outcome including less complications and less incidence of recurrence.

Do we need to treat a Grade 3 scapholunate ligament injury according to Geissler classification in acute Distal Radius Fractures? Results of rearthroscopy at the time of Implant removal.

List of authors:
Rohit Arora*, Tobias Kastenberger, Gernot Schmidle, Markus Gabl
1 University Hospital Innsbruck, Department of Trauma Surgery (Innsbruck)

Objectives / Interrogation: Scapholunate (SL) ligament injuries in acute distal radius fractures (DRFs) are rare. While partial ruptures as Grade 1 and 2 according to Geissler are treated none-operatively and complete ruptures as Grade 4 are treated operatively there is no consensus weather or not Grade 3 injuries should be treated surgically at the time of fracture fixation. We report about the natural history of untreated Grade 3 SL ligament tears associated with acute DRFs.

Methods: Eleven patients (9 male and 2 female) with an average age of 56 years with acute DRF (all AO type C3) were treated using palmar plate fixation in 8 cases and dorsal plate fixation in 3 cases. In all patients an acute Grade 3 SL ligament injury was diagnosed arthroscopically. The SL ligament injuries were not treated in any of the patients. At the time of implant removal a rearthroscopy was performed to assess any progression of the SL ligament instability. Additionally radiological and clinical examination was assessed at the time of the last follow-up and compared to the uninjured side.

Results and Conclusions: The average follow-up time was 2.6 years. The wrist extension was 64°, flexion 57°, pronation 73° and supination 68°. Mean grip strength was 82% of the uninjured contralateral side. Mean DASH score and PRWE score were 10 points and 15 points, respectively. The mean pain assessed with the visual analogue scale was 2. The immediately post-operative SL gap on posterioranterior (PA) x-rays with the wrist in ulnar deviation was average 1.6 mm and at the final follow-up 1.8 mm. Three patients showed radiocarpal arthritis Grade 2 according to Knirk and Jupiter. The implant removal and rearthroscopy was performed at the average time of 1.8 years. During the rearthroscopy we could not detect any progression of SL instability from Grade 3 to Grade 4.
Grade 3 SL ligament injuries according to Geissler associated with acute DRFs treated without any surgical intervention showed no progression of SL instability to Grade 4 assessed with rearthroscopy at the time of implant removal.

Long-term outcomes after the intra-articular distal radius fractures with volar locking plate

List of authors:
Takafumi Tajima*, Yukichi Zenke¹, Kunitaka Menuki¹, Yoshiaki Yamanaka¹, Kenji Kosugi¹, Akinori Sakai¹
¹University of Occupational and Environmental Health, Department of Orthopaedic Surgery (Kitakyushu)

Objectives / Interrogation: To evaluate the long-term outcomes of treatment with volar locking plate (VLP) for the intra-articular distal radius fractures with clinical and radiological evaluation at least more than 5 years after surgery.

Methods: Twenty limbs (9 males and 11 women) of 44 distal radius intra-articular fractures that were treated surgically with VLP during the 5-year period from 2006 to 2010 were directly examined. Subjects included 1 limb of B3, 5 limbs of C1, 10 limbs of C2, and 4 limbs of C3 in AO classification. The mean age at surgery was 65.8 years (range, 48-81 years) and the mean postoperative follow-up period was 7.4 years (range, 5.1-9.8 years). X-ray parameters (RI; radial inclination, VT; volar tilt, UV; ulnar variance) at immediate post-operation and final follow-up, the articular gap and step-off on immediate postoperative X-ray, and osteoarthritic changes on final plain X-ray (evaluated by Knirk and Jupiter classification; KJ), Quick-DASH score, VAS score (full score of 10), range of motion, and grip strength were evaluated.

Results and Conclusions: Although there were no significant changes in RI and VT, the UV significantly increased from 0 mm at immediate postoperative X-ray to 0.7 mm at the final follow-up X-ray (p = 0.02). There were 4 limbs without joint space narrowing (KJ 0), 10 limbs with mild narrowing (KJ 1), 4 limbs with obvious narrowing (KJ 2), and 2 limbs with osteophytes and cyst formation (KJ 3). The articular gap and step-off on immediate postoperative X-ray averaged 1.1 mm. For the correlation between the articular gap and step-off and KJ classification, and between AO classification and KJ classification, greater residual articular gap and step-off and more complex fracture type significantly progressed osteoarthritic change (p < 0.01 and p = 0.02, respectively). Average Quick-DASH score was 3.3 points, and average VAS score was 0.55 points, indicating good self-assessment results. Quick-DASH score was not significantly correlated with KJ classification, however VAS score and KJ classification were significantly correlated (p = 0.03). The mean range of motion was almost the same as that on the unaffected side, and the mean ratio of grip strength on the affected side was 0.98, indicating good functional recovery.

We concluded that long-term outcomes of the distal radius fractures with VLP showed a significant correlation between fracture type or reduction status of the articular surface and osteoarthritic progression, however functional outcomes were good.

Keywords: intra-articular distal radius fracture, long-term outcome, KJ classification
The influence of arthroscopy, arthrotomy and conventional fluoroscopy in palmar locking plate fixation of intra-articular unstable distal radius fractures - a prospective randomized trial

List of authors:
Rohit Arora*, Tobias Kastenberger1, Lukas Horling1, Gernot Schmidle1, Markus Gabl1
1 University Hospital Innsbruck, Department of Trauma Surgery (Innsbruck)

Objectives / Interrogation: The objective is to evaluate arthroscopy (AS), arthrotomy (AT) and simple fluoroscopy (FS) in palmar plate fixation of intra-articular distal radius fractures (DRFs) and their correlation with clinical outcome. Our hypothesis was, that arthroscopy would lead to better reconstruction of the joint surface and detection of concomitant soft tissue injuries and thus leading to better clinical results

Methods: 58 patients (aged from 18 to 80) with intra-articular DRFs were randomized to one of the three groups (AS: n=20, AT: n=18, FS n=20). Palmar plate fixation was performed within 2 weeks. Pre- and postoperative CT scans were used to assess joint congruity and residual step off. Any additional soft tissue injuries that were detected were documented. On the follow up examinations at month 3, 6, and 12, patients were evaluated in terms of radiological parameters, pain, ROM and functional scores.

Results and Conclusions: Mean ROM: AS: Extension: 60°, Flexion 47°; FS: Extension: 59°, Flexion 46°; AT: Extension: 51°, Flexion 44°. Mean radial inclination: AS: 19.7°; FS: 20.1°; AT: 20.2°. Mean dorsopalmar tilt: AS: 5.9°; FS: 1.7°; AT: 2.5°. Mean ulnar variance was negative in all three groups (AS: -0.2 mm, AT: -0.2mm, FS: -0.5 mm). Post-operative mean step off in the joint: AS: 0.3mm; FS: 1.1mm; AT: 0.8mm. Mean grip-strength in AS: 28Kg; FS: 24Kg; AT: 21Kg. Partial scapholunate injuries (n=2 Grade 1 according to Geissler; n=1 Grade 2; n=2 Grade 3) were only seen in the AS group. Complete SL injuries were documented in the AS group (n=2 Grade 4), in the AT group (n=1 Grade 4) and none in the FS group. All complete SL ligament ruptures were treated by ligament fixation using bone anchors and K-wire fixation. Post-operative SL instability with an average increased SL-Joint gap in the stress X-rays of 2.1 mm compared to the uninjured side was measured in the FS group. TFCC lesions were detected in the AS group (n=3 Palmer type 1B; n=2 Palmer type 1C and n=2 Palmer type 1D).

Patients who were treated arthroscopically experienced significantly less pain over the entire follow up time compared to the other two groups. The average PRWE-Score at 12 months in the AS group was: 5 points; FS: 9 points; and in AT: 8 points. This difference was not significant.

The data shows a superiority of additional arthroscopy in palmar plate fixation in intra-articular DRFs, in regards to the radiological parameters, ROM, grip strength, pain and functional scores. Arthrotomy has the worst clinical outcome of the 3 groups.

Keywords: arthroscopy, arthrotomy, fluoroscopy, palmar plate fixation, intraarticular, distal radius fracture, joint surface
**The Arthroscopic Hook Test is Not Pathognomonic for a Foveal Tear of the Triangular Fibrocartilage**

**List of authors:**
Jeff Ecker*
1 Hand and Upper Limb Centre (Claremont)

**Objectives / Interrogation:** The purpose of this study is to evaluate the accuracy of the arthroscopic hook test in determining the presence of a foveal insertion tear using dry arthroscopy of the radiocarpal and distal radioulnar joint.

**Methods:** 63 dry arthroscopies of the distal radioulnar joint were performed between July 2016 and 2017 for the management of painful distal radioulnar joint instability. The presence of a positive or negative hook test was documented. The integrity of the foveal insertion was determined using debridement, visualisation with a 1.9mm arthroscope and probing.

**Results and Conclusions:** Of these 63 cases, 44 (70%) had a positive hook test and 19 (30%) had a negative hook test. Of the 44 cases with a positive hook test, 38 (60%) were found to have an intact fovea (false positive) and 6 (9.5%) were found to have a foveal tear (true positive). Of the 19 cases with a negative hook test, 17 (27%) were found to have an intact fovea (true negative) and 2 (3%) were found to have a foveal tear (false negative). By applying these values to the Statistical Measures of Validity, the specificity, sensitivity, false positive rate, false negative rate and diagnostic accuracy of the hook test in determining the presence of foveal pathology can be determined.

The specificity of the hook test in determining the presence of foveal pathology was found to be 0.31. The sensitivity was found to be 0.75. The false positive rate was found to be 0.69 and the false negative rate 0.25. The diagnostic accuracy was found to be 0.36.

All cases with a positive hook test were associated with a tear of the triangular fibrocartilage. However, the hook test was not found to be an indicator of the specific nature of the tear. It is important to debride and feel the mechanical integrity of the foveal insertion in order to determine if a foveal, peripheral or both foveal and peripheral repair is required.

Treatment of Hand and Wrist injuries in the Professional American Football Player: Return to Play

List of authors:
Glenn Glenn Buterbaugh*1, Joseph Imbriglia1, Kristin Buterbaugh2
1 Hand and UpperEx Center, University of Pittsburgh (Wexford)
2 University of Pennsylvania (Philadelphia)

Objectives / Interrogation: Objectives: This study reviews the evaluation and treatment of fifty six professional American Football players' hand and wrist injuries and the strategies on return to play.

Methods: Methods: The medical records and radiographs of fifty six professional American Football players treated by a single fellowship-trained Orthopedic Hand Surgeon from 2000-2018 were reviewed. An analysis of the treatment results including nonoperative and operative management along with specific equipment modification will be presented.

Results and Conclusions: Results: The injuries sustained included 14 Wrist injuries, 9 Thumb MP joint injuries,3 fractures at the thumb metacarpal base,3 metacarpal fractures of the fingers, 1 finger MP dislocation,5 proximal phalangeal fractures, 11 PIP dislocations, 3 middle phalanx fractures and 2 distal phalanx fractures and 5 extensor avulsion injuries. All patients returned to their pre-injury position. Strategies were individualized for the player and position. 21 players were treated operatively and 32 players were treated nonoperatively. Various techniques in equipment modification such orthoplast splinting, custom glove inserts, and cast immobilization allowed earlier return to play.
Conclusions: A strategic use of nonoperative and operative treatment with the addition of equipment modification will allow the professional athlete to minimize lost time and safely return to play.

Expectations and illness perceptions influence the success of non-operative treatment of first carpometacarpal osteoarthritis (CMC-1 OA)

Objectives / Interrogation: Recent research has outlined the pivotal role of psychological factors in pain and disability associated with first carpometacarpal osteoarthritis (CMC-1 OA). However, the association of pre-treatment expectations and illness perceptions (patients set of beliefs about their CMC-1) with treatment response after non-operative treatment is currently unknown. In the present study we aimed to assess the effect of psychological distress, pain catastrophizing, treatment outcome expectations and illness perceptions on the response to non-operative treatment for CMC-1 patients.

Methods: Between September 2017 and September 2018 all patients with CMC-1 OA who were non-operatively treated were included. As part of routine clinical care patients completed the Michigan Hand Questionnaire (MHQ, range 0-100) before and 3 months after treatment. A change score was calculated to measure the response to treatment. Patients also completed the Patient Health Questionnaire-4 (range 0-12), Pain Catastrophizing Scale (range 0-52), Credibility/expectancy Questionnaire (range 3-27) and the Brief Illness Perceptions Questionnaire (range 0-10) before treatment. Univariable and multivariable linear regression analysis were used to assess the effects of these factors on the change in MHQ.

Results and Conclusions: 219 patients were included in the study. Patients were predominately female (79%) and mean age was 59 years old, mean (±SD) change scores were 10.0 (±18), 5.1 (±16.4) and 5.6 (±12.8) for respectively pain, hand function and the MHQ total score. In the univariable analyses pre-treatment expectations and illness perceptions were significantly correlated with the MHQ change scores. Performing light physical labor, higher pain catastrophizing, higher expectations, and more understanding of the disease (B = 6.88[0.22 - 13.6], B = 0.38[0.05 - 0.71], B = 0.68[0.13 - 1.23] and B = 1.57[0.14 - 3.00]) were associated with more improvement in pain. Experiencing more consequences and more personal control from the illness was associated with more improvement in hand function (B = 1.33[0.02 - 2.64], B = 1.04[0.04 - 2.04]).

Discussion
Pre-treatment expectations and illness perceptions play a role in response to non-operative treatment for first carpometacarpal osteoarthritis. Our results suggest that optimizing patient expectations and illness perceptions at the start of a non-surgical treatment for thumb osteoarthritis could lead to better treatment outcomes.

HAND AND WRIST INJURIES FOLLOWING MOTORCYCLE TRAFFIC ACCIDENTS IN MEDAN, NORTH SUMATRA, INDONESIA

List of authors:
Aga Shahri Putra Ketaren¹, david kalim*¹, Defry Rivandra Utama², eliza nindita²
¹ Orthopedic & Traumatology Universitas Sumatera Utara (Medan)
² Plastic Reconstructive Surgery Universitas Sumatera Utara (Medan)

Objectives / Interrogation: To analyze the epidemiological profile of patients with hand and wrist injuries following motorcycle traffic accidents.

Methods: Data of this retrospective observational study was obtained from 227 patients' medical records who were admitted to orthopaedics department of Adam Malik General Hospital with hand and/or wrist injuries following motorcycle traffic accidents in 2016 to 2017.

Results and Conclusions: Results
Out of the total of 763 hand and wrist injury patients, 227 (29.7%) were identified as victims of motorcycle trauma events due to road traffic accidents. Hand injuries accounted for 68 (30%) of cases, wrist injuries were 127 (55.9%), and both hand and wrist injuries were 32 (14.1%). The male-to-female ratio was 3:1. The average age of patient was 26.6 years with a range from 1 to 78 years old, median age: 23 years. Adult group (19-64 years old) constitutes 68% of all cases, < 19 years old were 28%, and elderly ( >64 years old) were 4%. 146 patients (64.3%) sustained injuries to their dominant hand, while 81 (35.7%) were injured to the non-dominant hand. Hand fractures occurred in 61 (26.9%) patients, and wrist fractures were found in 129 (56.8%) patients. Of all cases, 17 patients (7.5%) needed an amputation.

Conclusion
The results indicate that hand and wrist injuries are commonly occurred in motorcyclist due to road traffic accidents and cause significant morbidity in their functions following the events. More than 50% of the hand and/or wrist injured patients involved in motorcycle accidents were adult male. Injuries more often found on the dominant hand than the non-dominant side.

Correlation between ultrasound image and surgery in De Quervain's tenosynovitis

List of authors:
Hugo Campo*, Alejandro Sandoval Daza¹, Alvaro Lombana¹
¹ Fundacion Valle del Lili-Colombia (Cali-Colombia)

Objectives / Interrogation: BACKGROUND
De Quervain's tenosinovitis is a common condition with a rate of men to women of 10:1 and an incidence of 0.5% and 1.3%, respectively, in the general population. It is a disorder with important repercussions on patients' professional lives due to the fact that they require an interruption of essential hand movement needed in their everyday jobs, which contributes to work absence. Additionally, it is a disorder in many cases incorrectly diagnosed; therefore, patients don't receive appropriate treatment. Previous studies have shown that ultrasound is a dependable technique for the diagnosis of De Quervain's tenosynovitis.

OBJECTIVES
General objective
To describe the usefulness of soft tissue ultrasound as a presurgical diagnostic complimentary method in chronic stenosing tenosynovitis or De Quervain's disease.

Methods: METHODS
A retrospective, observational, descriptive, cohort studio was performed. Between 2011 and 2015, 33 patients were included considering a prior De Quervain's tenosinovitis clinical diagnosis. All patients underwent ultrasound. To determine the correlation between the ultrasound and the findings after surgery, Spearman's rank correlation test was used.

Results and Conclusions: RESULTS
A total of 33 patients were chosen after meeting the stipulated selection criteria; 24% of these were men and 76% women. The mean age was 41.6, with a median of 39 years old. We found a positive correlation between the ultrasound and surgical findings in 85% (28 of 33) of the patients included.

CONCLUSIONS
There is a strong correlation between the ultrasound and the surgical findings in patients with a prior clinical diagnosis of De Quervain's tenosynovitis. The complimentary imaging technique favors the therapeutic approach, which is why it is a conduct recommended in these patients.

Nerve transfer for brachial plexus injuries: new surgical technique

List of authors:
Enrique Vergara Amador*¹, Laura Lopez Rincon¹
¹ Universidad Nacional de Colombia (Bogota)

Objectives / Interrogation: Brachial plexus injury is an entity that frequently affects the young population with a low incidence, but with a great impact on functionality and quality of life. Despite advances in reconstruction techniques, the treatment of this lesion remains difficult, requiring more research and development of new techniques that allow optimizing results. Our objective is to describe a surgical technique based on the transfer of median nerve's fascicles to the axillary nerve and its anatomical characterization.

Methods: the anatomical bases and the surgical technique were described in cadavers with subsequent implementation in a patient with brachial plexus lesion at the upper primary trunk level, previous informed consent and consecutive clinical follow-up.

Results and Conclusions: Results: Brachial plexus exploration was performed on five cadavers, identifying axillary nerve and median nerve. By intrafascicular dissection of the median nerve, the transfer is performed to the axillary nerve without any tension. This technique is applied in a selected patient with upper brachial plexus injury, through an axillary approach. Two years of follow-up, it found to be reinnervation of the deltoid muscle with functionality of 110° for shoulder abduction and 90° for external rotation.

Conclusion: As described in this technique the use of the fascicles of the median nerve for the transfer to the axillary nerve is an anatomically possible option to improve shoulder abduction in combination with spinal accessory nerve transfer to suprascapular nerve in patients with upper segments brachial plexus injuries, its benefit should be compared with techniques so far described.

Computer-assisted Fragment Reduction of Distal Radius Fractures Depends on Surgical Planning Experience

List of authors:
Christoph Zindel*, Phillip Fuernstahl¹, Andreas Schweizer¹, Simon Roner¹
¹ Universitätsklinik Balgrist (Zürich)

Objectives / Interrogation: Preoperative planning of fracture treatment leads to a better understanding of the pathology and its management, such as e.g. the surgical approach, the intraoperative challenges and the implant choice. Despite the advantages of 3D analysis and surgical planning in corrective osteotomies of the upper extremity, computer-assisted reduction of distal radius fractures has not been investigated so far. Current computer-based methods still rely strongly on clinical-based knowledge, which is mandatorily provided by a surgeon. Therefore, we hypothesize that the accuracy of fracture realignment is dependent on the surgical planning experience of the user.

Methods: A set of 3D bone models of distal radius fractures (n = 22) of varying complexity were presented to four readers with different surgical planning experience. The readers included a senior surgeon (SS, 23 years of experience), a resident surgeon (RS, 6y), a biomedical engineer (BE, 3y) and a medical student (MS, <1y). The objective was to perform a free-hand reduction of all fracture fragments with the use of a medical CAD planning software. To perform the final 3D displacement analysis, the fragment realignment of the SS was defined as the reference for the other three readers. The drawback of current computer-assisted displacement analyses requiring a coordinate system was solved by a newly introduced 3D-transformation. This displacement analysis consists of only two measurement parameters for each fragment: a pure shift (3D-translation) and a pure rotation (3D-angle).

Results and Conclusions: Regarding the 3D-translation, the post-hoc analysis showed that the RS as well as the BE performed a significantly better fragment reduction compared to the MS (p =0.03). Regarding the 3D-angle, a statistical trend towards the RS as well as towards the BE was observed compared to the MS.

We conclude that computer-assisted reduction of distal radius fractures is depended on the surgical planning experience. The hereby newly described 3D displacement analysis showed to be a promising way to describe the displacement of bone fragments. It is coordinate-system-invariant, mathematically distinct, program-independent implementable, inter-experimental comparable and surgical intuitively understandable.

**Objectives / Interrogation:** The boutonniere deformity of the thumb is the most common deformity of rheumatoid thumb. Metacarpophalangeal (MP) joint arthroplasty is indicated for the deteriorated MP joint with preserved soft tissue stability. Feldon introduced to use flexible hinge toe implant for the MP joint reconstruction because of its better mechanical strength compared to finger joint implant. We hypothesized rheumatoid thumb reconstruction using flexible hinge toe implant would improve the clinical outcomes and radiological findings.

**Methods:** Swanson implant arthroplasty for at the thumb MP joint was performed on the 108 cases (male 11, female 97) between 1986 and 2014 with minimum follow up of 6 months. The average age was 61 yrs. old and the average follow-up period was 4 yrs. The duration of the rheumatoid arthritis at the time of surgery was 22 years. Combined with this MP joint arthroplasty, arthrodesis at the IP joint in 26 cases, capsulodesis at the IP joint in 4 cases, suspensionplasty at the CM joint (Thompson) was performed in one case. Radiological assessments were performed and MP flexion angle and IP extension angle were measured. Extension loss at MP joint was divided into 4 groups: normal (less than 5 degree), mild (5 to 19 degree), moderate (20 to 39 degree) and severe (40 and more degree).

**Results and Conclusions:** In the radiological assessment, the pre- and the postoperative flexion angles at the MP joint were 42 and 17 degrees, and extension angles at the IP joint were 37 and 0 degree(s). Preoperative severity was mild in 15 cases, moderate in 36 cases and severe in 56 case. Postoperative severity was improved to normal in 9 cases, mild in 50 cases, moderate in 44 cases and severe in 3 cases. In one case, postoperative infection occurred and implant was removal of required. 3 cases of implant fracture occurred and revision was performed in 2 cases and removal was performed in 1 case with a synovitis. Swanson implant with a grommets did not cause implant fracture. By the rheumatoid thumb surgery, deformity was corrected. The ratio of implant failure was lower than that in the previous reports.

Reasons to consult for late surgery and functional status of patients with congenital upper limb deformities persisting beyond childhood

List of authors:
Nathaniel Jr. Orillaza¹, Mark Anthony Ruanto²
¹ University of the Philippines Manila (Manila)
² UP Manila (Manila)

Objectives / Interrogation: Congenital upper limb anomalies present in a wide variety of clinical pictures. Function largely depends on multiple factors including mental capacity and clinical presentation of the anomaly. Correction, in general, if indicated, is recommended during early childhood to optimize function before formal education starts and sometimes to avoid perceived decrease in function because of deformity. There have been limited reports on these conditions persisting beyond the recommended age for reconstruction. Indications for surgery on a later time have also not been explored adequately.

We aim to describe the common reasons why patients consult for late surgery and assess baseline function of the patient prior to reconstructive surgery.

Methods: We report our series of patients with congenital anomalies consulting for late surgery of congenital anomalies, on the indications and functional status prior to surgery measured as by the Filipino DASH.

Results and Conclusions: We present a series of 17 patients. The most common indication for surgery is concerns regarding work opportunities. Hope for a better function, cosmesis, social pressure and hygiene were less commonly mentioned reasons. Most of the patients did not complain of significant problems in doing activities of daily living. This is supported by their DASH scores, educational attainment and employment status prior to surgery.

The common indications to request for surgery of common congenital anomalies in later years were mostly not due to loss of function. Most patients were able to adapt well but opted to have surgery to increase opportunities for employment or less commonly in the hope of improving social relations.

Anatomic distribution of the axillary nerve and its implications in the treatment of the paralytic shoulder

List of authors:
Fabio Suarez Romero¹, Alberto Rojas Vargas*², Aida Garcia Gomez², Deysi Celeita Medina¹, Sergio Bocanegra¹, Andres Arango Mejia¹, Guillermo Gonzalez Tamara³, Andres Ramirez Jaramillo¹
¹Hospital Militar Central (Bogota, DC)
²Hospital Santa Clara (Bogota)

Objectives / Interrogation: To evaluate the anatomic distribution of the main and terminal branches of the axillary nerve into the deltoid muscle through dissection and measurement in adult cadavers and to find the best donor for nerve transfer surgery based upon its distribution.

Methods: Anatomic study was performed on 20 shoulders of unembalmed cadavers. The relationships between the nerve and the tip of the acromion, coracoid process, greater tubercle of the humerus, subscapularis muscle, the quadrangular space and all of the nerve branches inside the deltoid muscle were measured regardless of the specimens age and gender. The anatomic branch pattern was also described on each specimen.

Results and Conclusions: The mean distance between the tip of the acromion and the axillary nerve was 6.1 cm (range, 4.6, 7.7 cm). The mean distance between the coracoid process and the axillary nerve was 4.8 cm (range, 4.0, 6.3 cm). The mean distance between the greater tubercle of the humerus and the axillary nerve was 5.2 cm (range, 4.0, 5.8 cm). The axillary nerve gave off no branches before entering into the quadrangular space in all of the specimens. The axillary nerve branched out at a distance of 1.4 cm (range, 0.8-2.4 cm) from the quadrangular space. The anterior branch of the axillary nerve supplied the anterior and middle parts of the deltoid muscle and the posterior branch supplied the posterior part of the deltoid muscle in 80% of the specimens (Type D pattern of distribution, Leechavengyongs et al). These findings regarding the innervation pattern show an important variation in the Colombian population. Our study suggests that nerve transfer to the anterior branch alone would not reinnervate the posterior part of the deltoid muscle in almost all the patients.

Forearm Corrective Osteotomy pitfalls: What Can Go Wrong Will Go Wrong!

List of authors:
Eva Schwameis¹, Martin Chochole*¹
¹Herz Jesu Hospital Vienna (Vienna)

Objectives / Interrogation: We present two cases of forearm corrective ostotomies with sequelae due to classical mistake with regard to pathology, planning and execution of surgery and the later restitution of function fit to daily life.

Both cases show the sequelae of typical error. These errors in relation to the relevant literature seem to us interesting for the hand surgery community.

Methods: Case 1: (K.B.) was operated at the age of 18: Arthroscopy and ulna resection osteotomy due to a central lesion of TFCC at the right wrist. No further symptoms of impaction syndrome. Ulna shortening ended with a minus of 5 mm. He then suffered from an overload of the DRUG as well as of the brachioradialis muscle with Wartenberg Syndrome. Release of the superficial branch of radial nerve was done in a first step. Followed by radius shortening osteotomy. The patient recovered completely with full forearm rotation and coping with his duty as manual worker.

Case 2: (T.Z.) hurts his right elbow and forearm whilst fleeing out of Afghanistan. He first presented to the doctors in Austria with a painful limitation of the elbow and forearm. The radial head is dislocated. The underlying Monteggia lesion remains unrecognised. He was then operated on performing a double osteotomy of the ulna and radius. To gain relocation of the radial head a double angulated ulna fixation is done and the radius plated in a queer manor. The proximal part of radius due to biceps traction in full supination is fused to the distal part in complete pronation. The now total blockade of forearm rotation is explained to him by the severe starting situation and he was given two options: Radial head resection or the one bone forearm. Asking about which to prefer he came to our institution. Our solution was removal of the hardware and ulna corrective osteotomy with anatomical plate in a first step. Later we did radial derotation osteotomy. He ended up with a nearly full ROM at the elbow and a forearm rotation with 40° prono-supination each.

Results and Conclusions: Both cases show the sequelae of typical error. These errors in relation to the relevant literature seem to us interesting for the hand surgery community.

Percutaneous advancement of proximal tendon stump with the pull-out technique for the treatment of acute mallet fingers

List of authors:
Juan Liu\textsuperscript{1}, Hanlin Liu\textsuperscript{1}, Zhenbing Chen\textsuperscript{1}, Huaiyuan Zheng*\textsuperscript{1}
\textsuperscript{1}Wuhan Union Hospital (Wuhan)

Objectives / Interrogation: Correction of extensor lag is the key point for treating acute mallet finger in order to avoid swan neck deformity. This study aims to investigate the therapeutic effect of percutaneous advancement of proximal tendon stump with the pull-out technique on treating acute mallet fingers.

Methods: In this prospective study, 22 cases of acute mallet finger received advancement of proximal tendon stump with the pull-out technique. A transverse 3-0 Prolene running beneath the skin was used to advance the tendon distally. The DIP joint was fixed at slight overextension with a 0.8 inch Kirschner wire for 6 weeks. After the removal of the pin, active DIP flexion was started.

Results and Conclusions: The mean extensor lag before surgery was 45° (range 20°-75°). At 6 month follow-up, 15 patients had nearly full range of motion (extension lag<5°), 5 patients had a residual deformity of 10° and two had a poor result with a 30° deformity. 21 patients were fully satisfied with the improvement of DIP extension and only one was unsatisfied, but did not want to receive further treatment. In this preliminary report, this technique using percutaneous advancement of proximal tendon stump with the pull-out technique provided a safe, economic and efficient way of correcting mallet finger deformities without obvious incision during surgery.

Immobilization after a TFCC operation

List of authors:
Hartmut Semsch*, Max Haerle, Rebekka Rath, Simone Pop
1 Ortema GmbH (Markgröningen)
2 Orthopädische Klinik Markgröningen (Markgröningen)

Objectives / Interrogation: The immobilization after a TFCC operation is needed. Do modern orthoses have an advantage over immobilization with a plaster cast?

Methods: The immobilization by orthosis brings some advantages for the patient, treating physician and therapist. These are mainly in the unproblematic handling and better hygienic conditions with a very good immobilization of the wrist and forearm. In our study, 150 patients were treated with a TFCC garment orthosis and interviewed after completion of the treatment by questionnaire.

Results and Conclusions: In the survey, the patients confirm that the restrictions in everyday life in the areas of personal care, dressing and undressing, preparation and meal intake are low. With regard to the handleability of the orthosis, the patients give top marks. Restrictions on mobility of the elbow and wrist caused by a rigid plaster supply are prevented by the construction of the orthosis and the given straight line of freedom. This ensures the earliest possible functional use of the operated hand.

Non-surgical treatment for symptomatic carpal tunnel syndrome: a randomized clinical trial comparing corticoid injection versus night splint.

List of authors:
João Carlos Belloti¹, Vinícius Ynoe Moraes², Jorge Raduan-Neto³, Aldo Okamura³, Marcela Fernandes⁴
¹ Hospital Alvorada - moema, UNIFESP (São Paulo - SP,)
² Hospital Alvorada - Amil, São Paulo, Brasil, Universidade Federal de São Paulo, São Paulo, Brazil (São Paulo - SP,)
³ Hospital Alvorada - moema - Amil , UNIFESP - Universidade Federal de São Paulo (São Paulo - SP,)
⁴ Hospital Alvorada - moema, UNIFESP - Universidade Federal de São Paulo (São Paulo - SP,)

Objectives / Interrogation: There is no consensus regarding to the non-surgical treatment of carpal tunnel syndrome. Among the treatment options, local corticoid injection (CI) and/or wrist immobilization with night splint (INS) are commonly prescribed. However, there is a lack of high quality evidence comparing these two modalities of treatment. The aim of this study was to compare INS versus CI for patients with CTS.

Methods: Randomized clinical trial comparing CI versus INS for confirmed CTS with a minimum post intervention follow-up of six months. The diagnosis of CTS was established according to the Graham’s criteria - CTS-6 (four or more criteria indicate CTS) with an eletroneuromiography. Patients were randomized (1:1 ratio) and allocated to either INS or CI. Clinical assessment were were performed just before the intervention, within the first week, one, three and six months after the intervention. Primary outcomes were defined as presence or absence of nocturnal paresthesia and of Boston-Levine (QB) questionnaire symptom scale. Secondary outcomes were: pain improvement assessed by visual analogue scale (VAS) and complications rates. Sample size was calculated to find a 30% (alpha, 5%; Beta, 80%) difference in the remission of nocturnal paresthesia.

Results and Conclusions: From 100 eligible included patients, 95 complete the study planned follow up (45 INS and 50 CI. Corticoid injections demonstrated to be superior to INS in the remission of nocturnal paresthesia (remission rates at 1 month, 84.6% vs. 43.83%, p=0.001; 3 month, 71.1% vs. 40.4%, p=0.00001; 6 month, 80.3% vs. 28.8%, p=0.0001). Boston-Levine scale results were higher for INS compared to CI (42.2 vs 32.7, p=0.001 at 1 month; 46.7 vs. 32.3, p=0.0001 at 3 months; and 51.4 vs. 32.3, p=0.001 at 6 months, for INS and CI arms respectively). VAS scores were lower for CI group compared to INS. Both groups presented no complications. We conclude that CI is superior to INS for improving carpal tunnel syndrome related nocturnal paresthesia and severe symptoms. We also report that both interventions were found to be safe with no complications were reported.

Full-Length Finger Reconstruction for Proximal Amputation With Expanded Wraparound Great Toe Flap and Vascularized Second Toe Joint

List of authors:
Wenhai Sun*¹
¹ Shanghai Ninth People’s Hospital (Shanghai)

Objectives / Interrogation: Most of the frequently used methods for finger reconstruction have their own limitations. Reconstruction of a full-length finger with normal appearance, in patients with proximal digital amputation, remains a challenge.

Methods: Between January 2002 and November 2013, a total of 86 fingers (60 patients) with proximal phalanx amputation were surgically repaired. A compound flap comprising an expanded wraparound flap from the great toe and a vascularized proximal interphalangeal (PIP) joint from the second toe was harvested to reconstruct a full-length finger. The flap was used to reconstruct the nail, skin, and the distal phalanx; the PIP joint was used to reconstruct the PIP joint. To attain normal length of the finger and right PIP joint positioning, an iliac bone graft was inserted into the distal-middle or proximal phalanx.

Results and Conclusions: All reconstructed fingers retained their viability and natural appearance and were of near-normal length with a normal PIP joint positioning; 12.8% (9/86) of the procedures required re-exploration owing to compromised circulation. Secondary procedures were required in 71% (61/86) of the cases. With the exception of 1 case, the donor-site complications were mild; the average range of motion at the other PIP joints was 52 degrees (-15 to -5 degrees of extension, 25-90 degrees of flexion). Approximately 80% of the normal functionality and 93% of the normal appearance with respect to aesthetics were restored.

CONCLUSIONS:
The full-length finger reconstruction procedure allows for construction of natural-appearing full-length fingers with normal PIP joint positioning and a near-normal functional recovery for proximal digital amputation. The operation is technically complex and time consuming and demands a skilled operator for successful outcomes.

Objectives / Interrogation: To evaluate the effectiveness of an app to implement a postsurgery exercise program.

Methods: We present 60 years-old woman with thumb base osteoarthritis. A trapezium exeresis and tenosuspension ligamentoplasty with FCR was performed using a modified Burton Pellegrini technique. After cast removal, surgery service provided access to an app with an individualized home exercise program. The objective of the program was to promote dynamic joint stability and rehabilitate muscles that reduce dorsoradial subluxation and instability through conscious neuromuscular training. At one week, 3 weeks and 3 months postsurgery, manual dexterity through Nine Hole Peg Test, functionality through QuickDash and grip and pinch strength and were evaluated. The app developed control motor oriented exercises that can be adapted to pain and range of motion.

Results and Conclusions: The patient showed improvement in all the measures. Baseline measures were: 45,65 seconds in Nine Hole Peg Test, 10 pounds in grip strength, 1 pound in pinch strength and 79,54 points in QuickDash. After 3 weeks the patient measures were 21,73 seconds in Nine Hole Peg Test, 15 pounds in grip strength, 2 pound in pinch strength and 75 points in QuickDash. Finally, at three months: 19,05 seconds in Nine Hole Peg Test, 25 pounds in grip strength, 4 pound in pinch strength and 63,63 points in QuickDash. Difference from baseline to 3 month measures were: -26,6 seconds in Nine Hole Peg Test, +15 pounds in grip strength, +3 pound in pinch strength and -15,91 points in QuickDash. Patient completed the program with a 76% of adherence and report using the app as an enjoyable and easy way to develop exercises.

Conclusions: apps seems to be an optimal format for sensorimotor approach in postsurgery process. These results suggests the suitability of a tablet app for postsurgery exercise program in thumb base osteoarthritis.

**Objectives / Interrogation:** Objectives: To investigate the changes in the length of the palmar, proximal and dorsal subregions of the scapholunate interosseous ligament (SLIL) in healthy human subjects during the wrist flexion-extension in vivo.

**Methods:** Methods: We obtained computed tomography scans in six wrists of healthy volunteers. The scans were performed with the wrist at 5 positions, from 60° of flexion to 60° of extension, 30° increments. We reconstructed three-dimensional images of scaphoid and lunate with software. The paths of three different fibers of SLIL were modeled. Each subregions of SLIL are divided into three beams. The lengths of each beams of SLIL between their respective origin and insertion points were measured and compared among different positions of wrist flexion-extension.

**Results and Conclusions:** Results: From neutral position to flexion of 60°, the plamar and proximal subregions of SLIL lengthened significantly. From neutral position to extension of 60°, the intermediate and dorsal beams of proximal subgions lengthened significantly. From neutral position to flexion of 30° and extension of 30°, the distal beam of plamar subregions lengthened significantly.

Conclusions: During the wrist flexion-extension, the length of the palmar and proximal subregions of the SLIL changed substantially, but the dorsal subregions changed minimally.

Union in Scaphoid Fractures: Single versus Double Screw Fixation

List of authors:
Egemen Ayhan¹, Ali Nazmican GUROZ², Zeynep Tuna³
¹ University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology- Hand Surgery (Ankara)
² University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology (Ankara)
³ Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation (Ankara)

Objectives / Interrogation: Scaphoid fractures or nonunion are treated by a variety of surgical techniques. Recently, the number of screws (single or double) for fixation was reported to be important for union. As the double screwing provides two axes of fixation with increased stability, we hypothesized that the union rates would be better especially for the waist nonunion. In this study, we aimed to compare the union rates in patients with single- or double-screw fixation in different clinical presentations of scaphoid problems.

Methods: In total, 41 patients with scaphoid fractures were identified who were operated between October 2016 and June 2018. Of the 29 patients with postoperative follow-up; patients were grouped as acute cases, proximal pole and waist nonunion. Patients were treated with screwing while the proximal pole nonunions were treated additional vascularized bone grafting, and waist nonunions were treated with additional nonvascularized autografting. We determined the union by assessing the radiograph, return the work and pain with palpation at last visit. For statistical analysis, union rates were compared within each group in regards to single- or double-screw fixations.

Results and Conclusions: The mean age of the patients was 31.6 years and the mean follow-up was 7.9 months. There were six patients with fracture, eight patients with proximal pole nonunion, and 15 patients with waist nonunion. Union was achieved in all acute cases independent from the number of screws. Proximal pole union was achieved in 100% (3/3) of patients with double-screw and 80% (4/5) of patients with single-screw fixation (p=0.408). Waist union was achieved in 77.8 % (7/9) of patients with double-screw and 66.6% (4/6) of patients with single-screw fixation (p=0.634). All of the patients with union returned to work and were pain-free with palpation. When the radiographs and computerized tomography images were assessed in detail for the five patients with persisting nonunion, mal-reduction was observed for all of the patients.

In this study, although we observed increased union rates for double screwing for both proximal pole and waist nonunion, the differences were not statistically significant. This might be related to the small number of our cases and further studies with larger sample sizes are needed. Surgery for acute cases arises as a good choice for union independent of screw count. When the nonunion cases were reviewed, not the screw count but the anatomic reduction appears as the most important predictor of union.

A systematic review of the quality of distal radius systematic reviews: Methodology and reporting assessment

List of authors:
Vinícius Ynoe Moraes¹, Jorge Raduan-Neto², Marcela Fernandes³, Aldo Okamura², João Carlos Belloti⁴
¹ Hospital Alvorada - Amil, São Paulo, Brasil, Universidade Federal de São Paulo, São Paulo, Brazil (São Paulo - SP,)
² Hospital Alvorada - moema - Amil, UNIFESP - Universidade Federal de São Paulo (São Paulo - SP,)
³ Hospital Alvorada - moema, UNIFESP - Universidade Federal de São Paulo (São Paulo - SP,)
⁴ Hospital Alvorada - moema, UNIFESP (São Paulo - SP,)

Objectives / Interrogation: Many systematic reviews (SRs) have been published about the various treatments for distal radius fractures (DRF). The heterogeneity of SRs results may come from the misuse of SR methods, and literature overviews have demonstrated that SRs should be considered with caution as they may not always be synonymous with high-quality standards. Our objective is to evaluate the quality of published SRs on the treatment of DRF through these tools.

Methods: The methods utilized in this review were previously published in the PROSPERO database. We performed an analysis of the current literature of 41 SRs of surgical and nonsurgical interventions for acute DRF in adults. A comprehensive search strategy was performed in the MEDLINE database and we manually searched the grey literature for non-indexed research. Data were independently extracted by two authors. We assessed SR internal validity and reporting using AMSTAR (Assessing the Methodological Quality of Systematic Reviews and PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyzes). Scores were calculated as the sum of reported items. We also extracted article characteristics and provided Spearman's correlation measurements.

Results and Conclusions: Forty-one articles fulfilled the eligibility criteria. The mean score for PRISMA was 15.90 (CI 95%, 13.9 - 17.89) and AMSTAR was 6.48 (CI 95% 5.72 - 7.23). SRs that considered only RCTs had better AMSTAR [7.56 (2.1) vs. 5.62 (2.3); p=0.014] and PRISMA scores [18.61 (5.22) vs. 13.93 (6.47), p=0.027]. The presence of meta-analysis on the SRs altered PRISMA scores [19.17 (4.75) vs. 10.21 (4.51), p<0.001] and AMSTAR scores [7.68 (1.9) vs. 4.39 (1.66), p<0.001]. Journal impact factor or declaration of conflict of interest did not change PRISMA and AMSTAR scores. We found substantial inter observer agreement for PRISMA (0.82, 95% CI 0.62 - 0.94; p=0.01) and AMSTAR (0.65, 95% CI 0.43 - 0.81; p=0.01), and moderate correlation between PRISMA and AMSTAR scores (0.83, 95% CI 0.62 - 0.92; p=0.01). We conclude that DRF RCT-only SRs have better PRISMA and AMSTAR scores. These tools have substantial inter-observer agreement and moderate inter-tool correlation. We exposed the current research panorama and pointed out some factors that can contribute to improvements on the topic.

Ulnar nerve decompression or transposition under wide-awake local anesthesia without tourniquet management of cubital tunnel syndrome

List of authors:
shuguo xing*, Tian Mao¹, guheng wang¹
¹ Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Objective: Ulnar nerve decompression or transposition at the elbow traditionally requires regional or general anesthesia. The purpose of this study was to assess the feasibility and the outcome of performing these procedures under wide-awake local anesthesia without tourniquet and sedation.

Methods: Methods: We examined retrospectively the charts of 18 consecutive patients having undergone ulnar nerve entrapment surgery under wide-awake local anesthesia without tourniquet. All the patients were performed in minor operating procedure suites. 12 patients were performed in situ decompression with minimal incision; 4 patients were performed in situ decompression with long incision; 2 patients were performed ulnar nerve anterior subcutaneous transposition. The bleeding and pain during the operation was evaluated. The complications of this procedure were surveyed. After the operation, the patients were asked how patients feel about this procedure.

Results and Conclusions: Results: All the patients had successful decompression of ulnar never under local anesthesia without tourniquet and sedation. During the operation, adequate pain control was reported by all the patients, adequate bleeding control was achieved with no need for a temporary tourniquet. There were no hematoma and infection of incision in the group. All the patients stated that they would choose to have the operation performed under wide-awake local anesthesia without tourniquet again, but one would have favoured general anaesthetic because of anxiety. Conclusion: Ulnar nerve decompression or transposition at the elbow under wide-awake local anesthesia without tourniquet is a reliable procedure and is well tolerated by the majority of patients.

Fibro - adipose vascular anomaly in the forearm, a new and rare disorder.

List of authors: lorena parra*, boris leon², guillermo droppelmann¹, jasna sapunar¹
¹ MEDS (santiago) ² Hospital Clinico Jose Joaquin Aguirre (santiago)

Objectives / Interrogation: Fibro-adipose vascular anomaly (FAVA) is a distinctive malformation due to its radiological and histopathological characteristics. It is a mesenchymal malformation that presents in focal and diffuse form, whose changes include muscle adipose infiltration, phlebectasia, venous anomalies and malformation of the subcutaneous lymphatic system that tend to surround the neural structures. The aim of this study is to describe a clinical case in a 22-year-old woman with a diagnosis of a fibroadipose vascular anomaly in the forearm.

Methods: Retrospective evaluation of a 22-year-old female, with no morbid background, that presented on consultation with approximately 3 years of evolution of volume increase in medial region of left forearm, of progressive growth and oscillating size and which is associated with progressive lack of force of the limb and digital flexion deficit. Studied with sonogram and MRI with confirmed a vascular tumor (hemangioma) of the forearm infiltrating the carpal tunnel and the flexor muscles at the forearm.

Results and Conclusions: Multidisciplinary evaluation of the patient and images with the radiologists concluded that it was a fibro adipose vascular anomaly out of the reach for sclerotherapy. She went under surgery for tumor resection. Surgery findings included an extensive adipose tumor that infiltrated all the flexor muscles at the forearm deep to the pronator muscle and surrounding the median nerve. The hole of the tumor was excised. Good post operative evolution with full wrist and finger motion and transitory median nerve neuropraxia that spontaneously recovered within 3 months.

From the clinical point of view it is important to recognize the FAVA since it may require a different treatment to the classic vascular malformations, due to the abundant fibro-adipose formation that makes the sclero-therapy of little or no utility, making surgical resection necessary.

Keywords: Anomaly, fibroadipose vascular, forearm, malformation.
Outcomes of flexor tendon repairs in zones 2 under wide-awake local anesthesia no tourniquet

List of authors:  
shuguo xing*, Tian Mao1, guheng wang1  
1 Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Objective: We retrospectively reported the outcomes of flexor tendon repairs in zone 2 under wide-awake local anesthesia no tourniquet.

Methods: Methods: From January 2015 to October 2017, we performed primary or delayed primary repair for completely divisions of flexor digitorum profundus (FDP) tendon in zone 2 in 23 fingers (20 patients) under wide-awake local anesthesia no tourniquet. We repaired the FDP tendons using 6-strand M-Tang core suture with 4-0 looped sutures, followed by a running peripheral suture using a 6-0 nylon suture. A digital active extension-flexion test was performed during the operation after tendon repair to determine the strength of tendon repair and the venting extent of A4 pulley or A2 pulley. Active partial range flexion exercise were initiated from day 3 to 5 after surgery during early active mobilization. The outcomes were evaluated with Strickland criteria and Tang criteria.

Results and Conclusions: Result: A total of 23 fingers were followed up more than 6 months (mean 10 months). By the Strickland criteria, 15 had excellent, 5 had good, 2 fair, and 1 had poor results. According to Tang criteria, excellent and good function was achieved in 9 and 10 fingers, fair in 2 and poor in 2 fingers at the final follow-up, respectively. No repaired tendon had rupture.

Conclusion: We conclude that flexor tendon repair in zone 2 under wide-awake local anesthesia no tourniquet yields good outcomes.

The impact of coagulation disorders on complex hand trauma management

List of authors:  
Raluca Laura Stefanescu*, Bogdan Caraban
1 County Emergency Hospital Constanta (Constanta)

Objectives / Interrogation: Simply by definition (damage to at least two functional structures within the hand) or by mechanism (avulsion, extensive damage) complex hand trauma of the hand represent challenging conditions in regard to treatment and rehabilitation. If there is also a preexistent bleeding disorder, the whole management must be reassessed.

Methods: Either drug-induced, congenital or idiopathic, there are no universal peri-operative recommendations guiding the surgical plan for patients with bleeding disorders.

Results and Conclusions: Illustrated by clinical cases, the authors highlight the difficulties encountered with such patients during the treatment of complex traumatic hand injuries.

Radial Dysplasia: Intrinsic soft tissue changes and their effect on disease progression.

List of authors:
George Murphy*, Bran Sivakumar¹, Gill Smith², Malcolm Logan²
¹ Great Ormond St Hospital (London)
² Randall Division of cell and molecular biophysics (London)

Objectives / Interrogation: Objectives
Radial dysplasia (RD) affects approximately 1:8,000 live births. Recurrent ‘wrist’ deviation during growth affects all current treatment approaches; the underlying cause of this recurrence is unknown.

Previous animal work suggests connective tissue fibroblasts shape the developing limb musculature, and mutations restricted to these fibroblasts cause abnormal extracellular matrix production and reproduce the wider soft tissue anomalies seen in RD. This study investigated intrinsic changes to limb connective tissue in RD patients, as a potential cause of the disease phenotype and recurrence.

Methods: Methods
Ethical approval and informed parental consent were obtained. Limb fascial biopsies from RD patients and age-matched normal controls (hand trauma patients) were dissociated and cultured in vitro. Extracellular matrix (ECM) proteins were fluorescently stained and both the ECM proteins expressed and their organisation were quantified. The ability of RD and control patient fibroblasts to shape muscle development was assessed by culture with a normal human muscle cell line.

Results and Conclusions: Results
RD patient fibroblasts produced significantly less organised ECM than control fibroblasts (p<0.001). RD ECM differed in composition from control ECM, and was significantly less able to support organised muscle growth in culture.

Conclusions
These results support the hypothesis that there are intrinsic soft tissue changes in RD, which are developmentally distinct from the skeletal defects. These soft tissue changes plausibly contribute to recurrent ‘wrist’ deviation during growth, and present a target for both surgical and genetic treatment.

Aesthetic and functional Reconstruction after fingertip injuries: Pivot flap technique

**List of authors:**
Roberto Adani*, Giovanna Petrella¹, Giulia Colzani², Anna Brandolini¹
¹Hand and Microsurgery Department, Modena, Italy, Policlinico di Modena (Modena)

**Objectives / Interrogation:** The fingertip is one of the regions most often exposed to trauma of the hand. Loss of the tactile function and capability of the pinch can affect the hand functions irreversibly and seriously. Reconstruction with glabrous and sensation skin is essential for ideal resurfacing of fingertip after injuries. The purpose of this study is to analyze the palmar pivot flap as an option for fingertip and pulp defect in selected cases.

**Methods:** We used the palmar pivot flap to repair fingertip and pulp defect in 12 patients (9M, 3F) with age ranging from 29 to 52 years (mean 38y) There were two cases of index finger, 6 middle finger injuries and 4 ring finger injuries. We observed oblique or transverse defect with or without bone exposure. The flap is an axial pattern flap based on the subcutaneous transverse branches of the digital artery. The flap is pivoted up to 90° in order to reach adjacent defect. The donor defect is limited to the same digit avoiding scars in different finger. The average size of affected area was 2cm x 2cm up to 2.5 cm x 3 cm. Eleven patients were treated in emergency. We never used skin graft to cover donor site, all healed primarily. Outcomes measured PIP and DIP range of motion, sensation, pain, cold intolerance, percussion tenderness and aesthetic result.

**Results and Conclusions:** All flaps survived. We achieved complete mobility of PIP joint (>95°) and DIP joint (>80°). Sensory recovery was demonstrated in all flaps after 8 weeks (mean 2 SPD was 6.4), no painful tips reported, 2 cases had mild cold intolerance, no mild percussion tenderness; Only 1 patient was not satisfied with aesthetic appearance because onychodystrophy occurred. The palmar pivot flap can provide sensate glabrous skin for the effective reconstruction of finger tip and pulp defects, resulting in aesthetically and good functional outcomes. Because of simple technique procedure, it may be employed in outpatient surgery under local anesthesia.

pivot flap, finger tip, pulp loss
Treatment of pink pulseless hand following supracondylar humeral fractures in children at our hospital

List of authors: Daishi Hamada¹, Hokuto Morii², Inokuchi Koichi²

¹ 1-1 (Fukuoka Kitakyushu)
² 1981 (Saitama, Kawagoe)

Objectives / Interrogation: (Objectives) Pink Pulseless Hand (PPH) is characterized by radial pulselessness in a complex of good hand perfusion which can remain pink and warm. The management and treatment of this condition is still very debated.

Methods: (Methods) We report 4 cases of arm traumas which occurred in pediatric patients at our hospital since June 2016. Four cases were all fall trauma, presenting pucker sign, anterior interosseous nerve paralysis. In all cases, after the fixation of the fracture by the orthopedic surgeon, the clinical evaluation demonstrated the PPH.

Results and Conclusions: (Results) We decided to proceed with an immediate surgical exploration and decompression followed by a prompt recovery of the pulsatility. In 2 cases, we found the brachial arteries in spasm, using papaverine improved blood flow well. In 1 case, the blood flow was disrupted, inner membrane injury and thrombus formation were observed, veins were collected from the left lower thigh by diagnosis of brachial artery injury and revascularization was performed. In 1 case showed thrombus formation, and thrombectomy was performed with a fogarty catheter. Postoperative course was uneventful. At 2-year follow-up, the young patients have a normal hand function with no neurovascular damages and regular peripheral signals.

[Conclusions] According to the literature, observation is the treatment of choice for many authors. But Blakey et al. reported a long-term outcomes study of 26 patients with PPH who had delayed presentation, 23 had signs of Volkmann's ischaemic fibrosis in the affected limb. And White et al reported brachial arterial injuries could be proven in 70% no return of pulse after closed reduction. 2 cases of 4 our patients (50%), presented brachial artery injuries. In addition, reperfusion injury following PPH which treated conservative follow-up has been reported with a frequency of 0-33 %. PPH requires urgent surgical exploration if no return of pulse after closed reduction.

Vascularised bone graft from distal femur in upper extremity reconstruction

List of authors:
Igor Golubev*, Maksim Merkulov1, Oleg Bushuev1, Ilya Kutepov1, Ivan Kukin1, Maksim Sautin2
1 Priorov State Medical Research Centre (Moscow)
2 ECSTO (Moscow)

Objectives / Interrogation: To analyse our experience and indications for vascularised bone graft from distal femur and its application in upper extremity reconstruction.

Methods: Since 2012 to 2018 authors have performed 53 surgical procedures using free vascularised femur condyle bone grafts. 51 of them were medial femoral condyle grafts (MFC) and 2 - lateral femoral condyle grafts (LFC). MFC were used for scaphoid bone grafting (19), Kienböck's disease (7), bone defects after tumor excision (2), osteochondritis dissecans of the humerus condyle (1). It was also used in cases of forearm bones (14), humerus (5), metacarpal bones (2) and clavicle (1) nonunions. LFC were made for the scaphoid nonunion and in case of a gunshot injury of 3-5 metacarpal bones. Osteochondral graft was performed in 11 cases. In one case we used osteocutaneous flap.

Results and Conclusions: We have used a. descendens genicularis and her transverse branch for the MFC. Average length of the pedicle was 5,7 cm (from 1,5 to 8 cm). LFC was taken with the superior lateral artery (average length 3,75 cm). Average volume of the bone graft was 7,44 cm³ (1 to 28,1 cm³). For the osteochondral graft it was 3,38 cm³ (2 to 6,9 cm³). Bone healing was achieved in 36 of 39 (92.3%) cases which were investigated in one year after surgery.

We have analysed donor site morbidity after MFC harvest. Complaints of 13 patients' were analysed. They included pain, numbness and instability. 3 patients with MFC (23%) reported issues: pain in 3 (23%) and numbness in 1 (8%). Swelling occurred in 2 (15%) of patients. There was no statistically significant correlation between the postoperative time and patients' complaints (p>0,05). We conducted a survey using the Lower Extremity Functional Scale (LEFS). In MFC group LEFS minimum score was 71 points, maximum - 80, average - 77,6.

According to our practice main indication for MFC and LFC flaps are proximal scaphoid nonunion with failure of previous operation or destruction of proximal pole, Kienböck's disease stage IIIA, long bone defects less than 5 cm with at least one failure of surgical treatment and Koenig disease of capitulum humeri with bone necrosis of more than 50% of it.

High rate of success and low donor site mobility make distal femur the main donor area for relatively small bone defects and convex cartilage bone defects.

Arthroscopic partial resection arthroplasty and allograft tendon interposition in stage III trapeziometacarpal osteoarthritis

List of authors:
José Alexandre Marques¹, Paulo Gil Ribeiro*, Ana Catarina Quintas¹, Paulo Costa¹
¹ Centro Hospitalar e Universitário de Coimbra (Coimbra)

Objectives / Interrogation: Trapeziometacarpal joint arthritis is a frequent joint degenerative disease. Nowadays there are various surgical options available for the treatment of this pathology that provide good clinical results. The arthroscopic technique is offered as an alternative to the open surgical options providing the benefits of less tissue aggression, less post-surgery pain and the diagnose of chondral lesions not identified in radiographic studies.

Methods: The authors present 17 cases of trapeziometacarpal joint arthritis, Eaton-Littler stage III, treated in the ambulatory surgery unit. Most patients are female, mean age 61,38 ± 6,71 years-old. All patients were submitted to trapeziometacarpal chondroplasty, osteophyte removal and tendinous allograft interposition (semitendinosus, semimembranosus or tibialis anterior muscle). The joint was stabilized with the use of a percutaneous trapezio-metacarpal K-wire. The patient used a wrist splint for 4 weeks and a wrist splint for 2 months at night. All patients were assigned a specific physical rehabilitation program for 4 weeks and were then evaluated clinically and functionally.

Results and Conclusions: The mean follow-up time was 20,29 months. The mean Visual Analogue Scale (VAS) improved from 8,47±0,83 before surgery to 1,63±0,96 after surgery. The anterior and lateral grip strength of the thumb improved from 3,81Kg and 2,83Kg before surgery to 6,4Kg and 5,4Kg after surgery, respectively. There were 3 cases of temporary hypoesthesia that resolved with cutaneus care and 2 cases of partial tendinous exteriorization that were resolved surgically. There were no complications related to the use of an allograft.

Discussion: Although there are multiple surgical options there isn't a consensus on the best technique for the treatment of the trapeziometacarpal joint arthritis. This work shows the results of an arthroscopic technique with tendinous interposition applied to 17 patients, all performed by the same surgeon. The use of a tendinous allograft allows for less surgical injury and less surgery time.

Conclusions: The use of arthroscopic trapeziometacarpal chondroplasty and tendinous allograft interposition is a safe and reliable procedure that allowed to improve VAS and thumb grip strength. If these results endure and can be reproduced this procedure could be considered a “biological arthroplasty”.

Surgical Treatment of DIP Ganglion by Excision and DIP Synovecctomy without skin flap: 10 cases

List of authors:
Romina Lachenmeier*, Helen Segmüller†
† Spitalzentrum Biel (Bienne)

Objectives / Interrogation: To show that surgical treatment of ganglion cysts (mucous cysts) of the DIP joint can be done with careful complete excision of the ganglion and stalk resection combined with dorsal synovecctomy. A small area of thin skin overlying the cyst can be resected and left open. No skin flap is necessary.

Methods: Retrospective review of 10 cases. Mean follow-up time is 25 months. There were 8 index and 2 middle fingers. Mean age is 60 years.

Surgical technique:
All operations were performed in axillary block anaesthesia, with upper arm tourniquet.
The incision was Y-shaped, centered dorsally over the DIP joint. The ganglion with the stalk coming from the DIP joint was carefully excised. In cases with very thin skin overlying the ganglion maximally 3x3 mm of the skin were excised and left open for spontaneous granulation.

Results and Conclusions: Results:
After a mean follow-up of two years all of the 10 operated patients showed normalized nail growth, no scarring, a good aesthetic result, good ROM, no recurrence of the ganglion.

Conclusion:
The surgical treatment of DIP ganglion cysts needs to consist of careful resection of the cyst with the stalk and dorsal synovecctomy. In some cases resection of a small area of thin skin overlying the ganglion is necessary. This area can be left open, coverage with skin flaps is not necessary.

Composite Graft and Temporary Dermo-dermal Fusion to the Palm - A Treatment Option of Fingertip Amputation in Children

List of authors:
Max Mann*, Darja Sippel1, Frank Winkler1, Wiebke Hülsemann1
1 KKh-Wilhelmstift, Handchirurgie (Hamburg)

Objectives / Interrogation: Fingertip amputation in toddlers or children of preschool age is frequent. Loss of more than half of the nail bed and exposure of bone asks for coverage and reconstruction of nail bed and length. In small children the reconstruction by microsurgical replantation is impossible. In adults Paavilainen et al described 2009 a successful reconstruction by refixation of the tip by composite graft and temporary dermo-dermal fusion of the deepithelized fingertip to the palm to improve blood supply temporarily. Encouraged by his results we wanted to check if this technique is efficient in the not cooperating young children too.

Methods: From 2000 to 2018 we performed the dermo-dermal fusion in 28 children, 17 of them were in preschool age. The median age of was 5.3 years. In 22 cases the amputation level was in zone 2 and 6 in zone 3 of Rosenthal classification. The amputations were caused by squeezing and avulsion in 27 fingers and by a clean cut in 1 patient. Postoperative they were immobilized in a fist bandage pressing the tip into the palm and a forearm finger cast for 4 weeks.

Results and Conclusions: In 22 of 28 cases the fingertip refixation was successful and the major part of the pulp and nail length could be preserved. In 3 cases the children had torn their finger out of the palm in the first 10 days postop ahead of time. These 3 patients healed secondarily with a good result in 2 and a satisfying result with some shortening of the tip in 1 patient. In 3 patients the fingertip was lost due to necrosis and infection.

This technique is an option to preserve length of the distal phalanges and nail bed in comparison to the treatment with semi-occlusive dressings and local flaps. In the aftercare it is essential to protect the injured finger against pull out.

Keywords: Fingertip amputation, children
Early results of first patients with Motec wrist arthroplasty in Latin America

List of authors:
lorena parra¹, felipe pizarro², guillermo droppelmann¹, arturo verdugo¹, Cristobal Greene¹
¹ MEDS (santiago)
² Universidad Catolica del Maule (talca)

Objectives / Interrogation: Multiple solutions exist to treat a wrist with posttraumatic degenerative changes. Depending on the extension of the degenerative osteoarthritis and on the functional condition of the patient, salvatage are indicated such as four corner fusion or proximal row carpectomy. When the degenerative osteoarthritis compromises the radiocarpal joint, the surgery more commonly performed in active patients is Total Wrist Arthrodesis that allows pain control but sacrificing mobility. Long term studies in patients with TWA have demonstrated an important functional disability. In the last years, there have been published very promising results in non rheumatoid patients. Motec Wrist (Swemac Orthopedics) is a new model of arthroplasty, with ceramic covered implant, ball and socket joint type with a metal on metal or metal on peek pair of friction. Indicated for all kinds of degenerative osteoarthritis in high demand patients. The follow-up to 3.2 years of 30 hard-working patients operated with Motec, demonstrated good results. The aim of this study is to show the early functional and radiologic results of the first patients that underwent total wrist arthroplasty with Motec in Latin America.

Methods: Non probabilistic sample of patients that underwent Motec Wrist Arthroplasty in 2018. Patients were evaluated at pre op, 3 and 6 months post operative with AP and lateral wrist x rays, wrist range of motion (º), grip force with a JAMAR dynamometer (kgs), DASH and PRWE. Results were analyzed with tables of frequencies, ranges and medians. Statistical analysis with R software.

Results and Conclusions: 3 patients were operated in 2018 with Motec arthroplasty. All male, mean age of 48 yo. The pre-op diagnose was snac wrist IV in 2 cases and a failed proximal row carpectomy (due to kiembock disease) in one case. Mean pre op DASH was 40, and PRWE 50 pts. Mean wrist extension of 30º, and 60º flexion, radial deviation 0º, ulnar deviation 10º. Mean Grip strength 17 kg. All were operated with the standard technique with no intraoperative complications. At 6 months post-op. No signs of implant loosening at x-rays. Mean wrist extension 50º, flexion 50º, radial deviation 30º, ulnar deviation 30º. Grip strength 25 kg. All 3 patients with no pain. DASH 15, PRWE 10 pts.

Conclusion: Motec wrist arthroplasty is a good alternative of treatment for post traumatic osteoarthritis of the wrist in young high demand patients, with good functional results in the short term and no significant complications for this small sample.

Mycetoma of the upper extremity caused by Nocadia brasiliensis- Casereport

List of authors:
Britta Wieskoetter*¹, Martin Langer¹, Simon Oeckenpöhler¹, Niklas Grüneweller¹
¹ Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Albert-Schweitzer-Campus 1 (Münster)

Objectives / Interrogation: OBJECTIVES: Since traveling around the world is a mass phenomenon, the confrontation with exotic and particularly rare symptoms of infections of the hands and upper extremity is inevitable.

Methods: PRESENTATION OF CASE: The patient (52 year old man) - with a severe pyarthrosis of the right radiocarpal joint with massive destruction of soft tissue and a palmar abscess as well as a severe pyarthrosis of the left elbow with neurotmesis N. radialis - was transferred from another hospital after multiple debridement and stabilisation of the joints with an external fixateur. Secondary diagnoses: Colitis ulcerosa (i.d. 1994, therapy: Mesalazin, Prednisolon 7,5 mg / d), pulmonary sarcoidosis. The pathogen was Nocardia brasiliensis, gram-positive actinomycetes bacteria that causes Mycetoma, which is a chronic, frequently subcutaneous, granulomatous infection that commonly affects the feet. The disease usually occurs in tropical and subtropical areas and is endemic to Latin America, India, and Africa. Long-term infection is associated with multifocal osteomyelitis.

INTERVENTIONS: The treatment consisted of multiple irrigation and debridement procedures including resection of the affected bone, soft tissue coverage by local rotational flap and the use of i.v. and oral antibiotics: Amikacin 1g 1-0-0-0, AmoxiClav 2,2 g 1-1-1-1, Imipenem 1g 1-1-1-1.

Results and Conclusions: RESULTS: After eradication of infection, intensive ergotherapy was necessary to regain adequate function of the right hand and left elbow, the neurotmesis of the radial nerve was temporary.

CONCLUSIONS: Mycetoma of the upper extremity caused by Nocadia brasiliensis is very rare. Treatment consists of identifying the pathogen and then administrating the appropriate antibiotics and surgical débridement as required. To achieve optimal results, interdisciplinary communication and treatment is mandatory. In some cases, amputation is necessary. Super-infection with other types of bacteria can result in sepsis and death.

Dynamic Distal Radioulnar Stabilization for Acute Triangular Fibrocartilage Complex Injury

List of authors:
Samuel Pajares Cabanillas*¹, Natalia Martinez Catalan²
¹ Hospital Fundación Jimenez Diaz (Madrid)
² Hospital Fundacion Jimenez Diaz (Madrid)

Objectives / Interrogation: Distal radial fractures, with or without fracture of the ulnar styloid, and radial shaft fractures may result in instability after disruption of the distal radioulnar ligaments or a tear of the peripheral triangular fibrocartilage complex (TFCC). Regardless of the approach taken (i.e. conservative treatment, K-wire fixation, open or arthroscopic repair), correct treatment of this rupture requires immobilization of the wrist and elbow for a period of six to eight weeks. The purpose of this study was to describe the results of distal radio-ulnar joint instability treatment using dynamic stabilization to allow early mobilization of both the radiocarpal and distal radioulnar joint as soon as week one postsurgery.

Methods: Between July 2008 and February 2013, a retrospective study was performed of 16 consecutive patients presenting distal radius fracture or Galeazzi fracture dislocation who exhibited an unstable DRUJ during intraoperative manual stress testing (via the Ballottement test) after fixation of the distal radius. Once instability was confirmed, dynamic stabilization was performed. All patients had radiographic evaluation of their wrist. CT arthrography (CTR) was performed at 3 months to evaluate TFCC healing. After surgery patients were immobilized one week with a short cast. All patients were monitored at 1 month, 3 months, 6 months and 1 year after the fracture. Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire, Ballottement test, radio-ulnar joint Range of motion (ROM), pain, grip strength, return to work, radiographic angulation and complications were monitored.

Results and Conclusions: All patients were followed for an average of 12 months after surgery. After 1 month, all patients were satisfied with good range of motion and grip strength. The Ballottement test was negative in 15 patients (93.75%), and only 1 patient showed persistent instability probably related with osteoporotic bone. TFCC healing was observed in 14 patients (87.5%) and fracture healing was observed in all 16 patients. Revision surgery was performed in one patient (6.25%) due to flex-extension limitation and no other complications were recorded. The high incidence of DRUJ instability in fractures of the distal radius and Galeazzi fracture-dislocations is well described in the literature. The technique presented in this article illustrates a reliable method for dynamic stabilization of the DRUJ with satisfactory results at short-term follow-up.

Keywords: Radioulnar joint, triangular fibrocartilage complex, distal radius fracture, instability, Galeazzi fracture-dislocation.
SL reconstruction with fibertape- a possibility of a gentle SL reconstruction? First experience with a new surgical technique

Hans- Georg Damert*
1 Helios Bördeklinik (Oschersleben)

Objectives / Interrogation: Small ligament- great impact; that could be the description of the scapholunar ligament. Damage to the SL ligament can lead to instability and cause scapholunate advanced collapse or SLAC wrist. Over the years various ligament reconstruction or tenodesis techniques have been described. However, as of today, there is no internationally recognised "gold standard". The long- term clinical results are usually limited and some techniques result in disproportionate collateral damage.

Methods: Recently, we use the fibertape ( Fa. Arthrex), which is among others used in the arthroscopic rotator cuff repair, in combination with two anchors for fixation. In this technique, small incisions are made over the dorsal capsule for the introduction of the anchors, while preserving the ligamentous structures. With the development of new anchors the tape can be installed with a pretension after the reduction. Up to now we refused on the transfixation pinning of the carpus, because of the clinical and radiological stability during mobilisation. Additional morbidity from e.g. harvesting tendons may be dropped. After the surgery the patients are immobilised in a splint for 6 weeks, and full stressing is possible after 12 weeks.

Results and Conclusions: So far, nine patients with the appropriate indication were supplied with these surgical technique. The longest follow-up period is 5 years. Active wrist range of motion, grip strength and radiological appearance are promising.

After cadaver training, we are using this new method on suitable patients. The first experience has been encouraging. Larger numbers of cases and long- term results will show, if these method can become established. A positiv effect is the less effort, the gentle preparation while preserving ligaments, waiving of transfixation and shorter immobilization.

A Standardized Patient Education Video Program for Improvement of Post-operative Pain Management after Outpatient Upper Extremity Surgery

List of authors:
Soleille Everest*, 1. Cassandra Mierisch², Cay Mierisch², Peter Apel², Cesar Bravo², Hugh Hagan², Anthony Capito², Horatiu Dancea², Allison Bell²
1 Virginia Tech Carilion School of Medicine (Roanoke)
2 Carilion Clinic (Roanoke)

Objectives / Interrogation: Pain after surgery is common and not always well controlled. Results of a recent survey of adult surgical patients showed 86% experienced pain after surgery; of these, 75% had moderate/extreme pain during the immediate post-surgical period, with 74% still experiencing these levels of pain after discharge. Post-surgical pain was the most prominent pre-surgical patient concern, and nearly half reported they had high anxiety levels about pain. The importance of patient education regarding pain management is agreed upon, although support in the literature, especially in the outpatient setting, is not strong.

The objective of this prospective, randomized, placebo-controlled experimental study is to investigate the effect of adding a formalized patient education program (videos and recovery diary handout) to the current standard-of-care counseling on patient experience after outpatient orthopedic upper extremity surgery.

Methods: One hundred and three adult patients undergoing elective outpatient, upper extremity surgeries were randomized to view one of two educational programs: 1) a 2-video series regarding post-operative pain management or 2) a video regarding wound care. Randomization was stratified based on the expected postoperative opioid prescription size. Outcome measures included both validated (PROMIS Pain Intensity) and non-validated (pain scale, measures of satisfaction and knowledge) scores.

Results and Conclusions: Eighty-nine patients completed the study, resulting in analysis of 47 patients in the wound care group and 42 patients who received formalized education in pain management. Patients who received the additional wound care education showed an increase in pain intensity as measured by the PROMIS Pain Intensity Short Form 3a administered 3 days after surgery (average of 0.13 points on a 5 point scale) compared to pre-operative levels, whereas patients who had received pain management education showed a decrease in their PROMIS Pain Intensity Score of 0.81 points (p=0.04). Similarly, patients undergoing the pain management education reported significantly lower pain scores (pain rated on a scale from 0-10; average 2.7 vs 3.1, p=0.004) with the most clinically significant benefit on post-operative days one to five.

A formalized pain management education program can significantly decrease the pain experienced by patients after outpatient upper extremity orthopedic surgery. The authors recommend that a comprehensive approach to pain management include a focus on patient education.

A prospective randomized trial comparing clinical outcomes of treatment with buddy taping of 4th and 5th metacarpal vs closed reduction and cast immobilization in fifth metacarpal neck fractures with less than 70° of volar angulation.

List of authors:
Natalia Martinez Catalan*, Samuel Pajares Cabanillas2, Emilio Calvo Crespo 1
1 Hospital Fundacion Jimenez Diaz (Madrid)
2 Hospital Fundación Jimenez Diaz (Madrid)

Objectives / Interrogation: The ideal treatment for fifth metacarpal neck fractures is still under debate. Although these fractures are typically treated nonoperatively, most often with closed reduction and splint immobilization, cast immobilization seems to not be superior to soft wrap without reduction in most cases.

The aim of this study was to determine if the outcomes of buddy taping for three weeks was not inferior to reduction and cast immobilization for fifth metacarpal neck fractures with volar angulation < 70° and no rotational deformity.

Methods: Between August 2016 and March 2018, 72 patients with fifth metacarpal neck fractures were prospectively enrolled and treated with buddy taping or a cast with previous reduction during 3 weeks according to an established randomization sequence. All patients were monitored at 3 and 9 weeks after fracture and the primary outcome was measured by the Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire. Range of motion (ROM) of the metacarpal phalangeal (MCP) joint, pain, grip strength, return to work, radiographic angulation and complications were recorded.

Results and Conclusions: After 3 weeks, patients treated with buddy taping were satisfied with good fifth MCP joint ROM and their DASH score was significantly lower than the other group.
At 9 weeks, clinical outcomes in the soft wrap group were better in terms of grip strength, range of motion and score obtained in DASH questionnaire, but this statistical difference was without clinical relevance.
A subjective long-term evaluation was performed by phone; at a median of 1 year, a QuickDash score gave a median of 0 points. There were more complications in the group of patients treated with cast immobilization. Increased fracture angulation was not significantly different between the groups. Duration of time off work was 28 days shorter with the soft wrap compared to the cast treatment (P <0.001).
There is no benefit to reduction and splint immobilization of fifth metacarpal neck fractures with initial angulation of less than 70°. The use of soft wrap and buddy taping with early mobilization resulted in satisfied patients, good clinical results and significant improvement in lost work time.

Cerclage wiring and its modification for long oblique/spiral fracture of the metacarpal shaft

List of authors:
Soya Nagao¹, Koji Tanimoto², Hisataka Takesako³, Kana Kataoka², Yoshiaki Tomizuka², Masahiro Nagaoka²
¹Itabashi Medical Association Hospital, Department of Orthopaedics (Tokyo)
²Nihon University Hospital, Department of Orthopaedic Surgery (Tokyo)

Objectives / Interrogation: It is not so easy to perform lag screw technique for long oblique/spiral fracture of the metacarpal shaft because of difficulty to place the screws, measure correct length of the screws and develop a crack. The purpose of this study is to reveal the postoperative outcome of cerclage wiring procedure reported by Gropper and Al-Qattan, and introduce our modification of this procedure.

Methods: Sixteen metacarpals in 15 hands in 14 cases (12 males and 2 females) were treated for long oblique/spiral metacarpal shaft fracture. Initial 7 metacarpals were immobilized by original 2 or 3 single looped cerclage stainless-steel wires of nearly 0.5mm in diameter. Next 4 metacarpals were stabilized by double looped cerclage sutures with #2-0 FiberWire to avoid the removal. Recent 5 metacarpals were treated by double looped cerclage wires to improve the stability. Affected hands were immobilized with intrinsic plus position by plaster splint for within 2 weeks postoperatively. Postoperative outcome and complications were investigated in all cases.

Results and Conclusions: Bone union was achieved without rotational malunion and shortening in all 16 cases. However, wire aberrance to the fracture site was occurred in an initial metacarpal, and mild limitation of the affected metacarpophalangeal joint in an oldest (77 years) initial case. Also, constriction of the cortex was appeared in 3 metacarpals treated by cerclage sutures. No complications were seen in all recent metacarpals treated by double looped cerclage wires. Cerclage wiring procedure is easy, cost-effective and reliable compared with other procedures. Double looped wire is more stable and reliable than single looped wire. We are going to continue performing double looped cerclage wiring technique for long oblique/spiral metacarpal shaft fractures.

Scaphoidectomy and double column arthrodesis for SLAC and SNAC wrist

List of authors: Riccardo Luchetti1*, Roberto Cozzolino1
1 Rimini Hand Centre, Via Pietro da Rimini, 4 (Rimini)

Objectives / Interrogation: To evaluate the functional and radiographic results of a scaphoid excision and four-corner arthrodesis technique using percutaneous headless compression screws.

Methods: A cohort of 84 patients, mean age 45 (range, 20-66) years, was treated for SLAC 3 and SNAC 3. After scaphoid excision and removal of cartilage and subchondral bone in the midcarpal joint the DISI deformity was corrected. Luno-capitate fixation was achieved with two Herbert screws and triquetro-hamate fixation was done with one or two Herbert screws, always in a proximal to distal direction. Bone graft was never used.

Results and Conclusions: At a mean follow-up of 9 months (ranged from 3 to 24 months), 34 patients were reviewed (30 males and 4 females). Pain at rest and under load improved passing from 7 and 8 to 0 and 3 respectively, flexion-extension decreased from 83° (flexion 41° / extension 42°) to 54° (flexion 24° / extension 30°), grip strength increased from 20 to 21 kg, Mayo Wrist Score increased from 34 to 55. Radiological examination were done every months and CT-scan in some doubt case in which the consolidation was not clear. X-ray images demonstrated the consolidation of the luno-capitate arthrodesis in almost 2 months, the triquetrum-hamate arthrodesis reached the consolidation one month later. Some patients complaints discomfort in the ulnar side for almost 3 months. All patients return at previous work or status in 3 months but one. This case was reoperated for nonunion with the same technique using Herbert screw of bigger dimension and obtained healing in 2 months. No radiological osteochondritic/arthritis changes were observed at follow-up due to the lunate holes created by screws.

Conclusions: These results were comparable to or better than the results of previously published techniques in terms of fusion rates, alleviation of pain, grip strength, range of motion; Mayo wrist score. The technique showed the real advantages of strong compression for arthrodesis healing.

Results of Fascia Lata Soft Tissue Interposition Elbow Arthroplasty for Chronic Neglected Posterior Dislocations of the Elbow of more than 1 year duration

List of authors:
Abhijeet Wahegaonkar¹, Satish Mane², Anup Bansode², Chaitanya Karande Patil²
¹ Sancheti Institute for Orthopedics & Rehabilitation, Jehangir Hospital (Pune)
² The Hand Surgery Clinics, Sahyadri Hospital (Pune)

Objectives / Interrogation: Neglected posterior dislocation of the elbow is common in developing countries. Neglected posterior dislocations often present with myositis ossificans from massage and treatment from bone-setters in developing countries. Such problems in young, active patients present a challenging problem to the upper extremity surgeon. Pain and loss of motion associated with elbow stiffness is poorly tolerated and constitutes a major functional impairment.

Methods: We evaluated the clinical results of open reduction and fascia lata interposition arthroplasty in patients with neglected posterior dislocation of the elbow of more than 1 year duration associated with myositis ossificans, focusing on range of motion, stability & pain. All patients underwent open reduction, contracture release, triceps plasty, fascia lata interposition arthroplasty with a hinge elbow fixator distractor and collateral ligament reconstruction.

Results and Conclusions: 11 patients (all males) were treated for neglected dislocation of the elbow between Jan 2009 and Dec 2015 at our Institute. Mean time from injury was 15.7 months (range, 12-24 months). The mean period of follow-up was 29.33 months (range, 14-48 months). All patients had satisfactory pain relief. 8 out of 11 (72.7%) patients had an excellent or good result by the objective criteria of the Mayo Elbow Performance score. 2 patients had fair outcomes. In 1 patient instability of the elbow, both before and after surgery, was found to be associated with an unsatisfactory result.

Conclusion: Interposition arthroplasty, combined with hinged external fixation, is a viable solution for neglected posterior dislocations of the elbow in young active individuals in developing countries. The use of a fascia lata graft provides a stable and adequate interposition material without overstuffed the joint. Our mid and long term results are encouraging and we feel that this is a viable and robust non-prosthetic arthroplasty option in carefully selected patients.

Keywords:
Distal Digital Nerve Repair Using Nerve Allograft with a Dermal Substitute

List of authors:
Desirae McKee1, Bradley Osemwengie1, Cameron Cox1, Brendan Mackay1
1 Texas Tech University Health Sciences Center (Lubbock)

Objectives / Interrogation: In this case, we demonstrated the effectiveness of allograft in repairing traumatic digital nerve injuries distal to the trifurcation.
We also show the utility of dermal skin substitutes in reconstruction following complex hand injuries.
These techniques allow for a greater range of options for hand surgeons offering reduced morbidity for patients with traumatic injuries.

Methods: A 17-year-old male presented with full thickness open wounds to the left index and long digits along the radial contact surfaces of the left index and long digits. Portions of the radial digital nerve were missing on both the index and long fingers with gaps of 2.2 cm and 1.6 cm respectively. The gap in the index finger was distal to the trifurcation, and the long finger was at the trifurcation. The index and long digits had skin loss of 3 x 1.8 cm and 3.2 x 1.6 cm, respectively, on the volar radial aspect of both digits.
1-2mm diameter allografts were selected to match the native nerve. The allograft was positioned between ends of the nerve segments followed by a nerve connector over each anastomosis.
Considering the distal nature of the nerve repair in the index digit, we chose to connect the nerve allograft to multiple small nerve ends.
Due to multiple digits involved and difficulty gaining distal coverage of the fingers, we elected to place dermal substitute. We placed bilayer meshed integra directly over the nerve repair and wound for the soft tissue coverage.
Six months after follow up, the patient reported improvements in strength and return of full range of motion. The patient reported normal sensation, and Semmes-Weinstein sensory mapping correlated with these results.

Results and Conclusions: Nerve allograft placement is a viable alternative in cases of traumatic injury to digital nerves as it mitigates the unorganized distribution of nerve fibers found in nerve conduits as well as donor site morbidities found with autografts.
We used a dermal substitute to cover and protect the underlying subdermal structures including the nerve allograft. The porosity of this material allows it to better approximate the physiological function of the skin originally covering the wound, resulting in a more complete return to normal functionality as well as superior aesthetic outcomes. This case indicates that dermal skin substitute can be used as an alternative to autograft and skin flaps for increased functionality and reduced donor site morbidity.

Cell-loaded custom made fibrin glue nerve conduits optimize the repair of peripheral nerves in a sciatic nerve graft model in rats

List of authors:
Elias Vollkmer*, Thomas Holzbach¹, Christian Krug¹, Riccardo Giunta¹, Julius Meyer¹, Maximilian Saller²
¹ LMU München, Abteilung für Handchirurgie, Plastische Chirurgie, und Ästhetische Chirurgie (München)
² LMU München, ExperiMed (München)

Objectives / Interrogation: Incomplete nerve regeneration after injuries to the peripheral nervous system remains a significant problem in clinical routine and raises the need for supportive strategies. We examined the effect of an additional adipose derived progenitor cell-loaded fibrin glue conduit in the model of a 20 mm long peripheral nerve defect in the rat treated with an autologous nerve transplant.

Methods: Cells were isolated from the inguinal fat pad of the rats using the ARC centrifuge (Ingeneron). To improve the regenerative potential of adipose derived progenitor cells, we preconditioned the cells in 2% of hypoxia for 3 days before they were applied. Cells were suspended in liquid fibrin glue (ARTISS; Baxter) which was then cast into a solid nerve conduit of 25mm in length and 2mm of wall thickness. The cell-containing conduits were then applied around a 20mm autologous nerve graft in a sciatic nerve defect model covering both coaptation sites. While the experimental group (n=9) received hypoxically preconditioned cells, the control groups received either the fibrin conduit alone (n=9), the conduit containing non-preconditioned adipose derived progenitor cells (n=9) or no conduit at all (n=9). During the trial period of 16 weeks we conducted weekly walking-track and static foot-print-analyses. Afterwards the animals were sacrificed and the bilateral gastrocnemius muscle was weighed. Histological evaluation including axon density and axon size was carried out.

Results and Conclusions: Functional analysis in terms of sciatic function index showed significant improvement in all groups treated additionally with fibrin conduits when compared to the control group that did neither receive conduit nor cells indicating faster functional regeneration. The group that received hypoxically preconditioned cells produced the best results, followed by the non-preconditioning group, which in turn yielded better results than the fibrin conduit group without cells. The gastrocnemius muscle’s weight was significantly higher in conduit groups and conduit-treated animals showed an increased axon density when compared to control group without conduit. Slightly higher numbers of axons in animals with cell-containing conduits were detected. These results indicate the beneficial effect of an adipose derived progenitor cell-loaded fibrin glue nerve conduit in addition to microsurgical nerve repair in the model of an autologous nerve transplant in the rat, yet the underlying mechanisms need to be further investigated.

Long Term Functional Results of Camitz opponensplasty in Severe Carpal Tunnel Syndrome with Severe Thenar Atrophy

List of authors:
Nash Naam*, Abdel Hakim Massoud
1 Southern Illinois Hand Center, Southern Illinois University (Effingham)
2 Al Azhar University (Cairo Egypt)

Objectives / Interrogation: Introduction: Camitz opponensplasty is a tendon transfer of the palmaris longus tendon to the thumb for patients with loss of thumb opposition and abduction in severe carpal tunnel syndrome. The purpose of this study is to evaluate the long-term functional results of patients with more than 10 years after surgery.

Methods: Methods:
A retrospective review of patients who had Camitz opponensplasty for more than 10 years was conducted. All patients who had the surgery before 2007 were reviewed. 63 patients had the surgery between 1987 and 2007. 32 patients were available for review. Their age at the time of surgery averaged 68 years (range 58-72).
All patients presented with severe numbness and tingling and complete loss of active thumb abduction or opposition. Electrodiagnostic studies confirmed severe carpal tunnel syndrome and the complete loss of motor unit recruitment in the abductor pollicis brevis muscle. The procedure was combined with open carpal tunnel release.
All patients were evaluated clinically for grip and pinch strength, active range of motion of thumb palmar and radial abduction, sensory evaluation and Kapandji score. No electrodiagnostic studies were performed. DASH score was also obtained.

Results and Conclusions: Results:
31 patients were satisfied with the procedure. Active thumb palmar abduction significantly improved from a preoperative average of 15 degrees to 52 degrees. The grip strength improved from a preoperative average of 42% of the contralateral side to 87% (range 56-92%). Pulp pinch strength improved from a preoperative average of 40% of the contralateral side to 88%. Kapandji score improved from an average of 2 to a postoperative average of 9.5 (range 8-10).
Semmes-Weinstein Monofilament test showed improvement from an average of 6.65 preoperatively to 3.61 postoperatively.
DASH scores averaged 8 (range 2-23). We did not have preoperative DASH scores to compare with.
When compared with the final values at time of patients' discharge there was a significant improvement of Pinch strength, Kapandji score, Active thumb radial and palmar abduction and return of sensibility.

Conclusions: This study shows that patients have open carpal tunnel release and Camitz opponensplasty continue to improve and maintained the improvement for a long time. Therefore, It is considered a reasonable choice for patients with loss of abduction and opposition of the thumb secondary to severe CTS.

Complex thumb metacarpophalangeal joint dislocation caused by ulnar collateral ligament entrapment in a 6 year old.

List of authors:
Eleanor Duck¹, Isabel Teo¹, Ian McNab¹
¹John Radcliffe Hospital (Oxford)

Objectives / Interrogation: Case Report

Methods: A right handed 6-year-old girl presented to the hand trauma clinic with a painful left thumb having fallen on it whilst playing 11 days previously. On examination, her thumb was tender and dorsally angulated at the level of the MCPJ. There was minimal active movement at the joint. Examination and stress manipulation of the joint was not performed given the child's age and discomfort. An xray showed a dorso-radial dislocation at the thumb MCPJ. Under general anesthetic, a further attempt at closed reduction proved futile. Open surgical exploration by a dorsal approach of the metacarpophalangeal joint revealed avulsion of the proximal origin of the ulnar collateral ligament with a slip of periosteum. This was identified within the joint space and tethered by fibrous tissue. There was no damage to the radial collateral ligament or volar plate. The avulsion was mobilised and a successful reduction was achieved. The ligament was re-attached to its anatomical position on the metacarpal head using a transosseous suture.

Results and Conclusions: In irreducible thumb metacarpophalangeal (MCPJ) dislocations, the volar plate is most commonly found in the joint preventing closed reduction. We present a 6 year old child with an irreducible thumb MCPJ, of which we identified the ulnar collateral ligament as the culprit interposing soft tissue stopping reduction. This has not been described before and we wish to share our clinical and surgical management of this unique case.

The Endoscopic Carpal Tunnel Release in 175 Patients: Learning Curve, Complications and 1.5 Year Review

List of authors:
Alexander Schütz¹, Kristina Haas¹, Denise Löhnert¹
¹ sporthopädieum Straubing (Straubing)

Objectives / Interrogation: The most common peripheral neuropathy is caused by the idiopathic carpal tunnel syndrome (CTS). The surgical decompression is usually performed with an open (OCTR) or endoscopic carpal tunnel release (ECTR). The ECTR is supposed to show a flat and complicated learning curve and to be technically more demanding than the OCTR. Therefore, we wanted to examine the learning curve while establishing ECTR in our clinic and monitored a total of 175 patients for complications and outcome during a 1.5 year period. Moreover, we wanted to figure out, which operative method shows the higher patient acceptance.

Methods: From April to November 2017, 52 patients with idiopathic CTS were included in a pilot study, operated in a single center by one surgeon using the one-portal ECTR-procedure. The operative time was measured and any remaining hematoma was scored at the time of stitch removal 12 days after surgery. The postoperative pain level was evaluated (VAS 0-10). Regression of the typical CTS symptoms such as nocturnal numbness and pain (NMP) was also monitored. From November 2017 to September 2018 another 123 patients were operated with ECTR and monitored identically. Finally, 8 patients who were operated bilaterally with OCTR and ECTR by the same surgeon were interviewed, which operative procedure they preferred.

Results and Conclusions: In the beginning, 30 ECTR were needed to establish a stable and representable process. In the first 30 patients, greater variabilities in the operative time from 6 to 27 min. were recorded and 2 ECTR-procedures were converted into an open surgical approach. In the first third of 52 patients (1-17), the average operative time was 11.8 min., in the second third (18-35) 8.0 min. and in the last third (36-52) 5.5 min. were needed. During the learning phase, operative revisions, due to complications, were not observed. However, there was one iatrogenic partial lesion of a three-part motoric thenar branch in an extremely obese patient (patient no. 119), that had to be reconstructed microsurgically during the same operation. By all 175 patients, the NMP disappeared post-operatively and the pain level was low (VAS 0-2). In case of a CTS, 7 of 8 patients who were operated bilaterally, wanted to be operated again with ECTR, 0 of 8 preferred OCTR and one patient was indecisive. Thus, these results do not confirm the assumed prolonged learning process. If the guidelines are respected, the ECTR is confirmed to be a save and favorable procedure with a high patient acceptance.

FREE VASCULARIZED INTERDIGITAL JOINT TRANSFER OF THE HAND: TWO CASES SERIES

List of authors:
Julio Echazabal\textsuperscript{1}, Mario Andres Humeres Rios*\textsuperscript{2}, Soledad Sanchez\textsuperscript{3}
\textsuperscript{1} Clinica Fusat, Hospital De Rengo (Santiago)
\textsuperscript{2} Hospital del Salvador, Universidad De Santiago De Chile, Hospital de Rengo (Santiago)
\textsuperscript{3} Hospital de Rengo (Santiago)

Objectives / Interrogation: Show innovative surgical technique for the reconstruction of dysfunctional joints of the hand. A viable option is presented to reestablish the interphalangeal joint function. Will this technique be a good option?

Methods: We present two cases of patients with loss of interphalangeal joint functionality of the hand, secondary to a circular saw. Non-vascularized joint transfer from functional metacarpo-phalangeal to dysfunctional interfalangia is performed to re-establish joint function. First case: 62-year-old man. It has amputation at F1 level in the 5th finger and arthrodesis of proximal PIP of second finger. A non-vascularized transfer of the 5th metacarpophalangeal joint to the proximal interphalangeal joint of the index finger was performed. Joint resection of MTF and PIP joint, edges regularization, MTF joint placement replacing the PIP in index, fixation with minifragment screws without head, through articular cartilage. Repair in second surgery of flexor tendons. Second patient: male, 34 years old. Trauma with amputation at the index finger F1 level, dysfunctional PIP of third finger of the same hand. Resection is performed devascularized MTF block of the index finger, transferred to PIP of third finger. The technique was modified, cortical-spongy bone wedge construction with articular cartilage was made, both wedges are adapted to F1 and F2 bones, achieving adaptation with non-osteosynthesis material.

Results and Conclusions: The first case, articular cartilage necrosis was generated, so the osteosynthesis material had to be removed. Patient can still perform work, with limited mobility of PIP transfer. No pain and partial functionality. The second case do not generate articular cartilage necrosis. We think that it was secondary because we did not place osteosynthesis and bone wedge was left for osseointegration. Joint transfer is a viable option in patients suffering from interdigital joint dysfunction. The context of the patient, the donor joint, the receiving joint, the receiving site where the transfer is made, the state of the soft tissues and also explain the patient that it has a failure rate, series describe up to 15% must be taken into account. The greater follow-up is necessary, as well as increasing the number of patients who perform this type of surgeries. In our center, with low resources, in a context where agriculture is the main work, the functionality of the hand is essential. This is why it is a viable option to re-establish joint functionality.

JOINT TRANSFER, HAND, FINGER, MICROSURGERY
Technical tips for managing pilon proximal interphalangeal joint fractures.

List of authors:
Isabel Teo*, Ian McNab¹, Nicholas Riley¹
¹John Radcliff Hospital (Oxford)

Objectives / Interrogation: Proximal interphalangeal joint (PIPJ) pilon fractures of the hand are common and difficult to treat. This is often from an axial loading pattern of injury, resulting in splaying of the PIPJ with compression of the central portion of the articular surface. In select patients, operative management is undertaken in the form of dynamic frames such as a Suzuki frame or open reduction internal fixation (ORIF) with plates, with or without bone grafting.

Methods: Invariably, traction is required intra-operatively to assess reduction. It is often difficult to maintain accurate reduction with the lead surgeon or assistant pulling on the end of the digit, and often leads to the clinicians fingers being inadvertently exposed to radiation. In our practice, we have found an effective method to apply traction and avoid radiation exposure to our surgeons hands. We pass a 15cm transverse kirshner wire (k-wire), usually a 1.1 or 1.3 through the head of the middle phalanx, and leave the ends long. A surgical swab is wrapped around on each end of the k-wire and traction can be applied. Should reduction be acceptable with traction, this wire can then be the distal wire of an external fixation such as a Hynes Giddens or Suzuki frame. When the fracture extends distally to involve the distal aspect of the middle phalanx, this transverse wire is passed transversely through the base of the distal phalanx. This can be removed at the end of the ORIF. In addition to traction, the wire ends aid in retraction the other fingers dorsally during ORIF.

Results and Conclusions: We have found this maneuver extremely useful in managing what is often a tricky fracture. We would like to share this tip with photos and imaging.

Keywords:
Stuntspecific traumata of the hand and wrist at professional stuntwomen and stuntmen

List of authors:
Arne Tenbrock*, Martin Lautenbach
1 Waldfriede Hospital Berlin, Dep. Handsurgery, upper Extremity and Footsurgery (Berlin)

Objectives / Interrogation: The body-stress and risk of accidents of the hands and wrist’s for professional stuntwomen and stuntmen do not correspond to those of actors, but much more to those of professional competitive athletes in various hand-involved sports. Thus, there is a high risk of specific hand and wrist injuries in this profession, even if special job-specific and stunt-specific protectors are used and protective measures are carried out. Nevertheless, this has not yet been specifically recorded in the literature. The question of how occupational disabilities and their durations in this particularly risky occupational group can be traced back to injuries of the wrist’s and hands is not adequately described in the literature.

Methods: The aim of the present retrospective study was therefore to record the occupation-specific risk for hand and wrist injuries in professional stuntwomen and stuntmen. For this reason, in a period of 12 months 120 professional stuntwomen and stuntmen (definition of professionalism is the predominant > 80% income protection of the injured by the activity in the above-mentioned profession) in German-speaking countries were interviewed to injuries of the hands and wrists, in the past 10 years as part of their professional activity. The detected injuries were grouped by type and by accident mechanism (type of stunt leading to injury). In addition, the forms of treatment, resulting occupational disabilities and persistent limitations of stunt ability after hand injuries as stuntwoman and stuntmen were recorded.

Results and Conclusions: The results showed that despite the high risk of injuries in the context of the occupational activities mentioned above serious injuries occurred significantly less often than minor injuries in the surveyed group. Most common injuries were joint and bony injuries of more than 40%, followed by tendon and other soft tissue injuries. Specific injury patterns of the wrist’s and hand could be assigned to typical common stunt forms. Thus, the study allows the creation of a stunt-dependent risk profile for wrist and hand injuries. In addition, thus stunt-dependent risks for the emergence of resulting occupational disabilities periods and their duration can be derived. This is here of interest not only for private accident insurances, but also for the German social accident insurance institution - Berufsgenossenschaft. From this, however, stunt-specific hand-protective measures can be derived and recommended. These are presented in connection with the stunt-forms.

Does timing of carpal tunnel release influence the results?

List of authors:
Zoltan Nemeth*, Balazs Lenkei1, Adrienn Lakatos1, Zsolt Szabo1
1 Hand Surgery Center, Miskolc (Miskolc)

Objectives / Interrogation: In case of carpal tunnel syndrome, the patients’ fear of the operation may lead to long lasting symptoms. Our hypothesis was that the longer the patient waits till the operation, the worse the results will be.

Methods: We performed a retrospective evaluation of our database on carpal tunnel syndrome. The preoperative and postoperative findings were collected prospectively. In the period between 2014 to 2018 467 patients underwent median nerve release for carpal tunnel syndrome in our center. 24 patients were excluded due to missing data. In each case we performed open carpal tunnel release without synovectomy. The grip and pinch strength were measured with a dynamometer. The changes in numbness, night pain and satisfaction were registered. For the evaluation of subjective findings, a visual analogue scale of 1-10 was used. The patients were selected into 5 groups according to the time interval between the first symptoms and the operation. Significance was evaluated using Z-test (p=0.05).

Results and Conclusions: Values of preoperative daytime and nighttime numbness were similar in all 5 groups. In the first group (symptoms for less than 3 months), the daytime numbness was 6.5, the nighttime numbness was 7.67. The night pain was 6.97 points. These values at the end of the first week, were 5.29 for the daytime numbness, and 4.13 for the nighttime numbness. The night pain almost totally disappeared. All the other groups gave similar results, with only two significant difference. The grip strength increased significantly during the first three months in the first group compared to the preoperative values. Opposite to this in the fifth group (symptoms for more than 3 years) the grip strength did not reach the preoperative level after 3 months. The satisfaction of the patients was similar in all groups, but in the first group there was an increasing tendency during checkups, and the fifth group was the most satisfied (9.2) after 1 week and the values showed a decreasing tendency.

Based on our results we can conclude that regardless of the time from the appearance of the first symptoms the subjective complaints decrease with no significant difference after neurolysis. An early operation will result in a continuously improving tendency in the postoperative stage. Patients with longer anamnesis will reach an early improvement of symptoms thus high satisfaction at 1 week postoperatively. However, with time they do not improve their results. This way our hypothesis failed.

Surgical treatment of proximal nerve entrapment at the elbow by release of the lacertus fibrosus release with ultrasound surgery and WALANT

List of authors:
Gilles Candelier*, Yann Erwan Favennec¹, Thomas Apard¹
¹ Hand and Ultrasound surgery center, Private Hospital St Martin (Caen cedex)

Objectives / Interrogation: Compression of the median nerve to the elbow (PMNE) is considered rare. Difficult to diagnose, simulating a carpal tunnel with which it can sometimes be associated, it is rarely detected with conduction studies. The purpose of this study was to assess the feasibility and benefits of the ultrasound-guided release of lacertus fibrosus with Walant for the treatment of PMNE.

Methods: We conducted a prospective study from April 2015 to January 2017. Only patients with an isolated PMNE were included.
All patients received a bilateral clinical examination including muscle testing, a scratch collapse test, the search for a Tinel sign (elbow and wrist) and a Phalen sign. The strength was measured with a Jamar and the function was evaluated with a Quick DASH. All the patients have had a conduction study Diagnostic criteria were: an anomaly in the FPL, FCR and FDP II tests, a Tinel sign at the elbow below the Lacertus, a positive scratch collapse test, which disappears after cold application, an absence of clinical signs suggestive for a carpal tunnel syndrome and normal conduction study. Anesthesia was performed according to the WALANT protocol. A limited incision was made at the proximal edge of the lacertus. The section was performed with a kemis knife and an ultrasound guidance with a 6-15mHz probe. At the end of the procedure a testing of the FPL and the FDP II was performed to confirm the improvement of the immediate recovery of the motor function. All the patients have had a clinical review at D8, D45, and D90.

Results and Conclusions: We included 36 patients (20 women and 16 men) with an average age of 46.2 years (19-70). The dominant side injury involved 21 patients, two patients had bilateral injuries. No adverse events were noted during the procedure and no additional anesthesia was useful. Two postoperative hematoma was observed, which did not require resumption, and motor testing was normalized for all patients at the last follow up. The average preoperative Quick DASH was 38.9 (12 - 68.2). At the last follow up the average Quick Dask was 11 (0 - 38).
Conclusion: The Ultrasound-guided release of the lacertus fibrosus is effective and reliable for the treatment of the pronator median nerve entrapment. The Walant protocol allows immediate evaluation of the effectiveness of the treatment.

Surgical reconstruction for congenital thumb hypoplasia: a retrospective review of long-term results

List of authors:
Konrad Mende*1, Annelie Suurmeijer2, Michael Tonkin3
1 Universitätsspital Basel (Basel)
2 Onze Lieve Vrouwen Gasthuis (Amsterdam)
3 Royal North Shore Hospital, The Children's Hospital at Westmead, University of Sydney (Sydney)

Objectives / Interrogation: Congenital thumb hypoplasia is a malformation involving abnormal development and differentiation in the longitudinal radial axis. Various surgical reconstructions are available for each deficiency, but empirical evidence that allows for evaluation of the results of the different techniques is scarce. This retrospective study analyses the outcomes of patients who underwent surgical reconstruction for congenital thumb hypoplasia in our institution.

Methods: All patients who underwent surgical reconstruction for congenital thumb hypoplasia, performed by the senior author, and for whom a minimum of 3 years of follow-up data were available, were identified by a retrospective records review and were recalled for clinical assessment. Case notes, clinical assessments, and radiological data obtained from the medical records were reviewed. At follow-up, objective and subjective measurements were conducted.

Results and Conclusions: From 32 reconstructions for thumb hypoplasia in 29 patients, 19 patients (22 affected thumbs) could be included for analysis. The mean (SD) follow-up duration was 9.0 (3.9) years (range 3.6 years - 16.2 years). Our results for range of motion and subjective parameters are in line with data from comparable studies. The percentage of unstable metacarpophalangeal (MP) joints in this study was relatively high (45.5% in extension and 72.7% in 30° flexion) compared to the literature. Imbrication of local tissue alone at the ulnar side of the MP joint for ulnar collateral ligament reconstruction seems to stretch and fail with time. Furthermore, a secondary arthrodesis due to painful instability at the MP joint was required in four patients. The abductor digiti minimi (ADM) was the preferred method to restore opposition in our study in most cases. Compared to studies that used predominantly a Flexor digitorum profundus (FDS) opposition transfer, our patients had higher results in grip strength (77% of normal), despite the higher number of MP joint instability. However, the inconsistency of application of pre-operative classification is a problem with most outcomes studies on this topic and renders comparison difficult. The establishment of a valid, age-related assessment method for thumb hypoplasia, which considers preoperative measurements, includes intraoperative findings, and is applicable in the preoperative age category (1-3 years) would be a valuable contribution for the future.

Keywords: Congenital, thumb hypoplasia, reconstruction
Severe Dupuytrens Contracture treated by the McCash Technique (open palm) and Full Thickness Skin Grafts to the Involved Fingers: Results and Complications.

List of authors:
Joseph Imbriglia\(^1\), Glenn Glenn Buterbaugh\(^1\), William Hagberg\(^1\)
\(^1\)Hand and UpperEx Center, University of Pittsburgh (Wexford)

Objectives / Interrogation: Objective: We hypothesized that using an open palm technique and full thickness skin grafts would result in satisfactory correction of the flexion contractures with minimal complications.

Methods: Methods: 95 patients with severe Dupuytrens contracture were operated on between 2010 and 2017 by the senior authors. The patients were evaluated pre and post op by the surgeons. The average follow up was 18 months.

We evaluated:
1-ROM of MCP?\(^s\) + PIP?\(^s\) pre and post op
2-Post- operative pain
3-Time for healing of the open wound
4-Complications:
    flare reaction (RSD)
    loss of FTSG
    nerve injury

Results and Conclusions: Results: Patients were all seen initially at 3-5 days post op. They were then followed 2 weeks post-op. The average VAS pain score was 3.4 at 3-5 days post op and all patients were off any strong medication by 1 week.

ROM   pre-op           post-op
MCP   5 degrees        55 degrees
PIP   25 degrees       75 degrees

Time for healing of open of open wound was 18 days.

Complications:
flame reaction (RSD symptoms)- 3
loss of FTSG- 2
nerve injury/ neuropraxia- 2

Conclusion: Severe Dupuytrens contracture can safely be treated by using an open palm technique and small transverse finger incisions. Defects in the fingers are treated by full thickness skin grafts. The use of the open technique and small incisions results in very few severe complications.

Keywords:
Severe Dupuytrens, FTSG
The use of dorsal butters wire in treatment of distal radio fracture

List of authors:
Abdel Hakim Hakim Massoud¹, Nash Naam², Ahmad Akar¹, Tarek Badr¹, Amro Fouad¹
¹ Al Azhar Faculty of Medicine (Cairo)
² Southern Illinois Hand Center, Southern Illinois University (Effingham)

Objectives / Interrogation: Some cases with comminuted intra articular distal radius fracture have an associated dorsal rim fracture, this fracture may cause re displacement of the fracture and/or carpal bone dorsal subluxation. This study was aimed to assess the effectiveness of dorsal buttress wire in preventing re displacement of the fracture and carpal subluxation.

Methods: The study included 79 patient with AO type C unstable distal radius, all of them had a dorsal rim fragment that compromised the stability of the fixation after either ORIF or CRIF of the main fragments. An Intra-focal K-wire was inserted in the fracture site just proximal to the dorsal fragment obliquely to buttress it. The stability of the fracture was reexamined under fluoroscopy. This technique was used with volar plating in 16 patient and with CR and pining in the remaining patients.

Results and Conclusions: After a mean follow up of 18 months, there were no cases of fracture redisplacement during follow up period. However, CR did not achieve acceptable reduction in 7 patients secondary to more than 2 mm radial shortening and/or loss of solar tilt. The average Mayo wrist score was 72 point. Two cases developed CRPS that responded to conservative treatment. 17 patient were unsatisfied with the scar at the site of pin insertion.

Dorsal buttress k wire add in the stability of distal radius fracture post reduction and may represent a good alternative to simultaneous dorsal and solar plating.

Dorsal rim; Distal radius fracture; intra focal pinning
Arthroscopic Treatment of Thumb Basal Joint Arthritis

List of authors:
Abhijeet Wahegaonkar¹, Anup Bansode², Satish Mane², Chaitanya Karande Patil²
¹ Sancheti Institute for Orthopedics & Rehabilitation, Jehangir Hospital (Pune)
² The Hand Surgery Clinics, Sahyadri Hospital (Pune)

Objectives / Interrogation: Thumb carpometacarpal (CMC) joint arthritis is a common problem in clinical practice in the Western and other populations, with a variety of treatment options. However, it is not very common in the Indian sub-continent.

Patients, usually women, complain of pain, particularly with pinch and grip, which can interfere with daily activities.

When non-operative means of treatment fail, surgery is an option. Surgical options have included reconstruction of the ligaments about the thumb with or without removal of the joint surface, arthroscopic shrinkage of the ligaments or debridement, corrective osteotomy to redistribute contact forces in early stages of arthritis, arthroscopic and open procedures, thumb carpometacarpal (CMC) fusion, and excision of all or part of the trapezium with or without interposition of any materials.

Recent advances in small joint arthroscopy have established the role of this technique in the treatment of Grade II and early Grade III CMC arthritis of the thumb.

Arthroscopic treatment is relatively new and is performed only in select centers in the Indian sub-continent. It allows for joint visualization and treatment and staging of disease in a minimally invasive fashion with the ability to revise the surgery to complete trapeziectomy if necessary with progression of symptoms.

In this paper, which is the first report of arthroscopic treatment of thumb CMC arthritis, we describe our experience of arthroscopic debridement and ligament shrinkage in the treatment of CMC arthritis of the thumb in the Indian population.

Methods: We reviewed 12 patients who underwent arthroscopic debridement and thermal shrinkage in Eaton Stage II & III CMC arthritis of the thumb. We measured the grip and pinch strength and the range of motion.

Results and Conclusions: The minimum follow up was 1 year. All patients had a satisfactory reduction in their pain levels. There was a statistically significant improvement in the post-operative pain scores and the pinch strength while the ROM remained mostly unchanged. 3 patients had radiological deterioration of the arthritic changes with pain only on strenuous activities. There were no complications and all patients were satisfied with their outcomes.

Conclusion: Thumb arthroscopy and arthroscopically assisted treatment of the thumb CMC arthritis combined with thermal shrinkage of the capsule and ligaments is a safe and effective technique for Eaton stage II & III arthritis.

Surgery for the tetraplegic upper limb: Initial experience and early results

List of authors:
Erich Mennen*
1 Muelmed Rehabilitation Centre (Pretoria)

Objectives / Interrogation: The need for upper limb surgery for tetraplegic patients was identified at a large spinal rehabilitation centre. (100 bed unit)
A clinic dedicated to the care of these patients was established in 2013 focusing on a team approach including surgeons, occupational and physiotherapists.
This study is a retrospective review of the first 21 patients treated surgically at our unit.

Methods: Tetraplegic patients are seen once a month at a dedicated clinic for evaluation and possible upper limb surgical reconstruction.
Surgical procedures consisted of either posterior deltoid to triceps, or biceps to triceps transfer for restoration of elbow extension.
Grasp and pinch reconstruction was performed according to principles described as the Alphabet procedure.
Nerve transfers limited to the supinator nerve to the posterior interosseous nerve in selected early cases.

Results and Conclusions: Patients in the biceps to triceps group improved an average of 2 MRC grades of elbow extension.
Grasp reconstruction patients exhibited an improvement in pinch grip and finger flexion power.
All surgeries evaluated according to the Canadian Occupational Performance Measure (COPM)
Nerve transfers performed end to end and encouraging early results achieved.

Surgical reconstruction of the upper limb in tetraplegia is to the benefit of the patient.
Patients express a high level of satisfaction following procedures performed for elbow extension and grasp and pinch reconstruction.
We aim to continue offering upper limb surgery to these patients and hope to improve our approach and techniques.

Keywords:
Philological role of the upper limb and other parts of the body

List of authors:
Igor Golubev\*\(^1\), Bella Gazimieva\(^2\), Maksim Sautin\(^2\)
\(^1\) Priorov State Medical Research Centre (Moscow)
\(^2\) ECSTO (Moscow)

Objectives / Interrogation: Human perception of the body directly affects the formation of language. The significance of certain body parts can be represented by the actions and verbs associated with them. Knowing this connection can help assess their value.

Methods: We compiled a questionnaire with one hundred of the most frequently used verbs of English according to Linguasorb.com and five body parts: eyes, ears, upper and lower limbs, and the heart. The interviewees were asked to select which verbs they associated with the given body parts. By association we considered subjective - rational or intuitive - opinion that certain body parts logically relate to actions described by the verbs. It was necessary to indicate participants' age, gender, level of proficiency in English and native language.

Results and Conclusions: Overall 40 people participated in the survey. Average age was 30 years, from 19 to 48. The percentage of males was 42.5%, females - 57.5%. The native language for the majority (36 people) was Russian, one each for German, French, Spanish and Karachai. The level of English was determined as A1 by 3 people, as A2 - by 4, as B1 - by 9, as B2 - by 10, as C1 and C2 - by 7 for each. We analyzed the answers to the questionnaire. There were no verbs for which respondents would uniquely give a single answer, although for each verb the answer was predominant. We estimated the most frequent body part-verb connection. For example, for the verb "be" the most frequent association was with heart, for "go" - legs, for "put" - hands. Then we evaluated body parts that were chosen more than others for each verb. Thus, 40 verbs were associated with hands, 20 - eyes, 19 - legs, 17 - heart, 4 - ears.

Human perception of organs, segments and parts of the body has a natural reflection in the use of verbs. From philological point of view, amongst different parts of the body, upper limb and especially hand has been considered a unique and indispensable tool, being the most functional one, whereas the sense organs can be referred to as specific and monofunctional.

The Safety of Hand and Upper-Extremity Surgical Procedures at a Freestanding Ambulatory Surgery Center: An Updated Review of 41,751 Cases

List of authors:
Glenn Glenn Buterbaugh*, Jennifer Peterson2, Joseph Imbriglia1
1 Hand and UpperEx Center, University of Pittsburgh (Wexford)
2 Western PA Surgery Center (Wexford)

Objectives / Interrogation: More Procedures are being completed on an outpatient basis at freestanding ambulatory surgery centers. The purpose of our study was to determine the safety and rate of adverse events in outpatient hand and upper-extremity surgical procedures.

Methods: A retrospective review of cases at a single, freestanding ambulatory surgery center over an sixteen-year period was performed. In our analysis, 41,751 cases were performed and were included. Adverse events were defined as serious complications causing harm to a patient or leading to additional treatment. Using state-reportable adverse events criteria as a guideline, we divided the adverse events into seven categories: infection requiring intravenous antibiotics or return to the operating room, postoperative transfer to a hospital, wrong-site surgical procedure, retention of a foreign object, postoperative symptomatic thromboembolism, medication error, and bleeding complications. These adverse events were then analyzed to determine if they led to additional laboratory testing, hospital admission, return to the operating room, emergency department visits, or physical or mental permanent disability.

Results and Conclusions: Results: There were eighty-six reported adverse events, for an overall rate of 0.21%. There were no deaths. There were twenty-five infections, twenty-four postoperative transfers to a hospital, thirty-two hospital admissions after discharge, one medication error, and four postoperative hematomas. There were no cases of wrong-site surgical procedures or retained foreign bodies.

Conclusion: Our study shows that, with a selected patient population, a very low adverse event rate (0.21%) can be achieved. Our review showing few adverse events, no deaths, and no wrong-site surgical procedures supports our view that hand and upper-extremity surgical procedures can be completed safely in the outpatient setting at a freestanding ambulatory surgery center.

Preliminary experience with the litos/ dynamic finger distractor for proximal interphalangeal joint fracture dislocations

List of authors:
Hannes Granberg*, Allan Ibsen-Sørensen1, Peter Axelsson1
1 Sahlgrenska University Hospital, Department of Hand Surgery (Gothenburg)

Objectives / Interrogation: Objectives:
We aimed to establish clinical and radiographic outcomes of unstable proximal interphalangeal (PIP) joint fractures treated with the litos/ finger distractor device.

Methods: Methods:
We retrospectively reviewed notes of 18 consecutive cases of patients with unstable fractures involving the PIP joint. We recorded infections and re-operations. Active range of motion was reviewed at 4-6 weeks and at 8-12 weeks. Joint defects of more than 1mm and incongruity were assessed using plain radiographs.

Results and Conclusions: Results:
A total of 10 men and 8 women with an average age of 34.5 (range 17-65) years were included. The average extension lag at 4-6 weeks, before removal of the distractor, was 20° (0-50) with active flexion to 65° (40-90). At 8-12 weeks post operatively was 20° (5-55) and 75° (60-95) respectively. Out of the 18 cases, one required a re-operation due to surgical issue and there were five superficial pin site infections requiring a course of oral antibiotics. Two joint surfaces had a step >1mm and four a defect of >1mm. Two patients had subluxed joints on follow up x-rays following removal of the distractor.

Conclusions:
Fractures involving the PIP joints of the fingers are difficult fractures to manage surgically with unpredictable outcomes. These fractures are frequently complicated by dislocation of the joint, which demands distraction to align the joint surfaces yet allowing early motion in order to prevent stiffness. There are multiple methods for addressing this but many are technically demanding. The litos/ finger joint distractor offers an alternative in a ready-made package. This system relies on three K-wires and two spring-loaded adjustable distractors holding the reduction while allowing movement of the PIP joint immediately after the operation.
The litos/ finger joint distractor system was relatively easy to use and the post-operative range of motion and the radiographic results were good considering the type of injury. There was a substantial amount of complications but only one required surgical intervention.

Revision-Arthrodesis after Failed Total Wrist Arthroplasty

List of authors:
Martin Lautenbach*, Arne Tenbrock
1 Waldfriede Hospital Berlin, Dep. Hand Surgery, upper Extremity and Foot Surgery (Berlin)

Objectives / Interrogation: Traumatic arthrosis, osteo arthrosis, rheumatoid arthritis and other lesions at the region of the wrist may lead to severe pain, malposition, instability and malfunction of the wrist joint. Resections of parts of the destroyed joint, partial fusions and the wrist arthrodesis are today the standard methods to treat these complaints. Different types of total wrist arthroplasties were developed to preserve painfree motion. But there is a high incidence of failures of total wrist arthroplasties. We review our experiences in revising total wrist implant arthroplasties to arthrodeses. The most common mode of failure of the arthroplasties in our series was metacarpal loosening with dorsal perforation of the stem. Loosening of the proximal stem, progressive malposition of the wrist and other causes appeared. We used for the revision arthrodesis in all our cases tricortical iliac crest bone grafts and additional spongiosa transplants from this donor site region. In one case we used a vascularized iliac crest bone graft to bridge the bone defect because of a bad host quality of the recipient area. Fixation was achieved with plates and screws.

Methods: Our average follow-up period was 60 month. 81 patients with failed wrist implants (7 different types) were treated with this technique. 80 wrist's undergoing arthrodesis achieved a solid painless fusion after a single operation. In one case a non-union with a loosening of the screws due to using a non-rigid plate was seen. In this case a revision was necessary to achieve a bone healing. In defined time spans all patients received examinations of range of movement of the finger joints and the force of the hands. Clinical and radiological control was carried out in comparison of both hands. The assessment of the result after healing according to the DASH-score (Disability of Arm/Shoulder /Hand) was done.

Results and Conclusions: All patients were satisfied, pain free and achieved an increased pinch and grip strength after bony fusion (measured with Yamar-Vigorimeter). A persisting loss of carpal height was seen in all cases. Arthrodesis after failed total wrist arthroplasty is a satisfactory salvage procedure even in cases with a bad quality of the recipient area. We recommend a rigid fixation technique to prevent non-unions.

Keywords: Failed Total Wrist Arthroplasty
INTRAMEDULLARY CANNULATED HEADLESS COMPRESSION SCREWS OSTEOSYNTHESIS FOR METACARPAL AND PHALANGEAL FRACTURES

List of authors:
Alessandro Fagetti*, Francesca Fissore, Paolo Borelli, Denise Girotto, Mario Cherubino, Michele Francesco Surace
1 Ospedale Circolo Fondazione Macchi Varese
2 Insubria University - Varese-Como
3 Casa di Cura San Camillo

Objectives / Interrogation: Intramedullary fixation of metacarpal and phalangeal fractures using cannulated headless screws is an effective technique with several theoretical advantages, among which minimal local invasiveness and early mobilization. The aim of our study is to evaluate the functional results and subjective evaluation.

Methods: 29 patients with a total of 33 fractures (26 metacarpal and 7 phalangeal) were surgical treated by the same surgeon with intramedullary cannulated headless screws. 3 patients had multiple fracture and they were all treated with this technique and in 4 cases there were severe soft tissue injury associated. Five were open fractures. Patients were followed prospectively until bone radiographical healing and a last evaluation was performed with a minimum 6 months follow-up. Functional results were evaluated in terms of active range of motion, grip force and pinch key, MHQ (Michigan Hand outcome Questionaire) and VAS (Visual Analogc Scale).

Results and Conclusions: At the latest follow-up (average 14 months, range 6-28) the mean total active motion was 239° (range 105°-280°), 250° (150-280) for metacarpals and 197° (105-280) for phalanges. Even if the technique requires a violation of the extensor tendon, the mean extension LAG at the MF was 1° and 0.7° at the PIP (excluding patients with concomitant tendon lesions). Patients recovered grip strength that was not significantly different from the contralateral limb. The average MHQ evaluation of patients with no associated lesions was 98% (compared to 75% of patients with associated soft tissue traumas). Patients with transverse and short oblique fractures obtained objective and subjective better results than patients with comminuted fractures. There were no cases of secondary displacement, malunion or non-union, rotational defects, infections or CRPS. Complications in terms of decreased range of motion and functional poor results were observed only in 3 of the 4 patients with associated soft tissue trauma (tenolysis is already planned for two of them). Despite intramedullary devices for treatment of metacarpal and phalangeal fractures has been known for a long time, the use of intramedullary compression cannulated headless screws has recently been increased. In our experience and according to literature, this technique leads to better results in transverse and short oblique fractures and allow early mobilization and faster coming back to activities.

Clinical and ultrasonographical follow-up after early removal of distal radius volar plates positioned distal to the watershed line

List of authors:
Pieter-Bastiaan De Keyzer\textsuperscript{1}, Chul Ki Goorens\textsuperscript{2}, Jean Goubau\textsuperscript{3}
\textsuperscript{1} UZ Brussel (Jette)
\textsuperscript{2} RZ Tienen (Tienen)
\textsuperscript{3} AZ Sint-Jan Brugge, UZ Brussel (Jette)

Objectives / Interrogation: Volar plating is accepted as standard treatment for distal radius fractures. Marginal fracture types may require plate positioning distal to the watershed line or volar rim precontoured plates to obtain stable anatomical fixation. Hardware distal to the watershed line is associated with increased flexor tendon pathology, with the flexor pollicis longus tendon (FPL) most at risk. We've performed early plate removal after bony consolidation to prevent these complications. Our purpose is to evaluate the procedure relevance of early hardware removal of plates distal to the watershed line was evaluated.

Methods: 20 patients, treated between 2013 and 2017, with plate positioning grade 1 or 2 according to Soong classification were included. Assessment was performed with mobility and grip strength measurements, function scoring with Quickdash, patient satisfaction questionnaire and ultrasonographical measurements of the distance of FPL to the volar rim and pronator quadratus (PQ) diameter.

Results and Conclusions: 8 cases had Soong grade 1 prominence, 12 were grade 2. Standard volar plate was used in 12 cases, volar rim plate in 8 cases. Anatomical reduction and bony consolidation were achieved in all cases. Mean time from placement to removal was 10.8 months. Mean time from removal to assessment was 2.9 years. Mean flexion and extension was respectively 87% and 90% compared to the contralateral side, ulnar and radial deviation 90% and 88%. Pro- and supination was symmetrical. Mean grip strength was 95% compared to the opposite side. Mean Quickdash score was 21.5. 85% of patients described their result as good to excellent with sense of improved mobility and decreased flexor tendon friction. 80% would undergo the intervention again. No refracture occurred. 1 patient suffered CRPS. After plate removal, the distance between FPL and volar rim increased from direct contact between tendon and bony prominence with plate in place, but was significantly lower in neutral (p=0.013) position and in full flexion (p=0.046) compared to the opposite side. PQ diameter showed no significant difference compared to the opposite side.

We conclude that early hardware removal for prominent plates results in high patient satisfaction, with a partial normalization of the flexor tendon positioning in reference to the distal radius on ultrasound.

Inflammatory processes and elevated osteoclast activity chaperon atrophic non-union formation in a murine model.

List of authors:
Björn Behr¹, Sonja Schmidt², Christoph Wallner², Mehran Dadras², Mustafa Becerikli², Marcus Lehnhardt¹, Johannes Maximilian Wagner*²
¹ BG Universitätsklinikum Bergmannsheil Bochum, Klinik für Plastische Chirurgie, Handchirurgiezentrum (Bochum)
² University Hospital Bergmannsheil Bochum (Bochum)

Objectives / Interrogation: Delayed bone healing, especially in long bones poses one of the biggest problems in orthopeadic and reconstructive surgery and causes tremendous costs every year. There is a need for adequate therapy but first of all we need to explore the causes. Earlier investigations of human scaphoid non-union revealed an elevated osteoclast activity, accompanied by upregulated levels of TGF-beta and RANKL. Interestingly, scaphoid non-union seemed to be well vascularized.

Methods: In the current study, we used a murine femur-defect model to study atrophic non unions. Different points of times were chosen over an observation period of 10 weeks, to gather insights into the dynamic processes of non-union formation.

Results and Conclusions: Histological and gen-expression analysis indicated enhanced osteoclast activity throughout the observation period, ongoing with elevated levels of TGF-beta, TNF-alpha, MMP9, MMP13 and RANKL. To our surprise, osteoblastogenesis seemed to be unaffected during early stages of non-union formation. Taken together we gained first insights into the formation process of atrophic non unions, in which inflammatory processes with a highly elevated osteoclast activity seem to play a leading role. Based on this findings new therapeutic options and treatment strategies could be investigated.

Keywords: non-union, osteoclast, RANKL
Correction of Thumb Duplication: A Systematic Review of Surgical Techniques

List of authors:
Robert Miller*, Dariush Nikkhah
1 Royal London Hospital (London)
2 Queen Victoria Hospital (East Grindstead)

Objectives / Interrogation: Surgical intervention for thumb duplication can be divided into three categories: simple excision of the accessory thumb, excision of the accessory thumb with reconstruction from available 'spare parts' and combining the two thumbs into one, as described by Bilhaut. This prospectively PROSPERO registered systematic review evaluates the overall, aesthetic and functional outcomes for the latter two options, aiming to facilitate evidence-based decision making when addressing thumb duplication and direct future research.

Methods: The review was performed in accordance with the Cochrane Handbook of Systematic reviews and PRISMA statement. Embase, PubMed, Medline and Cochrane databases were systematically searched. Studies offering comparisons of techniques were included. Risk of bias was assessed using the ROBINS-I tool. The quality of the evidence was assessed using the GRADE.

Results and Conclusions: Ten retrospective observational studies were included. Data did not consistently allow analysis by procedure type. Four studies reported similar overall outcomes between techniques, whilst two specifically reported poor overall outcomes for the Bilhaut procedure. Two studies reported comparatively worse aesthetic outcomes for the Bilhaut procedure with four studies reporting comparatively improved functional outcomes for this procedure. Overall, interpretation of outcomes was challenging with no patient reported outcome measures used. The quality of the evidence was universally 'very low' due to all studies being at risk of methodological bias.

Based on the available evidence, surgical techniques for thumb duplication correction appear comparable regarding overall outcome. There is limited evidence suggesting reconstruction with spare parts offers superior aesthetic outcomes at the expense of stability. However, the quality of available evidence is poor with few comparative studies, much heterogeneity between methods regarding outcome reporting and significant challenges regarding bias.

Further research is needed in the form of well conducted prospective comparative studies comparing surgical techniques. These should use appropriate patient reported outcome measures to facilitate evidence-based, patient orientated, decision making regarding the surgical management of thumb duplication.

Ulnar dimelia with mirror hand - Current treatment strategies

List of authors:
Mike Ruettermann*¹, Rolf Habenicht²
¹ University Medical Center Groningen, HPC Oldenburg (Bunde)
² Katholisches Kinderkrankenhaus Wilhelmstift (Hamburg)

Objectives / Interrogation: Ulna dimelia is a rare congenital disorder, presenting with mirror hand, a term that describes the clinical presentation of this condition. But not all patients present with symmetry. There are numerous variations of digits in this condition, mostly seven fingers are present. The normal pre-axial or radial structures, like thumb, index, trapezium, scaphoid and radius are missing and the radius is replaced by a second ulna.
As genetic knowledge about limb bud formation increases, there is still a paucity of data regarding optimal treatment of this condition.

Methods: Problems that need to be taken into account in the treatment of mirror hands with ulnar dimelia are:
Limited elbow movement, decreased pro-/supination of the forearm, flexion contracture of the wrist with radial deviation, absent or weak extensor tendons, supernumerous digits but absent thumb, absent first webspace and thenar, thus no opposition, furthermore there may be syndactyly, divergent metacarpals and/or a palmar cleft.

In order to achieve an optimal functional outcome with an aesthetically pleasing, or at least inconspicuous, result one has to combine multiple steps of treatment that should be carefully planned and combined, if feasible, in order to minimize patient and his family’s burden.

The authors present their experience in treating several cases including the treatment protocol that developed over time as well as intraoperative steps and long-term follow-up.

Results and Conclusions: Our treatment strategies are derived from experience with congenital disorders. This knowledge lead to optimisation of the treatment of mirror hand. Furthermore experience with our own cases and their follow-up improved our strategy. The rarity of this congenital anomaly prevents feasibility of randomized controlled trials, because even if those would be ethically accepted, there would not be enough statistical power to those studies due to the limited number of cases. Thus the best available evidence is level IV.

The first step is adequate diagnosis, clinical and radiologic examination. When elbow flexion is feasible, which is mostly the case in young babies, the deviated wrist is splinted to correct deviation. The next step is a 3-dimensional distraction, similar to radial club hand treatment and thereafter a modified centralization. Thereafter a modified pollicisation with a reasonable compromise between form and function follows. Later a modified resection arthroplasty of one of the olecrans is helpful in improving pro-/supination.

Concealed TFCC Tears Revealed- Role of Wrist Arthroscopy in the Diagnosis & Treatment of Occult Chronic TFCC Injury

List of authors:
Abhijeet Wahegaonkar¹, Chaitanya Karande Patil², Anup Bansode², Satish Mane²
¹ Sancheti Institute for Orthopedics & Rehabilitation, Jehangir Hospital (Pune)
² The Hand Surgery Clinics, Sahyadri Hospital (Pune)

Objectives / Interrogation: The triangular fibrocartilage complex (TFCC) is an important stabilizer and load absorber in the wrist. There is a significant load borne by the ulnar aspect of the wrist during different wrist positions that pass predominantly through the TFCC. Injury to the TFCC is a frequent cause of pain and disability in the wrist. Good results have been reported with open repair. Advances in wrist arthroscopy have enabled these lesions to be repaired by minimally invasive methods. Arthroscopic repair of peripheral TFCC tears can provide satisfactory results with significant pain relief, increased grip strength, and an increased capacity to perform daily activities.

There is a large cohort of patients with an acute on chronic type of TFCC injury, who are clinically diagnosed with a TFCC tear with or without DRUJ instability, however the MRI is often unequivocal. We believe that this is due to scar formation in the injury zone that masks the lesion on an MRI. Arthroscopic examination and shaving of the scar tissue reveals the tear and allows optimal treatment of the lesion.

Methods: In this paper we describe our experience of 25 cases with chronic TFCC injury and an unequivocal MRI report. Arthroscopic evaluation and shaving followed by repair was performed. All patients were followed up for a minimum of 12 months. ROM, grip strength, pain scores and DRUJ stability were measured for outcomes measures.

Results and Conclusions: All patients had a significant improvement in their post-operative average Mayo Wrist Scores as compared to the pre-operative scores.

Arthroscopy of the wrist is considered the "gold standard" for evaluating and treating many intra-articular wrist conditions, such as triangular fibrocartilage complex tears, chondral injuries, distal radius fractures, carpal fractures, wrist ligament injuries, loose bodies, and ganglia. However, a thorough knowledge of wrist anatomy and surface landmarks is essential to proper diagnosis and treatment.

Diagnosis und therapy of isolated flexor pollicis longus fascicle lesions

List of authors:
Johannes Mayer*1, Andreas Gohritz2, Stefan Salminger3, Gerd Bodner4, Jan Friden2, Oskar C. Aszmann3
1 CD Laboratory for Restoration of Extremity Function, Med. University Vienna/Eberhard Karls University Tuebingen (Vienna/Tuebingen)
2 Swiss Paraplegic Center (Nottwil)
3 CD Laboratory for Restoration of Extremity Function, Division of Plastic and Reconstructive Surgery, Medical University of Vienna (Vienna)
4 Privat Ultrasound Center Vienna (Vienna)

Objectives / Interrogation: Isolated flexor pollicis longus (FPL) nerve fascicle lesion represents a rare differential diagnosis of thumb flexion deficiency. Iatrogenic lesions of the FPL nerve fascicles can occur during operations in the forearm (e.g. osteosynthesis, removal of osteosynthesis material) due to its anatomical location. Here we illustrate three clinical cases and discuss the diagnostic and therapeutic modalities of thumb flexion reconstruction.

Methods: We present three patients (1 female, 2 male) who developed a thumb flexion deficiency following osteosynthesis or removal of osteosynthesis material after forearm fracture. Additionally to a thorough clinical examination, electrodiagnostic studies as well as high-resolution ultrasound investigations were performed.
In all three cases surgical exploration of the anterior interosseous nerve was performed and the isolated FPL fascicle lesions were confirmed by inspection, palpation and electrostimulation. Reconstruction in two cases was performed using a single 35 mm long nerve graft from the distal AIN (n=2). One patient was beyond nerve surgical repair (5 years after the injury) as such a tendon transfer using the extensor carpi radialis longus was performed. Active range of motion was assessed using a goniometer at three, six and twelve months after surgery. Functional outcome was additionally documented with videography.

Results and Conclusions: All three patients regained excellent thumb interphalangeal flexion with fine motor skills as was documented in active range of motion and videography.
There was no clinically detectable deficiency in forearm pronation after nerve harvest of the distal AIN in these two cases.

Iatrogenic isolated flexor pollicis longus (FPL) nerve fascicle lesion is a rare differential diagnosis of thumb flexion deficiency. We present our clinical experience, diagnostic algorithm and therapeutic options with this rare phenomenon. Primary reconstruction of the fascicle lesion with a distal AIN graft is a viable option for reconstruction of thumb flexion in such cases. If patients present late after injury, tendon transfers are still feasible and lead to a good functional result.

Innovations in man-machine interface for control and feedback of bionic prostheses

List of authors:
Martin Aman¹, Matthias Sporer², Christopher Festin³, Christian Hofer⁴, Michael Friedrich Russold⁴, Oskar C. Aszmann⁵
¹ CD Labororatory for Extremityreconstruction, Department of Biomedical Reserach, Medical University Vienna (Wien)
² CD-Labor für Wiederherstellung für Extremitätenfunktionen, Plastische und Rekonstruktive Chirurgie (Wien)
³ CD-Labor für Wiederherstellung für Extremitätenfunktionen (Wien)
⁴ Otto Bock Healthcare Products (Wien)
⁵ CD Labor für Wiederherstellung von Extremitätenfunktionen, Abteilung für plastische und rekonstruktive Chirurgie, Medizinische Universität Wien (Wien)

Objectives / Interrogation: Bionic prostheses are an essential part of modern extremity reconstruction. Hereby the remaining bottle neck and main cause of high prostheses abandonment rates is the lack of a reliable interface between man and machine. Therefore, new implantable devices, capable of intuitive and sophisticated control as well as interfaces for sensory feedback, are important fields of research.
Aim of this study was to investigate an intraneural electrode for control and feedback as well as a full implantable system for reliable control in a rat and a rabbit model.

Methods: In a rat model a longitudinal intraneural electrode was implanted into the sciatic nerve and evaluated over different time periods (4-12 weeks) for biocompatibility as well as functional aspects. Further, a full implantable system, containing electrodes for EMG based control as well as a neural electrode for creating feedback sensations was implanted in a rabbit model and analyzed for feasibility, biocompatibility, reliability as well as technical features.

Results and Conclusions: Intraneural electrodes showed fibrosis and encapsulation in the nerve. This nerve damage further resulted in distal muscle atrophy and loss of muscle force.
The full implantable system was successfully tested for the investigation period (8 weeks) and evaluated for biosafety as well as technical features.
Conclusions:
Peripheral nerve interfaces have the capability of afferent and efferent interfacing with the human body. Nevertheless, there is always a compromise between interface selectivity and nerve damage. Fibrosis and resulting changes in impedance, as well as challenges in control with neural signals, emphasize EMG based control. With the tested EMG based fully implantable system, disadvantages of surface electrodes could be overcome to create a reliable and sophisticated prosthetic control.

RADIOCARPAL FRACTURE DISLOCATIONS: A NEW CLASSIFICATION PROPOSAL

List of authors:
emygdio jose leomil de paula¹, rames mattar junior¹
¹ iot hcfmusp (sao paulo)

Objectives / Interrogation: A new classification proposal based on observation of 40 radiocarpal fracture dislocations.

Methods: The authors analyzed prospectively, the radiocarpal fracture dislocations patterns in 40 patients, utilizing Rx incidences in Post-anterior and Lateral views, and surgical findings, treated between 1995 and 2018 using the Dumontier Classification.

Results and Conclusions: There were 36 men and 4 women. The mean age was 24 years (range 18-45). They observed that in 30% (12) of the patients analyzed, had no correlation with the Dumontier classification. Nine patients, considered type II in Dumontiers Classification, presented fracture of the anterior lip that was interposed, or the Radio-lunate ligaments were torn. Three patients had a carpal bone fracture and no intrinsic ligament lesion was observed.

Conclusion: The Radiocarpal Fracture dislocation is a complex lesion and a more complete classification should be adopted.

Arthroscopy Assisted Partial Wrist Fusion without using Bone Graft

List of authors:
Abhijeet Wahegaonkar¹, Satish Mane², Chaitanya Karande Patil², Anup Bansode²
¹ Sancheti Institute for Orthopedics & Rehabilitation, Jehangir Hospital (Pune)
² The Hand Surgery Clinics, Sahyadri Hospital (Pune)

Objectives / Interrogation: Partial wrist fusion is an effective surgical procedure for providing pain relief while preserving motion of the wrist in patients with localized arthritis of the carpus. The key is to fuse the involved joints and to allow motion through the uninvolved joints. Common indications for partial wrist fusions include scapholunate advanced collapse (SLAC) and scaphoid nonunion advanced collapse (SNAC).

Wrist arthroscopy allows excellent visualization of the articular surfaces of the carpal bones and ligaments while preserving the vascularity and soft tissue integrity which is violated in procedures employing arthrotomy. This serves as an apt basis for performing arthroscopy assisted partial wrist fusions. All potential complications such as adhesions and loss of movements are minimized by arthroscopic partial wrist fusion combined percutaneous fixation techniques.

Methods: We report our results of arthroscopic partial wrist fusions for various pathologies like Kienbocks disease, scaphoid non-union and post traumatic radio-carpal arthritis. While most authors use bone grafting with these procedures, we report out results without the use of any bone graft. This reduces the surgical time and morbidity without affecting union rates.

Results and Conclusions: 18 patients underwent arthroscopy assisted partial wrist fusion between June 2013 to December 2016. The pathologies included Kienbocks disease, scaphoid non-union and post traumatic radio-carpal arthritis.

10 patients underwent lunate excision and scapho-capitate fusion for Kienbock’s disease, 6 patients with SNAC II/ III wrist following scaphoid non-union underwent a scaphoid excision and capito-lunate fusion, while 2 patients underwent a radio-scapho-lunate fusion following radiocarpal arthritis resulting from a malunited intra-articular fracture of the distal radius. No bone grafting was utilized in any of the cases.

All patients had a significant improvement in their post-operative VAS and Mayo Wrist scores.

No post-surgical complications were observed and uneventful radiologic union was obtained in all cases.

Onychomatricoma in the hand - three cases

List of authors:
Sarah Breiter*, Martin Franz Langer2, Simon Oeckenpöhler3, Britta Wieskötter1, Johanna Ueberberg1
1 Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)
2 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)

Objectives / Interrogation: Onychomatricoma is a rare benign fibroepithelial tumor developing from the nail matrix with striking clinical and histologic features. Onychomatricoma was first described in the literature in 1992 by Baran and Kint and less than 60 cases are described in the hand.

Methods: We report three case of onychomatricoma occurring in two female and one male with many years history of asymptomatic thickening of the fingernail. There was no history of preceding trauma. Nail clippings for mycology were negative on three occasions and hand radiographs showed no bony abnormality. Examination revealed diffuse thickening of the fingernail with increased transverse over-curvature. The nail was yellowish in color and there were longitudinal hollows visible as holes in the distal border. The nails of other fingers and toes were normal.

Results and Conclusions: Several clinical signs are striking enough to either make the diagnosis or at least to arouse suspicion:
- Longitudinal thickening of a part of the nail plate that often spares a portion of the normal pinkish nail
- Transverse and longitudinal overcurvature of the affected portion of the nail
- Xanthonychia of the affected part of the affected nail
- Longitudinal ridging that is sometimes quite prominent on the surface of the nail
- Splinter hemorrhages that are mostly proximal but sometimes distal
- Honeycomb cavities at the frontal margin of the thickened nail plate

Increased awareness of this entity is required among dermatologists, hand surgeons and histopathologists to ensure it is correctly diagnosed as there is a paucity of information in standard textbooks.

Paediatric Peripheral Nerve Injury: Long term Sensorimotor Recovery following Primary Surgical Repair

List of authors:
Benjamin Langridge*, Michelle Griffin, Mo Akhavani, Peter Butler

1 Department of Plastic and Reconstructive Surgery, Royal Free London NHS Foundation Trust (London)

Objectives / Interrogation: Peripheral nerve injuries in children are uncommon and complex to manage. A low threshold for surgical exploration should be used where there is a possibility of underlying nerve injury. Due to peripheral nerve injury being uncommon in this population there is a paucity of data on long term sensorimotor and functional outcomes following surgical repair. We present an 11-year retrospective analysis of paediatric peripheral nerve repair to identify long-term functional outcomes and risk factors for suboptimal recovery.

Methods: We conducted a retrospective analysis of our centre’s trauma database over an 11-year period to identify all patients under the age of 18 years presenting with peripheral nerve injury who underwent primary surgical repair, with nerve injury being confirmed intra-operatively. Electronic medical records were analysed to extract procedure type, time to surgery, mechanism of injury, past medical history, post-operative complications, post-operative sensorimotor recovery and post-operative follow up period. Descriptive statistics were applied to characterise the patient cohort. Statistical analyses were conducted to identify risk factors for suboptimal sensorimotor recovery.

Results and Conclusions: A total of 108 patients were identified over an 11-year period (2006-2018) from our dataset analysis. 13 patients were excluded due to incomplete data and 8 were lost to follow up. Of the 87 patients (61 male, 26 female) included in our study, the mean age at the time of injury was 7 years (0-16 years). Mean time to surgery from presentation was 2.2 days (0-8 days). Mechanisms of injury were predominantly lacerations with sharp objects or crush injuries. Of 87 patients with follow up data, 4 did not have sensorimotor improvement, 83 patients had either partial or complete sensorimotor recovery (95.4%). Post-operative complications were rare.

Long term sensorimotor recovery in paediatric patients with peripheral nerve injury requiring surgical repair is excellent. Post-operative complications are uncommon. Age at time of injury is inversely correlated with sensorimotor recovery, time to surgical repair is not correlated with sensorimotor recovery.

Botulinum Toxin A in the treatment of Raynaud's phenomenon secondary to Systemic Sclerosis; results of an open cohort study

List of authors:
Michelle Griffin.*, Kiran Dhaliwal¹, Ben Langridge¹, Kevin Howell², Christopher Denton², Peter Butler¹
¹ Royal Free Hospital, Plastic Surgery Department (London)
² Royal Free Hospital, Rheumatology Department (London)

Objectives / Interrogation: Among patients with systemic sclerosis Raynaud's phenomenon (RP) is common causing pain, paraesthesia, ulceration, and gangrene. Botulinum toxin A (Btx-A) can be an effective treatment for RP when injected via a digital palmar approach. However, this technique can cause hand weakness resulting from lumbrical malfunction. This study aimed to determine the effect of Btx-A injected via a dorsal innovative approach to treat RP, limiting potential complications and to improve efficacy.

Methods: Thirty-eight patients received 100 units of Btx-x injected into both hands via a dorsal approach. Each patient had a baseline and 6-week hand assessment and thermographic image (FLIR E60bx).
Hand assessment included pinch and power grip strength measurements (Jammar plus digital pinch gauge and dynameter), range of movement using a goniometer, Kapandji thumb opposition test and a pain score using the visual analogue scale (VAS score 0-10). Patients were asked to report any symptoms of pain, colour change, cold intolerance on a weekly basis. Furthermore, patients were asked to complete a Disabilities of the Arm, Shoulder and Hand (DASH) score. Post injection, the hand assessment and thermography was performed at 15 minutes and at 6 weeks in a temperature controlled room at 23.7 +/- 2°C.

Results and Conclusions: Eighty-eight percent of patients reported an improvement in symptoms with a decrease in pain, swelling and improve colour change. Furthermore, 80% reported an improvement in cold intolerance with a decrease in their frequency and severity of Raynaud's attacks (p < 0.01). There was also a significant improvement in both the DASH score (p = 0.001), Kapandji score (p=0.001) and Hand strength (p<0.05) after 6 weeks. No patients reported any weakness at 6 weeks.
There was a significant mean increase in the temperature of all fingers after 6 weeks compared to baseline(p < 0.05). There was also a significant increase in the range of movement in all joints post Btx-A injection (p < 0.05). There were no complications with the innovative approach.

Btx-A injected via a dorsal approach improves symptoms and hand function of RP secondary to systemic sclerosis. We have shown an effective and safe surgical technique to treat RP in systemic sclerosis patients that can be delivered in an outpatient setting.

Does intra-articular and extra-articular soft tissue procedures can improve global shoulder function and glenohumeral deformity in OBPP patients? Retrospective cohort of 17 patients.

List of authors:
Alvaro Cho*, Marco Moraes, Gustavo Bersani, Raquel Iamaguchi, Laura Lorimier, Lendro Kiyohara, Rames Mattar Júnior, Marcelo Rezende, Teng Wei
1 Instituto de Ortopedia e Traumatologia da FMUSP, Grupo de Mão e Microcirurgia da FMABC (sao paulo)
2 Instituto de Ortopedia e Traumatologia da FMUSP (sao paulo)

Objectives / Interrogation: Whether or not combined intra-articular and extra-articular soft tissue procedures can improve global shoulder function and glenohumeral deformity in OBPP patients.

Methods: From March 2013 to October 2018, 30 procedures where performed in 27 children with obstetric brachial plexus palsy to improve shoulder external rotation and abduction. These procedures included combined latissimus dorsi and teres major transfer to the rotator cuff, musculotendinous lengthening of the pectoralis major and/or subscapularis tendons, open glenohumeral joint reduction and coracoidectomy in selected cases. Indication for surgery was progressive or stablished internal rotation contracture. Inclusion criteria were children with minimum post-operative follow-up of 6 months, enough data to obtain pre and post-operative modified Mallet scores (including the internal rotation category) and imaging of the shoulder (CT and MRI) to access Waters' Classification. Ten patients did not meet the inclusion criteria due to insufficient follow-up or incomplete data. Therefore, 17 patients were included in this study.

Results and Conclusions: There were 6 boys and 11 girls with a mean age of 3,7 years, ranging from 1 to 10 years. The mean post operative follow-up was 29 months, ranging from 6 to 59 months. According to the Waters Classification, we had 9 patients with type IV, 7 patients with type III and 1 patient with type II glenohumeral deformity.

The average pre-operative modified Mallet score was 15.92 (SD:1.94). The average post-operative modified Mallet score was 20.21 (SD:2.08). The average increase in modified Mallet score was 4.28 (SD:2.78). Post-operative imaging was performed in 10 patients, and 70% of those presented significant joint remodelling. Although all patients but one showed improvement in global shoulder function, we found some loss of internal rotation in 57% of Waters type IV patients, and 12.5% of Waters type II or III patients (p=NS). The overall incidence of internal rotation loss, including all patients, was 33,33%.

Combined intra-articular and extra-articular soft tissue procedures can improve global shoulder function and glenohumeral congruency in OBPP. Some degree of internal rotation loss can be expected in approximately 1/3 of the patients as a side-effect of the subscapularis tendon lengthening.

Outcomes of Isolated Spinal Accessory to Suprascapular Nerve Transfers for Brachial Plexus Birth Injury: A Multi-Center Study

List of authors:
David Segal1, Francisco Soldado2, Dan Zlotolow3, Scott Kozin3, Roger Cornwall4, Kevin Little*4
1 Meir Medical Center, The Orthopaedic Department (Kfar-Saba)
2 Hospital Sant Joan de Déu Barcelona (Barcelona)
3 Shriner's Hospital for Children - Philadelphia (Philadelphia)
4 Cincinnati Children’s Hospital Medical Center, University of Cincinnati College of Medicine (Cincinnati)

Objectives / Interrogation: Brachial Plexus Birth Injury (BPBI) affects approximately 1.5 children per 1000 live births in the United States. While exploration and nerve grafting has been the mainstay of treatment for BPBI, nerve transfers have gained popularity as they avoid donor site morbidity and place the donor nerve close to the endplate, therefore minimize re-innervation time. Nerve transfers for shoulder function involving the Spinal accessory to Suprascapular nerve transfer (SAN-SSN) have been frequently used in BPBI, often simultaneously with other procedures, but there is limited data from isolated procedures, which are not performed with any other nerve or tendon surgery. We describe the shoulder function recovery of 53 patients that were operated upon at three medical centers and underwent an SAN-SSN through either an anterior or posterior approach.

Methods: We retrospectively reviewed the cases of 53 patients at three institutions who had undergone a SAN-SSN after BPBI. Inclusion criteria were patients with BPBI who underwent a solitary SAN-SSN and who had both preoperative and minimum 36 months postoperative Active Movement Scale (AMS) scores. Patients for whom the primary surgery involved nerve reconstruction or tendon transfers were excluded. The primary outcome measures were the AMS scores for shoulder abduction, forward flexion and external rotation and secondary outcomes included the need for further shoulder surgery to improve function.

Results and Conclusions: 42 (79.2%) patients obtained functional shoulder motion (AMS>5) following surgery, with 23 (43.4%) patient obtaining full recovery of shoulder function against gravity (AMS=7). 40 (75.5%) patients did not proceed to further tendon transfers or corrective osteotomies to augment shoulder function. The anterior and posterior approaches were both found to be equally effective for isolated SAN-SSN in BPBI. In a multivariable binomial logistic regression the institution at which the surgery was conducted was found to be the only statistically significant factor to affect the ER functional outcome (P=0.04) SAN-SSN were able to recover functional shoulder motion in brachial plexus birth injuries and prevent tendon transfer procedures and corrective osteotomies in approximately 80% patients. The institution where the surgery was performed was shown to be independently correlated to outcomes, which is likely due to variations in AMS scoring among institutions. Outcomes continue to improve throughout the first three postoperative years.

Brachial Plexus Birth Injury, Spinal Accessory Nerve Transfer, Shoulder Function
Neurogenic Thoracic Outlet Syndrome: Results from 52 surgically treated patients

List of authors:
Gerlinde WEIGEL¹, Werner GIRSCH²
¹ Handchirurgie Gänserndorf, Landesklinikum Mistelbach-Gänserndorf (Mistelbach)
² University Clinic Graz, Department of Plastic and Reconstructive Surgery (Graz)

Objectives / Interrogation: Central nerve stimulation (CNS) already has proved its efficacy for treatment of chronic severe pain. The aim of our clinical study was to prove the effectiveness of Peripheral Nerve Stimulation (PNS) with implanted systems for treatment of chronic neuropathic pain syndrome (CRPS2) of the extremities.

Methods: In sum we selected 31 patients (19 female, 12 male) suffering from CRPS2 for treatment, two patients suffering from causalgia due to complete posttraumatic brachial plexus lesion including root avulsion. Each patient had a history of microsurgical interventions to the nerves and every conservative treatment which was possible, but without any effect on the problem of neuropathic pain. None of the patients was able to use the extremity functionally. In all patients the VAS was in mean 9, even at rest. Stimulation leads were implanted close to the peripheral nerves (fascicles of the brachial plexus or sciatic or femoral nerve) and connected with percutaneous leads for temporary testing. Pain reduction of more than 4 points on the VAS scale gave indication for implantation of a pulse generator for continuous PNS.

Results and Conclusions: 28 patients were supported with the whole system. PNS was effective to reduce pain from VAS mean 9 to VAS mean 3 and to regain functional use of the extremity in most of the cases. Several technical complications, mostly electrode dislocation had to be noted. Relief from pain occurred immediately after onset of stimulation. The positive effect was directly correlated with PNS, and stable over years. On a scale from -5 to +5 patients rated +4.2 in answering the question if they would undergo the procedure again.

PNS reduced pain deriving from peripheral nerves reliable and effective. Regarding our follow up period of 3,5 years PNS produced a stable, nearby pain free interval in all patients. Positioning of the electrodes direct to the fascicles of the brachial plexus and close to the sciatic nerve at mid-thigh allowed movement of shoulder and hip at a nearby normal ROM. PNS seems to represent an important technology for treatment of chronic neuropathic pain in selected cases.

A Novel Technique for the Surgical Management of Chronic Lateral Epicondylitis

List of authors:
Abhijeet Wahegaonkar1, Sahil Sanghavi2, Satish Mane3, Anup Bansode3, Chaitanya Karande Patil3
1 Sancheti Institute for Orthopedics & Rehabilitation, Jehangir Hospital (Pune)
2 Sancheti Institute for Orthopedics & Rehabilitation (Pune)
3 The Hand Surgery Clinics, Sahyadri Hospital (Pune)

Objectives / Interrogation: Lateral epicondylitis is usually self-limiting and resolves within 8-12 months. Once it resolves, recurrence is rare. Conservative management remains the mainstay of treatment. When conservative treatment fails, surgery is required for resistant cases. Morrey had put forth three categories of failure following surgical management of chronic lateral epicondylitis. Type 1 failure occurs when an inaccurate initial diagnosis is made or when a concomitant diagnosis is present which contributes to the pathology. Type 2 failure results from inadequate debridement of the pathological tissue from the common extensor origin. Type 3 failures are iatrogenic in nature.

We describe a novel technique to address the confounding factors—which includes decompression of the PIN, arthrotomy, plica / synovial excision, multiple drill holes in the lateral epicondyle, tendon debridement and offloading the tendon by reattaching it approximately 1cm distal to its actual origin.

Methods: We prospectively reviewed 14 consecutive cases of resistant lateral epicondylitis operated at our Institute from 2013 to 2015 with a minimum 2 years follow up.

Results and Conclusions: All patients had a minimum of 12 months conservative treatment before surgery. The right side was involved in 10 patients and the left side in 4 patients. There were 9 males and 5 females. The mean age was 46.21 years (range 38-56 years). Mean duration of pre-operative symptoms was 23.07 months and the mean follow up period was 31.07 months (range 24-41 months). The average post-operative VAS score reduced to 1.35 (range 0-6) from the average pre-operative VAS score of 7.79 (range 6-10). Our patients recovered 85% of grip strength on the operated side as compared to the opposite side. 12 of the 14 patients (85.7%) in our series had good to excellent functional outcomes on the Mayo Elbow Performance Index.

Conclusion: Our novel technique simultaneously tackles all components of the disease with decreased incidence of surgical failure.

It addresses the tendon, intra-articular pathology and decompression of the PIN provides additional benefit. This technique can therefore be recommended for wider surgical use, however, prospective randomized studies with a longer follow-up would add further evidence about the effectiveness of our technique.

**Operative Versus Non-Operative Outcomes Of Middle Clavicle Fractures: A Systematic Review And Meta-Analysis**

**List of authors:**
Kamil Amer1, Dominick Congiusta1, Jennifer Thomson1, Matthew Li1, Rami Amer1, Ahmed Chaudhry1, Mark Reilly1, Mark Adams1, Michael Sirkin1
1 Rutgers New Jersey Medical School (Newark, New Jersey)

**Objectives / Interrogation:** Midshaft clavicle fractures are among the most common bone injuries to the body. Superiority of operative vs. nonoperative treatment remains unclear, but recent studies have shown that nonoperative outcomes are not as favorable as once thought. We present a meta-analysis comparing treatment modalities of clavicle fractures.

**Methods:** PubMed and OVID were queried to identify studies published before October 2017 that reported on outcomes after operative vs. nonoperative treatment for clavicle fractures. Primary outcomes included rates of nonunion, symptomatic malunion, shoulder function (Constant and DASH scores), and need for secondary operations. Secondary analysis compared outcomes after different types of operative fixation vs. nonoperative treatment. Data were analyzed using t-test on the mean differences for statistical differences.

**Results and Conclusions:** Sixteen studies (1,206 patients) met inclusion criteria. Risk of nonunion was lower in the operatively treated patients (RR=0.21, 95% CI=0.06-0.32). Risk of symptomatic malunion was lower in the operatively treated patients (RR=0.17, 95% CI= 0.06-0.32). Constant and DASH scores were higher with surgical fixation compared to nonoperative management with mean differences of 6.8 points (95% CI, 2.1-10.9). Surgery with plates resulted in better DASH and Constant scores, fewer complications, and lower patient dissatisfaction (p< 0.05). There was no difference in the risk of secondary operation between groups (p=0.27) or long-term function in patients treated with nails or plates (p=0.41). Patients treated with plate fixation had >2 times increased risk of treatment failure compared to those treated with nails (p=0.04).

RCT=Randomized Controlled Trial, NRCT=Nonrandomized Controlled Trial

This study is the largest, most current, and most inclusive meta-analysis of clavicle fracture management to date. Our data show that operative repair results in lower rates of malunion, nonunion, and complications, and higher DASH and Constant functional scores. There were higher rates of failure with plate fixation. Our primary limitation was variable heterogeneity. Further studies need to be conducted to confirm these findings.

OUTCOMES OF POSTERIOR INTEROSSEOUS NERVE NEURECTOMY IN ACUTE TRAUMA

List of authors:
Marcella Rodrigues Costa¹, Frederico Salomão Ataíde², Paulo Randal Pires Júnior¹, paulo randal pires*, Gustavo Pacheco Martins Ferreira²
¹Hospital Madre Teresa (BELO HORIZONTE)
²Hospital Maria Amélia Lins (BELO HORIZONTE)

Objectives / Interrogation: Wrist denervation for the management of chronic wrist pain is already known as a safe and effective procedure. However, there is no consensus on the performance of posterior interosseous nerve (PIN) neurectomy to reduce pain in acute trauma. The aim of this paper was to evaluate the PIN neurectomy effectiveness in improving analgesia in the postoperative period, when used associated to the surgical treatment of some acute affection.

Methods: This is a double-blind study lasting from March 2017 to March 2018. Thirty cases of wrist acute trauma that required surgical treatment with dorsal approach to the wrist were selected at an orthopedic trauma hospital. However, 10 patients were excluded because they did not complete the inclusion criteria, for example, isolated injury in the wrist without previous lesions. It was included 20 patients presenting perilunate dislocation, trans-scaphoid perilunate fracture dislocation or trans-radial-styloid trans-scaphoid perilunate fracture dislocation. They were randomized into two groups: the first group (10 patients) received the surgical treatment of their pathology associated with PIN neurectomy and the second group (10 patients) received the treatment without the neurectomy. The patients' degree of pain was assessed through a numerical scale of pain (1 to 10) on the preoperative period, on the first postoperative day and on the first return visit. Fisher's Chi-square test and the Mann-Whitney test with 95% confidence interval and p value <0.05 were used.

Results and Conclusions: The ratio of male gender was 85% and median age was 35.9 years (±14.36). The mean value of pain was 4.90, 2.85 and 1.85 on the preoperative period, on the first postoperative day and on the first return, respectively. The pathology with the highest degree of pain was transradial-styloid trans-scaphoid perilunate fracture dislocation (4.5, 2.8 and 2.0, respectively). The mean value of pain in the first group submitted to neurectomy was 4.50, 1.20 and 0.90 on the preoperative period, on the first postoperative day and on the first return, respectively. And the mean value of pain in the second group was 5.30, 4.50 and 2.80, respectively.

There was a statistically significant difference in the value of pain on the first postoperative day and on the first return (p = 0.01 and p = 0.04, respectively) among the two groups. The outcome showed that the association of the PIN neurectomy to the surgical treatment of acute affections reduced postoperative pain in the short and medium term.

Dysplasia Epiphysealis Hemimelica (Trevor's Disease) of the scaphoid in a 9 year-old boy.

List of authors:
emygdio jose leomil de paula¹, joao carlos nakamoto¹, marco aurelio de moraes¹
¹ iot hcfmusp (sao paulo)

Objectives / Interrogation: Dysplasia Epiphysealis Hemimelica (Trevor's Disease) is a rare disorder of the epiphysis in children, characterized by asymmetrical epiphyseal growth, considered a variant of osteochondromas. Its presentation in the upper limb is extremely rare. There is no malignancy reported. We demonstrate in this report a patient who underwent surgical treatment with preoperative programming through 3D-printing based on the CT scan images.

Methods: A 7-year-old boy entered the service with a complain of deformity in the left wrist associated with radial border pain without a history of trauma in February 2016. His orthopedic examination showed generalized restriction of left wrist range of motion. The wrist radiographs showed an enlarged, bipartite scaphoid with its extremities joined through a radiolucent halo with the distal portion oriented with a pronounced palmar tilt and more sclerotic than the remaining carpal bones. There were no adjacent joint changes. Magnetic resonance imaging demonstrating pericartilaginous hypersignal in the T2-weighted sequence. At first, clinical observation was chosen.

Results and Conclusions: The new exams showed an increase in the scaphoid with a pronounced worsening of the deformity, increase in the area of sclerosis and involvoment of the articular surface of the distal radius. Tomography ratified such changes. With these findings, surgical treatment with corrective osteotomy of the affected bone for joint rescue was chosen. For surgical program, biomodel reconstruction was used in 3D printing of the structure to be submitted to the intervention using DICOM® images. Process carried out without costs through the Information Technology Center Renato Archer, Campinas, Sao Paulo, Brazil.

Survival rates and outcomes for digital replantation

List of authors:
Mohsen Rafii¹, Christopher Deutsch*²
¹ University of Buckingham (Buckingham)
² Royal Free Hospital (London)

Objectives / Interrogation: Since the development of microsurgical vascular anastomoses, digital replantation has become a well-established procedure in the field of reconstructive hand surgery. Advancements in surgical techniques and peri-operative management of such patients has resulted in high survival rates globally, with increasing focus now falling on achieving optimal functional outcome. This review will assess the literature on the outcomes of digital replant surgery, exploring the evidence pertinent to survival rates and functional outcomes.

Methods: A systematic search of the MEDLINE database was performed using predefined criteria. 21 review papers met the criteria reporting on outcomes of 1142 patients. The literature was reviewed examining variables concerning the injury, the patient, and surgical management assessing the impact on replant survival and functionality. Assessment of functional outcomes evaluated: active range of movement, two point discrimination, grip strength and return to work.

Results and Conclusions: Findings demonstrated various factors influencing replant survival, including; mechanism and site of amputation, type and duration of ischaemic insult, surgical techniques, and postoperative care and rehabilitation. Factors shown to be most influential in replant survival were; patient's age, mechanism of injury and number of anastomoses. Patients >50 and those <5 years of age demonstrated the highest failure rates, while the optimum patient group was 11-20 years of age. Guillotine injuries exhibited the best survival outcomes overall, when compared to crush/avulsion injuries. Enhanced survival outcomes were demonstrated in Zone 2 relative to Zone 1 (Tamai classification) in distal injuries, and proximal to the MCP in proximal injuries. In the analysis of functional outcomes literature revealed optimum functional restoration in injuries distal to the insertion of flexor digitorum superficialis, however in cases of injury sustained to the tendon, early secondary flexor tendon reconstruction and digital motion should be considered.

Single Incision Repair of Distal Biceps Tendon Ruptures- Results & Complications

List of authors:
Joseph Imbriglia*1, Glenn Glenn Buterbaugh1, William Hagberg1
1 Hand and UpperEx Center, University of Pittsburgh (Wexford)

Objectives / Interrogation: Objective- Hypothesis: To review the objective results of single incision distal biceps repair. We hypothesized that function could be returned with few complications despite the literature suggesting a higher rate of PIN palsy and less return of strength when compared to the two incision technique.

Methods: Methods: The charts of 115 patients with distal biceps ruptures that were surgically repaired by two surgeons at the same institution over a 10 year period, were retrospectively reviewed. The post-operative ROM and strength were measured. Complication's including PIN palsy, lateral antebrachial cutaneous nerve paresthesias, heterotopic ossification and re-rupture were evaluated. The average follow up was 12 months.

Results and Conclusions: Results: The patient's average return of flexion strength was 105% of the contralateral side and supination strength was 90% of the contralateral side.

Complications:
PIN palsy-0
heterotopic ossification-2
radio ulnar synostosis-0
LABC neural paresthesias- 45%
Re-rupture of tendon- 0

No patient had to be re operated on for any complication.

Conclusions: Single incision repair of the distal biceps tendon can be performed with minimal serious complications. The return of function and strength is comparable to reported results of the 2 incision techniques.

Combination of two vascularized bone grafts for closing a huge defect of humerus. A case presentation.

List of authors:  
Uldis Krustins*, Dzintars Ozols¹, Janis Zarins¹, Ervins Lavrinovics¹, Vadims Nefjodovs¹  
¹Microsurgery Centre of Latvia, Riga East University Hospital (Riga)

Objectives / Interrogation: To demonstrate a rare case of combination of two vascularized bone grafts to save the upper arm of the young woman in a case of chronic osteomyelitis

Methods: Female, 26 y.o., right hand dominant, was presented in outpatient clinic with a deformation of the upper arm, full range of motion in the shoulder and wrist joints, limitation of elbow flexion 95 degrees and 40 degrees insufficiency of extension as well a 12 year history of haematogenous osteomyelitis of the humerus. During the childhood she underwent several surgical excisions of the inflamed bone and was administered to a peroral antibacterial therapy during the periods of the exacerbation of the disease. After the X-ray and MRI examination, head of the humerus and 2-3 cm of the proximal diaphysis, as well as distal 3 cm of the humerus were considered as healthy enough to be left for reconstruction.

Two different vascularized bone grafts - fibular as flow through graft and iliac crest were harvested to close the defect of the upper arm. The primary fixation of both bone grafts as well as vascular connections were performed on the operation table outside the body. Later this complex bone graft was fixated with DePyu Synthes Long Philos plate in the proximal part of the humerus and cannulated 3.5 mm screws in combination of 1.5 mm Kirschner wires in the distal part. Bone grafts were wrapped into the previously prepared periosteal flap. Anastamoses of the complex bone graft were connected end to side to brachial artery and veins. After treatment included 8 weeks of peroral antibiotics and workout of ROM which started from the third week after surgery. Scheduled visits were performed every 2 months with measurements of the ROM and X-ray controls.

Results and Conclusions: Within a year after surgery patient is back to almost all daily and sporting activities, despite of the limitation of elbow flexion and visual differences of both upper arms. She has full extension and 110 degrees flexion of the elbow. The DASH score is 35 points. An active bone formation is presented between all fragments. Non-standard decisions and technical solutions could be successful in microvascular bone flap surgery in cases of large osteomyelitic bone defects of the upper arm.

Treatment of marginal rim fracture of the distal radius using a new fragment-specific plate

List of authors:
Rafael Aquino Leal*, Massimo Corain¹, Filippo Zanotti¹, Mara Laterza¹
¹Hospital Policlinico Borgo Roma, Hand Surgery (Verona)

Objectives / Interrogation: Marginal intra-articular distal radius fractures pose a significant challenge to the treating surgeon, small fracture fragments that are distal to the watershed line represent a clinical challenge. Stability of the marginal rim fracture is critical to provide structural support of the carpus, and failure to maintain reduction of this fragment can lead to catastrophic volar carpal subluxation or dislocation. The objective of this study was to evaluate the outcomes of distal radius fractures treated with a new fragment-specific plate.

Methods: A consecutive series of 10 patients who sustained distal radius fractures underwent radial column plating alone or in conjunction with other implants, between May 2016 and August 2018. For all patients, radiographs were obtained in standard anteroposterior and lateral projections associated with CT, which allowed to identify and describe the fragment. All patients were treated surgically with reduction and fragment synthesis using Medartis® Hook Plates 1.5. After the surgery the patients kept a splint for 3 weeks, then starting a rehabilitation program of physiokinetic therapy. All patients were evaluated with post-operative radiographs and at 1, 3 and 6 months. We also evaluated the articular range of motion in flexion-extension and in prono-supination and strength with the Jamar test, comparing the results with the contralateral wrist.

Results and Conclusions: The average follow-up was 15 months (2 - 24 months). Clinical checks show a progressive improvement in strength and symptomatology and a 92% mean ROM recovery compared to the contralateral side. In 6 cases an standard plate from APTUS® Wrist Distal Radius System 2.5 was associated, in 3 cases K wires were associated (one of them with also external fixation associated), for 2 patients two mini anchors (Mitek®) were used to stabilize the ligaments. In only one case it was necessary to remove the plate which occurred following the mobilization of a screw. All patients returned to their work-recreational activities prior to the trauma. There was no case of dislocation or secondary loss of reduction. All the control radiographs showed the restoration and maintenance of joint congruence at the radiocarpic level. In conclusion: radial column plating of the distal radius is a safe treatment modality and a valuable adjunct in the setting of complex distal radius fractures with few complications and objective scores consistent with return to normal function.

Comparison of standard wrist CT and HR-pQCT (High Resolution Peripheral Quantitative Computed Tomography) in scaphoid nonunion after avascular bone graft and percutaneous screw fixation

List of authors:
Irena Krusche-Mandl*, Sabrina Holzer¹, Arastoo Nia³, Janina Patsch², Stefan Hajdu¹, Jochen Erhart³
¹ Medical University of Vienna, Department of Trauma Surgery (Vienna)
² Medical University of Vienna, Department of Radiology (Vienna)
³ Barmherzige Brüder Eisenstadt, Department of Orthopaedics and Traumatology (Eisenstadt)

Objectives / Interrogation: A surgical treatment option for scaphoid nonunion is avascular bone grafting and screw fixation. This requires postoperative 6-16 weeks immobilization until adequate bony consolidation. This is especially problematic as it mainly affects young working-age patients. Therefore, the further development of imaging with reduction of exposure to radiation is desirable. HR-pQCT assessment offers a reduction in radiation exposure compared to standard CT. The aim of this pilot study is to compare HR-pQCT with standard CT to assess bony consolidation in scaphoid pseudarthrosis after avascular bone graft and screw fixation.

Methods: Between 02/2011 and 10/2013, prospectively 9 consecutive patients (10 scaphoids) > 16 years with clinically relevant scaphoid pseudarthrosis requiring surgery were included in our clinic using avascular bone graft and screwing. Baseline data was recorded followed by clinical evaluation after 2, 4, 6 weeks and 3, 6 and 12 months. A standard CT and HR-pQCT scan was performed every 6 weeks and 3 months to compare the assessability of bony consolidation.

Results and Conclusions: All patients were male with a mean age of 26.2 years. In 7 cases the dominant hand was affected (1x both). The accident mechanism was a fall on the extended wrist in 7 patients, in 2 it was not recoverable. In 6 patients there was a DISI preoperatively (average 24°). Relevant concomitant pathologies were fractures of: radius (intra-articular), forearm, os hamatum and a bony triquetrum tear. Range of Motion (ROM), DASH, patient rated wrist evaluation (PRWE), pinch and grip force selectively on both sides are presented.

HR-pQCT provided at least comparable results in all cases compared to standard CT, although in one case HR-pQCT revealed an early consolidation.

The possibility of a more precise assessment of bony consolidation in scaphoid pseudarthrosis, treated with avascular bone graft and screwing, by HR-pQCT is desirable and could lead to an individualized better evaluation and thus an earlier mobilization.

Osseointegrated thumb prosthesis as an alternative for microsurgical thumb reconstruction

List of authors:
Johannes Mayer*, Stefan Salminger², Oskar C. Aszmann², Agnes Sturma³
1 CD Laboratory for Restoration of Extremity Function, Med. University Vienna/Eberhard Karls University Tuebingen (Vienna/Tuebingen)
2 CD Laboratory for Restoration of Extremity Function, Division of Plastic and Reconstructive Surgery, Medical University of Vienna (Vienna)
3 CD Laboratory for Restoration of Extremity Function, Medical University of Vienna (Vienna)

Objectives / Interrogation: Thumb amputation after traumatic injury or due to tumor resection leads to significant impairment of hand function, as well as psychological burden. Various techniques have been described, ranging from pollicization, phalangisation to complex microsurgical procedures, such as toe-to-thumb transfer. An osseointegrated thumb prosthesis via titanium fixation to the residual bone can provide a functionally and aesthetically viable reconstruction alternative for patients in which microsurgical techniques are not indicated. This retrospective study compares osseointegrated thumb prosthesis to other secondary reconstructive procedures (pollicization, toe to thumb transfer and lengthening).

Methods: We present one male patient who was treated with an osseointegrated thumb prosthesis 12 months after thumb amputation in the metacarpal joint because of an epitheloid cell sarcoma. There was no specific rehabilitation necessary. The outcome measures 9 and 24 months postoperatively included SHAP Test and were compared to patients with other secondary reconstructive procedures (pollicization, toe to thumb transfer and lengthening).

Results and Conclusions: In the performed SHAP Test (Southampton Hand Assessment Procedure) the patient with the osseointegrated thumb prosthesis reached 98 points. This correlates with standard values of healthy population. Furthermore the patient was very satisfied with the aesthetic appearance of the prosthesis. No complication (e.g. wound infection, implant loosening) were observed 24 months postoperatively.

An osseointegrated thumb prosthesis via titanium fixation to the residual bone can provide a functionally and aesthetically viable reconstruction alternative for patients in which microsurgical techniques are not indicated. Due to a stable fixation of the prosthetic finger to the bone, restoration of some sensory feedback with osseoperception can be achieved.

Distribution of hand surgical knowledge by an open access textbook

List of authors:
Richarda Boettcher*
1 Schwerpunkt für rekonstruktive Chirurgie, Unfallkrankenhaus Berlin (Berlin)

Objectives / Interrogation: Development of digital media and electronic publishing really advanced in the last decade. But access to knowledge and science is mostly limited by economic and copyright related barriers. Hand surgery is based on very specialized surgical education, research and current discussion. Commercial textbooks and journals are expensive and limited in distribution. Contents have to be revised in short time intervals and cause recent editions. Operative treatment and microsurgical techniques cannot be displayed adequate in printed media.

Methods: The beginning of this millennium is characterized by increasing information and communication technologies which allow the transfer of information through global communication systems. This opens up opportunities to create and share a wider array of educational resources. Social networking and collaborative learning becomes common. Based on these ideas an open access text book was created to spread hand surgical knowledge worldwide. First chapters are finished and include basics, extensive knowledge and technical videos.

Results and Conclusions: In the presentation the concepts and guidelines for OER, Open Access publishing and the use of Creative Common licences are explained. Using the concept for the Open Access Textbook the advantages and possibilities of OER are explained. Everybody with the possibility of internet use will have access to the complete actualized textbook. The license allows all material as text, tables, figures and videos to be used by everybody with slight restriction. Learning, teaching and developing of surgical techniques becomes easier and more established.

COLLATERAL LIGAMENT INJURIES OF METACARPOPHALANGEAL JOINTS IN ATHLETES

List of authors:
Jane C Messina*, Roberta Sartore1, Paolo Arrigoni1, Ferruccio Torretta1
1 Gaetano Pini Orthopaedic Institute- CTO (Milano)

Objectives / Interrogation: Collateral ligament injuries of metacarpo-phalangeal joint are frequent in athletes especially in ski and ball sports. Despite thumb collateral ulnar ligament injuries are well known, thumb collateral radial ligament and collateral ligament injuries of long fingers, may be sometimes underdiagnosed and thus can lead to chronic instability of metacarpo-phalangeal joint. The aim of this study is to evaluate the results of the treated cases and recovery of work and sports activity.

Methods: In our Unit 110 patients were treated in five years, 45 of them were athletes (ski, basketball, football, rugby, gymnastics). There were 32 ulnar thumb collateral ligament, 8 radial collateral ligaments (group I), 3 radial and 2 ulnar collateral ligaments of long fingers (Group II). There were four chronic cases in group I and one in group II. Mean age was 32 yo (17-52), 31 males and 14 females. Dominant hand was involved in 39 patients. In acute injuries reinsertion with bone anchor or pull-out was performed while in chronic injuries reconstruction with a graft was performed. Thirty three patients were reviewed and at a mean follow up of 2 years (4-51 months). Patients were assessed with VAS, DASH, Mayo score, measurement of pinch and grip, stability (grade I-III). Rehabilitation protocol was started after 3-5 weeks after surgery.

Results and Conclusions: Stability was restored in all patients of group I, and in all but one patient of group II. GRIP was restored in 98% of thumbs and 88% of long fingers. Pinch was restored in 92% of thumbs and 75% of long fingers. According to Mayo Hand score there were in group I: 20 excellent, 5 good, 3 fair results. In group II there were 2 excellent, 2 good and 1 fair result. In group I mean VAS was 1, during sports was 2; in group II mean VAS was 0 and during sports was 1. Mean DASH was 10,9 (1,7-29,3) in group I, and 6,7(0-15,8) in group II. In Group I 94% of patients were satisfied with the treatment and 100% in group II. Slight residual stiffness of mean 10° of flexion (0-22°) was recorded in group I, none in group II. All patients returned to work and sports activities.

Conclusions: Stability can be restored with surgical treatment in the great majority of cases with restoration of grip and pinch strength despite a minimal lack of flexion with a recovery of previous work and sports activities.

An Innovative Approach to Preoperative Planning and Performing Corrective Osteotomy of the Radius.

List of authors:
Kirill Turbin*, Anton Akulaev¹, Anastasia Filippova¹
¹ St Petersburg State University, The Pirogov Clinic of Advanced Medical Technologies (Saint-Petersburg)

Objectives / Interrogation: The aim of the study is to develop a new way of planning and implementation of the corrective osteotomy of the radius, using the 3D modeling and individual templates, and also to analyze the proposed method in comparison with the classical method.

Methods: In the course of this study, 15 patients aged from 24 to 70 years were examined. The study was conducted on a Toshiba Aquilion 64 computer tomograph using specially developed protocols. Using a complex of 3D-adapted software, we performed individual 3D modeling and prototyping of anatomical models on MakerBot Replicator Z18 and Raise3D N2 DUAL 3D-printers. Individual templates were made on a 3D printer. For reference, in comparison, the second group of patients underwent classical measurements with the help of radiographs.

Results and Conclusions: The new protocol for planning and performing the corrective osteotomy of the radius, using 3D modeling and prototyping was developed. The analysis of the results of the planning and implementation of corrective osteotomy of the radius in 15 patients was carried out. The results showed that the application of the calculations obtained by drawing on radiographs, is not an accurate and reliable option in preoperative planning. Performing surgery with the use of the individual template totally eliminates subjective errors as well as the need to change the plan during operations. After the surgical treatment, for control purposes, on the three-dimensional model the main angular parameters were once again calculated and compared with the planned preoperative calculations. The arrangements of osteotomized fragments and the plate were also taken into account.

The target, pre-planned spatial position of the fragments of the radial bone and the plate, corresponding to the preliminary calculations, was obtained in 94% of cases.

For the comparative analysis, we evaluated the archive results of 15 cases of planning the corrective osteotomy of the radius in patients with post-traumatic deformities using standard X-ray and radiographs of the radial bone in front and side projections. The spatial position of the proximal fragment of the radial bone and the location of the plate on the postoperative radiographs corresponded to preliminary calculations in 41 (79%) cases.

In addition, the comparative analysis of the calculations of 3D modeling and single-plane planning was conducted. The findings show that in 100% of cases the average difference in the measurement of the angular parameters was 6 ± 2 (p <0.05).

How successful are intercostal nerve transfers to restore elbow flexion in plexus palsy?

List of authors:
Ulrike Schnick*, Richarda Boettcher
1 Unfallkrankenhaus Berlin (Berlin)

Objectives / Interrogation: For incomplete injuries of the brachial plexus intraplexal nerve transfers as the Oberlin transfer are successful and well accepted. In case of complete lesions extraplexal transfers are necessary. Different donor nerves are under ongoing discussion. The alternatives to intercostal nerve transfers are nerve grafts in selected cases, transfers of the accessory or phrenic nerve, free muscle transfers and contralateral donors. The aim is to evaluate the extent of failures of the intercostal nerve transfers compared to Oberlin transfers.

Methods: 41 patients with brachial plexus injuries (age 15 - 60; 37 male and 4 female) were treated between January 2010 to July 2017 with reconstruction of elbow flexion by nerve transfers. Of these, 21 had intercostal nerve transfers to the musculocutaneous nerve and 20 were treated with the Oberlin transfer including modifications. In all cases with intercostal nerve transfers the terminal sensory branch was used for direct neurotization of the elbow flexor muscles. The minimum follow-up was 12 months.

Results and Conclusions: Follow up of 34 patients until October 2018 could be included in the analysis. Elbow flexion between 45 and 140° (median 97.5°) with M3 or more strength was achieved by transfer of intercostal nerves to musculocutaneous nerve with a success rate of 72.2% (13/18). The results of Oberlin-transfers showed a successful flexion of M3 or more between 80° and 140° (median 115°) in 93.8% (15/16). The median muscle force rated 4/5 MRC in both transfers.

Intercostal nerve transfers led to an useful elbow flexion in more than 70% of cases. This experience is similar to several published results and meta-analyses. One reason for these good results might be the regular use of direct muscle neurotization by the terminal sensory branch of musculocutaneous nerve. Certainly intraplexal transfers like the Oberlin transfer are more successful with reliable functional reconstruction and a shorter reinnervation latency due to shorter distance to the recipient muscle. But up to now no concept for complete plexus injuries was published with reliable better results. Therefor intercostal nerve transfers to the musculocutaneous nerve are a helpful tool in plexus surgery concepts.

Subungual exostosis of the fingers

List of authors:
Johanna Ueberberg*, Britta Wieskoetter, Simon Oeckenpöhler, Martin Franz Langer
1 Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)
2 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster, Sektion Hand (Münster)
3 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)

Objectives / Interrogation: Subungual exostosis (SE) is a benign bone tumor found on the distal phalanx of a digit, beneath or adjacent to the nail. Dupuytren gave the first description of the lesion (published after his death in 1847) when he reviewed his experience with 30 patients suffering from subungual exostoses of the great toe [1]. Nearly 80 percent of reported cases involve the great toe and the remaining cases involve other toes. Involvement of the finger by this lesion occurs very rarely, with less than 60 reported cases in the English language literature - most of them in the thumb. We report 3 cases of subungual exostosis in the fingers of female patients.

Methods: The patients underwent excision of the mass in the operating room in local anesthesia and finger block. After a short distal palmar incision the tumor was resected completely at the level of the normal periosteum. The distal border of the tumor was covered with cartilage.

Results and Conclusions: Finger SE are about 1.5 times more common in women than men. Unlike exostoses elsewhere in the body, SE often appear and continue to grow after skeletal maturity. About 50% present during the second or third decade of life, with the other half presenting in patients over age forty. Very often these lesions are misdiagnosed, leading to protracted morbidity from inadequate therapy or extreme treatments such as digital amputation or radiation therapy. We report three rare case of subungual exostosis on the fingers presenting as stony hard painful swellings in three female patients with complete and long time release of symptoms after surgery.

\textsuperscript{3} Sancheti Institute for Orthopedics & Rehabilitation (Pune)

Objectives / Interrogation: Molluscum Contagiosum (MC) is a benign and contagious skin infection caused by molluscum contagiosum virus (MCV) of poxvirus family. MC is a self-limiting condition affecting the skin and mucus membrane. It is commonly seen in children of age 2-5 years, but can be seen in sexually active adults and immunosuppressed individuals. Clinically MC presents with small, discrete, dome shaped papules with central umbilication. The clinical presentation of MC in most cases is diagnostic which can be further confirmed by histopathology examination in cases that are not clinically obvious.

We report a case of MC in an immunocompetent female with atypical clinical presentation and radiological findings which is confirmed by histopathological findings.

Methods: A 36 year old lady presented to our clinic with a painless swelling over the dorsum of her left ring finger since 3 months resulting in difficulty in wearing her finger ring. There was no history of any trauma. The swelling was non-tender, soft in consistency, of approximate size of 6 X 8 mm over the dorso-radial aspect of proximal phalanx of left ring finger.

Routine radiographs were unremarkable, while an MRI revealed a well defined, space occupying lesion of approximately 10 x 8 x 5.5 mm; indicating benign neoplastic lesion, possibly a fibroma.

An excision biopsy was advised.

Results and Conclusions: Histo-pathological examination revealed epidermis of skin lined by lobulated stratified squamous epithelium showing hyperkeratosis, acanthosis, and parakeratosis. A cyst filled with large eosinophilic inclusions infiltrating into the epidermis. Molluscum bodies or colonies of MCV were seen.

This case report is perhaps the first of its kind with a rare presentation of Molluscum Contagiosum in an immunocompetent adult at an unusual location (finger). The MRI was also confounding as was the clinical appearance.

Follow up after 12 months showed no recurrence.

How to deal with Selective Nerve Transfers - An Animal Study

List of authors:
Matthias Sporer¹, Martin Aman¹, Dieter Depisch¹, Bruno Podesser², Oskar Aszmann³
¹ CD-Labor für Wiederherstellung von Extremitätenfunktionen (Wien)
² Zentrum für Biomedizinische Forschung (Wien)
³ CD-Labor für Wiederherstellung von Extremitätenfunktionen, Plastische und Rekonstruktive Chirurgie (Wien)

Objectives / Interrogation: Selective nerve transfers (SNTs) have been used broadly for the past decade to treat slow nerve regeneration, neuroma pain and to improve prosthetic control. SNTs change the motor unit extensively by connecting motor neurons to new functional targets. Good outcomes have been reported but little is known of the structural and functional effects. On a basic scientific level even less is known about how much motor input is required in order to achieve sufficient functional regeneration.

Methods: In 10 male Sprague Dawley rats the ulnar nerve (UN) was selectively transferred to the long head of the biceps after neurotomy of the biceps motor branch. In another experimental group (n=10), the deep branch of the ulnar nerve (DBUN), which is even more selective, was used to restore elbow function. These transfers were compared against a sham group (n=10) and a positive control group (n=10), in which the musculocutaneus nerve was crushed. Additionally, the equivalent operations were conducted in 20 Thy1-GFP rats (n=5 each group) to analyze nerve regeneration and neuromuscular junction formation.

Results and Conclusions: In all animals the biceps muscle was successfully reinnervated. In the UN group tetanic muscle force was 1.23 +0.21 mN, compared against 1.12 +0.17 mN in the DBUN group. Retrograde Labelling and MUNE (Motor Unit Number Estimation) correlated well and showed a statistically equivalent amount of regenerated motor neurons (86 +11 after UN transfer and 81 +10 in the DBUN group). Sensory and motory immunhistochemical axon quantification of the UN and its deep branch offered valuable clues on how much donor nerve is needed to restore motor function. However, only the UN transfer resulted in massive neuroma formation close to the coaptation site, which was visualized in Thy1-GFP rats. Muscle fibre typing and neuromuscular junction staining revealed impressive changes on all levels of the motor unit.

Transferring not only a high capacity donor nerve, but also an even more selective fascicular group and exploring the effects on the motor unit provides us with a deeper understanding of the neuronal plasticity of the peripheral nervous system. Tetanic muscle force, MUNE and retrograde labelling indicate that the motor neurons merely of the deep branch of the ulnar nerve supported sufficient regeneration and a lot of the additional input resulted in neuroma formation. Hence, nerve transfers could be performed even more selectively from this point forward.

Objectives / Interrogation: The relationship between financial and material support on the quality of hand surgery research remains unknown. Based on the increased resources likely required to perform high-quality research, we hypothesize that funding and other support is associated with higher levels of evidence in hand surgery research.

Methods: We performed a systematic review of all articles published in the Journal of Hand Surgery-American Volume over a 10-year interval, from January 2006 through December 2015. Papers were reviewed to determine the following: date of publication, volume/issue, category (clinical vs. non-clinical), number of authors, country of origin, and type of support received, if any. Clinical studies were further subcategorized into type and Level of Evidence from I-V. Support was defined as financial and/or material support as designated in the first page footer or text body of the paper and subcategorized into one of four categories (1) Industry (2) Education/Societal (3) Government or (4) Multiple, i.e. some combination of 1 through 3. Chi-square analysis was performed to determine the potential relationships between the aforementioned variables.

Results and Conclusions: 1792 studies satisfied inclusion over the study interval. Majority of studies were clinical (1,113; 62.1%) versus non-clinical (679; 37.9%), and financial or material support was used in 515 (28.7%). Non-clinical studies received a significantly higher rate support than clinical studies (40.2% vs. 21.7%; Chi-square test P < 0.0001). Education was the most common support source (158), followed by industry (150), government (124), and multiple sources (83). Industry was more likely to support clinical studies, while education and government sources were more likely to support non-clinical studies (Chi-square test P = 0.015). Level I and Level III clinical studies were associated with higher levels of funding than Level II, IV and V studies (Chi-square test P < 0.0001). Prognostic studies were most likely to be associated with support, while therapeutic studies were least likely (Chi-square test P = 0.03). Studies from the United States were more likely than others to receive support (31.2% vs. 25.0%; Chi-square test P = 0.011).

Non-clinical studies are more likely receive financial or material support. Among clinical studies, prognostic studies and those with Level I and III evidence, and were mostly likely to receive support. Studies originating from the U.S. received the highest rate of support.

The Influence of reactive oxygen species on pathophysiological mechanisms of Dupuytren's disease

List of authors:
Lisa Oezel*, Carina Büren, Simon Thelen, Marie Wohltmann, Vera Grotheer, Joachim Windolf
1 Universitätsklinikum Düsseldorf, Klinik für Unfall- und Handchirurgie (Düsseldorf)

Objectives / Interrogation: Dupuytren's disease is characterized by an increased proliferation and differentiation of fibroblasts to myofibroblasts, which provides an enhanced expression of alpha Smooth Muscle Actin (alpha-SMA). alpha-SMA modulates the contraction of fibrotic nodules and cords of the palmar aponeurosis. In prior studies, we could already demonstrate, that exposure of myofibroblasts to blue light reduces alpha-SMA-expression and subsequently contraction of the palmar aponeurosis. Reason for this phenomenon seems to be increased concentrations of reactive oxygen species (ROS) due to photobiomodulation with blue light. Aim of this study was to examine how far exposure with blue light leads to higher concentrations of ROS. Moreover, the influence of ROS- concentrations on alpha-SMA-expression and on ROS- modulating enzymes like catalase and Manganese Superoxide Dismutase (M-SOD) as well as on the transcriptional factor Nuclear Factor- kB (NF-kB) was detected.

Methods: Isolation and cultivation of fibroblasts from palmar aponeurosis tissue of patients with Dupuytren's Disease (n=7) as well as from carpal tunnel tissue (CTS, n = 7), as control group, was ensued. Differentiation of fibroblasts to myofibroblasts was established by dispensation of Transforming Growth Factor beta (TGF-beta). LED-Arrays that emit at wavelength of 453 nm (40 Joule, 38 mW/cm2) were used for irradiation with blue light. Expression of catalase, alpha-SMA, NF-kB and Mn-SOD were detected by western blot analysis.

Results and Conclusions: In both experimental groups, exposure to blue light lead to decreased expressions of catalase, Mn-SOD and tendentially reduced levels of NF-kB. Moreover, augmentation with hydrogen peroxide showed a reduced alpha-SMA expression. This suggests, that the therapeutic benefit of decreased alpha-SMA expression by blue light treatment could be modulated by ROS concentrations, especially by hydrogen peroxide levels. Our results demonstrate that decreased expressions of catalase through blue light exposure appears to be the cause for higher ROS- concentrations and seems to participate relevantly in pathophysiological mechanisms as well as therapeutic options in Dupuytren's disease.

Dupuyten's contracture, blue light exposure, reactive oxygen species, catalase, alpha Smooth Muscle Actin
ULNAR HEAD PROSTHESIS IN RHEUMATOID ARTHRITIS

List of authors:
Jane C Messina¹, Barbara Boniforti¹, Ferruccio Torretta¹
¹ Gaetano Pini Orthopaedic Institute- CTO (Milano)

Objectives / Interrogation: Ulnar head implants are indicated in post-traumatic arthritis of DRUJ, failure of previous operations (Bowers, Sauvé-Kapandji, Darrach), tumor resection. This technique is also indicated in inflammatory arthritis with pain at DRUJ or limitation of pronosupination in alternative to other operations but it is still controversial. Controversy is related to the possibility of other surgical options as Sauvé-Kapandji, Darrach o Bowers procedures that are widely used in RA patients. Moreover diffuse concomitant or subsequent involvement of radiocarpal or intercapal joints of the same hand may necessitate a multiple operation plan. The aim of this study is to analyse the results and define the actual indications of this technique in RA patients

Methods: Out of 53 wrist treated with ulnar head implant in our Unit, 10 patients had inflammatory arthritis (9 RA and 1 Psoriatic arthritis) were treated as affected by akyosis or osteoarthritis type of RA according to Simmen Classification. Of those, one had a previous failed Bowers operation. All were females. Mean age 56yo (42-74). All patients had a limitation of pronosupination and elective pain at DRUJ. Five patients were reviewed with a mean follow up of 6 years (2-10 years). Mayo score, Dash and PRWE score were used to evaluate the results

Results and Conclusions: The results were good in 2 patients, fair in 3. Restoration of pronosupination was obtained in all patients except one who had a supination limited to 50°. Mean ulnar deviation was 27° (0-45°), mean radial deviation was 5° (0-15°), extension 20° (0-40°), flexion 21° (5-30°). Mean DASH was 42 (22.5-47.5) and PRWE was 31 (11-48.5). Pain was absent in 2 cases, occasional in 2 cases, moderate in 1 case. No complications recorded.

From our data the results were satisfactory in all patients even if arthritis can progress in other joints of the same hand and limb. There is a bias in the results of the wrist scores used as other joints of the upper limb are involved in RA and this creates worse clinical scores compared to post-traumatic patients. Among salvage procedures ulnar head implant gives a very good restoration of function and aesthetic appearance of the wrist. This technique is indicated in selected cases of isolated DRUJ arthritis without excessive laxity, with limitation of pronosupination and elective pain at distal radio-ulnar joint.

Keywords:
Corrective Osteotomy Arthroscopically assisted of Intra-Articular Distal Radius Malunions with out-in technique

List of authors:
alberto sgarbossa*¹
¹ ist clinico S.Anna (brescia)

Objectives / Interrogation: Conservative treatment or not correct surgical treatment of distal radial fractures carry out to healing with articular gap > 2mm with pain, loss of ROM and arthritic changes at midterm follow-up. The corrective osteotomy of intra-articular defects represent an complex challenge for surgeon. The surgical articular visualization is complex and a dorsal approach with capsula incision frequently evolve in stiffness as a result of capsular retraction. There was realized an technique for intra-articular distal radius malunions from outside to inside under dry arthroscopic visualization by the use of compass for define the correct site of osteotomy.

Methods: There performed surgery on 9 patients for intra-articular malunion of the distal radius 10 to 30 months after the injury, in all the cases the fractures was intra-articolar in 3 cases the step-offs was a consequence of incorrect surgical treatments in 6 cases was a consequence of conservative treatments in plaster. In 3 cases the osteotomy regarded more than 3 fragments. In 3 cases there was associated osteotomy of the extra-articolar distal radius.

Results and Conclusions: Follow-up ranged from 12 to 24 months. The articular joint was reconstruct without step-offs more than 1 mm, in 2 cases thers a partial dislocation of the fragment for not sufficient stable synthesis but the dislocation was less than 2 mm without clinical effect on rom restoration. According to the Gartland and Werley score, there were 3 excellent and 6 good results (mean score of 3.1). The Modified Green and O'Brien system achieved a mean score of 80, with 3 excellent, 5 good, and 1 fair results. The mobilization VAS has passed from 7 to 2 and the medium ROM improvement was 65°. Arthroscopically assisted osteotomy permits direct visualization of the site of osteotomy and preserve the dorsal capsula and ligaments, the outside-inside technique by use of compass provide to draw very well the line of osteotomy, in comparison with arthroscopy inside-outside there was realized any time after fracture, there was an economic solution in exchange with navigated solution or custom mask of cutting techniques.

Open CMC-1 fracture dislocation with avulsion of the thumb and laceration of first web space - severe hand trauma

List of authors:
Daniela Horackova*, Radek Kebrle¹, Alena Schmoranzova³, Lucie Smrckova¹
¹Hand and Plastic Institute (Vysoke nad Jizerou)

Objectives / Interrogation: Introduction: Open CMC-1 fracture dislocations is rare injury to the hand and thumb caused by high-energy trauma, such as explosions, thumb entrapments and punch press injuries. It is possible only in case of thenar and first web space laceration. In most cases additional massive injury to the hand and fingers is present whereas narrowing of first web and immobility of the thumb are in danger. Authors would like to point out importance of appropriate treatment for future function of the hand.

Methods: Patients and methods: 7 consecutive cases were reviewed between 2007 and 2018. Etiology were pyrotechnics (4 cases), dog bite (1 case), punch press (1 case) and thumb entrapment by ski lift rope (1 case). In all cases open reposition and fixation of 1st metacarpal and reconstruction of thenar muscles and first web were performed. Additional bone and soft tissues injuries were also reconstructed (2 ray amputations, osteosynthesis of metacarpals and falanges and soft tissue coverage performed) Local care and immediate hand therapy and splinting were part of treatment. Healing period took approximately 3 months. Thumb opposition, sensitivity and first web space span were evaluated as end result.

Results and Conclusions: Results: Residual adduction contracture of first web space appeared in all cases average 45 degree. 6 cases suffered from dysestesia of thumb and all cases had opposition lag (Kapandji 6 in 3 cases, Kapandji 5 in 2 cases and in 2 cases rough grip) but functional hand grip and thumb function were preserved.
Conclusion: open CMC-1 fracture dislocation is part of massive laceration of thenar muscles and first interossus muscle. NC bundles are seriously damaged while remain usually in continuity. Serious damage of bones and soft tissues require individualised treatment, specialized aftercare and additional surgical procedures can be expected.
Permanent consequences such as web space narrowing, loss of sensitivity and opposition can be expected.

DAVIDE SMARRELLI*1
1 HUMANITAS (BERGAMO)

Objectives / Interrogation: This trauma is potentially devastating for the hand. Usually the initial benign appearance of the 
wound can lead to underestimate the injury and then to delays in diagnosis and adequate treatment sometimes due to lack of 
common knowledge of the seriousness of this injury.

We compare our experience with what comes from literature, in order to get useful tips and tricks for the management

Methods: On between 2004 and 2014, we treated 25 patients suffering high pressure injuries. We reviewed all in 2018, 4 
patients were lost to our review.

the materials injected were: in 8 patients oil, in 4 paint, in 3 grease, in 2 air, one sand and one water.

10 patients underwent surgery within 6-12 hours; other 10 underwent delayed surgery because they were seen after several 
days up to 30days from trauma; one patient was treated conservatively for a subcutaneous emphysema of the right emysoma.
The age was in a range from 22 years to 62 years with a predominance of patients in their thirties.
The most affected site was dominant hand.
The mean hospitalization time was from 1 to 9 days.

Surgery included a common time of early and aggressive debridement followed by several surgical procedures as well as tenolisys 
and decompression of the anatomical structures involved, reconstructive techniques with pedicled flaps(9 times) up to not rare 
amputations 2 cases.

outcome was assessed by clinical examination and return to functional and working activities, patient's satisfaction rate, DASH 
score

Results and Conclusions: 9 patients had a return back to normal working activity; 4 patients were unsatisfied; 1 patient took 
long neurological discomfort over 2 years; 7 report mild functional recovery. Dash score was 6.2.

we can assess that the prognosis depends on several important factors: latency time, toxicity of the material injected, site of 
lesion, age of the patient, aggressive and prompt surgery. On our hands, the most important keys are: prompt diagnosis, early 
surgery, with a wide exploration, accurate debridement with detection of all the damaged tissue, and reconstructive surgery with 
flaps or tendon or skin graft; of course. Antibiotic therapy, the possibility of repeated or secondary surgery and early and intensive 
physiotherapy, are required and patients should be informed about possible poor prognosis.

Keywords:
Perilunate fractures and perilunate dislocations in polytrauma

List of authors:
Irena Krusche-Mandl*, Valerie Weihs1, Arastoo Nia1, Bernhard Maier1, Gerhild Thalhammer1, Stefan Hajdu1
1 Medical University of Vienna, Department of Trauma Surgery (Vienna)

Objectives / Interrogation: Generally there is a high rate of missed or incorrect diagnosis for perilunate (fracture) dislocations (PD). Especially in severe injured or polytrauma patients the focus of diagnosis and treatment is restoring vital functions, therefore wrist injuries are sometimes diagnosed or treated later. Thus the aim of this study was to analyze the diagnosis, management and outcome of PLF in polytrauma patients in our Level I Trauma Center.

Methods: In this retrospective study all PD in polytrauma between 10/1994 and 09/2017 were included. All 17 patients with a mean age of 36.1 years (range: 17.2-61.1) were male. The mechanism of injury included falls from > 3 meter in ten cases, < 3 meter in three cases and traffic accidents in four cases. The mean injury severity score was 40 (range: 25-75). Most cases (12) were initially diagnosed by conventional x-ray (Gilula-lines, SL-gap,) and by CT scan. In 3 cases it was diagnosed later at an average of 7 days (1-49). 2 patients were transferred to us from another centre.

Results and Conclusions: From the 17 patients one died in the OR, thus 16 were treated surgically. Reasons for late or alternative care were: precarious soft tissue situation, severe SHT, delayed diagnosis and exitus letalis. We found two cases of persistent carpal instabilities. Range of motion (ROM) will be presented.

Closed reduction should be performed acutely, followed by open reduction and ligamentous and bony repair with internal fixation, whenever possible. In the special setting of polytrauma life threatening injuries are of course prioritized influencing the outcome of these severe wrist injuries.

Keywords:

The use of Carboxymethylcellulose (Dynavisc®) to prevent adherences after WALANT flexor tendons repair

List of authors:
Regina Sonda*1, Diego Faccio1, Andrea Monticelli2, Cesare Tiengo2, Franco Bassetto1
1 UOC Chirurgia Plastica, Università degli studi di Padova (Padova)

Objectives / Interrogation: Perineural and peritendineous scar formation is responsible for loss of function, pain, loss of gliding in peripheral nerve and tendon surgery. Collagen synthesis rate is considerably increased during the 4th week. Dynavisc® is a carboxymethylcellulose (CMC) and Polyethylene Oxide (PEO) gel based on a novel surgical device designed to reduce postsurgical adhesions, creating a physical barrier combined with the immunomodulation of the inflammatory fase. Wide awake (WALANT) is a new-technique in hand surgery anesthesia without the use of turquet and the active movement and collaboration of the patient during the surgery. Their efficacy, when they are used in the same time, was assessed in a retrospective, randomized, controlled, clinical trial, comparing results of tenorrhaphy of flexor tenolysis in zone 2.

Methods: In control group of 12 consecutive flexor tendons repair a standard tenorrhaphy in local-regional anesthesia was performed whitout any anti-adhesion device. In treated group, 12 consecutive WALANT flexor tendons repair, Dynavisc® was applied into the flexor sheath. All patients were evaluated: early and late complications, secondary surgery and at 30, 60 and 180 days after surgery by testing Total Active Motion (TAM), Quick-DASH questionnaire.

Results and Conclusions: Patients in study group had a statistically better recovery of finger motion at long time intervals, specially after 60 and 180 days from the tenedon surgery. The use of wide-awake and Dynavisc® doesn't correlate with increase particoular types of complication. The objectives of the study were to measure the efficacity and to check the safety of WALANT Dynavisc® by assessing adverse effects. CMC-PEO gel can reduce peritendineous scar tissue. Long term hydrolysis (> 30 days) can protect, in our opinion, the surgical site from fibroblasts migration and differentiation, during an important period of collagen synthesis (4th post-operative week). The encouraging results confirmed the Dynavisc effectiveness in flexor tendon surgery.

Recruitment efficiency for randomised controlled trials in digital nerve repair

List of authors:
Sunil Parthiban, Dominic Power, Mark Foster, Suzanne Beale
1 Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: The gold standard treatment for a complete traumatic peripheral nerve lesion involves direct end-to-end microsurgical repair. Tension across the repair site contributes to formation of scar and the risk of neuroma formation. Conduits may be used to reduce scar tether at repair sites or to provide a supported segment of injured nerve for sutureless repair. A randomized controlled trial investigating the outcomes of digital nerve repair requires a two-stage recruitment process. This report summarises the recruitment efficiency and strategies that may result in enhanced participation.

Methods: Patients were assessed using the "ten-test" sensory evaluation following hand injury. Patients with reduced sensation in a digital nerve distribution were referred to a research nurse for consent and first stage recruitment to the CoNNECT study. Intra-operative confirmation of a complete nerve injury meeting inclusion criteria allowed second stage recruitment and randomisation. Analysis of screening data and recruitment logs from June 2017 to October 2018 enables assessment of recruitment efficiency.

Results and Conclusions: 236 patients met clinical screening criteria and 192 consented for trial recruitment (12 per month). At operation 113 patients did not meet the second stage recruitment criteria (75 patients no visible nerve injury, 20 with partial nerve injury, 8 had injuries outside of the target zone, 2 had a nerve gap requiring reconstruction with a graft, 1 proceeded to primary digit amputation and 7 patients were deemed by the operating surgeon not to fulfil the first stage eligibility criteria). 69 patients had at least one nerve injury meeting the second stage inclusion criteria. 3 patients did not proceed to randomisation due to limited operating time and 3 further patients were not randomised due to operator uncertainty regarding the trial protocol. 73 nerves in 63 patients were randomised to one of the three study arms. 1 patient has since withdrawn from the study after randomisation and completion of the procedure.

Our RCT demonstrated that only 27% of patients clinically screened participated in the study and 6 patients were missed at second stage recruitment due to time constraints or inadequate planning of theatre resources. Recruitment efficiency is 91% and retention is 98% for the CoNNECT study. Careful monitoring of recruitment efficiency highlights areas where training and resource allocation can optimise study participation.

Is the use of whole vial of collagenase Clostridium histolyticum dissolved in 1.0 ml of solvent safe and effective?

List of authors:
Ales Fibír*
1 University hospital Hradec Králové (Hradec Králové)

Objectives / Interrogation: Collagenase Clostridium histolyticum (CCH) is a widely accepted alternative treatment option to surgery for Dupuytren's disease (DD). Recommended amount of CCH for MCP joints is 0.58 mg in a volume of 0.25 ml and for PIP joints 0.58 mg in a volume of 0.20 ml. The rest of collagenase vial is disposed of. We think there is no reason not to use the whole vial of CCH. Also, the recommended total amount of injected volume seems to be so small to cure enough tissue affected with DD. We tried to use the whole vial of CCH with less concentrated dilution to find if this approach is safe and effective.

Methods: Patients with DD and with total finger extension deficit (MCP + PIP) more than 30 degrees were indicated for CCH treatment. We excluded patients with previous surgery at the site of CCH injection. In all cases, only one infiltration was applied. We used the whole vial of CCH (0.9 mg) and we dissolved it in the volume of 1.0 ml of solvent. The fingers were manipulated under the wrist block 24 hour later. The follow-up included a minimum of 4 weeks after the treatment.

Results and Conclusions: Between October 2014 and September 2018 total of forty-seven hands of forty-three patients were treated with more diluted CCH. All treated hands had a cord rupture or nodules dissolved at the site of injection. All patients respond and all patients improved their total extension deficit of treated finger. No one patients reported unsatisfactory results. Adverse effects occur in all patients, the most serious were larger skin tears and hematoma of arm and forearm and transient axillary lymphadenopathy. All these side-effects of CCH activity disappeared spontaneously or with conservative treatment (analgesics, cooling, local antibiotic ointments) during 3-10 days. Any major complications, e.g. tendon rupture, anaphylaxis, CRPS, continuous pain etc. were not recorded.
We demonstrate that the use of the whole vial of the CCH is safe. Based on our experience, we also think, that dilution of 0.9mg of CCH into 1.0 ml of the solvent has similar effectivity as original dilution and it allows for the treatment more amount of affected tissue. Total follow-up of 4 weeks we consider as enough time to find if our approach is effective and safe. We can conclude that dilution the whole vial of CCH into 1.0 ml of solvent seems to be safe and effective and increases a total amount of possibly treated tissue without decreasing the collagenase activity. Using whole vial od CCH can improve the economic aspects of DD treatment.

ARTHROSCOPIC PRE-OPERATIVE PLANNING IN WRIST OSTEO-ARTHRITIS

List of authors:
Jane C Messina¹, Riccardo Luchetti², Enrico Carità³
¹ Gaetano Pini Orthopaedic Institute- CTO (Milano)
² Rimini Hand Surgery Centre (Rimini)
³ Hand Centre (Verona)

Objectives / Interrogation: Wrist osteoarthritis can be localised to different articular surfaces of radiocarpal or inter-carpal joints and develops according to predictive patterns. The most frequent causes of the degenerative disease are post-traumatic (SLAC and SNAC wrist) that after many years lead to carpal collapse. Other causes can also related to deposition of calcium pyrophosphate in the joint (SCAC wrist), or advanced stages of osteonecrosis of lunate or carpal bones or previous infections while primary conditions are rare.

The degenerative condition can be studied with plain radiographs and advanced diagnostic imaging techniques as CT scan and MRI scan. Wrist arthroscopy is an additional technique that allows the direct visualization of articular surfaces and identify precisely the damaged intra-carpal joints. Arthroscopy has a higher sensibility and specificity compared to MRI and is considered the gold standard in evaluating cartilage damage. The aim of this study is to use arthroscopy as a guide to surgical choice in order to preserve the intact joints and avoid progression of arthritis.

Methods: Thirty-two patients underwent wrist arthroscopy before the planned surgical procedure. All patients had Xrays and CT scan or MRI scan pre-operatively. All were males, mean age 52 (38- 65). There were 16 SNAC, 13 SLAC and 3 Kienbock Disease. Arthroscopy can be performed as a separate-first step procedure or at the same operating time. Radio-carpal joint and midcarpal joints are examined with standard portals (3-4, 6R, MCR, MCU). Additional portals can be added if needed.

Results and Conclusions: The surgical treatment was modified according to arthroscopic finding in all patients. The disadvantage of this procedure is the increase of operating time or necessity of two procedures to be performed. Open surgical treatment was performed after arthroscopy in a one-step procedure in 7 cases and in two steps in 25 patients. With the use of arthroscopy the treatment can be tailored according to the residual intact cartilage surfaces in order to have more durable results. Sometimes it is possible to post-pone salvage procedures and find more conservative solutions especially in the early stages of SLAC and SNAC.

Keywords:
Definitive Management of Open Fractures of the Hand and Wrist in an Outpatient Setting: Is Urgent Debridement Necessary?

List of authors:
Lee Osterman*, Michael Gaspar¹, David Black¹, Patrick Kane¹
¹ Philadelphia Hand to Shoulder Center, Thomas Jefferson University (Philadelphia)

Objectives / Interrogation: We hypothesized that surgical debridement may be delayed up to one week from the time of injury for open fractures of the hand and carpus without increased risk of infection or secondary procedure.

Methods: We conducted a retrospective review of patients seen at our tertiary upper extremity referral center for open fractures from the carpus distally over a 6-year interval. Records were queried for patient demographic information, injury history, initial management and operative findings. The primary outcomes of interest were incidence of infection and need for additional surgery. Numerical outcomes were compared using independent t-testing and categorical outcomes with Fisher's exact testing.

Results and Conclusions: A total of 284 patients with a mean age of 43 ± 17 years were included. The mean BMI for the cohort was 27.1 ± 5.4 and included 79.2% males, 4.7% diabetics, 26.7% smokers, and 33.9% with associated workers’ compensation claims. All patients underwent bedside irrigation and debridement at the time of their initial presentation to the emergency department. The three most common mechanisms of injury were crush (46.6%), saw (20.8%), and traumatic amputation (9.7%). The median time interval from injury to surgery was 4 days (range, 0 to 34). The three most common methods for fracture stabilization were K-wire fixation alone (50.7%), splinting (41.4%), and plate and screw fixation (4.0%).

Complications occurred in 16 patients (6%), including 4 patients (1.4%) who developed infection. Two infections required debridement and two were successfully treated with oral antibiotics. Revision of nonunion, unplanned revision amputation for wound issues, and tenolysis for stiffness were each required in 3 patients. The most common planned revision surgeries were for coverage of soft-tissue defects (skin grafting in 5, local flaps in 4). Diabetes was the lone factor predictive of complications (complication rate = 18.8% in diabetics vs. 3.9% in non-diabetics; Fisher’s exact P = 0.033). Time interval from injury to initial surgery was not significantly different for the patients who developed complications (mean 4.9 ± 5.6 days) vs. those who did not (mean 5.3 ± 6.0 days; P = 0.78).

SUMMARY
Delayed treatment of open hand/wrist fractures does not lead to increased incidence of infection or complications. Diabetics with open hand/wrist fractures are at greater risk for developing postop complications. Revision surgery is most likely to be required for issues related to wound healing and coverage.

Keywords:
Porcine submucosa extracellular matrix nerve wrapping of scarred nerves

List of authors:
Pieter Jordaan*, Okezika Uhiara, Dominic Power
1 Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Scar tissue formation in the vicinity of a peripheral nerve causes compression, ischaemia, impaired glide and tether, resulting in a pain syndrome - neurostenalgia. Neurolysis of a scarred nerve may bring initial relief from pain but secondary scar formation usually follows. Adjunctive wrapping may reduce scar formation. Biological tissues may result in donor site morbidity. The AxoGuard® nerve protector (AxoGen Inc., Alachua FL) is a layered porcine submucosal extracellular collagen matrix that may be sutured around nerves following neurolysis providing a layer for revascularization and restoration of nerve gliding. This report is on utilization, safety and outcomes of the AxoGuard® in a tertiary referral peripheral nerve service.

Methods: After obtaining ethics form the institutional audit review board, a review was performed of all cases where AxoGuard® nerve protectors were used in primary or revision nerve surgery from June 2015 to July 2018. General demographic data, indications, nerves involved, complications and early follow up data were collected and evaluated.

Results and Conclusions: Over a 3-year period AxoGuard® nerve protectors were used in 71 patients. The indication for surgery was a scarred nerve after trauma in 32 cases, scarring after primary nerve surgery in 19 cases, primary trauma in 9 cases (including one nerve transfer due to a significant size mismatch), nerve scarring after elective non-nerve surgery in 5 cases and nerve tumours in 5 cases. The most commonly involved nerves were the ulnar nerve (32), median nerve (14), digital nerves (11) and the common peroneal nerve (3).

One patient had an early re-exploration due to a post-operative haematoma and one patient had a late exploration due to adjacent tendon adhesions. There have been no complications related to the AxoGuard® nerve protector and no cases of post-operative infection.

Conclusion
The AxoGuard® nerve protector is a versatile tool in complex peripheral nerve surgery with no reported device related complications in a consecutive series of 71 patients.

Concomitant Ipsilateral Endoscopic Carpal and Cubital Tunnel Release: A Single-Center Review of 103 Consecutive Cases

List of authors:
Lee Osterman*, Michael Gaspar, Shelby Smith, Meredith Osterman, Patrick Kane
1 Philadelphia Hand to Shoulder Center, Thomas Jefferson University (Philadelphia)

Objectives / Interrogation: Endoscopic carpal tunnel release (eCTR) performed in conjunction with endoscopic cubital tunnel release (eCuTR) would have a high rate of success in relieving symptoms related to both carpal and cubital tunnel syndrome, with low rates of complications and revisions.

Methods: We conducted a retrospective study of consecutive patients who underwent endoscopic decompression of the ulnar nerve at the elbow and median nerve at the wrist over a 5-year interval. Patients with less than 3 months of follow-up were excluded. Modified McGowan Grades were assigned to each patient pre- and postoperatively. Comparison of pre- and postoperative numerical outcomes was performed using paired t-testing.

Results and Conclusions: 103 patients with mean age 55.4 ± 11.6 years satisfied inclusion. QuickDASH scores improved significantly from 55.4 ± 23.2 preoperatively to 12.2 ± 15.9 postoperatively (paired t-test; P < 0.001). Grip strength improved from 89.8 ± 35.5% of the contralateral side preoperatively to 97.1 ± 36.8% postoperatively, although this difference only approached statistical significance (paired t-test; P = 0.071). Similarly, key pinch strength improved insignificantly from 96.5 ± 44.0% to 99.3 ± 34.6% (paired t-test; P = 0.65).

One patient was converted to open surgery with a modified medial epicondylectomy after the ulnar nerve was found to be unstable intraop and had complete resolution of his symptoms. Two patients had worsened McGowan grades postoperatively (Table 2) and required revision for recurrent symptoms; one male was found to have massive perineural scarring at 6.5 months and underwent revision neurolysis with anterior subcutaneous transposition, while the 2nd patient was found to have moderate scarring with a subluxating nerve at 3.5 months when she underwent a revision neurolysis with modified medial epicondylectomy. Both patients were active smokers, as smoking was the lone predictive factor of needing revision surgery (Fisher’s exact; P = 0.023). Eight patients had no change in their postoperative McGowan grade, while the remaining 93 patients improved by at least one grade.

Combined endoscopic decompression of the ulnar and median nerves is a safe and effective treatment option for patients with concomitant ipsilateral cubital and carpal syndrome. Patient-rated outcome scores improved significantly after surgery, while improvements in grip and pinch strength were not significant. Active smokers were at higher risk for requiring revision surgery and worsening of symptoms.

Keywords:
Arthroscopic spiral tenodesis reconstruction for SL instability

List of authors:
Andrea Atzei*, Mireia Esplugas, Riccardo Luchetti
1 Clinica Giovanni XXIII (Monastier di Treviso)
2 Kaplan Institute (Barcelona)
3 Rimini Hand Centre (Rimini)

Objectives / Interrogation: To report the anatomical study and preliminary clinical experience with an arthroscopic adaptation of the ECRL antipronation spiral tenodesis for Scapholunate and Radiolunate ligaments deficiency.

Methods: After an anatomical cadaveric study, 5 patients were operated using this technique. The following extended portals were used: 1-2; 4-5 and volar-radial. A 8cm distally based strip of the ECRL was passed within the STT joint and through a tunnel on the scaphoid, where it is blocked using a 3x8 mm interference screw. Then, it was retrieved in the dorsal radio-carpal joint, fixed on the dorsal ridge of the lunate with a bone anchor, and introduced in a tunnel through the triquetum, to exit on the volar aspect of the radio-carpal joint. Subsequently, the tendon graft is deployed through the volar-radial portal and fixed on the radial styloid using a fork tipped interference screw. The visual analog scale of pain (VAS), SL instability (as assessed using the Watson test to dislocate the proximal scaphoid over the dorsal rim of the radius), ability to return to work, range of motion (ROM), grip strength were used for evaluation at minimum follow-up of 12 months.

Results and Conclusions: No intra-operative complications were recorded. One patient developed significant post-operative osteopenia, without obvious signs of CRPS. Pain under load decreased from 7.5 to 2, all SL were stable (Watson test cannot dorsally dislocate the scaphoid). All patients returned to previous work. ROM was reduced of 27% compared to pre-op values. Grip strength increased fo 33%.

Conclusions: Arthroscopic spiral tenodesis reconstruction is feasible and safe, producing comparable results as the standard technique.

SL instability, Spiral reconstruction, arthroscopy, tenodesis
intraneural ganglion of the distal ulnar nerve- a case report

List of authors:
Johanna Ueberberg*, Martin Langer
1 Uniklinik Münster, Unfall-, Hand- und Wiederherstellungschirurgie (Münster)

Objectives / Interrogation: In our department for hand surgery we saw a 49 year old man who had been suffering from a weakness while spreading his small and ring finger for almost three months. No loss of sensation or dysesthesia had occurred. He had first presented himself to a neurologist who excluded pathologies of his cervical spine by an MRI and a CT scan.

Methods: During our clinical examination we saw an atrophy of his interosseous muscles of the fourth and fifth finger along with a weakness in spreading these fingers. He also brought an MRI which showed a cyst of unclear origin.

Because of the clinical findings we were sure that there was a pathology compromising the function of the distal ramus profundus of the ulnar nerve. That's why we saw the indication to explore the nerve in the OR.

During the surgery we saw an intraneural ganglion of the n. ulnaris and removed it.

Results and Conclusions: Intraneural ganglia of the distal ulnar nerve are a rare finding and can mostly be diagnosed by a detailed clinical examination.

We saw our patient again after three and six months. He has fully recovered the function of the hand and is again able to play the piano.

Keywords:
intraneural ganglion, n. ulnaris, nerve compression syndrome
Clinical, surgical and imagistic correlations in the carpal tunnel syndrome

List of authors:
Raluca Laura Stefanescu*, Florin Gabriel Panculescu, Ion Bordeianu
1 County Emergency Hospital Constanța (Constanța)
2 Faculty of General Medicine Ovidius University Constanța (Constanța)

Objectives / Interrogation: As one of the most common entrapment neuropathies, carpal tunnel syndrome raises significant costs through surgery and rehabilitation.

Methods: Although the diagnosis is mostly clinical, additional evaluation may be useful for confirmation of diagnosis and treatment management.

Results and Conclusions: In cases with divergent clinical and EMG findings, MRI may be helpful in selecting patients who would benefit from surgical release.

Keywords:
Irreducible palmar dislocated isolated fracture to the styloid process of second metacarpal - a unique fracture mechanism.

List of authors:
Simon Oeckenpöhler*, Martin Franz Langer, Sarah Breiter, Johanna Ueberberg, Britta Wieskoetter
1 Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)
2 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)
3 Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster, Sektion Hand (Münster)

Objectives / Interrogation: A 40-year-old patient came to our clinic with swelling on the back of his hand and pain 14 days after a fall. Radiographs showed a larger fragment palmar of the base of the Metacarpal II in the lateral radiograph and a gap in the area of the styloid process MC-II.

Methods:
The patient was operated on and the entire slightly wedge-shaped styloid process could be recovered from the palmar dislocation position and fixed with a screw osteosynthesis after cleansing to the anatomical position.
The fracture healed and after three month there was no pain and full ROM.

Results and Conclusions: The unique injury mechanism resulted from the wedge-shaped shape of the MC-II processus, and an injury mechanism that results in a dorsal displacement of the MC-II basis. The styloid process can't follow the dorsal displacement of the second metacarpal and after spontaneous reposition the styloid fragment is pushed palmar.
This is the same mechanism as in a perilunate dislocation.

To other similar cases in our unit are compared with this case.

Keywords:
irreducible fracture dislocation, styloid process of metacarpal base, unique fracture dislocation
**Distal radio-ulnar replacement: our early experience with a constrained prosthesis**

**List of authors:**
Najab Ellahee¹, Aisha Razik*¹, Shabna Khan¹, Al- Achraf Khoriatí¹, Hiba Khan¹, Gemma Green¹, Ravikanth Mallina¹, Ritesh Sharma¹

¹ Epsom & St Helier NHS Trust (Epsom)

**Objectives / Interrogation:** Objectives:
Arthropathy of the distal radioulnar joint (DRUJ) occurs due to a variety of pathology, including congenital instability, as well as inflammatory, degenerative and post-traumatic arthritis. Treatment consists of resection, fusion and arthroplasty. However in some cases, instability, pain or failure of primary procedure necessitate further intervention to regain improved function.
The Scheker (Aptis Medical) prosthesis allows for mechanical function with a semi-constrained mechanism in this group of patients, by use of a cobalt chromium radial plate containing a hemi-socket articulating with a UHMWP ball attached to a cobalt chromium fluted stem in the ulna.
Our aim is to assess the outcome of our patients, comparative to the positivity of other studies using the same implant.

**Methods:** Methods:
We evaluated the outcome of surgery in a series of consecutive patients from 2013 onwards, in a NHS hospital performed by a single surgeon, providing a regional service. Indications for surgery were in keeping with NICE guidelines. Outcomes were measured using clinical and radiological assessment, with the added use of functional scores and questionnaires. All patients underwent standardised rehabilitation with splinting and hand therapy over a minimum of a 6 week period.

**Results and Conclusions:** Results:
10 patients with mean age 56yrs, at time of surgery, were followed for a mean time of 2.5 years (max 6 years).
5 patients had arthritis following trauma, 2 had congenital deformity leading to instability, 2 had osteoarthritis & 1 patient had rheumatoid inflammatory disease with instability.
2 patients had previous ulnar head replacements, one had a failed radio-ulnar fusion with stump impingement & 3 had degenerative instability after wrist trauma. The other 4 had pain & instability due to their primary pathology.
All patients reported improved forearm rotational ROM (supination and pronation), reduced pain (VAS) and improved functional outcome (DASH & PRWE scores).
Implant survival is 100%, with no evidence of infection or need for further surgery to the DRUJ.
Patient satisfaction was high, with early visible improvement seen within weeks of the procedure.

Conclusion:
Early to mid-term results suggest that the semi-constrained Scheker prosthesis is a reliable implant in restoring functional stability for patients who have painful degenerative instability of the DRUJ. Further follow up is advised for long-term assessment to assess whether there may be potential for more widespread use.

Pedicled deltopectoral adipofascial flap and lipofilling techniques for management of recurrent thoracic outlet syndrome

List of authors:
Henk Giele\textsuperscript{1}, Aliabba Moosa\textsuperscript{*1}, Roisin Dolan\textsuperscript{1}
\textsuperscript{1} Oxford University Hospital NHS Foundation Trust (Oxford)

Objectives / Interrogation: Thoracic outlet syndrome (TOS) is a symptom complex caused by compression of one or more of three neurovascular structures: the brachial plexus, subclavian vein, or subclavian artery, between the first rib and clavicle. Management of recurrent cases of thoracic outlet syndrome present a challenging clinical conundrum. Various surgical techniques have been described to introduce a ‘firebreak’ in attempt to reduce recurrence rates.

We report for the first time, the novel technique of a pedicled adipofascial flap +/- adjunctive lipofilling in attempt to reduce further recurrence of TOS, improve functional outcomes and improve scar quality.

Methods: We analysed data from a prospectively maintained database comprising patients presenting consecutively for surgical management of TOS. All cases of recurrent TOS were identified and clinically assessed by the senior author (HG) at the Oxford University Hospitals NHS Trust between April 1997 and November 2017. All patients underwent standard pre-operative investigations to include: 1. clinical history and upper limb examination 2. provocative TOS tests for vascular and neural compression 3. MRI spine and brachial plexus 4. electrophysiological studies.

Patients diagnosed with recurrent TOS underwent brachial plexus re-exploration, neurolysis +/- arteriolyis and pedicled deltopectoral adipofascial flap overlying the clavicle +/- lipofilling.

Results and Conclusions: Recurrent cases of TOS were identified in 22% of our cohort (n=30). There was a female preponderance in this cohort (75%) and age ranged from 22-75 years (mean: 41 years).

80% of patient reported improved scar quality and 65% reported reduced pain scores following the procedure.

To conclude, we describe the novel technique of pedicled deltopectoral adipofascial flap +/- adjunctive lipofilling for the management of recurrent TOS, with good surgical and functional patient-reported outcomes.

Keywords: deltopectoral adipofascial flap, recurrent thoracic outlet syndrome
New ligament reconstruction for midcarpal instability - a case report

List of authors:
1 Ain Shams University (Cairo)

Objectives / Interrogation: Literature is scarce regarding reported cases and treatment of midcarpal instability. While diagnosis is reasonably well established but its treatment is still an unsolved problem. Poor results of soft tissue reconstruction led others to advocate arthrodesis but there is a considerable risk for radioscaphoid impingement and obliteration of the important dart throwing movement. We describe a novel technique in ligament reconstruction of the combined radiocarpal -midcarpal instability.

Methods: We are presenting a case of a 20-year old student male with a rare type of right dominant midcarpal instability (combined radiocarpal -midcarpal instability). The patient refused limited wrist fusion. A new technique for ligament reconstruction was utilized in this case using the extensor carpi radialis longus (ECRL) tendon. The tendon was used to reconstruct triple ligaments; the short radiolunate, the dorsal radiocarpal, and the dorsal intercarpal ligaments through a combined volar and dorsal approaches.

Results and Conclusions: The patient became pain free. The flexion-extension range of the wrist was 85% of the contralateral side. The wrist was stable with no clicking occurred up to 30-month follow up. The patient was satisfied with the results.

Conclusion: The technique in this case yielded satisfactory result at the short term. It can be an addition to the treatment of this perplexing condition. However, it needs to be applied on a larger number of patients to definitely judge its effectiveness.

Keywords:
Acquired vascular malformation on fingertips: a report of three cases

List of authors:
Amal Sharaf*, Sharmila Jivan
1 Mid Yorkshire Hospitals NHS Trust (Wakefield)

Objectives / Interrogation: Acquired digital arteriovenous malformation is a rare vascular anomaly usually involving the fingertip or periungual region.

We report three cases of acquired vascular malformation on fingertip of 3 adults.

Methods: Case 1:
A 48-year-old lady presented with a vascular lesion on the left ring finger pulp that has been present for one year. No history of trauma. Recent recurrent bright red pulsating bleeding following minor trauma was reported.

Examination revealed 5mm purplish skin on the ulnar border of the pulp which did not reduce in size with elevation. Ultrasound scan showed 2mm subcutaneous lesion surrounded superficially by prominent vascularity. The appearance was in keeping with vascular malformation.

Fingertip was explored and small lesion with overlying skin ellipse were biopsied. A small group of vessels at the base were cauterized. Histopathology showed proliferation of capillary channels with a bland of endothelial lining which confirmed the diagnosis of capillary hemangioma.

Case 2:
A 55-year-old lady presented with a few-year history of a vascular lesion on her left ring fingertip without previous trauma. This was previously cauterized by dermatologists, recurred and started to bleed repeatedly over the last year.

Examination revealed bluish compressible lesion on the radial border of the pulp. Doppler scan showed 1cm longitudinal subcutaneous lesion with increased venous vascularity. There was prominent flow but no feeding vessel or direct communication with digital vessels. These findings were consistent with hemangioma.

Pulp was explored and general oozing with no obvious leash of vessels was found. Vessels in the base were cauterized and the wound was closed directly. 3 months postoperatively, patient reported no further bleeding.

Case 3:
A 69-year-old retired right handed lady presented with 10-year history of a small vascular lesion on the tip of her right ring finger following minor trauma without open wounds. The lesion started recently to bleed with minimal trauma. Examination revealed 8X4mm capillary venous malformation. Treatment options were discussed and patient preferred having the base of the lesion cauterized without excising the overlying skin.

Results and Conclusions: Acquired digital arteriovenous malformations are rare acral vascular lesions that can involve fingertips usually with history of previous trauma. Treatment ranges from observing asymptomatic cases to complete excision of symptomatic lesions with or without local flap or skin graft reconstruction.

Keywords:
acquired digital vascular malformation, fingertip
Trigger Finger Percutaneous Release - Safe, Effective and Less days Off

List of authors:
Luís Vieira*, Diogo Guimaraes¹, Maria Manuel Mouzinho¹
¹Hospital de São José (Lisboa)

Objectives / Interrogation: To evaluate the safety, efficacy, recovery time and repercussion on the functional status of the percutaneous surgery technique for the treatment of trigger finger.

Methods: A two phase study was designed. In the first phase, percutaneous release of A1 pulley was performed in cadaver hands and verified by an incision over the A1 pulley. In the second phase, after informed consent, 20 patients underwent percutaneous release of the A1 pulley with an intramuscular needle. Preoperative and post operative functional status was assessed by the QuickDASH score before and 2 weeks after the procedure. Parameters like pain during the intervention and in the post-op period, time to return to work, patient satisfaction, recurrence of trigger finger and complications were also evaluated.

Results and Conclusions: Patients got back to daily life tasks and to work before than the mean time described in the literature with the open surgery procedure, as well as had a shorter time of pain post-op. We had few complications and all the patients improved their functional status measured with the QuickDASH score after the procedure. Percutaneous surgery for trigger finger has shown to be a safe technique, with faster recovery than the open surgery, even in centers more experienced with the open technique.

Percutaneous Trigger Finger Release
Cat Bite: an underrated injury

List of authors:
Amin Kheiran*, Vishal Palial¹, Clare Wildin¹, Rebecca Rollett¹, Urjit Chatterji¹, Harvinder Singh¹
¹ University Hospitals of Leicester (UHL) (Leicester)

Objectives / Interrogation: Domestic cat bites are common and are often minor wounds that can be treated by simple wound care and short term antibiotic therapy with good to excellent outcome. However, delayed presentation may lead to significant morbidity or even mortality. The authors report a case series of severe hand infections following cat bite resulting in significant morbidity.

Methods: 20 cases of cat bites to the hand and wrist that were referred to hand surgery unit for further treatment were retrospectively reviewed between July 2014 and August 2018. Data included patient demographics, anatomical site of injury, clinical diagnosis, radiographic features, inflammatory markers and microbiology results, method of treatment, antibiotic regimen, and functional outcome. The patients’ clinical notes were reviewed.

Results and Conclusions: The subjects consisted of 18 females and 2 males aged 27-86 years (mean age of 58 years). Eighteen patients underwent surgical intervention and 2 were managed non-operatively. Of those patients treated operatively; eleven underwent single surgery (irrigation and debridement), and 7 had multiple operations secondary to septic arthritis, osteomyelitis, necrotising fasciitis and deep soft tissue infection. Mean length of hospital stay was 11.6 days in those underwent multiple surgeries. The index finger was the most common site of injury. Pasteurella species was isolated from 39% of infected wounds. Four fingers underwent amputation due to extensive soft tissue infection, tissue destruction and necrosis, particularly in those presented late and had diabetes. Delayed presentation resulted in multiple surgeries, protracted hospital stay, longer antibiotic course, and significant soft tissue complication, which resulted in significant morbidity. Risk of amputation was significantly higher in a diabetic finger with peripheral neuropathy. The results of our case series suggest that any symptomatic cat bite to the upper limb, especially hand and wrist, must be treated promptly, essentially within 48 hours of injury and no later than 72 hours. Delayed presentation conveys complicated surgery and or significant morbidity.

Keywords: -
CoNNECT: 6 month follow up data for a randomised controlled trial in digital nerve repair

List of authors:
Sunil Parthiban*, Dominic Power¹, Mark Foster¹, Suzanne Beale¹, Dalia Ghalli¹
¹ Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Microsurgical repair of the injured digital nerve is considered to be the gold standard. Complications associated with neurorrhaphy include repair site scar and neuroma formation estimated at 5-9%. The CoNNECT study is a randomised controlled trial evaluating nerve repair using a Neurolac conduit (Polyganics) as an adjunct to microneurorrhaphy or as a detensioning sutureless nerve co-aptation.

Methods: Patients were recruited from a tertiary referral regional hand trauma service. Patients with sensory loss following an open injury were screened for eligibility then recruited and consented for trial participation. Confirmation of second stage eligibility was after surgical exploration and at that stage complete digital nor common digital nerve injuries amenable to direct repair were randomised in a 1:1:1 ratio (direct repair; repair plus conduit; conduit alone). Patients were assessed at 2 weeks, 6 weeks, 3 months and 6 months by a research hand therapist with DASH scores plus sensory evaluation using 2PD and monofilaments. Complications including clinically suspected neuroma, pain and cold intolerance were recorded.

Results and Conclusions: 63 patients with 73 nerve injuries have reached at least 6 months follow up under the study protocol. There have been no post-operative infections, conduit extrusions, allergic reactions or explantations during the study. No clinically suspected neuromas have been identified in the 73 nerves reaching 6 month follow-up.

The study is powered for 240 digital nerve repairs to allow for drop-out. The final sensory outcomes will be reported after closure of the recruitment period. The interim analysis of 73 nerves is part of the trial data monitoring and to date there are no adverse events attributable to the implanted Neurolac device. The study will be one of the largest randomised controlled trials evaluating digital nerve repair and will evaluate efficacy of a sutureless technique in nerve co-aptation.

Keywords: CoNNECT, digital nerve repair, digital nerve, neurorrhaphy, sutureless
Guyon canal syndrome: a not so common cause of cubital nerve entrapment

List of authors:
Marta Sá de Azevedo*, Rui Vieira1, Tiago Guedes1, Gustavo Coelho1, Horacio Costa1
1 Cirurgia Plástica, Reconstrutiva; C. H. V. N. de Gaia/E (Vila Nova de Gaia)

Objectives / Interrogation: Ulnar nerve compression can happen along its path in the upper limb, being more common, according to its anatomy, around the elbow. Its distal compression, at guyon canal, is rare but globally the ulnar entrapment is the second most common peripheral nerve entrapment neuropathy in the upper limb.

Ulnar compression at the Guyon’s canal can be caused by a number of factors, including acute or repetitive trauma, carpal bone fractures, additional muscles, tumors (lipoma, ganglion), diseases of the neighboring vessels, metabolic/degenerative diseases. The distal cubital lesion is classified according to its location in the Guyon’s canal and consequently the symptomatology that causes.

Methods: The authors present a case of a 58 year-old female patient with progressive loss of muscular strength with an acute onset, associated with paresthesia in the 4th and 5th fingers, of her right hand. With no history of recent trauma. In the physical examination the muscular atrophy of the thenar and hypothenar eminence was notorious. Wartenberg, Jeanne’s and Froment’s signs were positive, with no sensory dorsal alterations, no palpable masses, no traumatic lesions identified.

Electromyography showed a compression of the ulnar nerve at the wrist level, in the Guyon canal, mainly motor. Surgical decompression at the Guyon canal was decided, with identification and resection of a synovial cyst deeper to the ulnar nerve, at the carpal bones, causing ulnar nerve compression.

Results and Conclusions: Six months after the surgical procedure with electromyography showing improvements compared with the pre operative exam. Twelve-months follow up with improvement of the muscular strength and trophism, hand movements specially grasp, pinch, thumb adduction and 4th and 5th fingers’ movement and paresthesia.

Conclusion: Compression of the ulnar nerve is the second most common cause of nerve compression of the upper limb, although, its distal compression is rare. Medical history, physical examination and complementary studies allow its diagnosis, identification of the most probable etiology and help in its posterior treatment approach.

nail unit matrix transplantation - aesthetic surgery after traumatic amputation of the distal phalanx

List of authors:
Johanna Ueberberg*1, Martin Langer1
1 Uniklinik Münster, Unfall-, Hand- und Wiederherstellungschirurgie (Münster)

Objectives / Interrogation: A young man presented himself in our department with the wish of a nail transplantation. Years ago he had suffered from a traumatic partial amputation of the distal phalanx of his index finger causing the loss of his nail. Besides the floppy feeling aesthetic reasons were his main intention for wishing a reconstructive procedure.

Methods: We offered two different possibilities: a skin graft to simulate a nail which he didn't favor because the floppy feeling would persist. Second option was the transplantation of two half toe nail matrix grafts which would cause a narrowing of the toe nails while receiving one new nail for his index finger.

He chose the nail unit matrix transplantation which went really well. The donor toes were of the same side. The whole procedure was documented in detail.

The patient was able to leave the clinic on the same day and the whole surgery was performed in local anesthesia.

Results and Conclusions: In this case we received a good cosmetic result and a pleased patient. Nevertheless complications like infections, rejection of the nail and its matrix and unsatisfying cosmetic results have to be discussed before.

Keywords:
nail matrix unit transplantation, plastic surgery, amputation of the distal phalanx
RECONSTRUCTION OF THE RADIO ULNAR COLUMN WITH THIRD METATARSIAN FREE FLAP AND COMPUTED 3D PLANNING

List of authors:
Carlos Torres*, Lina Franco
1 Hospital de San José, Clínica la Carolina (Bogotá)
2 Hospital de San José, Clínica Santa Bárbara (Bogotá)

Objectives / Interrogation: The use of the third metatarsal allows reconstructing bone and cartilage defects of the distal radius with tissue of similar characteristics, we describe how to optimize the original technique using three-dimensional computer-assisted planning technology.

Methods: A 19-year-old woman referred from another city due to bone and cartilaginous defect of the lunate and sigmoid fossa of the right radius as a sequel to palmar plate removal of the radio six months previously. She presented intense pain with severe limitation of the mobility arches. Using three-dimensional images of the radius and the left foot, the cutting guides are designed to obtain a bone fragment of the third metatarsal to measure the size of the defect, preserving the plantar cortex, unlike the original technique, minimizing the morbidity of the donor area. The free flap of the third metatarsal is raised based on the lateral tarsal branch of the pedius dorsal artery, anastomosed in the recipient bed to the radial vessels and fixed with 1 bicortical screw. No more screws are placed because of the risk of bursting the bone fragment and altering its vascularization. The patient follow up shows improvement of pain, ranges of mobility in progression with physical therapy and without functional limitation of the donor area.

Results and Conclusions: The combination of microsurgery techniques and 3D computerized assistance allows to accurately reconstruct defects of high complexity in the upper extremity, providing healthy joint cartilage and sufficient bone support. Arthrodesis is restored. The tools are designed tailored to the patient's defect and allow the simulation of surgery and its possible inconvenience before they occur in the operating room, optimizing the original description of the technique.

Arthroscopic diagnosis of TFCC peripheral tears using "Trampoline Test" and "Hook test"

List of authors:
Andrea Atzei*1, Riccardo Luchetti2
1 Clinica Giovanni XXIII (Monastier di Treviso)
2 Rimini Hand Centre (Rimini)

Objectives / Interrogation: The Trampoline and Hook test are commonly used in the arthroscopic assessment of TFCC tears. This study aims to evaluated the reliability and the advantages of these tests to identify laceration of the distal or proximal component at the periphery of the TFCC

Methods: The study group included 135 patients (97 male, 38 female, mean age 43.5 yrs) into 2 groups. Group A: 80 patients with chronic ulnar sided wrist pain and positive "fovea sign". Group B (control group): 55 patients with other complaints. Clinical DRUJ instability was evaluated by the ballottement test. Radiocarpal and DRUJ were scoped using "Dry Technique" and TFCC was tested by the Trampoline and Hook test. Test specificity, sensibility and likelihood ratio were assessed. Statistical significance was evaluated with the Pearson chi-square and Fisher's exact test.
Patients diagnosed as having a laceration of the foveal insertions of the TFCC were treated with bone anchor refutation of the tear. Patients with distal tear an intact foveal insertions of the TFCC were repaired with a capsular suture.

Results and Conclusions: Results: Trampoline and Hook test showed an overall specificity of 67.27% and 96.36%. Test sensibility was 75% and 0% (p<.001) when TFCC foveal insertions were intact and 56% and 100% (p<.001) when they were lacerated, respectively. Trampoline test showed an overall positive likelihood ratio of 2.4. Hook test showed an overall positive likelihood ratio of 22.
All patients improved after the selected treatment was performed according the the arthroscopic findings.

Conclusions: Trampoline and Hook test are reliable to make a diagnosis of peripheral TFCC tear. The Hook test shows higher specificity and sensibility to recognize TFCC tears. Values of positive likelihood ratio suggest that the probability to detect any TFCC peripheral tears is higher for the Hook than for the Trampoline test, especially when the foveal insertion of the TFCC is lacerated. The positive Hook test circumvents the need of a confirmatory DRUJ arthroscopy in case of suspected foveal detachment of the TFCC.

Keywords:

Objectives / Interrogation: Does an intraoperative, single application of focused ESWT improve the consolidation of the scaphoid after reconstruction with a non-vascularized bone graft to treat scaphoid nonunion?

Methods: In a prospective, randomized study, patients with a scaphoid nonunion, mostly with compromised vascularity of the proximal pole fragment, had scaphoid reconstruction with a non-vascularized bone graft. Surgery was combined with focused, high-energy ESWT intraoperatively (intervention) or not (control group). Bony consolidation was evaluated by CT scans at 12 and 18 weeks, in case of failing or incomplete healing additionally at 24 weeks. The rate of patients without scaphoid consolidation after 24 weeks was calculated for each group. In those patients with a finally healed scaphoid, the extent of consolidation across the bone graft was assessed for each CT examination.

Results and Conclusions: In this ongoing study, 58 patients were enrolled so far, of which 9 did not finish follow up till 24 weeks. The rate of persistent nonunion was 22% in the ESWT group and 38% in the control group. Among the patients with scaphoid consolidation, the extent of scaphoid consolidation was 84% of the scaphoid's square area after ESWT and 73% in the control group 12 weeks postoperatively, 86% and 84% at 18 weeks, and 91% and 88% at 24 weeks.

Nerve transfers to the deltoid: Evolution of a surgical technique

List of authors:
Sunil Parthiban*, Dominic Power1, Devanshi Jimulia1
1 Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Deltoid paralysis follows injury to the C5 nerve root or the axillary nerve. Nerve transfer provides a reliable method of restoration of function and typically the donor nerve is from one of the triceps branches. The technique has evolved from the description of triceps to axillary nerve transfer through an anterior approach (Stoffel 1911) to the modifications of the posterior approach using the medial triceps branch (Mackinnon). The rationale for the technique evolution is defined with an algorithm for reconstruction.

Methods: A review of literature on nerve transfer to the deltoid was undertaken to develop an algorithm for reconstruction of axillary nerve function. The results of this algorithm were evaluated using the outcomes of 60 consecutive nerve transfers to deltoid performed in a specialist nerve injury service.

Results and Conclusions: The medial nerve to triceps is now the favoured donor nerve for restoration of axillary nerve function in isolated C5, C5 and C6 combined and isolated high-grade axillary nerve injury or rupture. The nerve is sutured to the main axillary nerve to reinnervate deltoid and teres minor when necessary. The avoidance of the long head triceps branch maintains the only intact shoulder stabilising muscle in the C5 and C6 combined injury and is now the preferred donor in all nerve transfers to deltoid; due to the higher motor axon count, the length of the donor allowing closer placement of the neurorrhaphy to the motor point and the low donor morbidity. In cases of associated C7 dysfunction or isolated posterior cord injury, the FCU fascicle of the ulnar nerve is the preferred donor nerve and the procedure is undertaken through a posterior approach. The nerve transfer to deltoid is performed synchronously with a posterior spinal accessory to suprascapular nerve transfer in cases of C5 complete injury.

The current reconstructive algorithm for deltoid function is effective and allows rapid reinnervation without loss of stabilising function of the long head of triceps at the glenohumeral joint.

Radiological analysis to determine risk factors for aseptic loosening in the linked-type total elbow arthroplasty

List of authors:
Hiroki Nishikawa*1, Katsunori Inagaki1, Jun Ikeda1, Keikichi Kawasaki1, Kazunari Tomita1, Naoya Nishinaka2
1 Showa University School of Medicine (Tokyo)
2 Showa University School of Medicine, Showa University Fujigaoka Hospital (Tokyo)

Objectives / Interrogation: Total elbow arthroplasty yields good long-term results but requires revision surgery in some cases. We have recently experienced a first case of aseptic loosening of a linked-type total elbow performed at our institute which needed revision. We have analysed radiological features which may predict aseptic loosening in the linked-type total elbow arthroplasty.

Methods: 27 elbows with the Coonrad-Morrey prosthesis who were operated at our institute and followed up for more than three years, were included. 21 were female and 6 were male, and the mean age at the time of operation was 68. Every operation was performed by a single senior surgeon by Campbell’s approach. Pre-operative x-rays and post-operative x-rays were analysed, including flexion-extension placement of both components, valgus-varus placement of both components, state of bone union at the anterior flange, state of cementing, and zone of osteolysis according to Hastings and degree of osteolysis according to Morrey.

Results and Conclusions: Type V osteolysis according to Morrey’s classification (gross loosening) was seen in two cases (one on the humeral side, another on the ulnar side), type IV in two cases (one on the humeral side, another on both sides), and type I-III in four cases (three on the humeral side, one on both sides). One of the cases with type V osteolysis needed revision surgery of the humeral component 7 years and 10 months after the primary operation. Osteolysis types VI-V were significantly cubitus varus post-operatively compared to types I-III (carrying angle: type IV-V 180.4°(±5.4); type I-III 172.0°(±7.7). p<0.05). Mean extension angle placement of the humeral components and mean flexion angle placement of the ulnar components were also significantly higher in types IV-V. Cases of gross loosening presented with osteolysis beginning around the joint and spreading to the components. Post-operative cubitus varus may be a factor to predict future aseptic loosening hence precise component placement at the primary operation is essential to avoid it.

² Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Universitätsklinikum Münster (Münster)
³ Universitätsklinikum Münster, Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Handchirurgie (Münster)

Objectives / Interrogation: Fractures of the pisiform bone are not uncommon. Almost always a conservative therapy is performed. For postoperative complaints due to arthrosis, a pisectomy is recommended. Can this osteosynthesis make sense?

Methods: 5 of the 7 patients could be followed up. Resting pain, stress pain, wrist mobility, DASH and exact clinical investigation of the pisiform area were examined.

Results and Conclusions:
There was no pain in any of the patients, no evidence of osteoarthritis was found. 2 patients did not remember which side had been operated on. Neither rest nor stress pain was reported. A slight reduction in hand mobility in dorsiflexion was found in 2 patients.

Osteosynthesis of the pisiform bone may be useful. A nonsensical operation is not according to our results.

THE TURNER SCIENTIFIC RESEARCH INSTITUTE FOR CHILDREN'S ORTHOPEDICS

List of authors:
Sergei Goliana*
1 TURNER SCIENTIFIC INSTITUTE FOR CHILDREN'S ORTHOPEDICS (Saint Petersburg)

Objectives / Interrogation: Traditional methods of the bone's replacement doesn't provide positive results in many cases, particularly in combination of bone, muscular, soft tissue and articular defects. Besides, the main difficulty of these methods is the impossibility of the restored segment to grow, since non of these methods doesn't provide the restoring of growth plate which is absent from the moment of birth or destroyed after the pathological involvement. Blood-supplied bone graft may have still functional growth plate, it also may be taken as a part of big complex of tissues, including skin, subcutaneous fatty tissue, fascia, muscles and nerves.

Methods: From 1993 up to the present time on the Department of Reconstructive Microsurgery and Hand pathology 85 children were treated by microsurgical transplantations of the bone grafts. Among them 51 children had congenital developmental defects and 34 - acquired deformations.

Results and Conclusions: For transplantation we used: diaphysis of the fibular bone or external part of the scapula in the replacement of the bone defect, diaphysis in the absence of involvement of the soft tissues, 1 or 2 metatarsal bones for the restoration of distal or proximal epimetaphysis of bones, one or two ribs as a part of thoracodorsal flap in replacement of extensive defects, metatarsophalangeal joint of the first and second toes for the reconstruction of underdeveloped or injured joints. Analysis of the obtained results showed significant perspectivity of the application of microsurgical transplantations of tissue complexes in severe bone defects in children with congenital and acquired pathologies.

Managing Painful Wrist and Trapezio-Metacarpal Arthritis in Patients with SCI Using Surgical Joint Denervation

List of authors:
Andreas Gohritz*
1 Swiss Paraplegic Centre (Nottwil)

Objectives / Interrogation: Patients with spinal cord injury (SCI) have an increased incidence of painful wrist and trapezio-metacarpal arthritis due to the accumulated long-term load on their upper extremity or post-traumatically. However, many of the affected individuals opt against standard bony procedures, such as arthroplasty, joint implants or arthrodesis for fear of lengthy immobilisation, loss of motion, and other complications, e.g. postoperative instability.

Methods: We have studied the effects of alternative surgical denervation in 8 wrist and 7 trapezio-metacarpal joints (2 bilateral, 1 combined) during a 4-year period in 8 paraplegic and 4 tetraplegic individuals.

Results and Conclusions: Pain intensity regarding dropped by at least 50% on the visual analogue scale in all cases and results were rated as satisfactory by all patients.
No conversion to total joint arthrodesis was necessary within the follow-up time.
Surgical joint denervation seems to be an underused option to treat painful osteoarthritis in SCI patients as we are unaware of a previous description.
However, compared to more invasive methods, it provides important advantages as preserved joint integrity, no need for postoperative immobilization, technical simplicity, inexpensiveness and with low risk profile. All alternatives remain possible for future, e. g. arthrodesis or arthroplasty prosthesis and results can be reliably anticipated by preoperative test nerve blocks.
This study shows that surgical denervation of the wrist and thumb carpo-metacarpal joint is a minimally invasive option to reduce pain and preserve motion and function in this population with special demands.

Engineering Drawing Analysis Applied to Complex Radiographs

List of authors:
David Nelson*
1 David L. Nelson, MD (GREENBRAE)

Objectives / Interrogation: To explore how engineering drawing analysis can be applied to understand x-rays of complex fractures.

Engineering drawing is a technical and graphical language with its own rules. It is useful to apply the principles of engineering drawing to complex radiographs when the supplied views do not supply enough information to identify the bones or fracture fragments.

Methods: The engineering drawing principle that is important in the application to interpreting radiographs is that in an isometric projection, the shortest distance between a point and a plane will be equidistant in all planes that contain that line and are perpendicular to the first plane. This principle is clearest when presented in an example. (NOTE: the abstract program does not allow uploading of images, which are an essential part of this submission.)

In this isometric projection of a house, the red line in the left view, called a front elevation view, will be the same length in the side elevation view on the right. It will also be the same length in any view in which the image of the house is rotated on the line (the plane of view will contain that line).

In radiology terms, a front view is a PA view, and the side view is a lateral view. Importantly, any view involving only pronation or supination (the oblique views) will show all distances which are purely proximal-distal as true-length lines. There is a restriction, which is normally easily met: the magnification of the radiology views must be the same.

Results and Conclusions: This method is best explained with an example.

In this complex wrist radiograph, the PA looks almost normal, but the lateral looks seriously abnormal. The presentation will demonstrate how engineering drawing principles can sort it out.

This view appears to clearly show the lunate:

But an engineering analysis shows that it is not, a different shadow on the lateral is the lunate: Identify the lunate on the PA, and extend horizontal lines to the lateral. The margins of the lunate must lie on these lines. The lines identify a different shadow on the lateral as the lunate.

So what is the apparent “lunate”?
It is a proximal scaphoid, which is fractured.

An engineering drawing analysis can help to identify fragments and bone in the PA, any oblique, or lateral view, as long that the images are taken with rotation about a longitudinal line, which is the same as any degree of pronation and supination. This can be helpful in analyzing complex fractures or dislocations.

The Opioid Epidemic in the US: A Method for Changing the Opioid Prescribing Habits of Surgeons

List of authors:
David Nelson*  
1 David L. Nelson, MD (GREENBRAE)

Objectives / Interrogation: The United States represents 5% of the world's population yet accounts for 99% of the global hydrocodone (Vicodin, Norco) production. Clearly, US physicians are overprescribing opioids. Orthopedic surgeons are the highest prescribing group of US physicians, and their habits need to be changed.

Objectives  (1) To determine what is the average, range, and nature of the opioid and other medication routinely prescribed by a US surgeon for a volar plating of a standardized surgical procedure (distal radius fracture, as determined in a prior study), and (2) To determine if feedback of this data to the surgeon result in a change of prescribing habits

Methods: The method was to interview surgeons by email who perform ORIF of distal radius fractures using a volar plate as to their normal perioperative pain management protocol, with specific reference to the choice of opioid and how many were prescribed. Opioid prescriptions were translated into Morphine Equivalents (MEs), for comparison. Feedback was given to the surgeon how they compared to the study average in terms of MEs, choice of opioid, supplementary medication, as well as the characteristics of the highest 5 prescribers and the lowest 5 prescribers in the study. A second interview was conducted to determine if this feedback prompted the surgeon modify their pain management protocol.

Results and Conclusions: 78 surgeons completed the first interview with enough data to allow completion of the analysis. The number of opioids ranged from 5 morphine equivalents (MEs) to 160 MEs, with a mean of 46.0 and a mode of 30. The lowest 5 respondents prescribed an average of 13 MEs, usually hydrocodone, reported that their patients' pain was well-controlled, and refill requests were rare. The highest 5 respondents prescribed an average of 115 MEs and used more Dilaudid and Percocet than the group as a whole. Fear of weekend requests for opioid refills was cited as a main reason for prescribing large amounts of opioids. Upon re-interview after feedback of the results, 95% had already begun, or planned to, decrease their opioid prescription number, change to less-addictive opioids, and to increase multimodal approaches.

Using ORIF of a distal radius fracture as an index procedure, it was found that merely giving feedback to surgeons regarding how they compare to their peers is useful in prompting evaluation of their perioperative pain program and in decreasing the quantity of opioids prescribed.

CASE REPORT PYOGENIC GRANULOMA INTRAVASCULAR

List of authors:
MERIDA VICTORIA CHOQUIN SALES¹, RAMON DE BEDOUT², CONSTANZA LUCIA MORENO SERRANO², JULIO BERMUDEZ², EDGAR PINILLA²
¹ Boulevard Minerva 8-80 condominio valle nuevo casa 250 (Mixco)
² FUNDACION SANTA FE DE BOGOTA (BOGOTA)

Objectives / Interrogation: OVERVIEW
Intravascular masses in the hand are uncommon and rarely reported on. Intravascular pyogenic granulomas were initially described 37 years ago by Cooper and others. In 2008 four cases were described in the hand and two fingers. Its incidence is related to the use of oral contraceptives or during pregnancy and, so far, its pathogenesis is unclear. It presents clinically as a small, soft, volar nodule. Definitive diagnosis is only made by histological analysis. Treatment is necessary since it may cause alterations in grip strength and range of motion of the fingers. These nodules can also contain elements of Masson tumor, so complete surgical resection is indicated. This paper presents the case of a 65 year old patient with a mass resulting in an intravascular pyogenic granuloma and a review of the medical literature pertaining to the subject.

Methods: CASE REPORT
The patient is a 65 year old male with no relevant medical history, who sustained a penetrating wound eight months before consulting. A splinter entered the thenar region of his left hand as he supported his weight on a staircase railing. The patient removed it completely, but soon noticed that a mass with progressive growth that developed at the puncture site (Figure No. 1). The patient consulted for pain when grasping, which limited hand function. Upon clinical evaluation a slightly mobile, non-painful, well defined mass, approximately 2x3 cm in size, and negative to trans-illumination was found in the palmar aspect of his hand. Finger range of motion was normal. Hand x-ray was unremarkable and an ultrasound reported a well-defined, hyper-ecogenic lesion in the thenar area. The mass was completely resected through a volar approach at the base of the thumb. A firm, well-defined, irregular mass of approximately 2 x 0.5 cm was obtained (Figure 2). Histological examination revealed a vascular tumor composed of wide spaces divided by thick walls with endovascular proliferation and endothelial hyperplasia and some hemosiderophages. (Figure 3) These findings are considered to be characteristic of a benign vascular tumor compatible with an intravascular pyogenic granuloma.

Results and Conclusions: Although the pathogenesis of pyogenic granulomas is unknown it should be suspected in patients who are pregnant or undergoing hormone replacement therapy. The intravascular variant is rare and clinically presents as a single, small, soft, slightly mobile, subcutaneous nodule, which should be completely removed because it has been related to Masson tumors.

Effectiveness of ultrasonography and nerve conduction studies in the diagnosing of carpal tunnel syndrome: clinical trial on accuracy

List of authors:
Benedito Felipe Rabay Pimentel¹, Flavio Faloppa², Marcel Tamaoki², João Carlos Belloti²
¹ Taubaté University Hospital, University of Taubaté, Federal University of São Paulo (Taubaté, São Paulo)
² Federal University of São Paulo (São Paulo, São Paulo)

Objectives / Interrogation: Objectives: The aim of this study was to evaluate the effectiveness of two diagnostic tests routinely used for diagnosing carpal tunnel syndrome, ultrasonography and nerve conduction studies by comparing their accuracy based on surgical results, with the remission of paresthesia as the reference standard.

Methods: Methods: We enrolled 115 patients, all of the female gender with a high probability of a clinical diagnosis of carpal tunnel syndrome. All patients underwent ultrasonography and nerve conduction studies for a diagnosis and subsequent surgical treatment. As a primary outcome, the accuracy of the ultrasonography and nerve conduction studies diagnoses was measured by comparing their diagnoses compared with those determined by the surgical outcomes. Their accuracy was secondarily evaluated based on before and after scores of the Boston Carpal Tunnel Questionnaire.

Results and Conclusions: Results: Overall, 104 patients (90.4%) were diagnosed with carpal tunnel syndrome by the surgical reference standard, 97 (84.3%) by nerve conduction studies, and 90 (78.3%) by ultrasonography. The concordance of nerve conduction studies and surgical treatment (p <0.001; kappa = 0.648) was superior to that of ultrasonography and surgical treatment (p <0.001; kappa = 0.423). The sensitivity and specificity of ultrasonography and nerve conduction studies were similar (p = 1.000 and p = 0.152, respectively: McNemar's test). The Boston Carpal tunnel Questionnaire scores were lower after surgery in patients diagnosed by both ultrasonography and nerve conduction studies (p <0.001 and p <0.001, respectively: analysis of variance).

Conclusions: Ultrasonography and nerve conduction studies effectively diagnosed CTS with good sensitivity but were not effective enough to rule out a suspicion of CTS.

Complications in severe upper limb open injury treated by a Katsaros flap

List of authors:
Luciano Torres*, Rames Mattar Jr, Guilherme Amariz, Guilherme Barreiro, Danielle Simao, Julio Cordoba, Sergio Okane
1 INSTITUTO DE ORTOPEDIA E TRAUMATOLOGIA DO HC FMUSP, residencial address (São Paulo)
2 INSTITUTO DE ORTOPEDIA E TRAUMATOLOGIA DO HC FMUSP (São Paulo)
3 UNICAMP (Campinas)

Objectives / Interrogation: Flap described by KATSAROS (1983) combines latissimus dorsi musculocutaneous flap merged with groin flap as a long thoracoabdominus skin island. It allows extensive coverage of upper limb including arm, elbow, forearm, wrist and even hand. There is primary donor site closure; proximal transferred portion is acutely inserted on arm. Distal flap portion works as "jumping flap" and needs revascularization before cutaneous pedicle division.

Flap never reach popularity between reconstructive surgeons. We aim to demonstrate a single case report with post-operative complications in its application, some of them related to flap.

Methods: The subject was a 40 years old male that has sustained an accident with hot plastic industry machine device. Upper limb was tractioned and trapped into 3 cilinders in very high temperature. The mechanics of trauma included crush and burn. On emergency patient developed compartment syndrome and 3rd and 4th (injury deeper than skin) degrees burn. On emergency surgery fasciotomy and desbridement. On second look: distal thumb amputation and desbridement. Transferred to our hospital there was bone and joint exposure at left elbow and left thumb. We made a Katsaros flap and associated an external fixator at iliac crest and forearm as made in some of isolated groin flaps.

Katsaros flap
At 2nd postoperative we noticed a Schantz pin loosed and compressed distal pedicle of flap. It caused vascular suffering on limitrophe area of flap intersection. At infirmary, after nine days of surgery, brachial artery sustained suddenly rupture. Patient was emergently taken to the theatre and stumps were ligated keep hand perfused (hemoglobin reached 4). Post operative was uneventfull, part of groin flap was reconnected to thumb and hand dorsum. Sucessive partial skin graft in staged surgeries until discharge.

**Results and Conclusions:** Despite vascular ligation, patient keep a functional upper limb. Our sugestion is avoid external fixation in Katsaros flap. Always be carefull with burns on antecubital fossa and late brachial artery injury. The authors believe it is an underrated big flap for upper limb.

upper limb, flaps, burns
Arthroplasty of the First Carpo-metacarpal Joint: a randomized, double blinded clinical trail

List of authors:
Mathias Glehr*, Andrea Fink¹, Gerald Gruber², Florian Amerstorfer³, Sebastian Klim³, Andreas Leithner¹, Gerwin Bernhardt³
¹ Medizinische Universität Graz, Universitätsklinik für Orthopädie und, Orthopädische Chirurgie (Graz)
² Medizinische Universität Graz, Universitätsklinik für Orthopädie (Graz)
³ Medizinische Universität Graz, Abteilung für Allgemeinchirurgie (Graz)

Objectives / Interrogation: Thumb pain secondary to arthritis at the basal joint of the thumb is a common condition, especially in women, and can be quite disabling. The present study was the first to use and evaluate early outcomes of Moovis prosthesis for arthroplasty of the first CMC in patients with Eaton-Littler stage III osteoarthritis.

Methods: In total, 50 patients were randomised to either Moovis prosthesis (n=23) or Epping-plastic procedure (n=27) and examined between 2014 and 2017. Beside patient characteristics, clinical outcomes concerning functional abilities and pinch strength were obtained preoperatively and at 6 weeks, 3, 6 and 12 months Follow-Up. In addition DASH-Score, Visual analog scale and SF-36 were assessed at the same time points. The mean and standard deviation were analyzed and t-tests and Mann-Whitney U-Tests were conducted to determine significant differences.

Results and Conclusions: Clinical outcomes showed statistical significant differences with higher scores in radial abduction (62.2° vs. 53.3°; p=0.008) 6 weeks postoperatively and in retropulsion of kapandji (2.8 vs. 2.3; p=0.007) 12 months postoperatively among patients with prosthesis compared to those with epping-plastic procedure. Mean DASH-score (p=0.001; p=0.023) and pain (p=0.013; p=0.029) was lower in the prosthesis group 6 weeks and 3 months postoperatively. Regarding quality of life, significant differences were found at 6 weeks, 3 and 6 months postoperatively but diminish after 12 months of operation.

The new carpometacarpal prosthesis Moovis have reliable Outcomes and a low complication rate also compared to the standard procedure.

Developing a Core Outcome Set for the Research and Treatment of Thumb Carpometacarpal Osteoarthritis: A Delphi Study

**List of authors:**
Amy Ladd⁴, Joseph Crisco², Deborah Kenney¹, Miriam Marks³, Douglas Moore², Arnold Peter C Weiss², Jennifer Wolf⁴, Amy Milena Hoang-Kim⁵

¹ Stanford University, Department of Orthopedic Surgery (Stanford)
² Brown University, Warren Alpert Medical School (Richmond)
³ Schulthess Clinic (Zurich)
⁴ University of Chicago Hospitals (Chicago)
⁵ University of Toronto (Toronto)

**Objectives / Interrogation:** We aim to establish a multidisciplinary consensus in developing a minimum core set of outcomes (COS) with research and clinical relevance for thumb carpometacarpal (CMC) osteoarthritis (OA). Comparative studies of treatment and clinical tools are lacking, since uniform outcome measures specific to CMC OA do not exist. Meaningful outcome measurements will minimize bias in both study design and interpretation of results. Agreed-upon outcomes similarly impact the robust design of clinical trials.

**Methods:** 32 experts in CMC OA treatment & research participated in the 2nd round of the CMC OA COS Delphi survey. Participants included hand surgeons, therapists, and scientists. The areas were: clinical record keeping (N=17); observational studies (N=29); clinical trials investigating symptom modification (N= 23); and clinical trials investigating structure modification (N=20). Outcomes were derived from the first Delphi round and a thorough review of the CMC OA literature. All outcomes were listed and categorized according to the OMERACT framework. The survey contained a list of 59 individual outcome measures, and an open text field to add missing outcomes perceived by participants. Using an anonymous online survey, participants scored each outcome on a 7-point Likert scale. A score of 1-3 represented an outcome of limited importance; 4-6, an important but not critical outcome, and a score of 7-9, a critically important outcome. Consensus was reached if at least 70% of total respondents rated the outcome critical (7-9) and less than 15% of respondent rated the outcome not-important.

**Results and Conclusions:** 32 of 46 stakeholders responded to this online survey. After the 2nd round consensus was reached for 5 outcomes in Clinical Record Keeping, 8 outcomes for Observational Studies, 6 outcomes for Clinical Trials - Symptom Modification, and 9 outcomes for Clinical Trials - Structure Modification. No consensus was reached for the 16 outcomes representing the economic impact of health condition for the individual, society, in the presence of a health impairment, and the resource use incurred by treatment of this condition.

In this second round of the CMC OA COS Delphi, participants reached consensus for outcomes in each of the clinical/study domains. Patient derived surveys are in process, and we will incorporate these findings in the final round of consensus of primary stakeholders. We will report on the final round, being held in November 2018 (Palo Alto, CA).

Evidence of microcirculatory effects of postoperative exercise therapy after partial fasciectomy in patients with Dupuytren’s Disease using Hyperspectral Imaging

List of authors:
Inga Langner¹, Claudia Sicher², Sebastian von Podewils², Torsten Eydner², Simon Kim¹, Andreas Eisenschenk¹, Michael Juenger², Georg Daeschlein²

¹ Department of Hand- and functional Microsurgery, University Medicine Greifswald (Greifswald)
² Department of Dermatology, University Medicine Greifswald (Greifswald)

Objectives / Interrogation: Dupuytren's disease (MD) affects 4-6 % of the caucasian population common connective tissue disorder of the hand. Without surgical treatment MD can lead to relevant loss of function of hands. Due to high recurrence rates and risk of contractures caused by scar tissue, patients usually receive early exercises of the finger joints supported by occupational therapists. But stretching of skin and connective tissue might disturb local blood flow and therefore may increase the risk of postoperative complications.

Hyperspectral Imaging (HSI) allows the quantitative evaluation of tissue perfusion by planar measuring oxygen saturation and tissue water content.

The aim of the work is to quantify the microcirculatory effects of direct postoperative exercises therapy after partial fasciectomy in MD using HSI.

Methods: In five MD patients spatial distribution of oxygen saturation and tissue water content of the palm were measured pre-operatively and on the first 2 post-operative days before and 20 min after of exercise using HSI.

Results and Conclusions: After exercise therapy, all patients showed a relative increase of oxygen saturation compared to the preoperative measurement values of 1.4 % - 23 % and a reduction of tissue water of 2.3 % - 16.7 %.

Using HSI increased oxygen saturation together with reduction of tissue water in the operated area could be demonstrated after partial fasciectomy following exercise therapy. This suggests a potential beneficial role in the prevention of postoperative complications what has to be evaluated in further studies.

Feasibility of a new pulley repair for multiple pulley ruptures: a cadaver study

List of authors:
Volker Schöffl*, Julia Meisel2, Christoph Lutter3, Isabelle Schöffl4
1 Zentrum für interdisziplinäre Sportmedizin, Klinik für Orthopädie und Unfallchirurgie, Klinikum Bamberg (Bamberg)
2 Institute of Anatomy and Department of Trauma Surgery, University Erlangen-Nuremberg (Erlangen)
3 Klinik für Orthopädie und Unfallchirurgie, Klinikum Bamberg (Bamberg)
4 Department of Pediatric Cardiology, University Erlangen-Nuremberg (Erlangen)

Objectives / Interrogation: As a consequence of the growing number of climbers and the increase in difficulty in this sport, the number of pulley injuries, and complex pulley ruptures in particular, has grown significantly. In multiple pulley ruptures various repair techniques are described. Mostly used are encircling techniques around the phalanx using a free tendon graft. While these provide a strong repair a bone loss to the proximal phalanx was recently described. In this study, the feasibility of a new pulley reconstruction in which the tendon graft is pulled through a tunnel in the proximal phalanx was evaluated using a cadaver model, with particular attention paid to the weakening of the bone structure by the drill hole.

Methods: 9 fingers from 6 cadaver hands presenting intact pulley systems were compared to 9 fingers from 6 cadaver hands with missing A2 to A4 pulleys, but which featured a repair using the new surgical technique. Each finger was then fixed to an isokinetic loading device which loaded the finger until repair failure or a fracture (first event) occurred. The forces in the flexor tendons were recorded for each finger.

Results and Conclusions: Comparing the forces recorded at the moment of the first event, the forces in the control group were significantly higher (292.4 N) for FDP than in the group with the operated fingers (212.4 N). Although the forces recorded for FDS at the moment of failure were also higher in the control group, the difference did not reach significance (216.3 N vs. 158.2 N). The most common event in the operated fingers was a graft failure. A fracture of the bone due to the drill hole was never observed.

The new pulley reconstruction could represent an alternative to existing reconstructive techniques. The cause for the higher forces recorded in the control group could be attributed to sutures used in the operated fingers. The new pulley reconstruction method may enable reduced extensor tendon irritation as it avoids contact with the extensor hood, and will hopefully prohibit cortical bone loss, a serious side effect in the "one and one half loop" technique.

Keywords:
Ultrasound diagnostics of A3 pulley injuries in multiple pulley injuries to define indication for a surgical repair

List of authors:
Volker Schöffl*, Johannes Deeg, Christoph Lutter, Thomas Bayer, Isabelle Schöffl

Objectives / Interrogation: The pulley rupture is the most common injury in sport climbing. Ruptures of the A2 and A4 pulleys have been studied extensively, and ultrasound has proven to be a highly sensitive and specific tool for their diagnosis. The diagnostics of an adjunct A3 pulley injury is crucial in suspected multiple pulley injuries to define a indication for a surgical repair. As the correct diagnosis of A3 pulley rupture remains a challenge we investigated a novel approach to this pathology.

Methods: fingers from 6 cadaver hands presenting intact pulley systems were compared to 9 fingers from 6 cadaver hands with missing A2 to A4 pulleys, but which featured a repair using the new surgical technique. Each finger was then fixed to an isokinetic loading device which loaded the finger until repair failure or a fracture (first event) occurred. The forces in the flexor tendons were recorded for each finger.

Results and Conclusions: Comparing the forces recorded at the moment of the first event, the forces in the control group were significantly higher (292.4 N) for FDP than in the group with the operated fingers (212.4 N). Although the forces recorded for FDS at the moment of failure were also higher in the control group, the difference did not reach significance (216.3 N vs. 158.2 N). The most common event in the operated fingers was a graft failure. A fracture of the bone due to the drill hole was never observed.

6 Institute of Occupational and Social Medicine, RWTH Aachen University (Aachen)
7 OrthoPlus (Munich)

Objectives / Interrogation: In the past few years, competition climbing has grown in popularity and younger people are being drawn to the sport. While the radiographic changes in long-term climbers are known, there is little data available on young climbers. The question arises as to whether climbing at high levels at a young age leads to radiographic changes and possibly an early onset of osteoarthritis of the finger joints.

Methods: 19 members of the German Junior National Team (GJNT) and 18 recreational climbers (RC) were examined clinically and through radiographs 1999. In 2011 we re-examined the members of the long-term study for a follow up (mean follow up: 11.3 +/-1.2 years). Radiographs were evaluated using a standard protocol searching for physiological adaptation as cortical thickness of the middle phalanx and an increased Barnett Nordin Index as well as for early onset osteoarthritic changes of the hand.

Results and Conclusions: Overall 15 out of 19 (follow up 78.9%) climbers of the GJNT and 13 out of 18 climbers of the RC team (follow up 72.2%) with a mean age of 26.8 years could be examined for the 11 year follow up. In 80% of GJNT members and 46% of RC group members radiographic stress reactions of the hand could be found: Cortical hypertrophy (73% GJNT, 23% RC), subchondral sclerosis (80% GJNT, 31%RC), broadened joint base PIP (67% GJNT, 38% RC), and broadened joint base DIP (53% GJNT, 31% RC), respectively. Training intensity in 1999 (p<0.05) and body weight in 1999 were significant (p<0.05) for the development of radiographic stress reactions in 2011. Signs of an early stage of osteoarthritis were seen in 6 climbers, 4 climbers (27%) of the GJNT group and 2 climbers of the RC group (15%). Significant statistical influences for the development of early onset osteoarthritis could be found for the overall sum of training-years (p=0.024), use of campusboard training in 1999 (p=0.033) and the climbing level (p=0.030).

One quarter of climbers who performed at a high level in their youth showed a "mild" form of osteoarthritis (Kellgren II), being less than 30 years old. Following the training regimes of our climbers for more than 10 years we may conclude, that intensive finger training e.g. campus board training can lead to early onset osteoarthritis of the hand. We could also demonstrate, that a high UIAA climbing level correlates with the risk for early onset osteoarthritis of the hand and therefore must be seen as a risk factor for developing early onset osteoarthritis of the finger joints.

Management of Proximal Interphalangeal Joint Repetitive Stress Epiphyseal Fractures in Sport Climbers

List of authors:
Christoph Lutter*, Volker Schöffl, Isabelle Schöffl, Yasser El-Sheikh, Sascha Flohé

1 Klinik für Orthopädie und Unfallchirurgie, Klinikum Bamberg (Bamberg)
2 Zentrum für interdisziplinäre Sportmedizin, Klinik für Orthopädie und Unfallchirurgie, Klinikum Bamberg (Bamberg)
3 Department of Pediatric Cardiology, University Erlangen-Nuremberg (Erlangen)
4 Department of Surgery, Division of Plastic & Reconstructive Surgery, North York General Hospital (Toronto)
5 Department of Trauma, Orthopedics and Hand Surgery, Klinikum Solingen (Solingen)

Objectives / Interrogation: Repetitive stress fracture of the middle phalanx epiphysis is an injury specific to elite adolescent sport climbers. As sport climbing becomes increasingly popular in younger age groups, an increased number of these injuries have been reported in recent years. To date, treatment of these fractures has been nonsurgical, with strict rest and physiotherapy prescribed until fracture union. However, when these patients present in a delayed fashion with an established nonunion, nonsurgical treatment may fail, leading to disabling chronic pain and/or digital deformity in some cases.

Methods: Adolescent patients with typical complaints after climbing were investigated using a questionnaire to analyze circumstances leading to the injury. After initial ultrasound and radiography, MRI of all fingers with a proven or highly suspected growth plate fractures were performed. CAT scans were performed in prolonged cases with suspected sclerosis of the growth plate exclusively. All 24 patients (n=28 fingers) were then treated conservatively as previously published. In five of these 24 cases, this conservative approach did not cause sufficient healing; therefore a new percutaneous spot drilling epiphysiodesis technique was used to stimulate bony healing.

Results and Conclusions: Of the 28 injured fingers, 95% concerned the middle finger; in 64.3% the crimp grip led to the injury and was the preferred handhold (71.4%). While 75% of the injured adolescents were male, the average age was 14.1 years and all of the adolescent athletes were within the year of their peak velocity growth. Half of the injuries occurred during bouldering competitions. 81% of the injuries were Salter Harris grade 3, only two were grade 1 and 5 respectively. Conservative approach led to full finger function in 19 adolescents, while 5 athletes (n=5 fingers) underwent the surgical procedure. All athletes regained their pre-injury climbing level and had full finger function.

Adolescent climbers are at a high risk for epiphyseal fractures especially during their growth spurt. While most cases show sufficient healing under rest, a surgical procedure is needed in cases refractory to this conservative approach. Percutaneous spot drilling epiphysiodesis is a quick and minimally invasive promising technique that needs to be considered.

Can Patterned Osteophyte Growth about the First Carpometacarpal Joint Provide Any Insight into the Etiology of Thumb Osteoarthritis?

List of authors:
APC Weiss*1, Amy Ladd2, JJ Crisco1
1 Intercongress GmbH (Freiburg)
2 Stanford University, Department of Orthopedic Surgery (Stanford)

Objectives / Interrogation: Osteophyte formation is a critical part of the degeneration of a joint with osteoarthritis (OA). While often qualitatively described, few studies have succeeded in quantifying osteophyte growth over time. In a longitudinal, observational study of thumb carpometacarpal (CMC) OA, our aim was to quantify osteophyte growth volume and location over a three-year period in men and women.

Methods: Ninety patients with early thumb OA were recruited and assessed at baseline, 1.5 years and 3 years. CT volume images were collected and the osteophyte volume and location on the trapezium and metacarpals were determined using 46 healthy controls as a reference database. Changes in growth over time and between sexes were assessed with two-way repeated ANOVA.

Results and Conclusions: There was a significant increase in osteophyte volume in both women and men over the three-year follow-up. At year three, after accounting for the larger bones, men still had larger osteophyte growth than women. The location of osteophyte growth initiation was consistent and non-opposing on each bone. Osteophyte growth occurred on the radial and ulnar margins of the trapezial facet, while on the MC1, growth occurred principally on the volar and dorsal margins of the facet.

Osteophyte growth occurred in early thumb osteoarthritis over three years. Growth was localized in non-opposing regions on the trapezium and on the metacarpal, raising questions about the etiology underlying osteophyte initiation and growth in osteoarthritis. Men having greater osteophyte growth may cause motion constraint and thereby less pain when compared to women.
Osteophyte growth progressed on the first metacarpal and on the trapezium in non-opposing directions. Growth is described by the volume within 5° segments about each respective facet, scaled by the median bone volume, and plotted as a function...

- Denervation of the MCP and the PIP joint - An effective treatment of osteoarthritis in the hand
- Denervation of the thumb carpometacarpal joint in the case of osteoarthritis: results of a controversial treatment option
- Determinants of subjective and clinical outcomes one year after proximal interphalangeal joint surface replacement
- Developing a Core Outcome Set for the Research and Treatment of Thumb Carpometacarpal Osteoarthritis: A Delphi Study
- Distal interphalangeal joint arthrodesis using the ADS memory staple - The London Experience
- Distal interphalangeal joint osteoarthritis: Silicone arthroplasty versus screw arthrodesis
- DISTAL RADIOLUNAR JOINT REPLACEMENT WITH WRIST ARTHRODESIS A LONG TERM FOLLOW UP
- Does Ligament Reconstruction and Tendon Interposition (LRTI) destabilise the carpus?
- Does pre-operative depression and anxiety affect outcome after trapeziectomy?
- Earlier Intervention for Osteoarthritis of the Basal Joint Is Reflected to More Optimal Outcome
- Early result of Pyrodisc interposition arthroplasty for advanced thumb CMC joint osteoarthritis
- Early results of first patients with Motec wrist arthroplasty in Latin America
- Effective Period of Conservative Treatments in Patients with Acute Calcific Periarthritis of the Hand
- Effect of proximal interphalangeal (PIP) joint fusion on grip force and load distribution of the hand
- Expectations and illness perceptions influence the success of non-operative treatment of first carpometacarpal osteoarthritis (CMC-1 OA)
- Factors associated with surgical intervention in osteoarthritis of the thumb carpometacarpal joint
- Fat graft interposition arthroplasty as a source of stem cells in radiocarpal arthrofibrosis treatment. A Case report of a novel technique.
- Functional outcome of distal interphalangeal joint arthrodesis
- High reoperation rate in 13 total wrist arthroplasties after 4 years
- Ideal cup position in trapeziometacarpal joint arthroplasty: a biomechanical cadaver study
- Injection therapy for base of thumb osteoarthritis: a systematic review and meta-analysis
- In Vivo Changes of Subchondral Bone and Cartilage in First Carpometacarpal Joint Osteoarthritis Across Severity Stages
- Is hand dominance and a history of hand injury associated with a higher prevalence of hand pain and osteoarthritis in cricketers?
- JOINT SPACER - A NOVEL THERAPEUTIC OPTION FOR RHIZARTHRROSIS
- Ligament constraint of the first carpometacarpal joint
• Ligament Reconstruction and Tendon Interposition and Partial Trapezoidectomy for Pantrapezial Arthritis

IFSSH19-782

• Long-term Radiographic Adaptations to the Stress of High-Level and Recreational Rock Climbing in young Athletes

IFSSH19-2007

• Long-term results after total wrist fusion using the AO-plate

IFSSH19-980

• LONG-TERM RESULTS OF TREATMENT OF SCAPHO-TRAPEZIUM-TRAPEZOID (STT) ARTHRITIS BY USE OF PYROCARBON IMPLANT (STPI)

IFSSH19-1778

• May be the arthroplasty with spacer the best solution of CMC arthrosis in under seventy patients.

IFSSH19-1772

• Medium to long term outcomes of pyrocarbon total PIP joint arthroplasty

IFSSH19-692

• Midterm results of scaphoid excision and bicolumnar carpal fusion using retrograde headless screws

IFSSH19-1150

• Modified Eaton-Littler’s reconstruction for chronic instability of the carpometacarpal joint of the thumb: A report of 2 cases

IFSSH19-56

• Nitinoll Intramedullary Fixation for DIP Arthrodesis Restores Biomechanically Stable Pinch and Grasp

IFSSH19-866

• Our results with distal radioulnar joint hemiarthroplasty

IFSSH19-663

• Patient-reported outcomes and utility of trapeziectomy with ligament reconstruction and tendon interposition

IFSSH19-90

• PIP joint lateral stability in healthy joints compared to surface replacement and silicone arthroplasty

IFSSH19-537

• Prospective Cohort Study of the NuGrip CMC Implant for Carpometacarpal Osteoarthritis

IFSSH19-115

• Prospective study of Stage III Thumb Carpometacarpal Joint Osteoarthritis Treated with Arthroscopic Arthrodesis

IFSSH19-1208

• Prothetic Arthroplasty of the proximal interphalangeal joint using a modular surface gliding implant: A retrospective study

IFSSH19-271

• Proximal Interphalangeal Joint(PIPJ) Arthroplasty for Osteoarthritis(OA) of the Index Finger

IFSSH19-1563

• Psychological factors are more strongly related to pain in CMC-1 osteoarthritis patients than radiographic features

IFSSH19-847

• Pyrocarbon disc interposition for CMC thumb joint osteoarthritis; Difference in use of the FCR or APL tendon?

IFSSH19-1562

• Pyrocarbon Interposition Arthroplasty for The Thumb Carpo-Metacarpal Joint Osteoarthritis - mid to long term outcome analysis

IFSSH19-1293

• Pyrocarbon Interposition with PyroDisk Implant for Trapeziometacarpal Osteoarthritis: A Ten-Year Follow-Up study

IFSSH19-909

• RADIOCARPAL WRIST ARTHRODESIS WITH CANNULATED SCREWS, CASE REPORT

IFSSH19-778

• Restoring Functional Motion in the Arthritic Wrist through Circumduction

IFSSH19-864

• Revision of trapeziometacarpal prosthesis by replacement with another prosthesis: a report of 8 cases.

IFSSH19-464

• Risk factors and outcomes of revision trapeziometacarpal arthroplasty

IFSSH19-538
• Scaphoidectomy and double column arthrodesis for SLAC and SNAC wrist

• Shorter versus longer immobilization after surgery for thumb carpometacarpal osteoarthritis: a propensity score matched study

• Short to mid-term result of Pyrocarbon implant in the TMC 1 joint for osteoarthritis

• Stage III basal joint arthritis of the thumb: Clinical and radiological outcome after total trapeziectomy and ligament reconstruction and tendon interposition (LRTI) with partial Flexor carpi radialis (FCR) tendon

• Surgical technique of the trapeziometacarpal and scapho-trapezoid-trapezoidal pyrocarbon "burger arthroplasty"

• Surgical Treatment of DIP Ganglion by Excision and DIP Synovectomy without skin flap: 10 cases

• Survival of Apts Distal Radioulnar Joint (DRUJ) Implant Arthroplasty.

• Suture button suspensioplasty vs Sigfusson-Lundborg ligamentoplasty for basilar thumb arthritis treatment

• Ten-year outcomes of the Arpe prosthesis to treat osteoarthritis of the trapeziometacarpal joint

• The management of thumb base osteoarthritis - A multicentre service evaluation project

• Therapeutic interventions for osteoarthritis of the wrist: a systematic review

• The Results of Surgical Treatment for Osteoarthritis of the Thumb Trapeziometacarpal Joint: The Correlation With Tenosynovitis

• The Results of Surgical Treatment for Osteoarthritis of the Thumb Trapeziometacarpal Joint: The Correlation With Trapezial Space Height

• Thumb IP joint arthroplasty with a surface gliding implant: One-year follow-up

• TOTAL ARTHROPLASTY OF THE PROXIMAL INTERPHALANGEAL JOINT USING SEMI CONSTRAINED PROSTHESIS: CASE SERIES

• Total Thumb Trapeziometacarpal Joint Arthroplasty: A Retrospective Study of 12 Prostheses Implanted with WALANT Technique.

• Total Wrist replacement using the MOTEC® PEEK Cup

• Trapeziometacarpal and scapho-trapezoid-trapezoidal pyrocarbon "burger arthroplasty" for early peritrapezial osteoarthritis

• Trapeziometacarpal arthroplasty, Case report with Ball and socket type prostheses.

• Trapezium bone resection arthroplasty and suspension with suture-button for the treatment of trapezium-metacarpal osteoarthritis: long-term follow-up in a Colombian cohort

• Treatment of osteoarthritis of the carpometacarpal joint of the thumb with trapeziectomy and tendon allograft interposition.

• What is the role of psychological distress, pain catastrophizing and illness perceptions in pre-operative pain of CMC-1 patients?

• Wide-awake local anesthesia no tourniquet (WALANT) proximal row carpectomy

• Wrist replacement of keramik implantates
### Rheumatoid

- A new approach in treatment of rheumatoid arthritis in metacarpophalangeal and interphalangeal joints
- Boutonniere deformity of the rheumatoid thumb - Radiographic evaluation of Swanson hinge toe implant arthroplasty
- Combined Total Wrist Arthroplasty with Ulna Head Prosthesis in a Rheumatoid Patient with gross Distal Radio-Ulnar Joint instability using Interosseous Membrane Reconstruction with Brachioradialis tendon graft
- Computed tomography-based three-dimensional preoperative planning for total wrist arthroplasty
- Functional and radiographic assessment in rheumatoid patients submitted to total wrist arthroplasty - 4 years of follow up
- Interposition arthroplasty with the Amandys pyrocarbon implant in rheumatoid wrist
- Mid-term results of K now total elbow arthroplasty
- Mid-to-long term Outcomes of Convertible Total Elbow Arthroplasty for Patients with Rheumatoid Arthritis
- Multiple flexor tendon rupture in a 34-year old patient with rheumatoid arthritis.
- Reconstruction of Extensor Tendons in Multiple Subcutaneous Rupture of Rheumatoid Fingers
- Risk factors contributing to the early implant fracture of AVANTA silicone implant for the treatment of MP joint arthroplasty
- Soft tissue reconstruction for preserving metacarpophalangeal joints in the rheumatoid hand
- Study of independent extension of little finger after reconstruction of extensor tendon rupture of ring and little fingers in rheumatoid arthritis
- Ten-year follow-up results of rheumatoid wrist surgery without prosthesis.
- Total wrist arthroplasty in rheumatoid and post traumatic wrist: long term follow-up.
- **ULNAR HEAD PROSTHESIS IN RHEUMATOID ARTHRITIS**

### Scar and Aesthetics

- Aesthetic reconstruction of fingers with re-shaped 2nd toe in one-stage operation
- Bilhaut-Cloquet procedure: the type and aesthetic evaluation of nail deformity
- Endoscopic carpal tunnel release with or without a suture. Is there a difference?
- Functional and aesthetic reconstruction of the digital flexion contracture with full-thickness plantar skin grafting in children
- nail unit matrix transplantation- aesthetic surgery after traumatic amputation of the distal phalanx
- Precision in the design and division of the thenar flap:Achieving a good result without donor complications or PIPJ contracture
- The reconstruction of lateral nail fold in radial polydactyly with a common nail
- **USE OF BIOLOGICAL THERAPY IN POST-SURGICAL SCAR ADHERENCES IN PERFORMING MUSICIANS**
