Is it necessary to use the entire root as donor when doing contralateral C7 nerve transferring to median nerve?

List of authors:
Kaiming Gao\textsuperscript{*}, Jie Lao\textsuperscript{1}
\textsuperscript{1} Huashan Hospital (Shanghai)

Objectives / Interrogation: Previously articles reported that entire harvested cC7 nerve root transfer could obtain significantly better recovery than partial harvested cC7 nerve root transfer. We suppose that the harvesting of the entire cC7 nerve root might be the key factor for the good result of cC7 nerve transfer procedure. In order to confirm it, we conducted the current clinical and experimental study which aimed to determine whether it is necessary to use the entire root but not partial cC7 root to be the donor in the treating total BPAI.

Methods: In clinical study, a retrospective review of 73 patients with total BPAI was conducted. In group 1, the cC7 nerve was used to transfer to median nerve only. Three ways were used to harvest cC7 root which were the entire cC7, the posterior division + the lateral part of the anterior division the anterior or the posterior division alone. In group 2, the cC7 nerve was used to transfer to two nerves simultaneously. The entire cC7 transfer to median nerve and biceps branch in 12 and transfer to median nerve and triceps branch in 10 patients.

In experimental study, 54 SD rats were separated into 3 groups. In Group A: The entire root of cC7 was transected and transferred to median nerve; Group B: Only posterior division of cC7 root was transected and transferred to median nerve; Group C: The entire root of cC7 was transected while only the posterior division was transferred to median nerve. The regeneration of recipient nerve was evaluated post-operatively.

Results and Conclusions: The clinical study showed that entire harvested cC7 nerve root transfer could obtain significantly better recovery than partial harvested cC7 nerve root transfer when repairing median nerve. While if the entire cC7 nerve root was harvested for the transfer to median nerve together with biceps branch simultaneously, in which situation the donor for median nerve was just equal to partial cC7 root transfer, both of the two recipient nerves could achieve good recovery.

In experimental study, the evaluation of median nerve and FDS showed no statistical difference in the regeneration of median nerve between group A and C but significantly better group B.

We concluded that for the same recipient nerve, harvesting of the entire contralateral C7 root achieved significantly better recovery than partial harvesting, even if only part of the entire root was used for transfer. This result indicates that the entire root should be used as a donor when transferring contralateral C7 nerve.

Keywords: brachial plexus, avulsion injury, contralateral C7, nerve transfer
Neural Perforasomes of the Upper Extremity

List of authors:
Steven Koehler¹, David Ruch², Suhail Mithani³
¹ SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)
² Duke University Medical Center, Department of Orthopaedic Surgery (Durham)
³ Duke University Medical Center, Department of Plastic and Reconstructive Surgery (Durham)

Objectives / Interrogation: In the setting of the rapid advancement of integumentary vascular knowledge, we hypothesized that the extrinsic blood supply to the major peripheral nerves of the upper extremity could be categorized into discrete neural "perforasomes".

Methods: Total limb perfusion of the arterial system was performed with gelatin-red lead oxide in cadaveric upper limbs. The perforating vessels to the radial, median and ulnar nerves were identified, confirmed with fluoroscopy and dissected. Distances to major anatomic landmarks of the upper extremity were measured. Additional cadaveric limbs’ nerves were dissected and source arteries were selectively cannulated and injected to assess specific contribution to extrinsic nerve perfusion. The perfusion of each nerve was then calculated among all specimens.

Results and Conclusions: The radial, median and ulnar nerve perforators were mapped. The corresponding neural perforasomes were mapped (Figure 1).
The distal portions of the superficial radial nerve and the posterior interosseous nerve demonstrated a lack of staining. Similarly, at the carpal tunnel and at the proximal 25% of the median nerve (corresponding to the pronator teres), the nerve lacked vascular staining. At Guyon’s canal and the flexor carpi ulnaris (FCU) the ulnar nerve demonstrated a lack of vascular staining (Figure 2).

Map of the perforasomes of the median, ulnar and radial nerves. Yellow areas of the nerves had absent or limited staining. Well perfused areas are colored with their respective source vessel and amount of perfusion labeled.

Peripheral nerves can be divided into neural perforasomes with limited overlap. The extrinsic perfusion of peripheral nerves is highly segmental. Absent staining within the nerves correspond to common sites of compression. It is possible that these sites are watershed areas, between neural perforasomes, and are thus vulnerable to hypoperfusion and at risk for ischemia.

Upper Extremity Free Flap Transfers: An Analysis of the National Surgical Quality Improvement Program Database

List of authors:
Steven Koehler*, George Beyer¹, Jared Newman¹, Neil Shah¹, Suhail Mithani²
¹ SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)
² Duke University Medical Center, Department of Plastic and Reconstructive Surgery (Durham)

Objectives / Interrogation: The hypothesis of this study was that upper extremity free tissue transfers can be performed with a low complication rate.

Methods: This study used the National Surgical Quality Improvement Program (NSQIP) database to identify all patients who underwent upper extremity free flap transfer procedures performed between 2008 and 2016. A total of 111 patients with CPT codes corresponding to free flap transfers with concomitant procedures on the upper extremity were selected. The patients had a mean age of 37 years (range, 18 to 82 years), and were 76.6% men and 23.4% women, and 78.4% were white, 6.3% were black and 15.3% were others. The types of flaps included muscle or myocutaneous free flaps (45.9%), free fasciocutaneous flap (8.1%), fascial flap (2.7%), free vascularized bone graft with microanastomosis (1.8%), free metatarsal flap (10.8%), other free vascularized bone graft with microanastomosis (27.9%), and free osteocutaneous flap (2.7%). Complications, reoperations, and readmissions were queried from the database. Chi-square was used to evaluate differences in sex, race and insurance type. The frequency of complications was reported, and the total reoperation rate and procedures performed, along with readmissions for suspected flap failure and total readmission percentage and corresponding diagnoses were identified.

Results and Conclusions: The 30-day complications included superficial surgical site infection (2.7%), pneumonia (0.9%), deep venous thrombosis (0.9%), intraoperative transfusions (14.3%), and postoperative transfusions (0.9%). The re-operation rate was 4.5%, and most commonly occurred for incision and drainage (1.8%), secondary closure of surgical wound (0.9%), debridement (0.9%), or other procedure of the integumentary system (0.9%). The readmission rate was 3.6% and was for suspected flap failure (0.9%), pleural effusion (0.9%), fever (0.9%), and infected postoperative serosa (0.9%); of note, the mean time from discharge to readmission was 12.5 days. In conclusion, free flap transfers to the upper extremity can be performed with a low rate of complications. The 30-day re-operation rate was 4.5%, and most commonly for incision and drainage, and the readmission rate within 30-days was 3.6%.

Free Gracilis Muscle Transfers Compared with Non-Free Muscle Transfer for Elbow Flexion Reanimation: A Meta-Analysis

List of authors:
Steven Koehler*, Jared Newman1, Erika Kuehn1, Neil Shah1
1 SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)

Objectives / Interrogation: The hypothesis of the present study was that free gracilis muscle transfers will have similar results as compared to non-free muscle transfers (tendon transfers, nerve transfers, Steindler procedure, and pedicle muscle transfers) for elbow flexion reanimation.

Methods: A literature search was performed for randomized clinical trials and comparative studies that evaluated free gracilis muscle transfers versus non-free muscle transfers to the elbow published between the inception of the databases to January 2018. The outcomes included failure, which was defined as strength that was ≤ M3 (unable to raise arm against gravity) or acute loss of graft, range-of-motion (ROM), and Disabilities of the Arm, Shoulder and Hand (DASH) score. Studies were included if they had at least one of the outcomes of interest. To compare the two groups, the pooled odds ratios (OR) and 95% confidence intervals (95% CI) were used to calculate the failures, and the pooled mean differences (MD) and 95% CI were used to calculate differences in strength, ROM, and DASH scores.

Results and Conclusions: A total of 5 studies involving 294 patients were included for analysis. Compared to the non-free muscle transfer group, the gracilis free muscle transfer group had a lower failure rate (OR= 0.29; 95% CI, 0.13 to 0.61; p=0.001).

The gracilis free muscle transfer group had better strength compared to the non-free muscle transfer group, but this was not significant (MD= -0.12; 95% CI, -0.37 to 0.14; p=0.370). Also, when DASH scores were evaluated, there was a trend towards better scores in the gracilis free muscle transfer group, but this was not statistically significant (MD= -3.21; 95% CI, -14.01 to 7.59; p=0.560). In conclusion, both gracilis free muscle transfers and non-free muscle transfers to the elbow can have similar outcomes for reanimation of elbow flexion. The use of gracilis free muscle transfers had a significantly lower failure rate, but tended to have better strength and DASH scores compared to the non-free muscle transfer group, however, these were not statistically significant.

Keywords:
elbow, elbow flexion, reanimation, free gracilis, nerve transfer, tendon transfer, steindler
The 100 Most Impactful Papers in Hand and Upper Extremity Surgery over the Last 25 Years: A Bibliometric Analysis

List of authors:
Steven Koehler*, Neil Shah¹, Jared Newman¹, Bassel Diebo¹
¹ SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)

Objectives / Interrogation: Despite growth in hand/upper extremity investigation, truly impactful studies have not been thoroughly identified. While previous studies were limited to a subspecialty-specific scope, this study sought to identify (by citations) and characterize the most impactful papers in hand/upper extremity over the last 25 years.

Methods: The top 1,000 cited studies published between 1992 and 2018 related to the hand/upper extremity were identified with Thomson ISI Web of Science. Studies were organized in descending order by number of citations, and the title and abstract of each study was screened for relevance. Following exclusion of unrelated studies, the top 100 articles by number of citations were identified and reviewed to identify study type, institutional origin, level of evidence, and journal impact factor.

Results and Conclusions: Among the top 100 studies, all were cited ≥ 100 times, and the mean number of authors and citations were 4.51 and 169.4, respectively. The top five study types were case series (n=52), randomized controlled trial (n=17), prospective cohort (n=16), retrospective cohort (n=8), and basic science (n=4). The topics covered were mostly commonly related to shoulder (n=34), wrist/forearm (n=21), hand (n=17), and elbow (n=14). Among shoulder studies, rotator cuff injuries (n=18) were most common, while distal radius fractures (n=12) were most common among wrist/forearm studies and nerve/nerve repair (n=10) among hand studies. Most studies were published from institutions originating in the USA (n=63). The journal that published the most among the top 100 cited was the Journal of Hand Surgery-American Volume (JHS Am, n=33), with 5,092 citations three among the top 10. Mean journal impact factor was 3.29. The majority of studies were of level IV (n=51) and level II (n=16) evidence. However, the number of level I studies has increased since 1992 (3 in 1992-2006 vs. 5 in 2007-2011). The impact of more recent studies is greater, with mean citations per year in 2011 at 82.7/year, compared to 16.1/year in 1992 (R²=0.54). In conclusion, mean citations per year have progressively increased over the past quarter century. The majority of the top 100 articles were published in the JHS Am, were case series, and focused on the shoulder. The majority were level IV or II, retrospective, and non-randomized studies, emphasizing the call for higher-quality, prospective, randomized trials to bolster evidence-based practice.

Keywords: evidence-based medicine, impact, impactful papers, upper extremity, hand, bibliometrics,
Characterizing Hand Infections in an Underserved Population: The Role of Diabetic Status in Antibiotic Choice and Infection Location

List of authors:
Steven Koehler*, Andrew Hayden, Neil Shah, Gregory Penny, Sarah Stroud, Erika Kuehn, Bassel Diebo

1 SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)

Objectives / Interrogation: Diabetics (DM) in underserved communities are at greater risk for hand infections compared to the general population. Such infections in the setting of DM can yield devastating consequences without prompt and aggressive treatment. Moreover, vancomycin resistance constitutes a growing challenge for the treatment of infections in both diabetics and non-diabetics. We aimed to determine which features of were suggestive of infection severity by comparing hand infections by diabetic status, presenting to an urban hospital with respect to: (1) inflammatory markers, (2) infection site, (3) microbiology, and (4) antibiotic choice.

Methods: A prospectively collected, single-center database of 53 patients who presented from 2014-2016 with any hand infection was retrospectively reviewed; patients were stratified by presence (n=24) or absence (n=24) of DM and location of infection (Proximal [proximal to digit] vs. Distal [within the digit]). Univariate analyses compared laboratory/culture results. Analysis of variance compared antibiotic regimens within and between disease groups. Multivariate analyses were employed to identify significant predictors of labs or infection location.

Results and Conclusions: Mean ESR was significantly higher in DM (76.2 vs. 51.3 mm/hr); mean WBC, CRP were comparable. Regression analysis showed that diabetics had higher odds of having increased ESR than non-diabetics (OR=1.03) (all p<0.02). Proximal infections had higher mean CRP (136.9 vs. 50.5 mg/L, p=0.001) and WBC (5.2 vs. 3.9 103/µL, p=0.02). Regression analysis showed that proximal infections were associated with increased odds of resulting in higher CRP (OR 1.02, p=0.003). Rates of Staphylococcus aureus, MRSA, and gram-negative organisms were comparable between DM groups. Diabetics received vancomycin/piperacillin/tazobactam (VAN-PTZ) more often (52% vs. 8%). Providers treated DM with VAN-PTZ or any VAN-containing regimen more often than with any other regimen (all p<0.05). In conclusion, this study underlies the need for systematic criteria to aid in risk-stratifying patients for appropriate antibiotic use. The microbiology of hand infections in diabetics may not differ compared to non-diabetics as much as was previously thought. It may not be appropriate to treat both groups differently in urban populations similar to our own; antibiotic selection in this population may be overly-aggressive and contribute to drug-resistance.

Eliminating Opioid Use for Postoperative Pain Management following Soft Tissue Surgery Produces Acceptable Outcomes When Performed Using Wide Awake Local Anesthesia No Tourniquet (WALANT)

List of authors:
Steven Koehler*, David Choueka1, Neil Shah1, Jared Newman1
1 SUNY Downstate Medical Center, Department of Orthopaedic Surgery, Hand and Microsurgery (Brooklyn)

Objectives / Interrogation: In recent years, there has been an exponential increase in opioid prescriptions provided to patients, leading to the current “opioid epidemic.” We have instituted opioid-restricting, postoperative analgesic measures. We hypothesized that patients’ reported VAS pain scale would be lower postoperatively, obviating the need for postoperative opioid analgesics, and that patient-specific factors would not impact this hypothesis.

Methods: Consecutive patients from a single, fellowship-trained hand surgeon from July 2017 - January 2018 undergoing soft tissue hand/upper extremity procedures were selected. All patients under 18 years of age were excluded. All surgeries were performed using the Wide Awake Local Anesthesia No Tourniquet (WALANT) technique. Univariate analysis (paired two-tailed t-test) was employed to compare patients' preoperative VAS pain scores to postoperative scores at postoperative day (POD)1 and POD14. Scores were also compared between POD1 and POD14. All statistical testing was performed using IBM SPSS v.24.0. Furthermore, each patient's Charlson Comorbidity Index (CCI) was calculated and reported.

Results and Conclusions: A total of 36 patients underwent 40 soft tissue procedures. The mean age of patients was 49.3 years (range, 14 to 81 years), with a 2:1 female to male ratio and mean BMI of 31.8 kg/m2. A large proportion of patients were African American (n=31, 86.1%) and were insured by Medicaid (n=18, 50%); four patients (11.1%) were insured by Medicare. Mean CCI for these patients was 2.36. The most common procedure performed was trigger finger release (n=12), followed by carpal tunnel release (n=10, 25%). Compared to mean preoperative score (3.36), mean VAS pain scores at POD1 (1.53) and POD14 (0.22) significantly decreased (p<0.001). Furthermore, mean VAS pain score decreased significantly (p<0.001) at POD14 when compared to POD1. Of note, only one patient was prescribed opioid analgesia between discharge and POD14 (from the emergency department). In conclusion, patients' mean reported pain following soft tissue hand/upper extremity procedures with WALANT and opioid restriction declined from pre- to postoperative time-points, with a substantial decrease also found between POD1 and POD14 time-points. In the medically disadvantaged population we serve, this postoperative analgesic regimen had acceptable outcomes and could be employed safely as a possible treatment plan in a medically-underserved area and for patients with considerable morbidity and mortality risk.

Biomechanical testing of the transosseous fixation of the distal radioulnar ligament

List of authors:
Christian Spies¹, Johannes Oppermann², Anja Niehoff³, Lars P Müller², Martin Langer⁴, Peter Hahn¹, Frank Unglaub³
¹ Abteilung für Handchirurgie, Vulpius Klinik (Bad Rappenau)
² Klinik und Poliklinik für Orthopädie und Unfallchirurgie (Köln)
³ Institut für Biomechanik und Orthopädie (Köln)
⁴ Abteilung für Unfall-, Hand- und Wiederherstellungschirurgie (Münster)

Objectives / Interrogation: We hypothesized that the re-fixation of the deep and superficial fibres of the distal radioulnar ligaments provide improved stability compared to reconstruction of the deep fibres alone.

Methods: Fourteen fresh-frozen cadaver upper extremities were used for biomechanical testing. Transosseous refixation of the deep fibres of the distal radioulnar ligaments alone (single mattress suture group; n = 7) was compared to the transosseous reattachment of the deep and superficial fibres (double mattress suture group; n = 7). Cyclic load application provoked palmar translation of the radius with respect to the rigidly affixed ulna. Creep, stiffness, and hysteresis were obtained from the load-deformation curves, respectively. Testing was done in neutral forearm rotation, 60° pronation, and 60° supination.

Results and Conclusions: The refixation techniques did not differ significantly regarding the viscoelastic parameters creep, hysteresis, and stiffness. Several significant differences of one cycle to the consecutive one within each refixation group could be detected especially for creep and hysteresis. No significant differences between the different forearm positions could be detected for each viscoelastic parameter.

The refixation techniques did not differ significantly regarding creep, hysteresis, and stiffness. This means that the additional reattachment of the superficial fibres may not provide greater stability to the DRUJ. Bearing in mind that the study was a cadaver examination with a limited number of specimens we may suppose that the reattachment of the superficial fibres seem to be unnecessary. A gradual decline of creep and hysteresis from first to last loading-unloading cycle is to be expected and typical of ligaments which are viscoelastic.

Keywords:
biomechanics, DRUJ instability, radioulnar ligament refixation, transosseous refixation technique
Sonographical parameters of the finger pulley system in healthy adults

List of authors: Christian Spies*, Dominik Bassemir¹, Thomas Bruckner², Peter Hahn³, Lars P Müller³, Frank Unglaub¹
¹ Abteilung für Handchirurgie, Vulpius Klinik (Bad Rappenau)
² The Department of Medical Biometry and Informatics (Heidelberg)
³ Klinik und Poliklinik für Orthopädie und Unfallchirurgie (Köln)

Objectives / Interrogation: To establish normative values of tendon to bone distances (TBDs) to evaluate the A2 and A4 annular pulley integrity, we hypothesized that these values correlate with gender, athletic exercise, occupation, individual's age and body height.

Methods: Ultrasonography of 200 healthy individuals was performed prospectively. TBDs for the A2 and A4 pulley sections were measured for all fingers. Evaluation was performed in resting position and active forced flexion. Examination parameters included gender, age, body height, occupation, athletic exercise level, and hand dominance. Assessment of resting position and active forced flexion was done.

Results and Conclusions: No clinically relevant differences of TBDs with respect to the aforementioned parameters were observed. But TBDs were significantly greater in active forced flexion than in resting position for all measured pulley sections. Intraobserver reliability was very satisfactory. Establishing normative values will help to detect injured pulleys more precisely and examination should be performed both in resting position and active forced flexion.

Keywords: A2 annular pulley, A4 annular pulley, ultrasonography
Functional outcome after endoscopic assisted release of the ulnar nerve for cubital tunnel syndrome: mid-to-long term results

List of authors:
Christian Spies*, Melanie Schäfer¹, Martin Langer², Thomas Bruckner³, Lars P Müller⁴, Frank Unglaub¹
¹ Abteilung für Handchirurgie, Vulpius Klinik (Bad Rappenau)
² Abteilung für Unfall-, Hand- und Wiederherstellungschirurgie (Münster)
³ The Department of Medical Biometry and Informatics (Heidelberg)
⁴ Klinik und Poliklinik für Orthopädie und Unfallchirurgie (Köln)

Objectives / Interrogation: The aim of the study was to investigate functional and patient-rated outcome parameters after endoscopic assisted release of the ulnar nerve for cubital tunnel syndrome.

Methods: One hundred of 204 consecutive patients between 2006 and 2011 met the inclusion/exclusion criteria. Fifty-one of these patients were recruited and evaluated clinically and by questionnaire testing retrospectively after a mean follow-up of 82 months (range: 60-116).

Results and Conclusions: Neurological parameters (two-point-discrimination, application of Semmes-Weinstein monofilaments, Tinel's test), grip, and three-point pinch strength were not significantly different from the contralateral extremity at the time of examination, whereas key pinch strength was significantly weaker. Mean Disabilities of the Arm, Shoulder, and Hand score was 20.82. Patients' overall opinion was good/excellent for 78% of the study population.

The examined surgical procedure proved to be as efficacious as open in-situ decompression regarding functional outcome with fewer post-operative complications. Regarding the results it might be postulated that grip strength and three-point pinch strength determination is not necessarily relevant for ulnar nerve evaluation.

Endoscopic assisted release of the ulnar nerve is a reliable and safe treatment option for cubital tunnel syndrome with satisfactory mid-to-long term functional and patient-rated outcomes.

Keywords:
cubital tunnel syndrome, endoscopic assisted release, nerve entrapment, ulnar nerve
Functionality After Arthroscopic Debridement of Central Triangular Fibrocartilage Tears With Central Perforations

List of authors:
Christian Spies¹, Meike Möldner¹, Peter Hahn¹, Lars P Müller², Thomas Bruckner³, Frank Unglaub¹
¹ Abteilung für Handchirurgie, Vulpius Klinik (Bad Rappenau)
² Klinik und Poliklinik für Orthopädie und Unfallchirurgie (Köln)
³ The Department of Medical Biometry and Informatics (Heidelberg)

Objectives / Interrogation: To investigate functional and subjective outcome parameters after arthroscopic debridement of central articular disc lesions (Palmer type 2C) and to correlate these findings with ulna length.

Methods: Fifty patients (15 men; 35 women; mean age, 47 y) with Palmer type 2C lesions underwent arthroscopic debridement. Nine of these patients (3 men; 6 women; mean static ulnar variance, 2.4 mm; SD, 0.5 mm) later underwent ulnar shortening osteotomy because of persistent pain and had a mean follow-up of 36 months. Mean follow-up was 38 months for patients with debridement only (mean static ulnar variance, 0.5 mm; SD, 1.2 mm). Examination parameters included range of motion, grip and pinch strengths, pain (visual analog scale), and functional outcome scores (Modified Mayo Wrist score [MMWS] and Disabilities of the Arm, Shoulder, and Hand [DASH] questionnaire).

Results and Conclusions: Patients who had debridement only reached a DASH questionnaire score of 18 and an MMWS of 89 with significant pain reduction from 7.6 to 2.0 on the visual analog scale. Patients with additional ulnar shortening reached a DASH questionnaire score of 18 and an MMWS of 88, with significant pain reduction from 7.4 to 2.5. Neither surgical treatment compromised grip and pinch strength in comparison with the contralateral side. We identified 1.8 mm or more of positive ulnar variance as an indication for early ulnar shortening in the case of persistent ulnar-sided wrist pain after arthroscopic debridement. Arthroscopic debridement was a sufficient and reliable treatment option for the majority of patients with Palmer type 2C lesions. Because reliable predictors of the necessity for ulnar shortening are lacking, we recommend arthroscopic debridement as a first-line treatment for all triangular fibrocartilage 2C lesions, and, in the presence of persistent ulnar-sided wrist pain, ulnar shortening osteotomy after an interval of 6 months. Ulnar shortening proved to be sufficient and safe for these patients. Patients with persistent ulnar-sided wrist pain after debridement who had preoperative static positive ulnar variance of 1.8 mm or more may be treated by ulnar shortening earlier in order to spare them prolonged symptoms.

Keywords: degenerative triangular fibrocartilage lesion, ulna impaction syndrome, ulnar shortening osteotomy.
Intramedullary nail fixation for displaced and unstable distal radial fractures in patients fifty years of age and older

List of authors:
Takuma Wakasugi*1, Kenta Saito1, Hidetsugu Suzuki2
1 Department of Hand Surgery, Department of Orthopedic Surgery, Konan Hospital (Ibaraki)
2 Department of Orthopedic Surgery, Tsuchiura Kyodo Hospital (Ibaraki)

Objectives / Interrogation: Distal radius fractures are now commonly treated with a volar locking plate. However, flexor tendon problems such as tendon irritation and rupture caused by prominence of the implant have been reported. Intramedullary implants can stabilize distal radius fracture and minimally affect flexor tendons and muscles around the site, but the literatures about radiographic and functional results of placing such implants are limited.

Object of this study was to investigate the radiographic and functional results and complications of distal radius fracture treated with intramedullary implants in patients older than 50 years old.

Methods: From among the patients with extra-articular or simple intra-articular fractures with a sagittal fracture line who we treated, we retrospectively evaluated those over 50 years old treated by intramedullary implant (Micronail, Wright Medical Technology) who had at least 6 months follow up. We investigated fracture type using the AO classification, radiographic parameters, range of motion, grip strength, complications, and the Mayo modified wrist score.

Results and Conclusions: We evaluated 90 patients (11 men, 79 women; mean age 69.5 years, 50-88 years). According to the AO classification, there were 54 type A patients, 36 type C patients. Preoperative mean radial inclination was 18 degrees, volar tilt was -17.5 degrees, and ulnar variance was 2.0 mm. Immediate postoperative average radial inclination was 25.8 degrees, volar tilt 9.3 degrees, and ulnar variance -0.2 mm. At final follow up, all fractures had bony union, and the average radial inclination was 25.1 degrees, volar tilt 11.7 degrees, and ulnar variance 0.2 mm. Average range of motion was 70.6 degrees of dorsal wrist flexion, 61 degrees of palmar wrist flexion, 79.1 degrees of forearm pronation, and 89.6 degrees of forearm supination. Average percentile grip strength of the uninjured side was 95.8%. No patients had flexor tendon irritation or rupture. Two patient had neuritis of a superficial branch of the radial nerve, which resolved within 3 months. The average Mayo modified wrist score at final follow up was 93.4 points, with 56 patients graded as excellent, 29 good, 5 fair.

Conclusions
Intramedullary implants to treat dorsally displaced extra-articular or simple intra-articular distal radius fracture afforded good radiological and functional outcomes. This procedure was free from flexor tendon problems, and specific complications about radial nerve sensory branch were temporary.

Versatility of oblique Neurovascular flap for fingertip amputations with rapid healing and return to work

List of authors:
Chaitanya Dodakundi*, Khalid Alawadi1, Nebojsa Jovanovic1, Bassem Siraj1

1 Rashid hospital, Department of Trauma, Hand and Microsurgery Unit (Dubai)

Objectives / Interrogation: Fingertip amputations vary widely in mechanism, ranging from sharp lacerations to crush injuries that present with varying degrees of contamination and irregular skin loss. Injuries can be work or non-work related, and in either case rapid return to work without any dressing and rapid recovery of sensation in the fingertip is sought for by the injured. When bone is exposed with preservation of nail matrix a flap is required to restore the contact surface of the pulp. We report on the versatility of the neurovascular advancement flap (initially described by Venkatswami) especially in cases with irregular skin loss where conventional V-Y advancement flaps are tricky.

Methods: Prospective with retrospective study conducted in a large volume tertiary care center, where 22 fingers in 20 patients were studied. All patients had some part of nail bed preserved (Allen 3 and 4 types), but with varied obliquity and irregular skin loss. They underwent homodigital oblique neurovascular advancement flap described by Venkatswami with or without skin grafting for donor defects and no bone shortening of distal phalanx. Patients were assessed for time out of dressing, recovery in sensation and range of motion, patient satisfaction and return to work.

Results and Conclusions: Middle finger was most commonly affected with industrial accidents being the most common cause. All 22 flaps were viable and did not need any dressing by 21 days. Patients were followed up for a minimum of 6 months with the longest follow-up being for 14 months. One patient had stitch abscess which resolved with local measures and oral antibiotics. One patient who had associated uncontrolled diabetes ended with 20 degree flexion contracture at distal interphalangeal joint. One patient with Allen 4 type developed hooking of nail. All patients had preserved sensation, no cold intolerance, no scar tenderness and returned to their original occupation between 3 to 5 weeks. 18 patients were satisfied with the procedure in terms of appearance and function graded on a scale of 1 to 10.

Conclusion: In irregular Allen 3 or 4 fingertip amputations, this oblique homodigital neurovascular advancement flap provides adequate cover with fast recovery to pre-injury occupation and full preservation of sensations in the fingertip.

Keywords: fingertip amputation, neurovascular flap,
Wide-awake surgical operations performed over a 25-month period in Tianjin: Analysis of applications and technical extension

List of authors:
Jianhua Xu*, Ketong Gong¹, Haihua Zhan², Jianbing Zhang¹, Qiang Zhou¹, Li Han¹, Yijun Lu¹, Lu Yin¹, Zhonggang Yin¹, Bo Zhang¹
¹ Tianjin Hospital (Tianjin)
² Tianjin Hospital (Tianjin)

Objectives / Interrogation: WALANT hand surgery becomes increasingly popular. In this report we analyze our applications of wide-awake hand surgical procedures, especially the use of WALANT in emergency hand surgery procedures.

Methods: From February 2016 to March 2018, a total of 20 hand surgeons in our department performed WALANT procedures in 7673 patients. Among these patients, 5634 patients were operated in emergency settings because of open trauma, 2039 patients were operated as elective cases. In the emergency settings, we performed internal fixation for open digital and metacarpal fractures in 1380 patients. As elective cases, we operated on 340 closed fracture patients with open reduction and internal fixation of the phalangeal and metacarpal fractures. In addition, we performed 110 in situ cubital tunnel releases.

Results and Conclusions: WALANT surgery was predominantly in emergency surgeries in our department. 73% of the patients who we operated with WALANT were in emergency settings. All patients tolerated surgical procedures well in emergency settings. No epinephrine related tissue necrosis was found. We found that WALANT was feasible for internal fixation (including plating) in our 1380 patients treated in emergency settings. WALANT was very satisfactory for in situ cubital tunnel decompression in elective settings.

We conclude from our experience of WALANT surgeries in 7673 patients that this approach benefits our emergency patients greatly. We also conclude that WALANT can be used for internal fixation of phalangeal and metacarpal fractures including plating in needed patients and it provide very satisfactory approach for cubital tunnel release. Our large case series also indicates this approach is safe in both emergency and elective settings. The use of WALANT remarkably increased efficiency of emergency case of patients with hand trauma in our hospital.

Distribution and Surface Projections of Nerve Fascicles Innervating Lumbrical and interosseous Muscles

List of authors:
Yang Tong*1
1 Wuxi No.9 People’s Hospital Affiliated to Soochow University (Wuxi)

Objectives / Interrogation: Many surgeons lack clarity on the branches that innervate the lumbricals and interossei. Their surface anatomical knowledge is essential for designing surgical approach for nerve transfers and predicting lesions. We aimed to (1) determine the surface locations of the nerve fascicles (NFs) that innervate the lumbricals and interossei, (2) re-examine the branching pattern of the deep branch of the ulnar nerve (dUN), and (3) provide detailed information about their origin, entrance, and course.

Methods: Eleven fresh-frozen Chinese adult cadaver hands were investigated. We systematically recorded the origin, entrance, and course of every branch. NFs that innervate the lumbricals, interossei, and surface landmarks including the distal wrist crease and 2-5 proximal finger creases were marked by radio opaque fibers and subjected to X-ray. The images were uploaded and analyzed; we set a quadrant-linked hand surface. Subsequently, we measured the lengths of both axes and the coordinates of the locations of NFs in the quadrant.

Results and Conclusions: The branches that innervated the lumbricals and interossei were located from 29.81 ± 4.10% to 75.89 ± 3.33% and 19.39 ± 4.26% to 67.58 ± 4.13% of the X-axis and from 29.67 ± 2.81% to 60.58 ± 5.11% and 29.67 ± 2.81% to 44.41 ± 1.73% of the Y-axis, respectively. The branches of dUN exhibited a 4-group distribution pattern and two variants of innervation. In 4/11 hands, we found dual innervation of the third lumbrical (innervated by dUN and median nerve).

Novel methods for quantitatively locating the surface anatomy of the NFs that innervate the lumbricals and interossei; systematic description of the origin, entrance, and course of these branches; and the demonstration of a 4-group branching pattern of UN’s deep branch were established.

The Twist X-ray - A Novel Test for Dynamic Scapholunate Instability

List of authors:  
Sheena Sikora*, Eugene Ek, Andrew Rotstein, Harvey Jason, Tham Stephen  
1 Kelowna Plastic Surgery Group (Kelowna)  
2 Melbourne Orthopaedic Group, Dandenong Hospital, Monash University (Melbourne)  
3 Victoria House Medical Imaging (Melbourne)  
4 Orthosports Victoria (Melbourne)  
5 Victorian Hand Surgery Associates (Melbourne)

Objectives / Interrogation: Scapholunate instability (SLI) is the most common form of carpal instability. Early detection of SLI is imperative as early reconstructive procedures can potentially prevent the natural history of progressive degenerative arthritis. After wrist arthroscopy, MRI remains the next best non-invasive diagnostic option, however access still remains costly and often limited in many healthcare systems worldwide. In this paper, we describe a novel device that allows for dynamic x-rays to be taken, accentuating the SL widening.

Methods: Twist x-ray views are generated by the patient clenching a device which combines the standard clenched fist views with ulnar deviation and supination. The test is easy to perform and functions by combining a higher grip force with the ulnar deviation and pronation effects of the extensor carpi ulnaris tendon thus accentuating the scapholunate gap in dynamic instability.

We present a series of 4 patients with dynamic SLI and compare the findings of the Twist x-rays with conventional wrist x-rays series, including standard anteroposterior, lateral, radial and ulna deviation, clenched fist and pencil grip views.

Results and Conclusions: In all 4 patients there was substantial dynamic scapholunate widening. The SL interval increased from a mean of 1.8mm (range, 1.5-2.8) on PA x-rays to 6.3mm (range, 4.6-8.2) with the Twist views. Interestingly, on the pencil grip view, the mean widening was only 1.5mm (range, 1-2.8mm).

Here we describe a novel device that allows for improved detection of dynamic scapholunate ligament instability when performing stress x-ray views of the wrist.

Surgical strategy for angular deformity correction in thumb polydactyly reconstruction

List of authors:
Pobe Luangjarmekorn¹, Pravit Kitidumrongsook¹
¹ Department of Orthopaedics, King Chulalongkorn Memorial Hospital, Chulalongkorn University (Bangkok)

Objectives / Interrogation: Proposed surgical strategy and analyzed the result of soft tissue reconstruction with or without corrective osteotomy for correction angular deformity in thumb polydactyly surgery.

Methods: Surgical procedures for correction angular deformity of metacarpophalangeal (MCP) and interphalangeal (IP) joint in thumb polydactyly were retrospective reviewed. Classified by degrees of angulation into mild (< 30 degrees) and severe angulation (> 30 degrees), the operations and surgical outcomes were analyzed in terms of surgical procedures (soft tissue reconstructions with/without corrective osteotomy), post-operative complications and residual deformity.

Results and Conclusions: 42 thumb polydactyly were reviewed. Six were skin-tag type and treated by simple excision without complications and residual deformity. Other 36 patients were presented with angular deformity of MCP and/or IP joint.

For MCP joint deformity, there was 25 patients had mild MCP angulation (< 30 degrees). All 25 patients were treated by soft tissue reconstruction alone without osteotomy. The result in this group showed residual deformity only 8% (2/25 patients). In severe MCP angulation (> 30 degrees), there was 11 patients in this group. Only 6/11 patients (54.5%) achieved proper alignment from soft tissue procedure alone and other 5 patients (45.5%) need metacarpal osteotomy to correct MCP angulation. Prognosis of this group showed residual deformity up to 27.3% (3/11 patients).

For IP joint deformity, there was 27 patients had mild IP angulation (< 30 degrees). All 27 patients were treated by soft tissue reconstruction alone without requiring osteotomy. The result in this group showed no residual deformity. In severe IP angulation (> 30 degrees), there was 9 patients in this group. Only 3/9 patients (33.3%) achieved proper alignment from soft tissue procedure alone and other 6 patients (66.7%) need phalangeal osteotomy to correct IP angulation. Prognosis of this group showed residual deformity up to 77.8% (7/9 patients).

In conclusion, soft tissue reconstruction alone was the effective method for correction angular deformity in mild deformity (< 30 degrees) of MCP and IP joint with low residual deformity (8% for MCP and 0% for IP joint). However, severe angulation (> 30 degrees) of MCP and IP deformity need both soft tissue and corrective osteotomy to achieve proper deformity correction and less predictable results especially in IP joint deformity (long-term residual deformity 27.3% for MCP and up to 77.8% for severe IP joint deformity).

Extending application of wide-awake surgery: flap harvest and transfer in the hand in 39 patients

List of authors:
Shuguo Xing*, Tian Mao, Guheng Wang, Jinbo Tang
*Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: It is advised that wide-awake surgery under local anesthetic with epinephrine (WALANT) should not be used for flap surgery. We used WALANT in harvesting flaps in 39 patients. We report our experience of using WALANT in the flap harvest and transfer in the hand.

Methods: From April 2017 to May 2018, we used local anesthetic with epinephrine injection to the hands of 39 patients (18 to 67 years old, 23 man, 16 women) in performing 10 extended Segmüller flaps, 6 homodigital reverse digital artery flaps and 23 Atasoy flaps. The anesthetic with epinephrine was injected to proximal, middle and distal parts of the finger along volar midline before flap harvest. We evaluated intra-operative pain levels, easiness of flap harvest, and observed pulsation of the digital arteries during surgery. We also assessed postoperative flap survival and patient satisfaction.

Results and Conclusions: During the operation, no patients required the use of a temporary tourniquet, and our technique achieved adequate bleeding control. We observed normal pulsation of the digital arteries in all 16 digital artery pedicle flaps. No procedures required termination because of pain. All patients had successful transfer of the flaps with good blood perfusion to the flap 4-5 hours after surgery. All flaps survived completely, except that one extended Segmüller flap had a 3 mm wide strip of skin necrosis, likely caused by tight skin closure, which healed after simple debridement. The patients are satisfied with this approach and stated that they would choose this approach if they had the flap surgery in the hand again.

Our patient series showed that flap surgery in the hand can be performed under WALANT. The digital artery pulsates normally after epinephrine injection. We found digital artery pulsation is not affected by local epinephrine injection and injection of epinephrine does not cause flap failure. The one flap with narrow skin necrosis in one patient was due to tight skin suture, which appears unrelated to the epinephrine injection. WALANT is safe and provides excellent anesthetic in our cases in flap harvesting and transfer in the hand.

Comparison of radiological outcomes of closed reduction and percutaneous pinning through or not through the proximal first metacarpal in treatment of Bennett fractures

List of authors:
Shuguo Xing*, Tian Mao1, Guheng Wang1, Jinbo Tang1
1 Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Percutaneous pinning is used to maintain reduction of the Bennett fracture. However, it is unclear whether surgeons have to pass the K-wire through metacarpal bones. The purpose of this study is to compare the radiological outcomes of treating Bennett fractures with the K-wires passing or not passing the first metacarpals and the middle of the trapeziometacarpal joint.

Methods: From Jan 2014 to May 2017, a total of 28 patients with Bennett fractures were treated by percutaneous pinning with two K-wires. The fracture was reduced manually after traction and reduction under fluoroscopy. Thirteen patients were randomly chosen to have their first K-wires pass through the first metacarpal base to the trapezium and 15 patients were chosen to have their first K-wires passing lateral to the metacarpal base inserting only to the trapezium. After inserting the first K-wire in different ways, we inserted the second K-wires in the same fashion, from the first to the second metacarpal in all the patients. The K-wires were removed four or five weeks after surgery. We assessed the radiographic outcomes of two groups one year after surgery with plain radiographs (anteroposterior, oblique and lateral views).

Results and Conclusions: In both groups, there was no loss of reduction during the period of pinning fixation and no re-displacement of fracture after removal of the K-wires. Statistically, there is no difference in the timing of K-wire removal, the time required to completely heal the fracture and joint congruency (p > 0.05). Radiographically, we found all patients in two groups healed without any difference in reduction. Both methods maintained reduction well and did not show loss of reduction during the pinning periods.

We conclude that the surgeon does not need to pass the K-wire through the first metacarpal base to achieve reliable fracture reduction of Bennett fractures.

The effectiveness of engineered miRNAs targeting cyclooxygenases on reducing adhesions and improving strengths of healing flexor tendons

List of authors:
Youlang Zhou*, Qianqian Yang, Shuguo Xing, Luzhong Zhang, Jinbo Tang
1 Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: The objective is to deliver anti-inflammation gene to the healing digital flexor tendon to ensure high local gene concentration and to reduce the inflammatory responses of the injured tendon microenvironment to reduce adhesions and improve the healing strengths.

Methods: We designed a novel local sustained gene delivery system by using cyclooxygenases (COX-1 and COX-2) engineered miRNA plasmid/nanoparticles embedded in hyaluronic acid (HA) hydrogel. 64 completely transected digital flexor tendons of the long toes of both feet of 32 white Leghorn chickens were equally randomized into four groups: non-treated; hydrogel; hydrogel containing nanoparticle/negative plasmid complexes and hydrogel containing nanoparticle/COX-1 and COX-2 miRNA plasmid complexes group. At 6 weeks after surgery and gene therapy, severity of adhesions were scored. Gliding excursions, work of digital flexion and ultimate strengths of the healing tendons were tested in an Instron testing machine. We used two-way analysis of variance followed by post hoc Dunnett's t-test to analyze the differences in adhesion scores, gliding excursions, work of flexion and ultimate strengths.

Results and Conclusions: This local sustained gene delivery approach down-regulated COX-1 and COX-2 gene expression in tendons and surrounding subcutaneous tissues. At 6 weeks after treatment, adhesion scores in the COX-1 and COX-2 miRNA plasmid/nanoparticle group were significantly smaller than in the negative plasmid/nanoparticle group (p=0.028), unloaded hydrogel group (p=0.006) and non-treatment group (p=0.038). The gliding excursions were significantly increased in the COX-1 and COX-2 miRNA plasmid/nanoparticle group than in the negative plasmid/nanoparticle group (p=0.027), unloaded hydrogel group (p=0.028) and non-treatment group (p=0.009). However, there were no significant differences in the work of flexion among four groups. More importantly, the healing strengths in the COX-1 and COX-2 miRNA plasmid/nanoparticle group was significantly greater than that of negative miRNA plasmid/nanoparticle group (p=0.002), unloaded hydrogel (p=0.001) and non-treatment group (p=0.039).

Inhibition of the cyclooxygenases COX-1 and COX-2 was found to have remarkably increased the tendon healing strengths to 160% of the control and decreased adhesions in term of adhesion severity and gliding excursions. This approach may offer an effective therapeutic strategy to increase tendon healing strength and reduce adhesions.

Nanoparticles-coated sutures to provide sustained delivery of growth factors significantly increased tendon healing strengths at multiple time-points

List of authors:
Youlang Zhou*, Qianqian Yang†, Yingying Yian†, Luzhong Zhang†, Shuguo Xing†, Jinbo Tang†
† Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Rupture of the tendon is a common injury and often requires surgical treatment due to limited tendon healing capacity. The objective of this study is to test effectiveness of our designed nanoparticles-coated sutures carrying growth factors in accelerating tendon repair.

Methods: In this study, we developed a novel therapeutic approach to apply nanoparticles loaded with bFGF and VEGFA to sutures, and the effects of bFGF and VEGFA releasing sutures were tested in the chicken flexor tendon healing model. 72 toe flexor tendons were completely transected and repaired with bFGF and VEGFA-releasing sutures, bFGF-releasing sutures, VEGFA-releasing sutures and non-treatment control sutures. At 2, 4 and 6 weeks after surgery, ultimate strengths of healing tendons were evaluated in an Instron mechanical testing machine. Adhesions were scored and tendon gliding excursion and work of digital flexion were measured at week 6. We used two-way analysis of variance followed by post hoc Dunnett's t-test to analyze the differences in the ultimate strengths of repaired tendons, adhesion scores, gliding excursions and work of digital flexion.

Results and Conclusions: The ultimate strengths of repaired tendons treated with bFGF and VEGFA-releasing sutures (8.5±0.8N, 28.4±8.0N, 76.2±22.5N, at week 2, 4, 6, respectively) was significantly greater than the tendons repaired with non-treatment control sutures (5.7±1.5N, 13.7±6.8N, 48.6±9.2N, at week 2, 4, 6, respectively) at their corresponding time-points (p < 0.05 or p < 0.01). At 6 weeks, adhesion scores in the bFGF and VEGFA-releasing suture group (3.1±0.4) were significantly smaller than those of the non-treatment control suture group (3.9±0.4) (p=0.005). Tendon gliding excursions were significantly greater in the bFGF and VEGFA-releasing suture group (15±3mm) than in the unmodified control sutures (11±1mm) (p=0.006). Work of digital flexion was significantly decreased in the bFGF and VEGFA-releasing suture group (0.01±0.004J) than in the non-treatment control group (0.04±0.019J) (p=0.005).

We developed a novel platform for local and sustained delivery of growth factors based on the nanoparticles-coated sutures, which can effectively deliver growth factors to tissues and control the release of growth factors. Dual growth factors loaded nanoparticles-coated sutures can significantly promote tendon healing. This growth factors delivery system is an attractive therapeutic tool to repair injured tendons.

The WALANT approach to distal radius ORIF

List of authors:
Constantinos Kritiotis1, Zaf Naqui1, Lindsay Muir1, Adrian Pearce1
1 Manchester Hand Centre (Manchester)

Objectives / Interrogation: TO verify that open reduction and internal fixation of distal radius fractures is feasible, financially beneficial and safe for the patients

Methods: We present four cases that we performed using wide awake local anaesthesia no tourniquet in two countries (UK and Cyprus). We also present our injection technique

UK patients were operated as part of the NHS which offers universal free-for-all healthcare and patients in Cyprus were operated in a private healthcare setting with patients paying for their care from their budget.

In Cyprus, patients that receive their surgery wide awake, had the injection of the LA in the office, walked to theatre to receive their procedures and then were discharged immediately from theatre with no stay in a day case ward.

In the UK, patients received their LA injections in the ward, had their procedure in the clean air theatre and then discharged from the day case ward.

Results and Conclusions: Of the four patients the three had the procedure with no problem, tolerating it very well. Of the three, one of the patients had to have her distal radius osteotomised as three and a half weeks passed from the day of injury, tolerating it with no problems. For all patients, either the Medartis Aptus Adaptive or the Medartis FPL plate were used.

One of the patients expressed discomfort during surgery, but surgery was concluded without any further problems and without any sedation. No tourniquet was used.

All four patients went on to have their fractures healed and recovered a complete range of motion. No one developed any kind of infection or wound healing problems and returned to their pre-injury activities or occupations

Financial benefits for self-paying patients were in the range of 1000 euros, as this amount included the fees of the anaesthetist, the day case bed, the intraoperative medication as well as the increased stay in recovery.

In the NHS, the possibility to carry on with surgery without an anesthetist and the increased turn around time led to increased theatre utilization

Conclusion: The WALANT approach for the open reduction and internal fixation of distal radius fractures is a feasible and safe alternative to other methods of anaesthesia that can be utilised in developing countries with no universal healthcare as well as in overcrowded healthcare systems to maximise theatre and staff utilization.

**Suture Tape Stabilization of the Fifth Carpometacarpal Joint in an Elite Athlete**

**List of authors:**
Steven Shin\(^1\), Carola van Eck\(^2\), Dean Papaliodis\(^3\)
\(^1\) Kerlan-Jobe Orthopaedic Clinic, Cedars-Sinai Medical Center (Los Angeles)
\(^2\) University of Pittsburgh Medical Center (Pittsburgh)
\(^3\) Texas Health Physicians Group (Fort Worth)

**Objectives / Interrogation:** Treatment of CMC fracture-dislocations is usually surgical and includes open reduction and pinning. Post-operative immobilization is required for several weeks and may result in stiffness and muscular atrophy, which can be detrimental for athletes. This report is a description of a novel treatment (suture tape stabilization) used for a professional basketball player who sustained a fourth metacarpal fracture and concomitant fifth CMC joint dislocation of the dominant hand (Figure 1a & b).

Methods: After surgical exposure, the fourth metacarpal fracture was repaired with a plate and screw construct; however, rather than pinning the reduced fifth CMC joint, we proceeded with suture tape stabilization. The tape spanned the fifth CMC joint and was secured with two SwiveLock anchors (Figure 2a & b).

Drawing and Intraop Picture of Suture Tape Stabilization

Stable reduction of the fifth CMC joint was confirmed by fluoroscopy and direct observation.
At three days post-surgery, x-rays revealed a stable plate and screws on the fourth metacarpal and a congruent fifth CMC joint. Physical examination also revealed a stable fifth CMC joint. Hand therapy was initiated. By four weeks post-surgery, he achieved full, pain-free motion of his wrist and fingers. By five weeks post-surgery, grip strength was found to be 96% of the left, non-dominant hand. He was allowed to return to full basketball activities at this time, including dunking.

**Results and Conclusions:** Suture tape stabilization is a technique where joints are stabilized using synthetic materials. In this elite athlete, this technique allowed for shorter post-operative immobilization and earlier return to sport, without the disadvantages associated with Kirschner wire fixation and post-operative immobilization.

Modified Eaton-Littler's reconstruction for chronic instability of the carpometacarpal joint of the thumb: A report of 2 cases

List of authors:
Antonio García-Jiménez*, Lluís Pomerol, Javier Ochoa
1 SSIBE - Hospital de Palamós (Palamós)

Objectives / Interrogation: Chronic instability of the carpometacarpal (CMC) joint is an injury rarely reported in the literature. We present two patients with that lesion, very similar between them, treated with modified Eaton-Littler's ligament reconstruction.

Methods: Two patients, aged 46 and 49, presented to external consultation with pain on the base of the thumb and instability of CMC joint of their dominant hand. Both of them related their pain to their work. Clinical examination revealed in the two cases deformity of the CMC joint with a reduced and painful range of movement. Radiographs of the hand showed CMC subluxation of the thumb without associated fractures and with no signs of osteoarthritis. The study was completed with a CT scan in one case and with a MRI in the other case. Reconstruction was undertaken using a modified Eaton-Littler technique as described by Iyengar et al (J Hand Microsurg 2013): a FCR slip 2 to 2.5cm short of its insercion is directed in an oblique manner to reproduce the direction of the anterior oblique ligament and, by passing it through a bonny tunnel in the metacarpal base and under the APL, and suturing it back on to itself, it is ensured a reinforcement of the dorsoradial ligament.

Results and Conclusions: At 1 year follow-up evaluation, the patients were pain free with satisfactory thumb functions. They had no radiological evidences of instability or arthritic changes.

Posttraumatic boutonnière deformity of the thumb: A case report

List of authors:
Antonio García-Jiménez¹, Bernardo Uran¹, Javier Ochoa¹
¹ SSIBE - Hospital de Palamós (Palamós)

Objectives / Interrogation: Boutonnière deformity of the thumb is common in rheumatoid arthritis, but it is very rare when it is caused by a traumatism in a non-rheumatoid patient.
We present a case report of a patient who developed a boutonnière deformity of the thumb after a closed injury.

Methods: A 27-year-old women, massage therapist, hit her right hand (dominant extremity) with a box she was carrying. She presented 2 months after the injury, and complained of pain and deficit of extension of the metacarpophalangeal (MCP) joint. Radiographs of the thumb showed normality of the MCP joint. Magnetic resonance showed integrity of the extensor pollicis longus (EPL) tendon and disruption of the dorsal capsule.
Surgical findings included disruption of the dorsal capsule, partial detachment of the extensor pollicis brevis (EPB) tendon and ulnar luxation of the EPL tendon. The partial injury of the EPB tendon was sutured, as well as the dorsal capsule, with reduction of the EPL luxation. The MCP joint was immobilized with a cast for 4 weeks.

Results and Conclusions: After the immobilization, range of motion was started, but unfortunately only two weeks after she returned to the emergency room with boutonnière deformity of the operated thumb. She was reoperated, finding this time a new disruption of the dorsal capsule, an ulnar subluxation of the EPL tendon and integrity of the EPB tendon. We re-sutured the dorsal capsule, with reduction of the EPL tendon, and immobilized the MCP joint with a cast for 6 weeks. After that period of time, we started range of motion. At one year of follow-up, she complains of partial deficit of extention with normal flexion and reduced key pinch strength compared with contralateral hand.
Boutonnière deformity of the hand is an uncommon injury that should be recognized. There are few cases in literature, but we can observed that the results are worse when there is a long delay between the lesion and the surgery, and it is observed in the case report we present.

COMPLETE COMPLEX TYPE-4 SYNDACTYLY OF ALL DIGITS WITH ASD(L>R) : A Rare Case Report

List of authors:
Neeraj Godara*1
1 Ganga Hospital & Medical center (coimbatore)

Objectives / Interrogation: Syndactyly is defined as the failure of separation of the digits during early gestation. It is one of the most common congenital anomalies. The incidence of syndactyly is uncertain, but estimates range from 1 in 2,500 live births. During development, the fingers are webbed. This remains so, until apoptosis and skin recession allow for formation of the digital interspaces. Full inter-digital spaces are usually present by the end of the 6th week of gestation. Here we present a patient who presented to us with syndactyly of all fingers of both upper and lower extremities. The patient, who was a 3-year-old girl, had complete complex type-4 syndactyly of all fingers and toes of both upper limb and lower limb. She underwent complete body workup and it was found associated with Ostium Secundum type (L>R).

Methods: 3 year old Female child presented to our clinic with all five fingers fused together in both hands and all the toes in both feet were also fused together. (Fig. 1). She was first born child of normal parents born out of non-consanguineous marriage. The perinatal history and family history were not contributory. On examination there was complete complex Type-4 syndactyly of all fingers and toes with ASD(L>R) (Fig. 2). No active movements were present in all digits. Rest of the sensory system, motor system were normal. All other developmental milestones were normal. X-Ray findings revealed evidence of bony anomalies & fusion in the Fused digits.

Results and Conclusions: The case reported here is a live born baby with complete complex Type-4 syndactyly. On observation this case was found to have all digits fused of both hand and foot. On gross examination of the extremities, it was seen that (Fig. 1) all five fingers were fused together in both hands and all the toes in both feet were fused together(Fig.2). It was associated with ASD Ostium Secundum type (L>R) which was detected on 2-D Echo (Fig. 3) and no other associated anomalies were found in this case. X-ray of the hand and feet showed bony fusion (Fig. 4).

REDUCTION OF DELAYED PRESENTED MALUNITING FRACTURE BOTH BONES FOREARM IN A YOUNG CHILD USING JESS FIXATOR - AN INNOVATIVE TECHNIQUE

List of authors:
Neeraj Godara*
1 Ganga Hospital & Medical center (coimbatore)

Objectives / Interrogation: ABSTRACT
Fracture of both bones forearm is a very common injury presented to orthopaedic trauma OPD worldwide. These fractures usually managed conservatively using closed reduction techniques followed by cast application as mentioned in multiple paediatric orthopaedic books. Closed reduction is difficult in cases where there is a single bone fracture forearm with overriding and fracture both bones forearm with severe overriding/bayoneting. There is no established technique available in literature to reduce such fractures with ease. Hereby we are presenting our case series of such cases (delayed presenting maluniting fracture forearm bones) which we have reduced with our new innovative technique of using simple JESS fixator for reduction

Extensor tendon rupture in non-traumatic osteoarthritis of distal radioulnar joint - A rare case report

List of authors:
Neeraj Godara*1
1 Ganga Hospital & Medical center (coimbatore)

Objectives / Interrogation: Abstract:
Osteoarthritis of DRUJ with rupture of extensor tendon is a rare problem seen in elderly, though it is commonly found in patients with rheumatoid arthritis. A rupture of dorsal capsule of DRUJ causes a dorsal dislocation of ulnar head. Tendon transfer with excision of ulnar head is a viable option. One should look out for 'scallop sign' in order to do surgery before the rupture of extensor tendon is possible. We present a case of extensor tendon rupture of 4th and 5th fingers in a patient with non-traumatic osteoarthritis of distal radioulnar joint.

Methods: A 60 year old right hand dominant woman presented in our OPD with complaints of inability to extend her right little and ring finger for three months. Initially little finger was involved and a month later the ring finger also got involved. There was no history of any trauma or any associated pain prior to it. Patient worked in a button making factory for thirty years. Thorough examination revealed a swelling over the dorsal aspect of wrist on the ulnar side. Patient was unable to actively extend her right little and ring fingers at the metacarpophalangeal joint (Figure 1). DRUJ was found to be unstable as per load and shift test. Blood cell count, erythrocyte sedimentation rate, and C-reactive protein were within normal parameters. Rheumatoid factor as well as Anti-CCP were negative. A study of the plain radiographs revealed osteoarthritic changes at the DRUJ. Deepening and widening of the sigmoid notch and radial shift and dislocation of the ulnar head with positive ulnar variance was suspected.

Results and Conclusions: In our case, we observed a definite scallop sign, a radial shift of the ulnar head, and a roughened ulnar head and positive ulnar variance. Our operative findings showed that the cause of the dorsal capsular perforation and extensor tendon rupture was mechanical friction with the dislocated roughened ulnar head. As far as treatment is concerned end-to-end repair of tendon is not possible because of the frayed margin and the gap between the ends. Tendon graft is also not a viable option as the patients are mostly elderly. Tendon transfer is only available option in these cases with good results as reported elsewhere and in our case also. In addition the dislocated ulnar head also needs to be excised to prevent the recurrence of and further rupture.

Objectives / Interrogation: To analyze: 1) if there are significant changes in the alignment of the unstable scaphoid relative to the rest of the proximal carpal row alignment during forearm rotations and 2) if there is one forearm rotation that best reduces scapholunate misalignment.

Methods: The changes in the alignment of both, scaphoid and the tandem lunate-triquetrum, were assessed in 8 fresh cadaver wrists using an electromagnetic motion tracking device. The wrists were isometrically loaded in three forearm rotations: 45° supination, neutral and 45° pronation. The experiment was subsequently repeated after complete scapholunate ligament (SLL) sectioning. The results were assessed using ANOVA with repeated measures. Significance was set at $p<0.05$.

¹ In this presentation, only rotations in the transverse plane (degrees ± standard deviation). Positive values: supination; negative values: pronation. *$<0.05$, and **$<0.01$ relative to neutral forearm rotation.
Forearm pronation increases both the scaphoid and triquetrum supination, whereas forearm supination accentuates the scaphoid pronation and the lunate-triquetrum supination/extension tendency seen in wrists where SLL is torn.

Consequently, forearm pronation reduces scapholunate misalignment and protects any type of surgical SLL repair.

Origami Medial Femoral Condyle Flap for Finger Joint Reconstruction

**List of authors:**
Hiroki Hachisuka*, Norikazu Hamada¹, Shoji Shimose¹, Takahiko Hamasaki¹, Yasunori Izuta¹, Jun Fujimori¹, Ryo Mori¹, Shingo Okawa¹, Shigeki Ishibashi¹
¹Kure Medical Center, Chu-goku Cancer Center (Kure, Hiroshima)

**Objectives / Interrogation:** Finger joint reconstruction is challenging for hand surgeons, especially when accompanied by severe soft tissue damage. Accordingly, we adopted use of a vascularized medial femoral condyle (MFC) flap. In our procedure, a finger joint is fabricated with origami-like folding of vascularized periosteum. We report our experience with this origami MFC flap for finger joint reconstruction.

**Methods:** Four woman and two men underwent finger joint reconstruction with an origami MFC flap. The affected joints were as follows: two metacarpophalangeal (MCP), one thumb interphalangeal (IP), and three proximal interphalangeal (PIP) joints. The mean age of the patients was 52. Original diagnosis of the patients was benign bone tumor in distal phalanx of the right thumb, incomplete amputation of left ring finger, and septic arthritis in the left middle finger. The mean follow-up period was 40 months. Two cases lost hemi-articular surfaces in each joint, and another four cases lost a bilateral articular surface, complicated with loss of soft tissues; skin, subcutaneous tissue, such as ligament, volar plate, and tendon attachment. The mean follow-up period was one year (six months to five years).

The results of surgery were evaluated retrospectively based on clinical course, plain X-rays, range of motion (ROM), functional Disability of the Arm, Shoulder and Hand (DASH) score, pinching power, and complications at the donor site.

**Results and Conclusions:** Joint spaces and joint function were maintained in all cases. Average ROM was 49° (range four to 100). Pinching power was achieved in 100% of the non-affected side in all cases. The average DASH score was 5.8 (range 0 to 21), and all patients returned to their original work, including heavy manual labor. No cases had complications at the donor site.

An origami MFC flap can reconstruct a functional IP joint with motion and stability. Donor site complications are minimal in this procedure. This procedure can be a solution in finger joint reconstruction for adult patients.

External Validation of the 2nd Metacarpal Cortical Index As A Simple Screening Tool for Osteopenia

List of authors:
Bhavika Patel*, Adeel Aqil1, Russell Jeffers1, David Dickson1
1 Bradford Teaching Hospitals Foundation Trust (Bradford)

Objectives / Interrogation: Osteopenia, is a known risk factor for sustaining hand and wrist fractures. Secondary prevention of further fractures has obvious clinical and economic advantages; however screening all patients using a DEXA is unfeasible. We wished to externally assess the use of the 2nd metacarpal cortical index (2MCI), as a simple screening tool for identifying patients at high risk of having osteopenia, and requiring treatment.

Methods: We retrospectively collected radiographic data on 206 patients who had a simple radiograph of the hand and dual energy X-ray absorptiometry (DEXA) within one year of each other, and from our picture archiving and communication system (PACS) database. The 2MCI was calculated for all patients. As data was parametric, a Pearson's correlation was performed to assess for an association between T-scores and the 2MCI. Further analysis involved the construction of receiver operating characteristic curves (ROC) to identify a 2MCI index, which would give the most appropriate sensitivity and specificity for identifying the presence of osteopenia.

Results and Conclusions: There was a statistically significant and moderate correlation between DEXA T-scores and 2MCI values (r=0.54, n=206, p<0.001). Further ROC curve analysis of normal and osteopenic subjects identified that a 2MCI of 41.5 had a sensitivity of 100% and specificity of 53% for detecting osteopenia.

Conclusion: Our results support the use of the 2MCI as a simple screening tool for identifying patients at risk of osteopenia.

Corrective Osteotomies of Forearm Bones in Distal Radioulnar Joint Instability by Three-dimensional Analysis and Surgical Navigation

List of authors:
Simon Roner*¹, Fabio Carrillo¹, Philipp Fürnstahl¹, Ladislav Nagy¹, Andreas Schweizer¹
¹Balgrist University Hospital (Zurich)

Objectives / Interrogation: Malunions of forearm bones can result in reduced pronosupination and/or in instability of the distal radioulnar joint. Despite several studies investigating the outcome of soft tissue repairs, limited data exists for stability restoration by isolated corrective osteotomies. Although a precise preoperative plan is of paramount importance to restore forearm bone alignment in corrective osteotomies, conventional deformity analyses are imprecise; especially rotational deformities are poorly assessed compared to analysis in 3D bone models. So far, preoperative 3D analysis of the forearm bones deformities and distal radioulnar joint incongruence has not been evaluated in patients with joint instability. Consecutively, we hereby present the outcome of corrective osteotomies performed by 3D printed patient-specific instruments.

Methods: Ten patients (age: 17.2 - 43.1 years) were included, treated at our institution between 2013 and 2018, with corrective osteotomies of the forearm bones by patient-specific instruments. Simultaneous corrective osteotomy of ulna and radius was performed in 6 cases and in the remaining 4 cases a corrective osteotomy only of the radius. Bone deformity analysis was performed by superimposing the malunion to the contralateral healthy bone models with the realignment of distal radioulnar joint congruency. The preoperative plan was executed by 3D printed patient-specific cutting and reduction instruments. Intraoperative length adaption along the long bone axis was ensured by an adaptable reduction guide to intraoperatively adjust the distal radioulnar joint congruity during pronosupination of the forearm.

Results and Conclusions: A volar instability was addressed in 8 patients and a dorsal instability/radioulnar impaction in the remaining 2 patients. In total, 7 out of 10 patients were clinically stable following a corrective osteotomy of the forearm. The residual error between the 3D preoperative plan and the postoperative result was similar to previously published results of navigation by patient-specific instruments (translational error +/- 1 mm, rotational error +/- 5°).

In the majority of the cases (7 out of 10), isolated corrective osteotomies of the forearm bones fully addressed distal radioulnar joint instability. Accurate execution of the preoperative plan considering three-dimensional analyses of bone deformities and joint incongruences was facilitated by patient-specific instruments.

The Hypothenar Fat Pad Flap Surgery for End Stage Carpal Tunnel Syndrome

List of authors:
Tom Lattré¹, Simone Brammer², Steven Parmentier¹, Carlo Van Holder¹
¹ Ziekenhuis Waregem (Waregem)
² Independant (Waregem)

Objectives / Interrogation: "End Stage Carpal Tunnel Syndrome" (ECTS) is occasionally seen in an elderly population. In this condition, there is no neurophysiological continuity of the median nerve at wrist level and it is classified as the last grade in the electrophysiological scale of Bland.

Methods: A prospective study was made of 20 patients with ECTS who were treated with the "Hypothenar Fat Pad Flap" surgery. This surgery was initially described by Cramer for treating recurrent CTS. Our patients did not have a history of carpal tunnel release. Assessments of sensibility, strength, symptoms and functional status were made pre-operative and post-operative after 3, 6, 12 months. Strength tests were grip force (Jamar), key-, tripod- and tip pinch recording the maximum/average strength. The Semmes Weinstein Monofilament Test and the Shape Texture Identification were used for the sensibility assessments. The Boston Carpal Tunnel Questionnaire (BCTQ) evaluated the symptoms and functional status. A control EMG was suggested after 1 year. One sided paired statistical analyses were made with the t-test or Wilcoxon test according to their normal distribution and the results were significant if p < 0.05.

Results and Conclusions: Significant results were found for all sensibility tests on every post-operative test moment. Loss of protective touch was seen before surgery but improved after one year to a level between diminished protective touch and diminished light touch. The maximum and average key- and tripod pinch were significant better after one year. The results for maximum- and average tip pinch were already significant after 6 months. The Jamar did not reveal any significant results. On every post-operative test moment the BCTQ scores for symptoms and functional status were significantly better. After one year ending with a score close to one, which is the minimum score. A limited number of cases agreed to an EMG control at one year and improved electrophysiological values were demonstrated. The hypothenar fat pad flap provides a valid and safe solution in the treatment of patients with end stage carpal tunnel syndrome.

Our study showed that sensibility and strength of the hand were significant improved, moreover the hand function returned to a nearly normal level.

Keywords: carpal tunnel syndrome, hypothenar fat pad flap, strength, sensibility, symptoms, functional status, end stage CTS
Single cell analysis of the fibrotic landscape in Dupuytren's Disease

List of authors:
Thomas Layton*, Dominic Furniss¹, Jagdeep Nanchahal¹, Fiona McCann¹, Lynn Williams¹, Marisa Cabrita¹, Marc Feldmann¹
¹ NDORMS (Oxford)

Objectives / Interrogation: Fibrosis is a major cause of morbidity and mortality. However, despite intense research efforts little progress has been made in clinical treatment across several diseases. In all forms of fibrosis, myofibroblasts are the key effector cell and drive pathogenesis through the secretion and remodeling of excess matrix proteins. We study Dupuytren's disease, a common fibrotic condition of the hand, as it provides an excellent human model to investigate mechanism behind fibrotic disease. This condition provides an abundant supply of primary human fibrotic tissue at a relatively early stage and through two distinct structures allows us to map and compare the early myofibroblast rich and later matrix rich stages of fibrosis.

Methods: We have completed a large scale single cell RNA-seq of Dupuytren's disease and built a molecular census of the complex cellular ecosystem in fibrosis. In addition, we have validated our gene expression data at the protein level using immunohistochemistry and flow cytometry. Moreover, through a novel live cell imaging assay we have quantified the force profiles of distinct stromal cell subsets.

Results and Conclusions: We have uncovered the molecular signatures of fibroblasts and myofibroblast and report novel gene markers of distinct stromal cell populations. Moreover, by integrating bulk and single cell transcriptome profiling we elucidate how the fibrotic microenvironment may influence stromal cell phenotypes. Finally, novel stromal cell populations have been interrogated with traction force microscopy, a live cell imaging assay that enables the dissection of mechanical force at single cell resolution. This has provided a unique lens into the biophysical signature of novel stromal cells in fibrotic disease.

This study is the first ever single cell RNA-seq of a human fibrotic disorder and provides a new perspective on musculoskeletal disease.

Advanced Techniques in Percutaneous Needle Fasciotomy and Collagenase - Going Beyond the MP Joint

List of authors:
Gary Pess
1 CJHS (Wayside)

Objectives / Interrogation: 1) Learn to apply the advanced techniques discussed to perform PNF and Collagenase on patients with severe Dupuytren Contracture.
2) Analyze contractures to predict the location of cords.
3) Assess a hand and formulate a plan to release severe contractures
4) Diagnose hidden cords that need to be released to achieve correction of the contracture

Methods: Percutaneous needle fasciotomy (PNF / NA) and Collagenase are newer minimally invasive techniques used to treat Dupuytren Contracture. Most Hand Surgeons are confident in using one of the two procedures for mild MP joint contractures. However, many surgeons do not feel it is safe to utilize either treatment for PIP joint contractures or combined MP and PIP joint contractures. Patients with severe contractures are often only offered open fasciectomy for treatment.

This presentation will demonstrate specific techniques that can be applied to perform PNF and Collagenase on patients with severe Dupuytren contracture. Attendees will be able to assess a hand and formulate a plan to release the severe contractures.

The surface and deep anatomy of Dupuytren cords and the neurovascular bundles will be reviewed. Contractures will be analyzed so that the location of cords causing the contracture can be predicted and then treated. Advanced tips and pearls for PNF and Collagenase will be discussed, including the diagnosis of hidden cords that need to be released to achieve full correction of the contracture. Step by step instructions for correction of severe contractures will be illustrated through the presentation of the most difficult cases.

Results and Conclusions: Experience performing over 7,000 PNF and 1,000 Collagenase procedures has revealed that severe Dupuytren contracture can be released successfully using minimally invasive techniques. It is important for doctors to learn these advanced techniques so minimally invasive alternatives for the treatment of severe Dupuytren contracture can be offered.

This presentation can be modified to only discuss PNF / NA, instead of both PNF / NA and Collagenase. It can also be offered as an instructional course or symposium with multiple experts collaborating together for the presentation.

Efficacy analysis of the dorsal approach into the double miniature locking plate in a comminuted fracture unstable dorsally displaced distal radius fractures

List of authors:
Xiaolong Du*, Yafei Liu, Xuehai Ou, Tao Song
1 Xi'an honghui hospital (Xi'an)
2 Xi'an honghui hospital (Xi'an)

Objectives / Interrogation: To study the dorsal approach into the double miniature locking plate in a comminuted fracture unstable dorsally displaced distal radius fractures of the clinical curative effect.

Methods: 17 cases distal radial fractures, male in 7 cases, female 10 cases; Age 23 to 67 years, average 36.5 years; The left 6 cases, right 11 cases. According to the AO fracture classification: B2 type 8 cases, C1 type 4 cases, 5 cases of C2. All cases took dorsal approach, all use open reduction double L form tiny lock plate fixation treatment, patients were followed up the radius length, palm obliquity, feet Pianjiao and wrist activities.

Results and Conclusions: patients with 17 during 10 to 24 months, mean 16 months, all of the patients to anatomical reattachment, good fracture healing. According to Gartland-Werley curative effect evaluation standard, optimal 14 cases “good” in 3. All cases without inner fixed loose, fracture shift complication.

Conservative treatment for refracture of post-operative mallet fractures. 2 case reports.

List of authors:
Hirokazu Tochigi*1, Yusuke Kawano2
1 Saiseikai Yokohama-city Nanbu Hospital, Orthopaedic department (Yokohama-city Kanagawa Pref)
2 Shizuoka municipal Shimizu Hospital, Orthopaedic department (Shizuoka-city Shizuoka Pref)

Objectives / Interrogation: Mallet fractures are common injuries in the finger, but refracture of post-operative mallet fracture is rare. Traditionally, surgeons recommended surgery for injuries involving more than one-third of the DIP joint articular surface and those with subluxation or displacement. If the patients who have mallet fracture involving more than one-third of the DIP joint articular surface don't want to choose the operative treatment, only the conservative treatment should be chosen. We reported the conservative treatment for two rare cases of refracture of post-operative mallet fracture in childhood.

Methods: case1: 13 y/o female injured her left ring finger during balleyball. 4 days after injury, closed pinning (Ishiguro method) was performed. X-ray showed good bone healing after 5 weeks, k-wires were removed and she started finger exercise. 3 months after operation, she injured same finger during balleyball. This time she refused the operative treatment, conservative treatment was started.

case2: 13 y/o female injured her right index finger during basketball. 5 days after injury, closed pinning (Ishiguro method) was performed. X-ray showed good bone healing after 5 weeks, k-wires were removed and she started finger exercise. 4 months after operation, she injured same finger during basketball. As the mallet bone fragment was little bit small compared to case1, so conservative treatment was chosen.

X-ray and ROM of injured DIP joint assessment were done. Milford criteria was used for clinical assessment.

Results and Conclusions: X-ray showed bone union at 4 months period for two cases. Each case of the ROM of DIP joint was almost full. Clinical assessments by Milford criteria were excellent in case1, and good in case2. But case 1 showed swan-neck deformity slightly. Conservative treatment for mallet refracture took 4 months period for bone union and showed almost good clinical results, if the DIP joint subluxation was not exist.

Clinical efficacy of collagen wrap following neurorraphy

**List of authors:**
Randy Bindra*  
1 Griffith Univ School of Medicine, Gold Coast Univ Hospital (Southport)

**Objectives / Interrogation:**
Tension-free epineural repair is the accepted treatment of a peripheral nerve injury. Neuroma formation and scarring to surrounding structures can adversely affect outcome of repair. Collagen nerve wraps (NeuraWrap, Integra Life Sciences, Plainsboro, NJ) are available for clinical use to cover the site of repair and potentially minimise these complications. We report a retrospective clinical series of 2 groups of forearm nerve repair - direct neurorraphy with and without a collagen wrap. The objective is to detect any difference between the two groups in clinical outcome and ultrasound appearance of the repaired nerve.

**Methods:** A retrospective review of our institutional records revealed 45 patients who underwent primary end-end forearm nerve repair. 13 patients (16 nerves) returned for follow up evaluation. There were 10 primary repairs (3 Median, 3 Ulnar, 3 Superficial Radial Nerve and 1 posterior cutaneous nerve) and 6 repairs (4 Median, 1 Ulnar and 1 superficial radial nerve) augmented with wrap in the study. Clinical examination was done to determine sensory recovery and grip strength and patient reported outcome was measured using the DASH score. Circumference and cross-sectional area of the nerve at the repair site was measured using ultrasound performed by a radiologist who was blinded to the type of repair performed.

**Results and Conclusions:** 3 of the 10 patients who had nerve repair without wrap had ongoing analgesic requirements whilst none of the 6 patients who had a repair with collagen wrap needed analgesia. There was no clinically significant difference on clinical examination (Sensation testing - no wrap 2.20 vs wrap 2.67 and grip strength - no wrap 26.99 vs wrap 30.68) or DASH score (no wrap 24 vs wrap 24.6). Circumference and cross-sectional area of the repair site on ultrasound when compared to the contralateral nerve was bigger for primary repair compared to wrap suggesting that the using of wrap reduces neuroma formation (Circumference - no wrap 302% bigger vs wrap 256% bigger). The sample size was too small to reach statistical significance. The study has demonstrated that the use of a nerve wrap leads to a smaller diameter of the repaired nerve and less pain and therefore decreased neuroma formation. Further prospective studies with larger numbers are required to demonstrate if this translates to improved clinical outcomes.

6. Catedra de Anatomia Universitat de Barcelona (Barcelona)

**Objectives / Interrogation:**
Abductor Pollicis Longus (APL), Extensor Carpi Radialis Longus (ECRL) and Extensor Carpi Radialis Brevis (ECRB) are the scapholunate joint stabilizer muscles in neutral forearm rotation. Extensor Carpi Ulnaris (ECU) is the destabilizer one. Forearm rotation modifies these muscles spatial anatomy.

Does forearm rotation modify ECRL, ECRB, APL and ECU scapholunate joint stabilizing role? Is there any forearm rotation in which the muscle-controlled scapholunate joint stability is impaired?

**Methods:**
The changes in the alignment of both, the scaphoid and the triquetrum, were assessed in 8 fresh cadaver wrists using an electromagnetic motion tracking device. APL, ECRL, ECRB, ECU were individually isometrically loaded in three forearm rotations: supination, neutral and pronation. The experiment was subsequently repeated after complete scapholunate ligament (SLL) sectioning. The results were assessed using ANOVA with repeated measures to compare the scaphoid and triquetrum rotation and elevation position data with those in neutral forearm rotation. Significance was set at p<0.05.

**Results and Conclusions:**

In this presentation, only the statistically significant rotations in the transverse plane and elevations in the sagittal one (degrees +/- standard deviation) relative to neutral forearm rotation. Positive values in rotation: supination; negative values: pronation. Positive values in elevation: flexion; negative values: extension.

- Forearm rotation modifies the scapholunate joint stabilizing muscles role.
- Forearm supination impairs the worst the muscle-controlled scapholunate joint stability capacity.
-The ECU muscle destabilizes the scapholunate joint in all forearm rotations.

Patient-reported outcomes and utility of trapeziectomy with ligament reconstruction and tendon interposition

List of authors: Johnny Ionut Efanov1, Ali Izadpanah1, Alain Michel Danino1, Patrick Harris1
1 Centre hospitalier de l'Université de Montréal (CHUM) (Montreal)

Objectives / Interrogation: Trapeziometacarpal joint osteoarthritis can illicit a significant burden for afflicted patients. Amongst different treatment options, trapeziectomy with ligament reconstruction and tendon interposition (LRTI) has been shown to produce positive outcomes in terms of pain relief and function. Although considered safe by most surgeons, postoperative complications persist and the decision to undergo this procedure should take into account the patient’s characteristics, baseline function and expectations. This study aims to gain more knowledge on the patient-reported functional outcomes and the utility measures of trapeziectomy with LRTI in the treatment of thumb osteoarthritis.

Methods: A survey was administered on consecutive patients who had underwent trapeziectomy with LRTI. Collected data consisted of demographic characteristics, the natural history of disease, the type of treatment received, the postoperative rehabilitation, the brief Michigan Hand Outcome Questionnaire (bMHQ) and the utility assessment questionnaires including the visual analogue scale (VAS), the time trade-off (TTO) and the standard gamble (SG) techniques. Quality adjusted life years (QALYs) were derived from these measures.

Results and Conclusions: In total, 32 patients were enrolled in this study, with a mean age of 60.8 years. Right-hand dominance was reported in 84% of patients, and the operated hand was the same as the dominance in 37.5%. Occupation was equally distributed between manual laborers and office/other at 25% each, whereas the other half was retired. A similar proportion of patients took more than two months of work leave (40.6%) and did not take any time off (34%). A significant majority of patients (84%) considered their operation to have been successful.

The mean normalized measure for patient-reported hand function on the bMHQ was calculated at 83.01. For utility measures, the VAS, SG and TTO produced a score of 0.2708, 0.7546, and 0.8350, respectively. The VAS, TTO and SG utility measures were significantly higher when patients perceived their operation to be successful (p=0.001). These utility health values translated into a mean of 37.73 QALYs for SG and 41.75 QALYs for TTO.

This is the first to study to quantify patients’ reported outcomes and utility measures after undergoing trapeziectomy with LRTI. Reporting these health burden values will serve as comparison with other disease states and provide further insight for policy makers to advocate for this type of procedure.

Keywords: trapeziectomy, utility, PRO
DOCUMENTARY PHOTOGRAPHY IN DUPUYTREN'S DISEASE SURGERY

List of authors:
Andrei Zhigalo*, Viktor Morozov2, Vladimir Pochtenko1
1 «International Medical Center «SOGAZ» (St. Petersburg)
2 Federal Scientific Center of Rehabilitation of the Disabled (St.Petersburg)

Objectives / Interrogation: Due to the rapid development of technology in the 21st century, the creation and processing of images became available to everyone. High-quality photos is now possible to do with a regular smartphone. A high level of modern photos allow to use such images in medicine to create reporting documents, conduct remote consultations, and to evaluate the results of patient treatment.

The main task of the work was to describe the rules and introduce standards for the performance of digital photos in Dupuytren's disease surgery for creating high-quality photo documents.

Methods: The materials for our study were represented by more than 60 000 digital photos for the period from 2003 to 2017.

Results and Conclusions: After studying, organizing and processing received images, optimal conditions, standard projections and principles of photographing hands of patients with Dupuytren's disease were revealed to obtain the most reliable data. We can estimate the stage of the disease; the number of palmar aponeurosis involved in the pathological process; the presence of changes on the skin (postoperative scars, skin retractions, nodes of the palmar aponeurosis); function of flexion of fingers when learning the received photo documents. Conformity analysis of the data obtained from the photo and in-person examination was carried out.

Conclusion. The described methods and standards will help in creating a high-quality personal photo and video archive, which is necessary for each practicing surgeon for systematization of observations, evaluate long-term results, and also to demonstrate their achievements to colleagues as evidence. The authors are sure that in the near future we will become witnesses and participants in the creation of a unified world database of clinical observations of patients. The appearance of such a resource will allow to unite the efforts of surgeons from all over the world in the fight against a common enemy - Dupuytren's disease.

Preliminary result of simultaneously bilateral perilunate dislocation- A Case report

List of authors:
Yu Hung Chen*1  
1 Far Eastern Memorial hospital (New Taipei City)

Objectives / Interrogation: Perilunate dislocations (PD) and perilunate fracture dislocations (PFD) are uncommon, challenging, generally high energy injuries that carry a guarded prognosis. These injuries are commonly missed in up to 25% cases due to other associated injuries requiring urgent attention and delayed or chronic injuries have worse outcomes as retrospective analysis demonstrating.

Methods: We present a case of simultaneous perilunate dislocation in right wrist and transcapoid perilunate dislocation in the contralateral wrist which occurred simultaneously in a young male following a two wheeler accident. Meanwhile, the patient sustained right fronto-temporal subdural hemorrhage, right parietal subarachnoid hemorrhage, right temporal bone fracture and comminuted facial bone in the primary survey. In the emergent room, upon diagnosis, we performed close reduction for the bilateral perilunate dislocation but failed. One week later, after stabilizing the patient’s condition, delayed operation of open reduction and internal fixation along with ligament repair was performed.

Results and Conclusions: The operation includes bilateral open reduction and internal fixation for the perilunate dislocation with pinning and ligamentous repair by transosseous maneuver for SLIL rupture; concurrently, open reduction and fixation with headless screw (Depuy Synthesis, PA, USA)) for left scaphoid fracture was performed. The pins were removed at approximately 8 weeks post-operatively and ROM exercise was initiated after the removal of cast. Nowadays, the patient was subsequently followed up for a period of two months and the preliminary results revealed good and progressing clinical and radiological outcome.

These injuries occurring simultaneously in bilateral wrists are exceptionally rare. These are high-velocity injuries and are often missed, particularly in presence of other major injuries. Accurate early diagnosis is essential and early intervention should be arranged to optimize the prognosis; delayed treatment worsens outcomes. Initial gentle, closed reduction is performed, followed by delayed open reduction, ligamentous and bony repair, and internal fixation. Despite optimum treatment, this injury carries a guarded prognosis, with permanent partial loss of wrist motion and grip strength.

Hiroyuki Ohi* 1
1 Hand & Microsurgery Center, Seirei Hamamatsu Hospital  (Hamamatsu Shizuoka)

Objectives / Interrogation: Tendon grafting to the digital sheaths of the hand sometimes does not give good results. One factor affecting the results may be that the grafts are usually from extracapsular tendons such as palmaris longus or plantaris tendons. The aim of this study was to analyze the outcomes of intracapsular tendon grafting harvested from toe flexor for secondary flexor tendon reconstruction.

Methods: From 2010 to 2015, I treated 7 patients. The intracapsular tendon harvested from the second or third toe. Three digits were staged tendon reconstructions. The tendons were sutured into the appropriate FDP tendon proximally using a Pulvertaft weave; the distal end of the graft was sutured to the base of the distal phalanx. The operations were performed by only one surgeon. Postoperative rehabilitation was active flexion and extension exercise with dorsal extension block splint.

Results and Conclusions: The finger TAM was 92.0% (range: 78.5-100%), the recovery rate was 94.2% (80.6-100%). The tenolysis did not undergo. One patient failed at the proximal suture site in the palm associated with infection at 3 weeks. Three months later, I transferred the ring flexor tendon to the proximal stump of the grafted tendon in the palm. All patients had residual limited flexion of the donor toe. However, gate was apparently normal.

This technique is feasible and gives a good result.

Current Trends in Operative Treatment of Carpometacarpal Osteoarthritis: A Survey of European Hand Surgeons

List of authors:
Qiqi Yin*1, Merel Berkhout2, Marco Ritt3
1 Amsterdam UMC location VUmc (Amsterdam)
2 Alrijne hospital, The Hand Clinic Amsterdam (Leiderdorp)
3 Amsterdam UMC location VUmc, The Hand Clinic Amsterdam (Amsterdam)

Objectives / Interrogation: We explored the prevailing surgical procedures and ultimate last resort surgical management for isolated carpometacarpal (CMC-1) osteoarthritis (OA) among hand surgeons in Europe.

Methods: An online survey was distributed to hand surgeons of participating member states of the Federation of European Societies for Surgery of the Hand. Respondents were asked about the country of practice, years of surgical experience, preferred surgical procedures for isolated CMC-1 OA, the last resort procedure if all other surgical procedures have failed, and considerations for choosing this particular procedure as last resort. Statistical analysis of correlations between demographic and treatment data was performed using Pearson chi-square test.

Results and Conclusions: We received 444 replies across Europe, representing an estimated response rate of 18%. Trapeziectomy with ligament reconstruction and tendon interposition was opted by 46% of the respondents as a procedure of first choice, followed by prosthetic joint replacement (25%) and trapeziectomy with interpositional arthroplasty (23%). Several differences in the choice of preferred surgical treatment between the countries of practice, and between junior and senior surgeons were found to be statistically significant. Regarding the ultimate last resort surgical procedure, 36% chose suspensionplasty, followed by trapeziectomy with or without complementary procedure (21%) and arthrodesis between the base of the first and second metacarpal (17%).

This is the first European-wide study providing insight in the prevailing surgical management for isolated CMC-1 OA. The current surgical practice for isolated CMC-1 OA is still largely based on experts’ experience and local tradition, rather than on evidence. Future prospective randomized studies comparing different techniques for (failed) CMC-1 surgery may help in validating one surgical procedure over another.

Keywords: carpometacarpal, CMC osteoarthritis, trapeziometacarpal, survey
Current Trends in Operative Treatment of Scaphotrapeziotrapezoid Osteoarthritis: A Survey among European Hand Surgeons

List of authors:
Qiqi Yin*, Merel Berkhout2, Marco Ritt3
1 Amsterdam UMC location VUMc (Amsterdam)
2 Alrijne hospital, The Hand Clinic Amsterdam (Leiderdorp)
3 Amsterdam UMC location VUMc, The Hand Clinic Amsterdam (Amsterdam)

Objectives / Interrogation: We present the results of an online survey, distributed in 20 participating member states of the FESSH to explore the prevailing surgical practice for isolated STT OA among European hand surgeons.

Methods: Respondents were asked about their country of practice, surgical experience, preferred surgical procedure, frequency of performing this procedure, factors in decision-making and other performed surgical procedures.

Results and Conclusions: We received 465 replies across Europe. The estimated response rate was 19%. Trapeziectomy with partial trapezoidal excision is the surgical treatment of choice among the participating hand surgeons in Europe (38%), followed by STT joint fusion (30%), and distal scaphoid excision (14%). Most surgeons performed less than 5 of the chosen preferred procedure in the last year. Patient characteristics and familiarity or training are considered to be the two most important factors in reasoning behind the surgeons' decisions for the surgical treatment of isolated STT OA.

This is the first survey that provides insight in the yet controversial surgical management of isolated STT OA among hand surgeons in Europe. A wide variety in preferred treatment techniques was found. Evidence concerning the optimal surgical treatment is yet scarce. Future prospective randomized studies comparing different techniques are warranted.

Survival analysis of the replantation for avulsion of upper arm

List of authors:
Xiaolong Du*
1 Xi’an honghui hospital (Xi’an)

Objectives / Interrogation: To analyze the reasons for the failure of the upper arm replantation of avulsion injuries, summarized upper arm replantation's indications and improved the replantation methods.

Methods: 2014-1 – 2016-1, our department had treated 17 cases of upper arm torn off from trauma patients, two cases had been amputated in period I, the upper arms had been replanted in 15 cases. Rapid debridement, simple and effective external fixation and internal fixation using microsurgical methods to repair blood vessels, nerves. Postoperation giving anti-inflammatory, anti-spasm, anticoagulation, rehydration and analgesic treatment, pay close attention to the blood supply situation.

Results and Conclusions: The postoperative patency rate: 100%, the incidence of skin necrosis: 73.3%; muscle necrosis rate: 80%; period II amputation rate: 20%; 1 case of upper arm torn off injuries replantation patients died; one case of postoperative acute renal failure, emergency amputation; one case after 10 days of discharge, hospital medication, muscle necrosis debridement rupture of blood vessels, amputation. Patients were followed up for 6-12 months, an average of 9 months. After 6 months of upper arm's function assessed according to the Chinese Medical Association limb amputated limb functional trial standards: The average score of 21.5 points, function deteriorated.

The upper arm torn off from traumatic injury for microsurgery is still a very difficult problem, without the forming upper extremity replantation guide, hemodynamic instability, multiple trauma, combined injuries are the high risk of replantation. From injury to the blood through needs a long time is the reason of surgical failure, period II amputation. Skilled microsurgical techniques can improve the successful rate of replantation.

Triquetral motion is limited in vivo after lunocapitate fusion.

List of authors:
Thorsten Schriever*1, Maria Wilcke1, Henrik Olivecrona2
1 Karolinska Institutet (KI), Department of Clinical Science and Education, (KI SÖS), S1, Department of Handsurgery, SÖS (Stockholm)
2 Department of Molecular Medicine and Surgery, Karolinska Institutet (Stockholm)

Objectives / Interrogation: Lunocapitate fusion (LCF) and four-corner fusion (4CF) are motion-preserving salvage procedures for painful wrist arthritis due to e.g. scaphoid nonunion advanced collapse (SNAC) and scaphoid lunate advanced collapse (SLAC). In LCF, the fusion is limited to the capitate and the lunate. Theoretically this maintains the adaptive motion of the triquetrum. It has not been shown in vivo if the triquetral motion really is sustained after LCF. Our aim was to test if computed tomography motion analysis (CTMA) can be used to assess individual motion of the carpal bones and to examine if triquetral mobility is sustained after LCF.

Methods: CTMA is a non-invasive method developed to detect early loosening of joint replacement implants. By comparing sequential standard CT scans, very small movements can be identified between bone and implants. In this study, CTMA was used to detect motion between the carpal bones. We analyzed eight patients operated at least one year earlier with a LCF. Bilateral CT wrist scans were obtained in two positions, extension-radial deviation and flexion-ulnar deviation (i.e. the end-positions of the dart-throwing motion) and the images were analysed using the volume fusion tool denominated CTMA provided by SectraTM. Using this tool, the lunatocapitate complex was brought into spatial alignment, i.e., "registered as fixed". Thereafter, the triquetrum would shift position between the two scans only if it moved relative the lunocapitate complex during the dart-throwing motion. In the non-operated wrists, the capitate was registered as the fixed segment. Motion was measured as degree of motion in space.

Results and Conclusions: CTMA could detect relative motion of individual carpal bones. The triquetrum showed mobility in vivo after LCF in 7/8 patients but the degree of motion was small compared to the non-operated wrist. Unexpectedly, mobility could also be demonstrated of the hamate relative the lunatocapitate complex. CTMA has potential to be used as a tool in wrist diagnostics.

The surgical treatment strategy of congenital clasped thumb according to pathological characteristics

List of authors:
Hao Yu*, Yansheng Wang¹, Xiandong Zeng¹
¹ Central Hospital Affiliated to Shenyang Medical College (Shenyang)

Objectives / Interrogation: The aim of this study was to evaluate the pathological characteristics of congenital clasped thumb, and the results of surgical procedure selection according to these characteristics.

Methods: We reviewed 34 congenital clasped thumbs between 2010 and 2017. The pathological characteristics were ascertained through preoperative examination and intraoperative surgical exploration. The most common pathological change was skin and soft tissue contractures at levels of the first web and thumb palmar in 94.1% cases, while 88.2% cases showed hypoplasia of Extensor Pollicis Brevis (EPB), which are threadlike or absent tendon, with occasional abnormal reinsertion. The contracture of Adductor Pollicis (deep head) and Flexor Pollicis Brevis (transverse head) were seen in 64.7% and 47.1% cases, respectively, often associated with abnormally stronger tendon. The characteristics of Abductor Pollicis Brevis (APB) hypoplasia (58.8%) were similar to EPB hypoplasia. The collateral ligament hypoplasia of MP joint in 38.2% cases was characterized as MP joint instability, ligament laxation, occasionally concurrent with palmar capsule contracture and dorsal capsule laxation, while 14.7% cases were EPL hypoplasia.

Results and Conclusions: Our surgical strategy was as follows: 1. Satisfactory passive motion and no active motion of MP joint was considered to result from extensor and concurrent APB hypoplasia. Tendon transfer was performed (EIP to EPB, one strand of FDS transferred to APB, the other strand transferred to EPL and EPB). 2. MP joint had poor passive and active motion. The first web space and thumb palmar skin was widened using our modified Z-plasty, which was followed by: a. improvement of passive extension and abduction of MP joint (refer to Item 1). b. no improvement of passive motion. Contractures of palmar intrinsic muscle and/or MP joint required attention. We preferred modified tendon lengthening on deep head of Adductor Pollicis and FPB transverse head, and MP joint arthrolysis. 3. Unstable MP joint caused by collateral ligament hypoplasia was provided imbricated ligament in mild cases and chondrodesis in severe cases. MP joint fixation with K-wire was needed. Tendon transfer was performed in the second stage. According to Gilbert assessment, the outcomes of our strategy were excellent/good in 70% cases, fair in 26.5% cases, and poor in 2.9% cases.

Surgical preference based on pathological characteristics of congenital clasped thumb is effective in improving thumb function and cosmetic appearance.

MULTIPLE TUMOURS ON THE THUMB

List of authors:
JUAN ESCUDERO*1, ANDRES VALENZUELA2
1 HOSPITAL DEL SALVADOR, UNIVERSIDAD DE SANTIAGO (SANTIAGO)
2 HOSPITAL DEL TRABAJADOR (SANTIAGO)

Objectives / Interrogation:
Objectives This work aims to characterize the presence of multiples tumours in the hand, with specific affectation in the thumb through case report. This study seeks to contribute to the specialized knowledge of these severe lesions in the hand.

Methods:
Descriptive analysis of a clinical case: male 49 years old, who refers a bulky zone on his thumb by two years, with pain in the last six months, and limitations on the extension function of the affected finger, without paresthesias.
Physical examination: Patient has a subcutaneous bulk, indurated on dorsal zone of his left thumb with affectation of interphalangeal joint and proximal phalanx. There is some swelling on the metacarpophalangeal joint. No affected skin.
Radiological examination: The lesion causes a soft tissue mass with cortical pressure erosion and calcifications on the proximal phalanx and there is a lytic lesion on the metacarpal metaphyseal arising in the medulla with a geographic pattern of bone destruction, bony expansion with cortical thinning.
MRI reveals a typical lobulated pattern suggestive of a cartilage tumour with soft tissue extension in the distal lesion.
Treatment: wide resection en-bloc for the distal lesion. Proximal lesion required simple curettage and bone grafting. After 3 weeks post op, a physical therapy program was carried out to recover full mobility of the involved joints.

Results and Conclusions:
Patient was carried out after 8 months, with good osteointegration of the graft and full function of the thumb. No pain and without infection. Biopsies: periosteal chondroma (distal lesion) and enchondroma (proximal lesion).
Although very uncommon, periosteal chondroma is a benign cartilaginous tumor arising at the periosteal surface of bone. It represents only the 20% of the total condromas. This lesion can arise in both long and small tubular bones. If it is situated close to a joint it is called juxta-articular chondroma. The mass is palpable and can be painful. To Histology in periosteal chondroma increased cellularity as compared to enchondroma is seen. The major differential diagnoses are periosteal osteosarcoma, periosteal chondrosarcoma and giant cell tumour of the tendon sheath. The recurrence rate is rather low (1-5%) for both types of tumours found. Discarding Ollier's disease, the coexistence of both tumours described is uncommon, presenting a diagnostic challenge for correct therapeutic management. This paper highlights the importance of increasing knowledge in this specific area of hand surgery and oncology.

Can we make a difference? The impact of handsurgery in chronic humanitarian conflicts and violent crisis

List of authors:
Stefan Krieger*¹
¹ Ärzte ohne Grenzen Deutschland, Praxisklinik Medicenter Düren, Unfall - und Handchirurgie (Düren)

Objectives / Interrogation: Since decades the Gazastrip suffers continuously from outbreaks of acute war violence within a chronic conflict setting. Acute or chronic sequelae of hand- and burntrauma are omnipresent and deteriorates the victim’s social life substantially. As an international NGO we provide since 1998 hand and burnsurgical treatment. Our aim is twofold: (1) on the individual level, the victim's ability to participate in the social life should be improved through adequate handsurgical treatment, and (2) a sustainable optimization of the handsurgical support should be achieved by investing in continuous handsurgical capacity building.

Methods: International hand - and plastic surgical teams and anesthetists with broad experience in child anesthesia were continuously providing support. Operations and postoperative treatment were undertaken either in inflatable OT tents or in a hospital setting. Postoperative physiotherapy was ensured by qualified local personnel. Supervision and training of the local surgeons was integrated in the daily routine.

Results and Conclusions: In acute war phases, handsurgery is secondary. During post-war and chronic conflict periods, handsurgical interventions became predominant. In 2015 in total 390 operations in hand - and burnsurgery were performed. Contracture release was done by low risk procedures like skin graft, local or fasciocutaneous flaps. Separation of syndactylie was performed, treatment of complex dysmelia, amelia or macrodaytylie is too resource demanding in the given context. Gunshot lesions of the radial nerve with persisting motoric deficit were treated by tendon transposition, those of the ulnar or median nerve by nerve interposition and/or tendon transposition. 2500 burn patients were treated with 35000 sessions of physiotherapy. 50 % did heal without functional sequelae, and a participation in their social life was achieved. In total, 39 % of all patients were younger than 5 years.

Hand - and burnsurgery are essentially in the portfolio of the humanitarian surgery in chronic conflicts. Offering handsurgical treatment has the potential of social life saving surgery, especially for children. Training of local personnel assures sustainability of qualified care. Preconditions for offering continuous support and capacity building are: acceptable security conditions, availability of experienced international handsurgical and anesthetic personnel and qualified physiotherapy.

Diagnostic Significance of Median Nerve Strain and Applied Pressure Measurement after Carpal Tunnel Release

List of authors:
Yuichi Yoshii*, Shin Teramura1, Hiroshi Yuine1, Tomoo Ishii2
1 Tokyo Medical University Ibaraki Medical Center (Ami)

Objectives / Interrogation: Characterization of the changes of ultrasound parameters after carpal tunnel release may be useful for clarifying recovery process of the carpal tunnel syndrome (CTS) treatment. We hypothesized that the strain and pressure around the median nerve may differ before and after carpal tunnel release in CTS patients. The aim of this study was to evaluate the diagnostic significance of median nerve strain and applied pressure measurement for clinical recovery after carpal tunnel release.

Methods: Twenty-six wrists from 23 idiopathic carpal tunnel syndrome patients (17 females and 6 males; age range 37-89, mean age 67.2 years), who underwent open carpal tunnel release, were evaluated by ultrasound. The pressure monitor ultrasound system were developed to apply pressure to the tissue with a pre-determined cycle and displacement of the transducer. Median nerve strain, applied pressure to the skin, and pressure-strain ratio were measured at the proximal carpal tunnel level. In addition, distal motor latency in an electrophysiological test was measured. The parameters were compared before and after carpal tunnel release. According to patient recovery, the receiver operating characteristic curves were calculated to determine the diagnostic value of the parameters. The areas under the receiver operating characteristic curves were compared among parameters.

Results and Conclusions: Before carpal tunnel release, the median nerve strain, pressure, and pressure-strain ratio were 0.15±/-0.04%, 87.1±/-13.0 gf, and 538.1±/-134.6 gf%, respectively. After carpal tunnel release, the median nerve strain, pressure, and pressure-strain ratio were 0.23±/-0.09%, 73.8±/-11.9 gf, and 331.9±/-153.6 gf%, respectively. There was a significant increase of strain after carpal tunnel release (P<0.01), and significant decreases of pressure and pressure-strain ratio (P<0.05: pressure, P<0.01: pressure-strain ratio) after carpal tunnel release. Before carpal tunnel release, distal latency was 7.3+/-.2.6ms. After carpal tunnel release, distal latency was 5.6+/-.1.9ms. There was a significant decrease in distal motor latency (P<0.01). The areas under the curves were 0.762, 0.691, 0.746, and 0.709 for the strain, pressure, pressure-strain ratio, and distal motor latency, respectively.

The median nerve strain and the pressure-strain ratio showed relatively higher relevance with clinical recovery after carpal tunnel release. The results of this study may be useful when considering median nerve recovery after carpal tunnel release.

Autologous Cancellous Bone Graft and Headless Compression Screw Fixation for Treatment of Scaphoid Waist Nonunion

List of authors: Chi Hoon Oh*, Soo-Hong Han¹, In Tae Hong¹, Eugene Baek¹, Minwook Kim¹ ¹CHA Bundang Medical Center (Seongnam)

Objectives / Interrogation: The authors performed an autologous cancellous bone graft from the iliac crest and headless compression screw fixation for the treatment of Mack-Lichtman type II scaphoid waist nonunion. The purpose of this study was to determine whether this procedure is effective in achieving bony union and restoration of alignment.

Methods: We retrospectively reviewed medical records and radiographs of 36 patients who underwent an autologous cancellous bone graft and headless compression screw fixation for scaphoid waist nonunion. There were 34 men and 2 women with a mean age of 33.1 year-old (range, 22-64 year-old). The mean time to surgery from initial injury was 9.6 months (range, 4-26 months) and the average follow up duration was 32.9 months (range, 12-53 months). The authors analyzed bony union, lateral intrascaphoid angle (LISA), scapholunate angle (SLA), radiolunate angle (RLA), and scaphoid length in radiographs and evaluated the modified Mayo wrist score (MMWS) as a functional outcome.

Results and Conclusions: Results: Bony union was achieved in all cases. The lateral LISA improved from 42° to 31° (P < 0.001). The SLA also improved from 62° to 53° (P = 0.009). The RLA changed from 8° to 4° (P = 0.048) and the scaphoid length changed from 21 mm to 27 mm (P < 0.001) postoperatively. The MMWS improved from 71.2 to 92.0 (P < 0.001) significantly at the last follow-up.

Conclusions: Non-structural autologous cancellous bone graft from the iliac crest and headless screw fixation provided reliable results for the treatment of scaphoid waist non-union. This method can be one of the effective treatment options for patients with symptomatic Mack-Lichtman type II non-union in the mid-third of the scaphoid.

Wrist replacement of keramik implantates

List of authors:
Timofey Alexandrov*, Valeriy Prohorenko¹, Sergey Chorniy¹, Katerina Simonova¹
¹ RNIITO Novosibirsk Russia (Novosibirsk)

Objectives / Interrogation: We have accumulated 10 years experience of endoprosthetics of the wrist joint. In Novosibirsk RNITO named Tsivyan used whole ceramic unbonded endoprosthesis Moje keramik MBW. The model uses one short distal stalk inserted into the capitatum bone and one short proximal leg inserted into the radial bone. The configuration of the distal ceramic component is circular, while the proximal component is elliptical. Such a construction feature allows to initially exclude cutting forces when moving in the wrist joint. The installation of the distal component in the capitatum allows preserving the interaction of the locomotor apparatus of the distal row of the bones of the wrist and carpometacarpal joints, which performs the damping function of the entire wrist joint.

Methods: In the traumatologic and orthopedic department ###6 of the Novosibirsk RNITO named Tsivyan in the period from 2010 to December 2017, performed 52 total endoprosthetics of the wrist joint using the Moje MBW ceramic implant. Patients admitted for surgical treatment can be divided into three groups. The first, the most numerous, included patients who underwent traumatic injury of the wrist joint (n = 38). The second group included patients with osteochondropathy of the wrist joint (n = 9). The third group includes patients suffering from rheumatoid arthritis (n = 5). The latter group, in our opinion, is the most problematic in view of the pronounced osteoporosis and systemic lesion of the ligamentous apparatus. For this reason, 5 operations were performed with minimal changes from the soft tissue side.

Results and Conclusions: In the preoperative period, patients underwent X-ray examination of the affected area in standard straight and lateral projections. Patients with severe deformity and osteolysis performed a tomography study to determine the extent of bone tissue damage. Patients with rheumatoid arthritis, in addition to clinical examination, densitometry was performed to determine the degree of osteopenia. In the detection of osteoporosis, surgery was not performed. Operative intervention was carried out according to the rules of technology.

A year after surgery, patients clearly understand the presence of an endoprosthesis of the wrist joint and assess changes in the quality of life. On average, on a ten-point scale of pain intensity decreases from 9 to 4. According to the Mayo wrist score, an increase in scoring from 30 to 70 is noted.

Prospective Cohort Study of the NuGrip CMC Implant for Carpometacarpal Osteoarthritis

List of authors:
Olivier van Not¹, Marco Ritt², Freek Lötters³, Hans Pieter van Not⁴
¹ Leids Universitair Medisch Centrum (Leiden)
² VUmc (Amsterdam)
³ Hand & Pols Centrum Dordrecht (Dordrecht)
⁴ Admiraal de Ruyter Ziekenhuis (Goes)

Objectives / Interrogation: Osteoarthritis of the carpometacarpal (CMC) joint of the thumb is a common type of osteoarthritis of the hand. Complaints can consist of pain, swelling and loss of strength and movement. Multiple operative techniques have been described for the treatment of CMC-1 osteoarthritis. So far, none of these techniques have shown superior outcome. To date, implants as a treatment option for CMC 1 joint osteoarthritis still are a matter of great debate. We investigated the outcome of the hemiarthroplasty Pyrocarbon implant called the NuGrip CMC Implant.

Methods: Between 2011 and 2017 we conducted a single surgeon, single center, prospective observational cohort study including 131 patients (mean age 58 years) with CMC 1 osteoarthritis who were treated with the NuGrip implant. Clinical outcome parameters were available at 12 months for 46 patients and at 24 months for 38 patients. They consisted of the DASH score, NRS pain score, movement of the MCP and IP joint, palmar abduction, Kapandji score, key pinch force, tip pinch-index finger force and grip strength. Outcome parameters were determined preoperative, at 12 and 24 months postoperatively.

Results and Conclusions: Mean follow up time was 23.8 months. During the course of the study 63 complications were registered in 47 patients (36%), including the removal of 11 NuGrips implants (8%). Most common complication was osteophyte formation (56%) which needed surgical removal. Further details on the complications will be discussed during the presentation. After 12 months, patients showed improvement in DASH score (40.5 to 26.7 points; P<0,001) and NRS pain score (5.7 to 2.5 points; P<0,001). A decrease was found in the total active range of motion of the MCP joint (66.3 to 59.5 degrees; P<0,05) and key pinch force (5.3 to 4.6 Newton; P<0,05). After 24 months, patients showed improvement in DASH score (41.3 to 25.5 points; P<0,001), grip strength (21.1 to 23.7 kg; P<0,05) and NRS pain score (5.6 to 2.0 points; P<0,001). A decrease was found in total active range of motion of the MCP joint (64.6 to 52.9 degrees; P<0,05).

The NuGrip CMC Implant shows an acceptable survival rate and relatively high number of complications, although not all complications are directly related to the implant. The NuGrip CMC Implant provides improvement in DASH score and NRS pain score after 12 and 24 months and grip strength after 24 months. A decrease was seen in key pinch force after 12 months and in active range of motion of the MCP joint after both 12 and 24 months.

Efficacy of endoscopic neurolysis for the motor (recurrent) branch of the median nerve during endoscopic carpal tunnel release surgery using the USE system

List of authors:
Aya Yoshida*, Ichiro Okutsu2, Ikki Hamanaka2
2 Okutsu Minimally Invasive Orthopaedic Clinic (Minato-ku, Tokyo)

Objectives / Interrogation: Until now, there have been no studies regarding endoscopic neurolysis for the motor (recurrent) branch of median nerve. During endoscopic carpal tunnel release (ECTR) surgery, we identified the motor branch and performed endoscopic neurolysis using the Universal Subcutaneous Endoscope (USE) system, which consists of a transparent closed sheath and an arthroscope. The same external neurolysis principles used in open surgery are applied with this system. To evaluate the efficacy of this procedure, we analyzed and compared clinical and electrophysiological results between the "with" and the "without" endoscopic neurolysis groups.

Methods: From November 2016 to December 2017, we performed endoscopic neurolysis during ECTR surgery for 226 hands. To more precisely evaluate postoperative motor recovery, we selected patients with both "zero" preoperative abductor pollicis brevis muscles using MMT (APB-MMT) and undetectable distal motor latency (DML) of the median nerve for this study. Twenty-four hands of 24 patients followed-up for more than six months were analyzed.

The USE system was inserted along the median nerve toward the thenar muscle during our ECTR procedure. We were able to identify the motor nerve branching and the branch was released from surrounding tissues with an external neurolysis procedure using the USE sheath.

For the non-neurolysis (control) group, we selected patients with the same preoperative clinical and electrophysiological conditions (195 hands) and matched follow-up periods (from 6 to 18 months). Patients in this group had received ECTR without endoscopic neurolysis before November 2016. We analyzed and compared pre- and postoperative APB-MMT and DML results between two groups.

Results and Conclusions: APB-MMT recovery rates showed better improvement in the neurolysis group with a statistical difference (p<0.05). Recovery periods to manual APB-MMT [5] showed shorter improvement periods in the neurolysis group with a statistical difference (p<0.01). Electrophysiological testing results of DML showed no statistical difference.

From those results, we conclude that endoscopic neurolysis for the motor branch of the median nerve combined with ECTR is effective treatment for severely atrophied thenar muscles.

Incision directly above versus Distal incision in Open Carpal Tunnel Release. Does the incision, which is avoided directly above the flexor retinaculum, lead to faster relief of the carpal pain? - A prospective randomized controlled trial -

List of authors:
Hiromichi Yasuoka*1
1 Tamana Central Hospital (Tamana)

Objectives / Interrogation: To compare postoperative carpal pain of incision directly above the flexor retinaculum with that of incision avoiding directly above (=distal) in patients with carpal tunnel syndrome and to prove that there is no difference concerning duration and cite of postoperative carpal pain between the two incisions.

Methods: The number of enrolled hand were 170 (220 hands were recruited, follow up rate 77%), 70 males and 100 females. The mean age was 73 years (24 to 95). In all cases, surgery was performed by the same surgeon. An original post-operation assessment sheet was developed and every four weeks after surgery, it was used to measure carpal pain by four hand therapists randomly. Patients who could attend follow up consultations, until tenderness had been lost, were enrolled into the study. Time when spontaneous pain has disappeared, time when tenderness has disappeared and location of tenderness were assessed. In all surgery, there was no attempt to identify or preserve the palmar cutaneous nerves.

Results and Conclusions: There were no significant differences between the two incisions in respect of time when spontaneous pain has disappeared (95% confidence interval [-0.8week, 0.8week], P=0.93) and tenderness has disappeared (95% confidence interval [-2.7week, 3.0week], P=0.80). The distribution pattern and ratio of tenderness location were very similar between the two incisions (Figure 1 & 2).
In open carpal tunnel release surgery, difference of incision site and preserving palmar cutaneous nerves are not factors that have influences on duration and location of carpal pain after surgery. It is supposed that division of the flexor retinaculum itself is a cause of carpal pain after carpal tunnel release.

¹ MUTUAL DE SEGURIDAD (SANTIAGO)

Objectives / Interrogation: The fingertip is a highly specialized structure, with prehensile and tactile functions that can be importantly reduced after an injury. The goal of the treatment of this injuries is to maintain the length, sensitivity and mobility of the finger, with a painless and padded stump.
There are many techniques described to treat these lesions, from simple regularization or v-y local flaps, through homodigital neurovascular flaps, to heterodigital, thenar or other flap alternatives.
The aim of this study is to compare clinical and functional outcomes of two surgical techniques: homodigital direct flow flaps (DFF) and homodigital reverse flow island flaps (RFF) to cover fingertip injuries in tri-phalangeal fingers performed between 2012 and 2018 in a workers insurance trauma center.

Methods: We reviewed the operative protocols performed between April 2012 and April 2018 by the hand surgeons of our institution and selected those who described homodigital neurovascular flaps to cover fingertip injuries.
Epidemiological data were collected, such as age, gender, laterality, finger involved and mechanism of injury.
The cases were classified by Allen's level of amputation, direction of injury [1], type of intervention (primary or secondary) and type of flap performed (DFF or RFF).
The outcomes we measured were time to labor, functional results (range of finger motion, strength, two points discrimination and sensibility) and the presence of complications and reinterventions.

Results and Conclusions: We obtained 43 cases, 92% of these were men, 77% were by crushing and 53% on the right hand.
The most frequent fingers involved were index (40%) and middle finger (35%). The most frequent diagnosis was amputation (62%) in a palmar oblique coronal direction (60%). The most frequent Allen's levels were II (42%) and I (37%). These data are consistent with the literature.
In 53% of cases a RFF was performed and in 47% it was a DFF. There were no epidemiological or functional differences between these groups.
Time to labor was 4.1 months in the DFF group and 5.4 months in the RFF group*.
A 41% of complications were observed; the most frequent ones were retractable scar (14%) and flap necrosis (11%).
The presence of complications was 3.4 times higher in the RFF group* and this group required 7 times more interventions*.
Based on ours results, we dare to recommend the DFF, since they are simpler to perform and have less complications, reinterventions and recovery time.

(*This differences were statistically significant)

Evaluation of altered little finger sensation in patients with carpal tunnel syndrome treated with median nerve surgical release

List of authors:
Larissa Miyashiro Yamashita*, Carlos Fernandes¹, Lia Miyamoto Meirelles¹, Flavio Faloppa¹, João Baptista Gomes dos Santos¹
¹Universidade Federal de São Paulo (São Paulo)

Objectives / Interrogation: Symptoms of altered sensation are frequently observed in patients with the diagnosis of carpal tunnel syndrome (CTS). The majority of these patients present with paresthesia and/or numbness in the median nerve distribution. We have observed that some of the CTS diagnosed subjects also reported the same symptoms in the little finger. The aim of this study was to evaluate the follow-up of altered sensation in the little finger in patients who underwent carpal tunnel surgical release.

Methods: One hundred and seventy patients with CTS and little finger paresthesia and/or numbness have been analyzed. Clinical exam and electrodiagnostic studies were performed in all patients and no signs of ulnar nerve compression were found. The sensory evaluation was assessed with Semmes-Weinstein nylon monofilaments both preoperatively and postoperatively (with two weeks, one month, three months and six months-time).

Results and Conclusions: The results were statistically analyzed and reviewed. We observed that there was improvement of little finger monofilament sensory findings from the first postoperative evaluation only two weeks after the procedure of carpal tunnel release, and that the major sensory gain in relation to preoperative values was noticed six months postoperatively. We concluded that in patients with CTS and decreased little finger sensation evaluated by Semmes Weinstein nylon monofilaments, the median nerve surgical decompression causes improved little finger sensation.

Keywords: carpal tunnel syndrome; little finger sensation; nylon monofilament assessment; Semmes-Weinstein assessment
Ten-year follow-up results of rheumatoid wrist surgery without prosthesis.

List of authors:
Asami Abe*, Hajime Ishikawa

1 Niigata Rheumatic Center, Department of Rheumatology (Shibata Niigata)

Objectives / Interrogation: With the advent of biological therapy, an early diagnosis and early treatment with tight control have become increasingly important for the treatment of rheumatoid arthritis (RA). Many patients with RA can live a normal life without joint deformity. With the more widespread use of various biological agents, the number of large joint surgeries has decreased, while the number of small joints has increased in our center hospital of rheumatic diseases. The objectives of this study is to investigate the long-term outcome of the rheumatoid wrist surgery without prosthesis.

Methods: We investigated the results of ten years after wrist surgeries without prosthesis in our hospital. All procedures were performed from November 2006 to December 2008. There were 84 wrists in 80 patients (male, n=15; female, n=65). The average age at operation were 61 years, the average duration of RA were 11 years. The operative procedures were as follows: limited arthrodesis (59 wrists), Sauvé-Kapandji's operation (7 wrists), Clayton's tendon transfer (16 wrists), and arthroplasty at the midcarpal joint using the palmaris longus (PL) tendon ball (18 wrists).

Ten years later, we obtained data from 48 wrists in 46 cases. We assessed the DASH score, grip power (GP), range of motion (ROM) and carried out a questionnaire survey. The questionnaire investigated the perioperative memory, current state and satisfaction with the operation.

Results and Conclusions: The mean age was 66 years, the mean duration between the onset of RA to the operation was 9.5 years, the mean DAS28-ESR(4) was 2.63, the mean of CRP level was 0.32mg/dL. The MTX medication ratio and its mean dose was 33/48 (67%), 8.3 mg/week. The PSL medication ratio and its mean dose was 26/48 (54.2%), 3.4 mg/day. Twenty-two patients were using biological agents. The average arc for extension/flexion had worsened (56.5±28.9 to 32.0±27.8), while the average arc for supination/pronation had improved (145.8±28.6 to 148.6±23.5). The average GP (139.0±67.8mmHg to 175.3±68.1 mmHg) and average DASH score (34.8±17.8 to 28.3±24.1) both showed improvement. The results of questionnaire showed that most patients were satisfied with their wrists at 10 years after the operation. Patients who were highly satisfied with the operation had a shorter disease duration and shorter interval between the onset of disease and their operation.

A long-term favorable outcome of rheumatoid wrist surgery without prosthesis is expected under the good medical control of the disease.

WristArt is the new concept of the total wrist joint prosthesis based on a fractal theory of the biomechanics of the wrist joint.

**List of authors:**
Lauren Gorelick*¹
¹Medical division of Fibioseq medical LTD (Kfar Rosh Haniqra)

**Objectives / Interrogation:** Wrist joint osteoarthritis for any reason is difficult to treat as condition especially in the end stage of the disease. Theoretically, total wrist replacement seems to be the preferred option for wrist joint surgical treatment as the issue to wrist motion and pain relief. However, practically it has not happened. The explanation is that most existing implants do not accurately reflect the biomechanics of the wrist. The wrist joint is nonlinear in their visual appearance. However, it is possible to find linearity of nearly all nonlinear biological systems on the base of the fractals. Autor finds linearity of the healthy human wrist joint according to the mathematical processing of the anthropometric data. With the help of the fractals, Fibonacci Golden section and spirals, a new opportunity was opened to explain the biomechanics of a human wrist joint. This opportunity logically can be defined as "A fractal theory of the biomechanics of the wrist joint" and help design and built the optimal and universal total wrist joint prosthesis called WristArt.

**Methods:** According to the fractals and spirals of Fibonacci, a linear model of the wrist joint built. That model determined two centers of rotation into the capitate bone. Universal one size and no side difference universal prosthesis were constructed. WristArt consists of three main parts: capitate, radial and articular. Articular part design allows for double motion. The capitate component connects to the Capitate bone only thru the plate-like fixation. Radial component reconstructs articular surface with the resurfacing plate and links to the distal radius as a dorsal radial plate. Two oblique locking screws connect between the dorsal radial plate and lower part of resurfacing plate and create strong Pyramid like structure.

**Results and Conclusions:** WristArt avoids conversion polyarthrodial joint into a diarthrodial. That prevents excessive shearing, and bending forces on the joint and potential fatigue and insufficiency of the exist prosthetic wrist devices. Conclusions: The Universe inside you. It is easy to find the solution when one has an open mind to explore our world and employ Universe and Nature's own design to create a solution. Perfection exists the knowledge and beauty solution exist in perfection. And the beauty solution for wrist replacement is the correct and ideal prosthetic design. WristArt design closed to Nature's design and may give hope return the patients fine movements without pain for a long time.

Prevalence of Osteoporosis in Patient with Distal Radius Fracture from Low-Energy Trauma

List of authors:
Şunyarn Niempoog*, Sorachat Sukkarnkosol1, Krit Boontanapibul1
1 Department of Orthopaedics, Faculty of Medicine, Thammasat University (Pathum Thani)

Objectives / Interrogation: Osteoporosis is a devastating problem leading to significant morbidity and mortality. Patients usually present with fractures from low-energy trauma and falls, which may precede more severe fractures like a fracture of the neck of femur. The distal radius is one of the common fracture sites in osteoporosis patients but data from Thailand are limited. We aimed to determine the prevalence of osteoporosis in patients with distal radius fracture from low-energy trauma.

Methods: This was a descriptive retrospective study, performed at our institution from January 2011 to June 2017. Patients aged ≥ 50 years with distal radial fractures from low-energy trauma and a bone mineral density result were included. Patients with known secondary causes of osteoporosis were excluded. Patients were grouped by age, sex, and bone mineral density status (normal, osteopenic and osteoporotic).

Results and Conclusions: 100 of 351 patients had bone mineral density data but 79 (73 females) met the inclusion criteria. Most patients were aged 60-69 years old (n=31, 42.5%). 47 (59.5%) patients were osteoporotic, 23 (29.1%) osteopenic, and 9 (11.4%) were normal (Table 1 and 2). 7 (6 osteoporotic) patients suffered a subsequent more severe fracture. No deaths were recorded.

Our small study found a high rate of osteoporosis in mostly females, consistent with the published literature. Assessing bone mineral density is an essential investigation in middle age/elderly patients with fractures to better manage osteoporosis and prevent more severe fractures in the future.

Endoscopically assisted distal biceps tendon repair

List of authors:
Paul Jarrett*1
1 Murdoch Orthopaedic Clinic, Suite 10 Murdoch Clinic (Murdoch)

Objectives / Interrogation: This paper aims to describe a surgical technique for endoscopic distal biceps tendon repair and analyse the outcomes.

Methods: With the forearm supinated a 2 cm volar incision approximately 3 cm distal to the elbow crease, medial to the extensor mass is utilised. The fascia is incised, and the lateral cutaneous nerve of the forearm is protected. A Karl Storz Hopkins wide angle Forward- Oblique telescope with optical dissector with distal spatula was utilised with when required a Cottle speculum. The radial tubercle is located using blunt dissection. The passageway for the tendon is identified and enlarged if required. A Zimmer Biomet Toggleloc anchor and placement equipment was create a bone tunnel and anchor for repair. The proximal end of the tendon is located via the single incision using the endoscope. The tendon end is delivered out of the incision, tendinopathic tissue removed and a healthy tendon end of appropriate dimensions created for repair. The tendon is sutured into the anchor and repaired into the radial tubercle tunnel.

Results and Conclusions: Results
Over the last six years, 50 patient’s distal biceps were repaired using this technique. The mean age was 52 years with 47 males and 3 female having surgery. Time from injury to surgery was on average 3 weeks with 40% having surgery within one week of injury. Follow-up was for at least three months for all patients. All patients regained full extension and flexion. The mean DASH was 11 with an average grip strength of 47 kg. There were no permanent neurological injuries but 16% of patients suffered minor transient sensory disturbance of the lateral cutaneous nerve of the forearm. Two patient suffered re-avulsion of the tendon, both of whom were non-compliant with their restrictions, and who went on to revision surgery and gained an excellent result following their second operation. One patient suffered from a superficial wound infection which responded to oral antibiotics and one patient suffered from a wound haematoma which resolved spontaneously. The mean incision length was 19 mm.

Conclusions
The above procedure is a straightforward procedure with low rate of complication, high patient satisfaction and short operative time. The results seem to be similar to previous open surgical technique utilised by the author but with a lower lateral cutaneous nerve of forearm neuropraxia rate.

Wartenberg’s Syndrome: Case Series

List of authors:
Paul Jarrett*1
1 Murdoch Orthopaedic Clinic, Suite 10 Murdoch Clinic (Murdoch)

Objectives / Interrogation: Wartenberg's syndrome, a mononeuropathy of the superficial branch of the radial nerve, is uncommon and the natural history and treatment outcomes are uncertain for individual patients. This study documents a case series of patients with chronic Wartenberg's syndrome, their investigations, treatment and outcomes.

Methods: Patients with isolated non-sharp trauma related superficial radial nerve dysfunction of greater than three months’ duration and of sufficient severity to justify treatment were retrospectively collected in practice over a ten-year period. Patient demographics, aetiological factors, investigation results, treatments initiated and treatment outcomes were recorded.

Results and Conclusions: RESULTS
Eleven patients, seven female and four males, were treated for chronic Wartenberg's syndrome. The patients' ages ranged from 27 to 64 years. Apparent causative factors included distal radial fracture, blunt hand or forearm trauma, excessive occupational forearm rotation with no cases related to the use of hand cuffs. Two patients responded adequately to hand therapy alone. The remaining nine patients went on to formal ultrasound assessment of the superficial radial nerve by musculoskeletal radiologists with universally a normal appearance of the nerve but an ultrasound guided corticosteroid injection resolved symptoms in all patients, with resolution of symptoms in five patients and transient response in the other four patients. One of these four patients chose to accept his symptoms and the remaining three underwent surgical decompression, one open and two endoscopic, with two making a complete recovery and one patient making a good partial recovery with a follow-up of over a year.

CONCLUSIONS
Despite ultrasound being able to define the superficial radial nerve with accuracy there have not been previous publications reporting on ultrasound in Wartenberg's syndrome and this study suggests ultrasound is not a reliable diagnostic tool for this condition. This study represents a relatively small case series of this uncommon condition. However, the author could identify few larger case series and no randomized studies for this condition. This study has demonstrated a good recovery for the majority of patients with a step-wise approach to treatment of hand therapy, followed by corticosteroid injections if required and surgery should steroid injection not produce a sufficient resolution of Wartenberg's syndrome.

Minimally invasive plate fixation of distal radial fractures

List of authors:
Paul Jarrett*
1 Murdoch Orthopaedic Clinic, Suite 10 Murdoch Clinic (Murdoch)

Objectives / Interrogation: Displaced distal radial fractures are commonly internally fixed with a volar locking plate using a moderate sized incision with pronator quadratus raised at its radial insertion. Minimally invasive techniques have evolved using a small incision and sliding the plate under pronator quadratus. The study's aimed to document a series of minimally invasive distal radial fracture fixations, assess the patient's results and comment on the potential relevance of this technique to wrist trauma practise.

Methods: The author performed distal radial fracture fixation of displaced distal radial fractures deemed optimally managed by a volar locking plate over a period of 24 months using a previous published technique with a 15-mm incision and sliding the plate deep to pronator quadratus. Following surgery, patients were provided with a thermoplastic splint for optional use as determined by comfort, and underwent hand therapy.

Data collected included: patient demographics, fracture morphology, fracture reduction, post-operative grips strengths, visual analogue pain scales, DASH scores and complications.

Results and Conclusions: Results

In this series, 25 minimally invasive distal radial fixations occurred. There were 16 females and 9 males with a mean age of 45. Reduction appeared satisfactory with a mean radial inclination post-operatively of 21 degrees and volar tilt of 10 degrees. At six weeks, the average grip strength was 55% of the contralateral side and at 12 weeks it was 70%. One patient ruptured extensor pollicis longus post-operatively with a well reduced fracture and no protruding dorsal metalwork, requiring tendon transfer. Three other patients had their plates removed due to patient preference. No other complications were noted.

Conclusions

The minimally invasive volar plate internal fixation technique is a relatively straightforward technique and with good results. The relevance of this technique modifications for non-hand surgeon practise will be discussed.

Tetanus Prophylaxis in Open Hand Injuries: are the guidelines fit for purpose?

List of authors:
mehul thakkar*, Sahiba Singh¹, Rachel Harrison¹, Donald Dewar¹
¹ Leeds Teaching Hospital (Leeds)

Objectives / Interrogation: To audit compliance of tetanus prophylaxis in open hand injuries with Public Health England guidelines

Methods: Retrospective audit on 60 patients with open hand injuries referred to the Plastic Surgery department. Two data collection windows of 2 weeks each consisting of 30 patients each. There was a departmental presentation between the two windows to educate and help improve compliance. Parameters included mechanism of injury, tetanus immunisation status and whether tetanus vaccine and/or prophylactic immunoglobulin was administered.

Results and Conclusions: In the first window, 18 patients didn't require a tetanus vaccine booster and 100% (18/18) of patients didn't receive it, 12 patients required a tetanus vaccine booster however only 83% (10/12) received it, 11 patients also required prophylactic tetanus immunoglobulin and it was only administered to 9% (1/11). In the second cycle after the intervention, 9 patients didn't require a tetanus vaccine booster and 100% (9/9) of patients did not receive it, 21 patients required a tetanus vaccine booster however only 71% (15/21) received it, 3 patients also required prophylactic tetanus immunoglobulin and none of them received it 0% (0/3).

Hand injuries are commonly referred to the Plastic Surgery Department. Tetanus is a life-threatening vaccine preventable infection with a total of 4 cases and no deaths reported in England in 2016. Five doses of tetanus vaccine should provide long lasting immunity against tetanus however if the wound is considered 'high risk' prophylactic tetanus immunoglobulin should be administered for immediate protection irrespective of immunisation history. Our audit highlights the poor compliance with prophylactic tetanus immunoglobulin and the importance of educating and raising awareness of the appropriate management guidelines amongst healthcare practitioners in the Plastic Surgery department as well as in the Emergency department and Minor injuries setting. Extrapolating our findings, it is likely that compliance rates are likely be similar across the country and despite this tetanus infections remain extremely rare. Prophylactic tetanus immunoglobulin is costly at £125 compared to a single Revaxis vaccine which costs £6.50 and currently a shortage of it in the NHS for management of tetanus prone wounds has led to an urgent review by Public Health England in 2018 to prioritise its use for susceptible individuals who have sustained high risk injuries and are at greatest risk.

Extensor pollicis longus tendon reconstruction by extensor indicis proprius transfer or free tendon graft using a novel 2 cm retroposition tension method

List of authors:
Fumiki Kamoi*, Makoto Kondo2, Shigeharu Uchiyama1, Hiroyuki Kato3
1 Okaya City Hospital (Okaya)
2 Hokkaido Orthopaedic Memorial Hospital (Sapporo)
3 Shinshu University School of Medicine (Matsumoto)

Objectives / Interrogation: In extensor pollicis longus (EPL) tendon reconstruction, 3 factors are important to obtain optimum post-operative thumb motion: the reconstruction method of either extensor indicis proprius tendon transfer (EIP TT) or free tendon graft (FTG), the tension applied to the EPL tendon and the muscle selection for the power source. Based on these, we have hypothesized that: 1) results are similar between EIP TT and FTG, and 2) our novel 2 cm retropulsion tension method is reliable for consistently deciding optimal tension.

Methods: Twenty-five consecutive patients with chronic rupture of the EPL tendon were treated by EIP TT or FTG between 2006 and 2014 by 3 different surgeons. EPL tendon rupture occurred after distal radius fracture in most cases. For all patients, tendon reconstruction was performed using a novel retropulsion tension method, in which we reconstructed the EPL tendon keeping the center of the thumb nail raised 2 cm above the operating table while the palm was pressed against the operation table with the elbow in extension, forearm in pronation, and wrist in a neutral position. FTG was carried out using the palmaris longus tendon within 3 months from episode to surgery in 7 patients. EIP TT was done in 13 patients after more than 3 months from episode to surgery. We examined 20 patients directly a minimum of 12 months after tendon reconstruction to assess Total Active Motion (TAM) of the thumb, elevation deficit of the thumb compared with the opposite thumb in active retropulsion position, flexion deficit of the thumb interphalangeal and metacarpophalangeal joints, and disabilities of the arm, shoulder and hand (DASH) scores.

Results and Conclusions: Mean TAM improved from preoperative 50% (range: 18-78%) to postoperative 90% (range: 60-100%). Mean elevation deficit was 1.2 cm (range: 0-2.5 cm) and mean flexion deficit was 10 degrees (range: -12-45 degrees) at follow-up. Mean DASH score improved from 28.6 to 7.7. There were no significant differences in clinical outcome between EIP TT and FTG or among the results of individual surgeons.

Various tension-deciding techniques have been proposed for EPL tendon reconstruction. By raising the thumb by 2 cm, we believe our new retropulsion tension technique is easy, reliable, and applicable for both EIP TT and FTG. With results comparable to EIP TT, FTG is recommended for patients within 3 months after tendon rupture to preserve independent index finger motion.

Examination on the clinical test of de Quervain's disease through tendon excursion of each test

List of authors:
Hiroyuki Ohi*
1 Hand & Microsurgery Center, Seirei Hamamatsu Hospital  (Hamamatsu Shizuoka)

Objectives / Interrogation: Purpose: de Quervain's disease which is tenosynovitis of the 1st extensor compartment is very common. de Quervain's disease has several clinical tests. We conducted a clinical test at the actual surgery and measured the tendon gliding distance of EPB and APL and considered its clinical significance.

Methods: Methods: Eight cases of de Quervain's disease was examined. Both an EPB and an APL tendon sheath were opened by local anesthetic surgery and five clinical tests were performed to measure tendon gliding distance. The clinical test is Finkelstein test, Nozue - Iwahara test, Aso test, the EPB test, the APL test. In Nozue - Iwahara test, pain is occurred when the thumb is active palmar abduction while the patient's wrist joint is palmar flexion. In Aso test, pain is occurred when the thumb is active extension while the patient's wrist joint is dorsal flexion. In the EPB test, pain is occurred when the MPj strongly passive flexion at neutral position of wrist joint. In the APL test, pain is occurred when the CMj strongly adduction at slightly ulnar deviation of wrist joint. The EPB and the APL test is my originally.

Results and Conclusions: Results: The gliding distance of EPB was 11.1 mm (range: 10-15) and APL was 9.3 mm (range: 5-15) on Finkelstein test. Nozue - Iwahara test was 9.1 mm (3-15) of EPB and 8.5 mm (3-15) of APL. Aso test was 10.9 mm (5-15) and 2.0 mm (0-5). The EPB test was 7.9 mm (5-10) and 1.1 mm (0-2). The ALP test was 1.8 mm (0 - 5) and 4.9 mm (4-6), respectively. Conclusions: Finkelstein test and Nozue - Iwahara test seemed to cause large gliding distance of both tendons and clinically it was difficult to distinguish between tendon sheaths of either tendon. In the Aso test and the EPB test, the movement of EPB was larger than that of APL, and it was considered to be a "Selective EPB test". The only one, the APL test was bigger than APL compared to EPB. In terms of thinking this as a "Selective APL test", the gliding distance and its difference were small.

Reconstruction of Low-Hand Syndrome with Tendon Transfer in Patients Injured in Syrian Civil War

List of authors:
Murat UCkı*1
1 Defne Private Hospital, Plastic and Reconstructive Surgery (Hatay)

Objectives / Interrogation: Radial nerve is one of most war-related injuries due to drilling cutter tool injury or gunshot wounds, resulting Low-Hand Syndrome. We aimed to evaluate the outcomes of tendon transfer in the patients with Low-Hand Syndrome who injured in Syrian Civil War.

Methods: We evaluated the results of 13 patients who injured in Syrian Civil War between 2015 and 2017 years. Palmaris longus tendon was used for transferring to extensor pollicis longus for thumb extension. Pronator teres was transferred to extensor carpi radialis brevis for wrist extension. The flexor carpi radialis were transferred to the extensor digiti communis for the 2th, 3th, 4th and 5th finger extension. All outcomes of thumb abduction and extension, wrist extension, wrist flexion and fingers extension were assessed.

Results and Conclusions: There was a high level of radial nerve injury in all patients included in the study. Post-injury transfer period was 1.5 months at the earliest and 9 months at the latest. Among the injuries, the gunshot wound was the most reason observed in 8 cases (61.5%). Drill cutter injury (n:3; 23.1%) and humerus fracture (n:2; 15.4%) followed the gunshot wounds. As a result, radial nerve injury may achieve successful results with the tendon transfer. All patients regained their thumb abduction as much as around 60 degrees. They have the ability of wrist bending and gripping, as all can extend their fingers in the positions of wrist flexion, neutral wrist and wrist extension. Although the reason for radial injury varies, the common point was that postoperative outcomes and rehabilitation period moved successfully in patients who underwent early repairs than 90 days.

Mid-to-long term Outcomes of Convertible Total Elbow Arthroplasty for Patients with Rheumatoid Arthritis

List of authors:
Jason Strelzow¹, Tym Frank², Ken Faber², George Athwal², Graham King²
¹ University of Chicago (Chicago)
² University of Western Ontario, Roth | McFarland Hand and upper Limb Center (London)

Objectives / Interrogation: Total elbow arthroplasty (TEA) is commonly performed in patients with rheumatoid arthritis (RA). Convertible systems provide the capability to choose between linked and unlinked designs intra-operatively using the same stems. There is a paucity of research comparing linked and unlinked designs in the rheumatoid population. We compared outcomes of linked and unlinked TEA arthroplasty using a single convertible implant in patients with rheumatoid patients.

Methods: All patients with RA who underwent total elbow arthroplasty at a single center and had a minimum of 2 years follow-up were reviewed. Exclusion criteria included patients with less than 2 years follow-up. Patient demographic information, outcome scores, functional assessment and radiographic parameters were evaluated.

Results and Conclusions: Eighty-two patients were evaluated. Mean age at index procedure was 60.9±10.5yrs with a mean follow-up of 5.6±4years. Twenty-seven unlinked and 55 linked TEAs were performed. Mean demographics were similar between linked and unlinked cohorts with the exception of follow-up (8±4years for unlinked & 5±3years for linked, p=0.001). No difference in range of motion or elbow strength compared to the contralateral elbow was noted between linked and unlinked cohorts other than pronation strength which was significantly better in the linked cohort (74±8% vs. 100±8%, p=0.03).

The mean patient reported outcome scores were MEPI (83±16), PREE (15±18), QuickDASH (34±20). There were no differences in outcome scores, incidence of radiographic lucency's or rates of reoperation (17% vs. 24%, p=0.4) complications (32% vs. 31%, p=0.4) and revision (13% vs. 17%, p=0.3) between the linked and unlinked cohorts (p>0.05). Ten patients developed post-operative infections (7 deep and 3 superficial) including 5 patients requiring 2-stage revision and 2 who were placed on suppressive antibiotics after I&D with implant retention. Superficial wound dehiscences were successfully treated without surgery. Four unlinked prosthesis were converted to a linked design for instability. 6 patients had ulnar nerve dysfunction postoperatively with 3 patients sustaining either partial or complete nerve transection.

TEA using a convertible implant provides good patient reported outcomes at mid-term follow-up in patients with RA. The lack of differences between these two designs suggests surgeons may elect to use either linked or unlinked designs as dictated by clinical and intra-operative findings.

Factors associated with surgical intervention in osteoarthritis of the thumb carpometacarpal joint

List of authors:
Ken Nishimura*, Kosuke Uehara¹, Sakae Tanaka¹, Yutaka Morizaki¹
¹ The University of Tokyo Hospital, 7-3-1, Hongo (Tokyo)

Objectives / Interrogation: It is unclear which patients will require future surgery for osteoarthritis of the thumb carpometacarpal (CM) joint. This study aimed to analyze factors associated with surgical intervention in osteoarthritis of the thumb CM joint noted at the first visit.

Methods: Patients who visited our hand surgery outpatient clinic between May 2012 and January 2015, were diagnosed with osteoarthritis of the thumb CM joint, and were followed up for >3 years were included in this study. A total of 47 patients (80 thumbs; 10 men [15 thumbs], 38 women [65 thumbs]; mean age, 63 years) were included. Patients were divided into a group that had surgery within 3 years or a group that did not have surgery within 3 years. Sex, age, age at onset, disease duration, dominant hand, pain visual analog scale (VAS) score (resting and during use), night pain, Eaton classification, presence of orthosis, number of injections, tender part, range of motion, grip strength, pinch strength, Kapandji abduction index, palmar abduction distance, grind test results, CM joint shape on an X-ray, dorsal subluxation ratio, volar tilt, CM joint space distance, osteophyte presence, osteophyte size, and presence or absence of ossicles were extracted as variables. Univariate analysis was performed of the variables described above and a logistic regression was performed of the variables with values of p < 0.05 with the objective variable being whether surgery was performed.

Results and Conclusions: Results
Resting pain VAS (p = 0.021), during use pain VAS (p = 0.043), dorsal subluxation ratio (p = 0.006), and presence of ossicles (p = 0.048) were significantly associated with surgical intervention on univariate analysis. Logistic regression analysis using these factors as explanatory variables revealed that resting pain VAS and dorsal subluxation ratio were significantly associated with surgical intervention.

Conclusions
In patients with osteoarthritis of the thumb CM joint, resting pain VAS and dorsal subluxation ratio at the first visit were associated with future surgical intervention within 3 years. This information may be useful for predicting future surgery during the first visit.

**Prognostic factors for simultaneous arthroscopic repair of deep and superficial TFCC portion for Atzei class 2 tear: prospective one-year follow-up study**

**List of authors:**
Takeshi Egi*, Masato Shigi

*1 Department of Orthopaedics, Osaka Saiseikai Nakatsu Hospital (Osaka)

**Objectives / Interrogation:** Detachment of deep portion of TFCC from the ulnar fovea induces DRUJ instability. According to biomechanical studies, superficial portion of TFCC, rather than the deeper portion, contributes toward stabilization of DRUJ in pronation; therefore, it would be reasonable to repair not only the deep but also superficial portions. We hypothesized that simultaneous arthroscopic repair of both portions would be effective for Atzei class 2 tear. This prospective study examined the postoperative outcomes and prognostic factors in patients who underwent the procedure.

**Methods:** We conducted a prospective study which included 33 patients [mean age, 31 years (range, 13-59 years)]; all patients were diagnosed with Atzei class 2 tears by physical examinations, MRI and DRUJ arthroscopy. The mean ulnar variance was +1.1 mm (range, -1 to +4 mm) on radiographs. Arthroscopic TFCC repair was performed using meniscus mender instruments; using 2-0 Fiberwire®, the deep portion was repaired into the fovea through radiocarpal and two dorsal DRUJ portals. Simultaneously, the superficial portion was repaired to the capsule using 3-0 PDS®. Postoperative subjective data were collected every 3 months until a year by Quick DASH score; Mayo wrist score; and grip strength.

**Results and Conclusions:** 3 cases required ulnar shortening osteotomy later. Another 2 cases stayed unsatisfied scores at a year, so 5 cases were categorized the poor. Mean Mayo wrist scores increased from 61 points to 77, 86, 90, and 93, respectively. Mean Quick DASH scores improved from 33 points to 22, 12, 7, and 6. For percentage of grip strength of the contralateral side, the preoperative average improved from 72% to 70, 82, 91, and 98.

As a result of univariate analysis between two groups depending on the results, high ulnar variance and workers compensation insurance users were associated with poor outcome, but the other points were unrelated, such as age, gender, preoperative subjective and objective score and smoking.

Considering the outcomes were excellent, this anatomical reconstructive procedure is recommended for the patients with Atzei class 2 TFCC tear except for workers compensation insurance users and high ulnar variance cases.

Clinical Outcomes With the Amandys® Wrist Implant: Results of Seven Patients

List of authors:
Benjamin Hope*, Greg Couzens, Mark Ross*
1 Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: The Amandys is a free interposition pyrocarbon implant that is designed to replace the lunate, proximal one-third to two-thirds of the scaphoid and the proximal capitate. It preserves bone in the carpus and radius and it does not compromise other options such as total fusion, total wrist replacement or proximal row carpectomy with capitate resurfacing. The design allows for a good range of stable movement whilst preserving the "dart-throwing motion". Its three axes of movement allow it to act as a mobile and adaptive spacer which can slide, roll and rotate. This study examined clinical and patient-reported outcomes of the Amandys implant in seven patients.

Methods: In our unit we treated seven patients with interposition arthroplasty using the Amandys implant. One of these patients had a primary diagnosis of Kienböck's disease. Median age at surgery was 58 years (range 41 - 67 years). Five patients had surgery on the dominant side. The median follow-up period was 24 months (range 3 - 73 months).

Results and Conclusions: Patients reported a median improvement in pain from 56 at pre-operative assessment to 36.5 at most recent follow up. Median PRWHE score decreased from 58.5/100 to 46.5/100. Median QuickDASH score decreased from 64/100 to 42/100. Median grip strength was 23 kg (61% of the contralateral side) before surgery versus 22 kg (70% of the contralateral side) at most recent follow-up. Patient satisfaction at most recent follow-up ranged from 66/100 to 95/100. No adverse events such as infection, subluxation or dislocation were reported.

The Amandys implant provides an alternative surgical option to wrist fusion and total wrist arthroplasty. Additionally, the minimal bone resection required allows for preservation of the important dorsal and volar extrinsic ligaments and motion at the radiocarpal and midcarpal joints.

Treatment of severe traumatic hand injuries

List of authors:
Hideyuki Mizushima*
1 Orthopedic surgery, Sakai city medical center (Sakai city, Osaka)

Objectives / Interrogation: Introduction: Severe traumatic hand injuries are difficult to treat, even for experienced hand surgeons. This study evaluated treatment outcomes. Severe traumatic hand injuries were defined as bone and joint injuries involving the carpal and metacarpal bones, with associated soft tissue injuries, or soft tissue defects with and without bone and joint injuries.

Methods: Materials: We reviewed 21 cases (men, 17; women, 4; average age, 46.1 years) of severe traumatic hand injuries treated between 2009 and 2017. The injuries included: amputation at a metacarpal or carpal bone (8), bone and joint injury between carpal and metacarpal bone, with associated soft tissue injury (4), and soft tissue defect with and without bone and joint injury (9).

Results and Conclusions: Results
Osteosynthesis and arthroplasty were performed in 13 and 5 cases, respectively. Tenorrhaphy, vascular anastomosis, and nerve suturing were performed in 13, 9, and 7 cases, respectively. A free or pedicled flap and skin grafting were needed in 10 and 13 cases, respectively. Amputated hands were saved in 6 of 7 cases. Microsurgical technique was needed in 13 cases. For functional recovery, joint mobilization, tenolysis, and free or local flaps were performed in 12, 9, and 13 cases, respectively. The average number of procedures for each case was 5.8.
Summary
Most cases of severe traumatic hand injury require multiple operations, leading to prolonged treatment, and functional disorders, such as contractures, tend to persist. Optimal treatment requires evaluation of the injured hand at the first visit and determination of the treatment goal in each case. Additional operations, such as joint mobilization, tenolysis, and free or local flaps must be effectively performed.

Predictors of outcome in untreated carpal tunnel syndrome: results of a longitudinal cohort study

List of authors:
Christina Jerosch-Herold*, Julie Houghton1, Ed Wilson2, Julian Blake3, Lee Shepstone1
1 University of East Anglia (Norwich)
2 Institute of Public Health, University of Cambridge (Cambridge)
3 Norfolk and Norwich University Hospital (Norwich)

Objectives / Interrogation: Several prognostic studies have been published which identify predictors for success in carpal tunnel syndrome (CTS) treated either operatively or by steroid injection. However, not all patients undergo surgical or non-surgical treatment or indeed need it. The purpose of this study was to describe the outcome of untreated CTS and explore what factors assessed at baseline are predictive of symptom severity at 18 months follow-up.

Methods: We conducted a prospective cohort study of patients diagnosed with CTS between 2013 and 2017 and followed up every 6 months up to 1.5 years. Data were collected through patient reported questionnaires including sociodemographics, clinical symptom severity using the shortened Boston Carpal Tunnel Questionnaire (BCTQ), hand function, general, physical and psychological health and quality of life. A general linear model was used to identify independent, baseline predictors of BCTQ symptom score at 18 months.

Results and Conclusions: A total of 626 patients were enrolled into the study. Of these 161 (25%) did not receive a steroid injection or surgery for their CTS over an 18 months follow-up and were included in this analysis. The median electrodiagnostic severity in this sub-group was grade 2 (mild). Mean baseline symptom severity assessed by shortened BCTQ was 2.4 (SD=0.82) decreasing to 1.8 (SD=0.83) by 18 months. The majority (68%) were female and the mean age was 58.5 years (SD=12.3). Over 41% had reported symptoms for more than a year.

Four independent baseline predictors of higher BCTQ at 18 months were identified: higher BCTQ scores at baseline (p<0.001), higher levels of comorbidity (p=0.009), female sex (p=0.005), and the absence of diabetes (p=0.027).

Where patients decline treatment or surgical intervention has become subject to restrictive policies, the predictive factors identified from this study will help to inform likely prognosis and aid shared decision-making.

Can We Use Clinical Radiographs and Three-dimensional Computer Tomography (CT) Scans to Evaluate Intracarpal Measurements?

List of authors:
Ronit Wollstein*, Aviv Kramer2, Catherine Petchprapa1
1 New York University School of Medicine (Huntington Station)
2 Technion, Israel Institute of Technology (Haifa)

Objectives / Interrogation: In articulations, the morphology of the joint dictates the way forces will travel through it. Understanding wrist structure and consequently function is complicated by multiple joints and ligamentous structures leading to a limited ability to diagnose and treat wrist conditions. Our purpose was to assess the associations between intracarpal measurements performed on radiographs (2D) to measurements performed on clinical 3-dimensional (3D) computed tomography (CT).

Methods: Retrospective review of normal wrist radiographs and corresponding normal wrist CT scans. Only imaging pairs with normal carpal alignment and technically optimal imaging were included. Evaluations included lunate, capitate and wrist type, capitate circumference and area, percent capitate circumference and area that articulates with the lunate, scapholunate ligament, scaphoid, hamate, trapezoid, base of the index and middle and ring metacarpal bones.

Results and Conclusions: There were more lunates type 1 than 2. Lunate and capitate type were correlated between X-rays and CT scans (lunate: r=0.78 p<0.001, capitate: r= 0.75 p<0.001). Lunate type 2 was seen more often on CT scan. Percent lunate-hamate contact on CT was a significant predictor of lunate type 2 on X-rays p<0.001. 7.8% contact on CT scan between lunate and hamate provided a sensitivity of 100% and specificity 79.4% for type 2 lunate. Other measurements correlated between 2D and 3D measurements were capitate -base of index and ring metacarpals and capitate-hamate contact area. Other measurements were not correlated or correlated weakly. Table 1

Conclusions:
1) This study supports the use of plain films and CT scans in the clinical setting especially to evaluate lunate and capitate type.
2) The retrospective nature of this study limited the technical quality of the measurements.
3) Further study using different methods may aid in a more exact evaluation of surface contact area.

Radioscapholunate fusion under Wide Awake Surgery

List of authors:
Nur Azree Ferdaus Kamudin*, Amir Adham Ahmad^2, Shalimar Abdullah^3
^1 Universiti Sultan Zainal Abidin, Faculty of Medicine, Orthopaedic & Traumatology Department (Kuala Terengganu)
^2 International Medical University, Faculty of Medicine, Orthopaedic Department (Seremban)
^3 Universiti Kebangsaan Malaysia, Faculty of Medicine, Orthopaedic & Traumatology Department (Kuala Lumpur)

Objectives / Interrogation: Scaphoid-non-union-advance collapse (SNAC) or scapholunate-advance collapse (SLAC) is one of the associated conditions following neglected unstable scaphoid fracture. Surgical treatment for degenerative joint disease of the radioscapholunate joint is arthrodesis. We document a radioscapholunate fusion done under wide awake surgery. The reason was due to limited general anaesthetic time.

A 39-year-old male sustained a motor vehicle accident and fell onto his outstretched right hand. Three months later he presented with worsening right wrist pain and limited range of motion for the past 3 months. He initially did not seek treatment as he thought it was just a sprain until his wrist pain had worsened considerably.

Methods: The RSL joint arthrodesis was done under local anesthesia using the "Walant" technique, also known as "wide-awake-local-anesthesia-no-tourniquet". Tumescent anesthesia technique was used to infiltrate the surrounding surgical field. Four different regions were injected with 10cc of anaesthetic solution beginning from 1) the subcutaneous area over the incision site surrounding the dorsal area of the wrist, 2) subperiosteally to the distal radius, 3) into the radial-scaphoid-lunate joint and 4) surrounding the carpal region. The solution comprised of normal saline, lignocaine, sodium bicarbonate and adrenaline with the adrenaline at a diluted strength of 1:100 000.

Results and Conclusions: The surgery was successfully completed within 1.5 hours with a NPRS (numerical pain rating score) of 0/10. There was no requirement for top-up injection. Thus, it is possible to utilize wide-awake-local-anesthesia-no-tourniquet (walant) for limited wrist fusion such as in RSL arthrodesis. As this is an elective surgery, it can be done earlier under daycare surgery saving potential cost for the patient and providing earlier pain relief.

Radiographic characteristics of wrists in idiopathic carpal tunnel syndrome patients.

List of authors:
Kazuhiro Ikeda¹, Yuichi Yoshii², Tomoo Ishii²
¹ Ryugasaki Saiseikai Hospital, Tokyo Medical University Ibaraki Medical Center (Ryugasaki-city)
² Tokyo Medical University Ibaraki Medical Center (Inashiki-gun Ami-machi)

Objectives / Interrogation: Radiographic characterization of the wrist in idiopathic carpal tunnel syndrome (CTS) patients has received little attention. To determine the radiographic characteristics of wrists in idiopathic CTS patients, we compared the radiographic parameters of the wrists between CTS patients and non-symptomatic controls.

Methods: Ninety-four wrists of 62 idiopathic CTS patients and 94 wrists of 94 asymptomatic controls were evaluated. The patients and controls were age/gender matched. CTS was diagnosed by clinical findings and nerve conduction studies. The lack of symptoms was confirmed with the medical record for the controls. Patients who had a history of osteoarthritis, rheumatoid arthritis, any upper extremity trauma or hemodialysis were excluded from both groups. X-ray images of the postero-anterior and lateral views of the wrist were taken by radiology technicians who were blinded to the clinical symptoms. The postero-anterior and lateral views were obtained with wrist neutral position. Using the obtained X-ray images, the indices of radial inclination (RI), ulnar variance (UV), volar tilt (VT), scapholunate angle (SLA), and transverse and antero-posterior diameters of the wrists were measured. The radiographic parameters were measured separately by two raters. Intraclass correlation coefficient (ICC) was evaluated for the inter-rater reliability. Average of the parameters of two raters measurements were compared between CTS patients and controls.

Results and Conclusions: The ICCs of the postero-anterior view parameters were 0.58, 0.77, and 0.99 for the RI, UV, and transverse diameter, respectively (P<0.01). The ICCs of the lateral view parameters were 0.60, 0.63, and 0.91 for the VT, SLA, and antero-posterior diameter, respectively (P<0.01). UV was significantly larger in the CTS patients compared to the controls (1.7 ± 1.8mm and 0.8 ± 1.5mm for the patients and controls, respectively, P<0.01). SLA was significantly smaller in the CTS patients compared with the controls (56.0 ± 8.8 degrees and 60.0 ± 6.4 degrees for the patients and controls, respectively, P<0.01). There were no significant differences in the RI, VT, transverse and antero-posterior diameters.

In this study, significant differences in the ulnar variance and scapholunate angle were observed. This suggests that the imbalance of radioulnar bone length and the lower carpal tunnel height were characteristic factors of CTS. The results may be useful for identifying the preclinical conditions of CTS.

Corrective intra-articular osteotomy after malunion in Bennett fractures: surgical technique and first results

List of authors:
Kjell Van Royen*, Jean Goubau
1 AZ Sint Jan Brugge, UZ Brussel (Brugge)

Objectives / Interrogation: A malunion with an intra-articular gap after a Bennett’s fracture can lead to a painful trapeziometacarpal (TMC) joint and patients can develop early osteoarthritis of the thumb base. We hypothesized a correction through an intra-articular osteotomy to be a valid procedure for those patients who present with pain and impaired strength.

Methods: Three patients were seen with a painful and debilitating malunion after a period of minimum 8 months that did not respond to conservative treatment. The malunion was diagnosed using conventional radiographs and confirmed with a cone beam CT scan. A Gedda-Moberg incision was used to expose the TMC joint and the intra-articular gap was identified. A closing wedge osteotomy was then performed under fluoroscopic control, thus excising the intra-articular gap and restoring joint congruency. The osteotomy was fixed with 3 1.5 mm screws. Patients were immobilized for a period of two weeks before active movement was initiated. Pain, mobility of the thumb and strength were assessed before the intervention and 6 months postoperative. A cone beam CT scan was used to control union of the osteotomy after 6 months.

Results and Conclusions: Mean pain according to the visual analogue scale decreased from 88/100 to 7/100. Opening of the first web, MP mobility, opposition and retropulsion did not change. Mean grip strength improved from 34 kg to 40 kg (42 kg contralateral), mean key pinch improved from 4 kg to 10 kg (10 kg contralateral) and mean precision pinch improved from 5 kg to 7 kg (7 kg contralateral). All three fractures showed union and restoration of the joint congruency after 6 months.

Intra-articular osteotomy of the first metacarpal base is a new technique to treat a malunited Bennett’s fracture. The first results show excellent pain relief, preservation of the joint mobility and restoration of strength to a near normal level. Larger studies with longer follow-up are needed to evaluate whether the procedure can prevent the natural progression towards osteoarthritis of the TMC joint.

Bennett’s fracture, malunion, trapeziometacarpal joint, osteoarthritis
Early active mobilization after flexor tendon grafts using extrasynovial tendons

List of authors:
Koji Moriya*, Takae Yoshizu*, Yutaka Maki*
1 Niigata Hand Surgery Foundation (Seiro-machi)

Objectives / Interrogation: Early active mobilization (EAM) is rarely performed after tendon grafting because of healing process of grafted tendon and weakness of junction between the distal end of the graft and the base of distal phalanx. We evaluated the outcomes of EAM after flexor tendon grafting using extrasynovial tendons.

Methods: Between 2008 and 2017, the flexor digitorum profundus (FDP) tendons of seven digits in seven patients were reconstructed using extrasynovial tendons, including the palmaris longus, plantaris, and extensor digitorum longus via single- or two-stage procedures. Six of the seven patients were male, and the average patient age was 48 (range, 30-66) years. The injuries involved two middle, two ring, and three little fingers. Three patients underwent single-stage reconstructions to treat a neglected FDP avulsion injury, a neglected zone 1 FDP laceration, and a subcutaneous FDP rupture caused by infection (one patient each). Four patients underwent second-stage reconstruction to treat flexion contractures developing after flexor tenolysis or tendon grafting (one patient each) and flexor tendon rupture after zone 2 primary repair (two patients). The tendons were proximally sutured into appropriate FDP tendons via end-weave anastomoses; the distal end of the graft was anchored using small bone anchor, interlacing suture to the distal stump of the FDP, and pull-through technique. For the first 3 postoperative weeks, the digits were mobilized with a combination of active extension and passive and active flexion in a protective splint. The follow-up period averaged 18 (range, 7-45) months.

Results and Conclusions: The passive range of motion of the proximal and distal interphalangeal (PIP and DIP) joints prior to flexor tendon grafting averaged 144 (range, 115-172)°. The mean active range of motion of these joints at final evaluation was 123 (range, 65-170)°. Using Strickland's formula to assess staged flexor tendon reconstruction, the mean recovery of active motion was 83 % (range, 50-100%). Using the Tang criteria, reconstruction of one digit was graded excellent; reconstructions of three were graded good, two fair, and one poor at final evaluation. We encountered no tendon rupture and no finger required tenolysis.

SUMMARY POINTS: The results indicate that extrasynovial tendons can survive and heal during EAM, with few adhesions of functional significance. We believe that our distal juncturing technique allows stresses encountered during EAM to be withstood.

Early active mobilisation; extrasynovial tendon; flexor tendon injury; tendon grafting
Avoiding vein grafts for arterial repair in avulsion amputations of thumb - Case series

List of authors:
Chaitanya Dodakundi*, Khalid Alawadi¹
¹ Rashid hospital, Department of Trauma, Hand and Microsurgery Unit (Dubai)

Objectives / Interrogation: The first replantation of a complete thumb amputation using microvascular anastomosis in a human was successfully conducted by Komatsu in 1968. Avulsion amputations of the thumb at the level of metacarpophalangeal joints pose a tedious task for direct arterial repair, even with adequate bone shortening. Owing to the short length of princeps pollicis from the deep arch, tight working space in the first web under microscope and the associated intimal injuries, we advise transposing the radial indices artery in such cases which gives adequate length and non-injured artery for a tension free repair.

Methods: Four cases with avulsion amputations at the level of thumb metacarpophalangeal joint were followed up for a period of 11 to 14 months.

Results and Conclusions: All four were avulsion type of amputations with one occurring in a female due to rodeo type injury where the thumb was avulsed while playing a tug of war game. All four cases of avulsed thumbs survived and were followed up for a period of 12 months. K wires were removed at 5 weeks and put on physiotherapy. All patients regained a useful protective sensation with 2 point discrimination of 7 to 9 mm, with good range of movements and were able to oppose the thumb to little finger.

Conclusion: In Avulsion amputations of thumb using this method of transposing radial indices artery avoids the tedious task of vein grafts for arterial repair, reducing the operating time and improving successful outcomes in thumb reimplantations.

Predictive factors for union time in adult diaphyseal forearm fractures

List of authors: Franck Atlan*, Shai Factor, Boaz Granoth, Daniel Tordjman, Yishai Rosenblatt, Tamir Pritsch
1 Tel Aviv Sourasky Medical Center (Tel Aviv)

Objectives / Interrogation: Although open reduction and internal fixation (ORIF) by plating is the treatment of choice of diaphyseal fractures of the forearm, delayed union and non-union remain existing complications. The goal of our study was to analyze predictive factors for union time in these fractures.

Methods: We present a retrospective study on 55 patients with 86 diaphyseal forearm fractures (31 patients had both bone forearm fractures). Union times have been distributed into 2 groups (3 months or less, or more than 3 months) and then compared through a multivariate regression analysis and Fisher's exact tests in order to stress out a statistical correlation with patient demographics, fracture pattern and characteristics, associated injuries, type of fixation used, and quality of postoperative reduction.

Results and Conclusions: Overall 65.1% of the fractures achieved union within 3 months, and 34.9% did not. Among these last, 31.3% did achieve union in more than 3 months, and 4.6% had an established non-union. The use of a locking plate was statistically associated with a higher chance of union within 3 months. Moreover, the gap width in the fracture site on post-operative Xrays also appeared significantly correlated with union time. None of the other parameters showed any correlation with union time.

Conclusion: The use of locking plates in ORIF of diaphyseal forearm fractures in adults increases the chance of achieving union within 3months postoperatively, even though exempting from postoperative immobilization. Furthermore, gap width in fracture site after reduction is qualitatively and quantitatively correlated with the probability of not achieving union within 3 months.

Keywords: non union, forearm fracture, locking plate, fracture gap
Surgical technique: about a new total and isoelastic wrist implant (Prosthelast®)

List of authors:
Philippe Liverneaux*¹
¹ Strasbourg University Hospital (Strasbourg)

Objectives / Interrogation: This study describes a new total wrist implant (Prosthelast®) designed to reduce the risk of distal migration of the carpal component.

Methods: The Prosthelast® implant consists in a one-block radial implant replacing the metaphysis and the articular surface fixed to a radial elastic centromedullar wire and a carpal component in titanium with an articular condylar surface in polyethylene.

Results and Conclusions: We operated on five patients (3 male patients and 2 female patients) and followed them up for 12 months on average. Two of the patients presented with rheumatoid arthritis of the wrist and an ulnar osteotomy (Darrach procedure) was carried out at the same time of the arthroplasty. All clinical variables improved post-operatively (Quick DASH score, pain score, range of motion) except from wrist flexion which was reduced. No patients underwent revision surgery. Two patients presented with a periprosthetic radiolucent loosening around the radial component but no implant migration was observed.
Overall, the preliminary results of our case series show that the new Prosthelast® implant presents comparable short-term results to those described in literature. We will follow up the patients to verify that long-term results are as satisfactory as the short terms results.

implant; wrist; isoelastic; carpal implant; radial implant
Designing a minimally-invasive, ultrasound-guided, percutaneous technique of washout of the flexor tendon sheath: an anatomical study

List of authors:
Philippe Liverneaux*1, Etienne Boyer1
1 Strasbourg University Hospital (Strasbour)

Objectives / Interrogation: The goal of this study was to develop a minimally-invasive, ultrasound-guided technique of percutaneous washout of flexor tendon sheath on an anatomical model.

Methods: Two catheters were inserted using ultrasound guidance at the proximal and distal ends of the tendon sheath of 20 fingers of cadaveric forearms. A percutaneous injection of saline solution colored with methylene blue enabled an anterograde washout of the flexor tendon sheath.

Results and Conclusions: The technique was successful in 13 out of 20 cases. The proximal catheter was in the right position in 17 cases and in 15 cases for the distal catheter. The flexor tendons were uninterrupted in all cases and bore puncture wounds in 9 cases.
Our results showed that this minimally-invasive, ultrasound-guided technique of percutaneous washout of the flexor tendon sheath was efficient in 65% of cases and safe in 100% of cases. In case of failure of the technique it is always possible to switch to a conventional open technique.

Keywords: minimally-invasive; percutaneous washout; flexor tendon sheath
Posterior interosseous nerve to the superficial terminal branch of the ulnar nerve transfer at the distal third of the forearm through a single anterior approach: Anatomical feasibility study

List of authors:
Philippe Liverneaux*¹
¹ Strasbourg University Hospital (Strasbourg)

Objectives / Interrogation: The purpose of this study was to determine on an anatomical model, if transfer of the posterior interosseous nerve (PIN) to the superficial terminal branch (STB) of the ulnar nerve by a single approach was feasible.

Methods: The experiment was carried out on 5 fresh cadavers. Their ulnar nerves were splitted into

Results and Conclusions: All sutures were without tension and technically possible with PINs all at least 50% of the STB's diameter.
Our results demonstrate feasibility of the PIN to STB transfer through a single anterior approach on anatomical model.

Keywords:
nerve transfer; ulnar nerve; posterior interosseous nerve; interosseous membrane; ulnar nerve lesion
Injection therapy for base of thumb osteoarthritis: a systematic review and meta-analysis

List of authors:
Benjamin Dean¹, Martinique Vella Baldacchino³, Neal Thurley¹, Nicholas Riley¹, Christopher Little¹, Sally Hopewell², Andrew Carr²
¹ Nuffield Orthopaedic Centre (Oxford)
² NDORMS, University of Oxford, Botnar Research Centre (Oxford)

Objectives / Interrogation: To evaluate the effectiveness of injection based therapy in base of thumb osteoarthritis.

Methods: Design: Systematic review and meta-analysis.

Data sources: The MEDLINE and EMBASE via OVID, CINAHL and SPORTDiscus via EBSCO were searched from database inception to 22nd May 2018.

Study selection: Randomised controlled clinical trials (RCTs) of adults with base of thumb osteoarthritis investigating an injection based intervention with a comparator.

Data extraction and analysis: Data were extracted and checked for accuracy and completeness by pairs of reviewers. Primary outcomes were pain and function. Comparative treatment effects were analysed by random effects at all time points.

Results and Conclusions: In total, nine RCTs involving 504 patients were identified for inclusion after screening. All these studies compared different injection based therapies with each other, while no prospective study comparing an injection based therapy with a non injection based intervention was identified. Twenty injection based intervention groups were present within these nine trials, consisting of hyaluronic acid (9), corticosteroid (7), saline placebo (3) and dextrose (1). Only limited meta-analysis was possible due to the heterogeneity in the injections and outcomes used, as well as incomplete outcome data. Meta-analysis of two studies (92 patients) demonstrated no statistically significant difference in pain or function with corticosteroid versus hyaluronic acid in the short and medium term. Overall the available evidence does not suggest that any of the commonly used injection therapies are superior to placebo, one another or a non-injection based comparator.

Current evidence is equivocal regarding the use of injection therapy in base of thumb osteoarthritis, both in terms of which injection based therapy is the most effective and in terms of whether any injection based therapy is more effective than other non injection based interventions. Given limited understanding of both the short and longer term effects, there is a need for large, methodologically robust multicentre RCTs investigating the commonly used injection therapies.

Therapeutic interventions for osteoarthritis of the wrist: a systematic review

List of authors:
Benjamin Dean*, Neal Thurley¹, Christopher Little¹, Shwan Henari¹, Ian McNab¹, Nicholas Riley¹
¹ Nuffield Orthopaedic Centre (Oxford)

Objectives / Interrogation: To evaluate the effectiveness of interventions for osteoarthritis of the wrist in adults.

Methods: Design: Systematic review and meta-analysis.
Data sources: The MEDLINE and EMBASE via OVID, CINAHL and SPORTDiscus via EBSCO were searched.

Study selection: Randomised controlled clinical trials (RCTs) and any prospective studies of adults with wrist osteoarthritis investigating any intervention with a comparator.

Data extraction and analysis: Data were extracted and checked for accuracy and completeness by pairs of reviewers. Primary outcomes were pain and function. Comparative treatment effects were analysed by random effects at all time points.

Results and Conclusions: Three RCTs were identified for inclusion after screening and all had a high risk of bias. Two compared proximal row carpectomy (PRC) with four corner fusion (4CF) for post-traumatic osteoarthritis, while the other compared leather with commercial wrist splints in patients with chronic wrist pain, of which a small group had wrist osteoarthritis.

There is no prospective study comparing operative to non-operative treatment for wrist osteoarthritis, while there is a paucity of prospective studies assessing the effectiveness of both non-operative and operative interventions. Further research is necessary in order to better define which patients benefit from which specific interventions.

What is wrong with the total wrist arthroplasty? The alternative understanding of wrist biomechanics according to the mathematical conversion of a non-linear biomechanical system to linear one.

List of authors:
Lauren Gorelick*/1
1 Medical division of Fibioseq medical LTD (Kfar Rosh Haniqra)

Objectives / Interrogation: Only about 1200 wrist joint replacements are carried out annually in the United States compared approximately 1.2M knee joint replacement and approximately 670K hip replacement surgeries. The simple calculation based on the number of patients with degenerative wrist disease for any reason shows that patients requiring surgical wrist replacement can reach one million per year only in the United States. So, the question is: "What is wrong with the total wrist replacement?" The author of the study assumes that a concept of all existing implants ignores the rules of Nature. According to the new vision and mathematical processing of the anthropometry of the joint may be possible to convert the non-linear biomechanical system to the linear one. That will allow creating a solution for wrist replacement closed to Nature's design.

Methods: Anthropometric measurements of the wrist joint structures made on the base of the PA radiograms 210 healthy wrist joints of the adult patients. Three distances evaluated in the measurements. The first is the distance between the base of the ulnar styloid to the apex of the interfacetal ridge. The second is the distance between the apex of the interfacetal ridge and the base of the radial styloid. The third is the distance between the base of the capitate and the apex of the interfacetal ridge. The ratio between the first and second distances and the ratio of the first plus second distances and third distance were determined.

Results and Conclusions: All determined ratios were measured close to 1.5 and 1.6 with the deviation of ±0.1. The results come very close to the number of Golden Section of Fibonacci (Phi-1.618). The same proportions data accepted on the Leonardo da Vinci paintings of the wrist anatomy. According to the fractals, linear model of the wrist joint was built. Two spirals of Fibonacci were drawing according to the fractals and determined two centers of rotation in the capitate bone. The wrist joint may be described on the base of the fractals and Fibonacci golden section as are the spiral appearance of the most galaxies and the DNA spirals. Autor finds linearity of the human wrist joint. A new opportunity was opened to explain the biomechanics of the wrist joint. This opportunity logically can be defined as "A fractal theory of the biomechanics of the wrist joint." That conversation will help design and built the optimal and universal wrist joint prosthesis similar to the structure created by Nature.

Keywords: wrist arthroplasty, Golden Section of Fibonacci, non-linear biomechanical system, linear system, fractals.
Cross-Sectional International Multicenter Study on Quality of Life and Reasons for Abandonment of Upper Limb Prostheses

List of authors:
Michiro Yamamoto¹, Hitoshi Hirata¹, Jumpei Oba², Hirotaka Tanaka³, Takaaki Chin⁴, Takashi Nakamura⁵, Kevin Chung⁶
¹ Nagoya University (Nagoya)
² Kobe Gakuin University (Kobe)
³ Chubu Rosai Hospital (Nagoya)
⁴ Hyogo Rehabilitation Center Central Hospital (Kobe)
⁵ National Rehabilitation Center (Tokorozawa)
⁶ University of Michigan (Ann Arbor)

Objectives / Interrogation: The purpose of this cross-sectional multicenter study was to examine prosthesis use and abandonment among patients with upper limb deficiencies in the USA and Japan. We determined the most common reasons for abandonment and compared prosthesis users and nonusers according to a variety of demographic and clinical characteristics. We hypothesized that prosthesis users would have higher QOL than nonusers, and that patients who used myoelectric prostheses were more likely to be employed full-time. We also compared EQ-5D scores between patients and live-in proxies to determine the agreement in QOL between patients and their close relationships, hypothesizing that patient-reported QOL would be superior to proxy-reported values.

Methods: Three rehabilitation centers in Japan and one academic medical center in the USA participated. Patients aged between 12 and 75 years with unilateral or bilateral upper limb absence from the level of wrist to shoulder disarticulation were included. Two questionnaires were used, an original questionnaire on prosthesis use and the EQ-5D, which was completed by both the participant and by a live-in proxy on the participant’s behalf.

Results and Conclusions: Among 367 patients invited, 174 patients with upper limb loss participated in this study. Male patients made up 65% of the study population. The most common amputation level was trans-radial. Trauma was the most common cause of limb loss. The prosthesis rejection rate was 9% (n=16). The most common reason for abandonment was prosthesis functionality. Ten of 16 prosthesis nonusers (63%) and 59 prosthesis users (38%) were unemployed, whereas only 5 prosthesis nonusers (31%) and 87 prosthesis users (56%) were working full-time or part-time. There were no significant demographic differences between prosthesis users and nonusers including age, gender, dominant or nondominant hand involvement, cohabitation status, or health status. The mean EQ-5D utility score of prosthesis users was significantly higher than that of nonusers (p<0.01). Live-in proxies significantly overestimated and underestimated the QOL in male and female patients, respectively.

It is beneficial for society to provide intensive rehabilitation to upper limb prosthesis users and minimize prosthesis rejection because prosthesis users have greater productivity than nonusers. Furthermore, particular attention should be given to avoiding the overestimation of QOL in male patients with upper limb deficiency.

New Developments in the Minimal invasive Treatment of Severe Dupuytren's Recurrences

List of authors:
Wolfgang Lenze¹, Jörg Pattke², Christiane Kremser³
¹ Chirurgische Praxis (Bielefeld)
² Ingenieur (Berlin)
³ Biologin (Bonn)

Objectives / Interrogation: Both needle fasciotomy (PNF) and the extensive needle fasciotomy with skin graft (PNF+) are minimal invasive treatments for severe recurrent Dupuytren's contractures which follow a partial fasciectomy (PF). It is not always possible to straighten the fingers completely. Sooner or later, depending on the patients individual fibrosis diathesis a further recurrence occurs. This work presents a completely new dynamic finger splint that can permanently correct a remaining contracture after a PF or PNF/PNF+.

Methods: Two test persons both with a high fibrosis diathesis and both suffering severe recurrences following partial fasciectomy were treated by PNF+ and PNF respectively.
A 56-year-old male patient underwent PNF+ with skin graft.
The contracture in the middle joint of his small finger, left hand, was reduced from 90 degrees (Tubiana 2) to 40 (Tubiana 1, fig. 1).
The contractures in the small finger of his right hand (Tubiana 4) were eased from 50 to 0 degrees in the base joint, and 90 degrees to 50 (Tubiana 2) in the middle joint (fig. 2).
The patient designed and fabricated his own completely new dynamic splint (video 1), which he wore 2-3 times a day for 2-3 hours at a time over a duration of 8 months.
A 32-year-old female patient suffered from a contracture of 90 degrees in the middle joint of her small finger, right hand. PNF released the contracture by a mere 15 degrees and only for the short time of 4-6 weeks (fig. 3a+b). The patient wore the newly developed dynamic splint several times a day for 1-3 hours at a time and during the night she wore a more comfortable dynamic splint (video 2) to prevent fist closure.

Results and Conclusions: After 8 months using his self-designed dynamic splint, the 56-year-old patient achieved a complete release of the contractures on both small fingers to stage 0 on the Tubiana scale (fig. 4+5). This condition has remained constant since October 2017 up until today. To maintain this status, it is essential that the dynamic splint is worn for 2-3 hours every day. After just 5 months, the 32-year-old patient achieved an almost complete straightening of the finger, 83 degrees, almost Tubiana stage 0 (fig. 6).
She continues to wear both dynamic splints, day and night, but for a shorter duration.

Both fibrous cords and scars resulting from a partial fasciectomy can be stretched.
The newly developed dynamic splints can release severe recurrent Dupuytren's contractures permanently.

Dupuytren's recurrences, severe contracture, dynamic splint
The vitamin D receptor expression in skeletal muscle of women with distal radius fracture

List of authors:
kahyun kim\textsuperscript{1}, Hyun Sik Gong\textsuperscript{2}, Goo Hyun Baek\textsuperscript{3}
\textsuperscript{1} Chunchon Sacred Heart Hospital (chuncheon)
\textsuperscript{2} Seoul National University Bundang Hospital (Sungnamcity)
\textsuperscript{3} Seoul National University Hospital (Seoul)

Objectives / Interrogation: We aimed to evaluate the relationship between the VDR expression in the muscle cell and the muscle mass in women with a distal radius fracture (DRF).

Methods: We prospectively recruited 45 women over 50 years of age (mean age, 66 years) with DRF and acquired biopsy of the forearm flexor muscle. The muscle cross-sectional area (CSA) and VDR expression were measured using immunohistochemistry staining. The clinical parameters including grip strength, gait speed, body mass index (BMI), bone mineral density (BMD), and serum vitamin D levels were compared between patients grouped by appendicular lean mass index and were correlated with the VDR expression.

Results and Conclusions: Twelve patients (27%) showed a decreased appendicular lean mass index, less than the cut-off value of 5.4 kg/m\textsuperscript{2} which was suggested by the Asian Working Group for Sarcopenia. Patients with a low appendicular lean mass index had significantly lower muscle CSA (p = 0.037), but a higher VDR expression (p = 0.045) than those with higher indices. VDR expression was negatively correlated with BMI (r = -0.417, p = 0.004) and appendicular lean mass index (r = -0.316, p = 0.044). DRF patients with low appendicular lean mass index presented high VDR expression and low CSA in forearm muscle cells. This suggests that the VDR expression might be upregulated in the attempt to compensate for the decreasing muscle mass. Further studies are necessary to explore the role of VDR in the progression of sarcopenia

Repairs the donor site of the free anterolateral thigh flap.

List of authors:
Gaofeng Liang*, Yunsheng Teng1, Yongming Guo1, Junwen Dong1, Zonghai Jia1, Xiaobo Quan1
1 Weapons Industrial Health Institute(521 Hospital) (Xi an)

Objectives / Interrogation: To explore and summarize the method of repairing the donor site of the free anterolateral thigh flap.

Methods: From March 2014 to May 2015, 8 patients suffered soft tissue defects of hand, foot, including 6 males and 2 females, which were repaired by the free anterolateral thigh flap, the area of donor flap was 9.0cm×6.0cm–14.0cm×8.0 cm. The defects of donor flap were repaired by the "Reading Man" Procedure technique, the perforated and the V-Y propulsion flap, the relay flap. Avoiding to damage the perforated vascular pedicle for ensuring the blood supply of flap, and to increase the movement distance of the flap, the vascular pedicle should be released and separated appropriately and adequately. The large tension of sutured wound increased the edema and the large tension of wounds, the sufficient drainage of wound improved the blood supply of flap, raising the chance of closing the wound directly, avoiding the necrosis of flap and skin grafting.

Results and Conclusions: Results: All free anterolateral thigh flaps and all donor flaps survived, except one the relay flap whose the distal part was bruising and necrotic then. Necrotic wound healed by the flap of local transposition.

Conclusion: trying not to add the trauma of the new donor when cutting flaps, the donor of the free anterolateral thigh flap was repaired by such methods of relay flap, kiss flap, local perforation advance, the "Reading Man" Procedure, the area of the donor flap was closed directly, without skin graft. Such methods are an efficient and quick repair methods for the small defect area of such donor flap.

A free vascularized tibia graft for the infectious bony defect of upper limb

List of authors:
Gaofeng Liang*1, Yunsheng Teng1, Yongming Guo1, Junwen Dong1, Zonghai Jia1, Xiaobo Quan1
1 Weapons Industrial Health Institute (521 Hospital) (Xi an)

Objectives / Interrogation: To explore the clinical application and effect of a free fibular transplantation in the treatment of the infectious bony defect of upper limb.

Methods: Form April 2009 to January 2015, the infectious bony defect of upper limb was treated by a free vascularized tibia graft. 11 patients suffered such bony defect, including 2 humeral shafts, 6 radial backbones and 3 Ulnar backbones. The infection was confirmed by sinus secretions preoperatively and bacterial culture at the lesion intraoperatively. After debridement, the length of bone defect was 5-20 cm. 6 cases were suffered by emergency surgery, 5 cases by elective surgery, bone defects were repaired with single fibular graft for all patients. The blood supply of the free vascularized tibia graft was monitored by the fibular flap in 9 cases. All the persons, fibulas were fixed by plates, the survival of the transplanted fibula and the healing of the bone were performed by imaging assessment postoperatively.

Results and Conclusions: Results: All cases were followed up for 12 months to 39 months, with an average of 24.5 months. All transplanted fibula survived and bone defect site achieved bone healing, the averaged length of transplanted fibulas was (6 ± 20) cm. The mean healing time of graft and bone graft was (5.5 ± 1.2) months, the supplyment of bone and reception of bone were no dysfunction, no infection recurrence and no stress fracture occurred for transplantation of fibulas.

Conclusion: It is conducive to treat the infectious bony defect of upper limb by the free fibular transplantation, the bony defect of upper limb achieved high bone healing rate, it is the ideal treatment.

Keywords: bony defect, infectious, upper limb, fibular transplantation
Modified reconstruction of the defect of the distal thumb

List of authors:
Gaofeng Liang¹, Yunsheng Teng¹, Yongming Guo¹, Junwen Dong¹, Zonghai Jia¹, Xiaobo Quan¹
¹ Weapons Industrial Health Institute (521 Hospital) (Xi an)

Objectives / Interrogation: Reported clinical effects of the hallux nail flap, the part of the second phalange, the part of the third phalange, the fibular flap of the toe transplanted for remodeling and reconstructing of the defect of the distal thumb or the mid and proximal segment defect of the distal thumb.

Methods: According to the appearance of the toe, the hallux nail flap, the part of the second phalange, the part of the third phalange, the fibular flap of the toe were chosen as the donor. In 45 cases the blood circulation was reconstructed by the use of the artery of the thumb anastomosed to the artery of toe, the vein of the thumb anastomosed to the vein of toe. there were 48 cases of the defect of the distal thumb or the mid and proximal segment defect of the distal thumb.

Results and Conclusions: Results: 47 reconstructed thumb all survived. The fibular flap of the toe was necrosis in one case, which was reconstructed by the Neighbour's flap of phalange. The patients were followed-up from 1 year to 3 years (averaged 1.5 years). According to the upper limb function of the Chinese Medical Association Hand Surgery Society, excellent in 40 cases, good in 5 cases, fair in 4 cases, the excellent rate was 93.8%.

Conclusion: According to the demands of the patients, flexibly choosing the hallux nail flap, the part of the second phalange, the part of the third phalange, the fibular flap of the toe transplanted for reconstruction the defect of the distal thumb or the mid and proximal segment defect of the distal thumb. What is the principle is "what is missing, what to fill", to achieve good functions and appearance. The transplantation of four kinds of free flap from the great toe was the optimal way to reconstruct the defect of the distal thumb or the mid and proximal segment defect of the distal thumb.

The classification of mutilated injuries of the hand and the methods and the clinical outcomes of such injuries reconstructed.

List of authors:
Gaofeng Liang*, Yunsheng Teng1, Junwen Dong1, Yongming Guo1, Zonghai Jia1, Xiaobo Quan1
1 Weapons Industrial Health Institute (521 Hospital) (Xi an)

Objectives / Interrogation: To investigate the classification of mutilated injuries of the hand and the methods and the clinical outcomes of such injuries reconstructed.

Methods: From October 1996 to October 2011, a retrospective study of 195 cases of mutilated injuries of the hand was carried out, including 341 fingers. The injuries were divided into two types, including simple type and complex type. The simple type of mutilated injuries of the hand was reconstructed by the following methods of the hallux nail flap, the part of the second phalange transplanted, modified reconstruction, and full-shaped reconstruction. The complex type was divided into seven subtypes, which were reconstructed primarily by the composite methods of the free anterolateral thigh flap, the hallux nail flap, the part of the second phalange transplanted, dorsalis peals flap.

Results and Conclusions: Results: Venous crisis happened in 14 cases, thrombus formed in anastomosis, venous crisis was solved by vascular grafted and the blood vessels re-matched. Arterial crisis happened in 8 cases, thrombus formed in 2 cases, arterial crisis was solved by vascular grafted and the blood vessels re-matched. Vascular pedicle reversed in 3 cases, arterial crisis was solved by re-adjusting the place of the blood vessels and re-anastomosis. Soft tissue tension is too large in 3 cases, arterial crisis was solved by re-stitching the wound and skin grafted. The distal part of the flap was necrosis in 6 cases, the wound healed by debridement and skin grafted, the rest of the organization survived primarily. According to the upper limb function of the Chinese Medical Association Hand Surgery Society, the upper limb partial function of the evaluation trial standard; reconstructed thumbs were excellent in 60 cases; good in 33 cases, fair in 16 cases, reconstructed fingers were excellent in 87 cases; good in 114 cases, fair in 23 cases, poor in 8 cases.

Conclusion: The classification of mutilated injuries of the hand is useful for the selective of proper operative procedures, it guides and regulates the reconstruction of mutilated injuries of the hand, the clinical outcome is satisfactory with a good appearance and function after reconstruction.

Julian Dorn*1, Robert Kemper2, Eva-Maria Baur2
1 Practice for Plastic- and Handsurgery, Dr. Baur & Dr. Fromberg (Murnau am Staffelsee)
2 Practice for Plastic- and Handsurgery, Dr. Baur / Dr. Fromberg (Murnau am Staffelsee)

Objectives / Interrogation: Since the introduction of arthroscopic refixation methods for ulnar avulsion lesions of the TFCC (Palmer IB) minimal invasive treatment has been continually gaining importance over the past two decades. A crucial progress was the anatomically correct transosseous reinsertion of the foveal attachment as described by Nakamura and others. From 2007 to 2018 we treated close to 100 patients by a modification of Nakamura's technique, achieving promising results in short-term follow-up. Interestingly most of our patients are concerned "chronic lesions" with >6 month of symptoms. There is still little data about long-term results of arthroscopic foveal refixation why we decided to clinically review an early sample of our collective.

Methods: Our operational technique is arthroscopically assisted transosseous refixation by opening the 6th extensor sheath, drill the holes on the floor of the sheath and tie the knot there. After refixation we gather the 6th extensor sheath, because especially in chronic cases it is commonly widened.

For this study we reexamined 10 patients with the longest follow-up times with modified Mayo-Wrist- and QuickDASH-score and clinically checked stability of the DRUJ. The average postoperative interval was 97 months (range 82-119 months). Average time since trauma / onset was 12 months (range 1-30 months, with 7 patients with >6 months of symptoms).

Results and Conclusions: Consistent with our former data every patient showed good stability of the DRUJ and satisfying to good pain relief. Pain at rest (or with load) was reduced from preoperative VAS 2,8 (6,5) to 0,5 (2,4). Average strength in pro-/supination and grip was equal in comparison to the contralateral side. Range of motion in pro-/supination was equal as well. Interestingly in an earlier follow-up (average 29 month after the operation) extension-flexion ROM was reduced (89%) but recovered in the long-term follow-up (97%).

An average modified Mayo-Wrist-score of 92 and a QuickDASH value of 14 points shows a good functional outcome.

Conclusions
Our data confirms the long-term efficacy of transosseous refixation of the TFCC on the floor of the 6th extensor sheath combined with a gathering of the sheath, even in patients with >6 months of symptoms.

By now it is well known, that refixation back to the bone is an important issue in the repair of foveal disruptions of the TFCC. Maybe the gathering of the 6th extensor sheath plays an additional important role for long-term stability, especially in the chronic cases.

Treatment of coronal fracture of the hamate with fixation of titanium miniplate crossing carpometacarpal joint

List of authors:
Yong Yang*, Ge Xiong1, Liying Sun1, Shanlin Chen1, Wen Tian1
1 Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To evaluate the treatment effects of coronal fracture of the hamate with fixation of titanium miniplate crossing carpometacarpal joint.

Methods: From December 2011 to June 2015, 17 patients suffered from coronal fracture of the hamate were treated with fixation of titanium miniplate crossing carpometacarpal joint. The patients were all males, aged from 18 to 43 years, average (28.9±7.0) years. According to the classification of Ebraheim's hamate body fracture, 2 cases were type A, 5 cases were type B, 10 cases were type C. All the hamate fractures were exposed by dorsal approach. After the reduction, the fractures were fixed with titanium miniplate crossing carpometacarpal joint dorsally. The Disabilities of the Arm, Shoulder and Hand (DASH), visual analogue scale (VAS), MAYO Wrist Score, grip strength and ring and small fingers total active motion (TAM) were employed to evaluate the functions. All patients took X rays during follow-up.

Results and Conclusions: All 17 patients were followed up from 13 to 42 months, average (18±7) months. Hamate fractures were healed from 6 to 10 weeks, average (7.1±1.1) weeks. Except two cases, all titanium miniplates and screws were removed at 3 to 4 months post-operatively. At final follow-up, DASH scores were from 0 to 10.8, with an average 1.9±3.5. MAYO Wrist Scores were from 65 to 100, with an average 93.8±10.7. Grip strength averaged (42.4 ± 4.8) kg on the injured side and averaged (41.6 ± 2.9) kg on the contralateral side. TAM of the ring and small fingers were 280°±5° and 271°±6° on the injured side, meanwhile 281°±3° and 272°±4° on the contralateral side. Grip strength and TAM of both sides showed no statistical significance. Conclusions Coronal fracture of hamate could be fixed with titanium miniplate crossing carpometacarpal joint. The procedure could provide stability and allow early motion, which could help maintain joint reduction and obtain reliable fracture healing and good hand function. This technique may be an optional choice in clinical practice.

Pyrocarbon Interposition Arthroplasty (Amandys ® ) for the Wrist: A Prospective Case Series

List of authors:
Rahel Meier*, Carsten Surke¹, Dietmar Bignion¹, Esther Vögelin¹
¹ Inselspital, Universität Bern (Bern)

Objectives / Interrogation: Post-traumatic, arthritic or degenerative destruction of the midcarpal and radiocarpal joint is difficult to treat. An arthroplasty with a free interposition pyrocarbon implant, Amandys ® , is proposed for the treatment of extensive destruction of midcarpal and radiocarpal joints. The purpose of this study was to evaluate the clinical and patient-rated outcome.

Methods: From October 2014 to March 2018, 17 Amandys ® interposition arthroplasties were performed. Patients were assessed preoperatively (baseline), at 3, 6, 12 and 24 months after surgery. Radiographs, range of motion and grip strength were evaluated. In addition, patients rated their pain using a numeric rating scale (NRS) as well as function and overall assessment of their condition and satisfaction using the Disabilities of the Arm, Shoulder and Hand (DASH) questionnaires.

Results and Conclusions: One patient died in the early follow-up period. Thus 16 patients were followed up with a mean of 18 months (rang 6-36). 12 (75%) patients were male and the median age was 56.5 (range 54.8 - 61.8) years. The indication to perform the operation was in 6 cases a SNAC in 5 cases a SLAC and in 3 cases a SCAC wrist. Another case was due to rheumatoid arthritis and one due to avascular necrosis of the scaphoid. 63 % of the patients had previous surgery. At last follow-up the mean pain score decreased from NRS 6.6/10 preoperatively to 2.4/10 postoperatively, the DASH score from 46 to 37 points respectively. 69% of the patients were satisfied or very satisfied. The postoperative mean range of motion (ROM) for flexion/extension was 56° (range 15-110), for pro-/supination 157° (range 115-180) and for radial-/ulnarduction 25° (range 10-40). The mean grip strength was 19kp (range 8-38), which averaged 64% of the unaffected side. All implants remained intact but there were two early dislocations with the need of revision and reposition of the implant. 3 patients developed a subsequent arthrosis with the need of revision and reposition of the implant with an average of 2.6 years (range 2-3) after primary surgery. After revision two of the patients were satisfied, the third followed a total wrist fusion. There was no infection.

Patients experienced a significant reduction in pain and DASH Score. Therefore, despite a 31% revision rate, preserving wrist mobility, Amandys ® interposition arthroplasty can still be a reasonable alternative for the treatment of extensive destruction of midcarpal and radiocarpal joints.

Treatment of mallet fractures with a transverse two-hole mini plate

List of authors:
Ge Xiong
1
1 Dept. of Hand Surgery, Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To evaluate the clinical results of the transverse two-hole mini plate for the mallet fractures.

Methods: We investigated 155 patients (157 fingers) who suffered from the mallet fracture and treated with a transverse two-hole mini plate. The series comprised 122 men and 33 women with an average age of 33.2±10.9 years (range: 16-62 years). The injury occurred in the right hand in 90 patients and in the left hand in 65. The little finger was the most commonly injured digit (66 cases), followed by the ring finger (48 cases), long (30 cases), index (11 cases) and thumb (2 cases). The acute cases (the time between the injury and operation was less than 2 weeks) were 126 while the chronic cases were 29. Preoperative anteroposterior and lateral radiographs were obtained in all cases. On the lateral view, the articular surface of the fragment was measured as a percentage of the entire joint surface.

Results and Conclusions: The average articular surface of the fragment was measured at 39% (range: 12-67%) of the joint surface with subluxation occurred in 31 injured fingers. Mean follow-up was 5.0±3.9 months. The extensor rupture was only found in 6.3% acute cases. All the patients got bone union. The average flexion of the distal interphalangeal joint was 66.5°±14.0°, and extensor lag was 2.3°±3.6°. According to Crawford's criteria, 47 out of 157 fingers got excellent results, 95 got good results, and 15 got a fair result. The complication rate 8.9%, including superficial infection, skin irritation and joint steps. Statistical analysis only showed a negative correlation between age and range of motion with a coefficient of -0.293 (p=0.026).

mallet fracture; internal fixation; transverse two-hole plate; distal interphalangeal joint
Histopathology findings of the lunate in stage III Kienböck's disease

List of authors:
Ge Xiong*¹
¹ Dept. of Hand Surgery, Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: The etiology of Kienböck's disease is unclear so far. Usually it is described as avascular necrosis of the lunate. Although histological research of the whole Kienböck lunate has been reported, the focus was put on comparing the histological pictures with their correlated MRI images. The authors hypothesize that the progress of Kienböck's disease can be speculated by analyzing different tissue types in different parts of the Kienböck lunates.

Methods: Five lunates from patients with stage III Kienböck's disease and one normal lunate were sampled. They were sectioned, H&E stained, and observed with an Olympus Brightfield microscope. The whole lunate was recorded with the NanoZoomer Digital Pathology system for further analysis.

Results and Conclusions: Results In the normal lunate, the bone trabeculae had a uniform distribution with fatty marrow filling the interspace between the trabeculae. In Kienböck lunates, the trabeculae fracture and necrosis were located in the central part with massive fibrous granular tissue proliferation. There was also some chondroid metaplasia at the palmar and dorsal ends. The trabeculae of the KD lunates were significantly thicker than in the normal lunates. The necrosis was localized around the fracture sites instead of in the whole lunate. Such focal necrosis is very common in different types of fracture ends. Even in stage III Kienböck lunates, the vessels were quite abundant. There was no sign of avascular necrosis for the whole lunate. Conclusions There is neither massive bone necrosis nor obvious avascular sign in our histopathology observations. We suggested that Kienböck's disease should be described as lunate nonunion advanced collapse instead of avascular necrosis.

Risk factors contributing to the early implant fracture of AVANTA silicone implant for the treatment of MP joint arthroplasty

List of authors:
Takuji Iwamoto*, Taku Suzuki¹, Noboru Matsumura¹, Masaya Nakamura¹, Morio Matsumoto¹, Kazuki Sato¹
¹ Department of Orthopaedic Surgery, Keio University School of Medicine (Tokyo)

Objectives / Interrogation: Flexible hinge arthroplasty has been the most accepted and widely performed technique for the treatment of MP joints deformities in rheumatoid arthritis (RA), however, the rate of implant fracture remains considerable. The purpose of this study was to identify the risk factors that affect the early implant fracture of AVANTA silicone implant using multiple logistic regression analysis.

Methods: We performed a retrospective review of all patients with MP joint arthroplasty in RA patients between 2008 and 2012. One hundred and thirteen fingers in 31 patients with a minimum follow-up period of 3 year were included in this study. The affected joints were index 29, middle 26, ring 29 and little 27. The average age at the time of surgery was 62 (range 37-86) years and all cases were female. The apparent implant fracture or severe deformity in either the coronal or the sagittal plane by plain radiographs within three years after surgery was regarded as the early implant fracture. Patient records were reviewed for the following potential risk factors: age, affected fingers, preoperative ulnar deviation angle, MP joint ROM before surgery and one year after surgery. Univariate regression analyses by Mann-Whitney test or Kruskal-Wallis test were performed. Multiple logistic regression analysis was conducted to identify the association between early implant fracture and selected risk factors.

Results and Conclusions: The early implant fracture was detected in 29 fingers (26%). Univariate analysis showed there to be significant association between the early implant fracture and MP joint ROM before and one year after surgery, especially for flexion angle (P<0.001). Multiple logistic regression analysis showed MP joint flexion angle one year after surgery as an independent risk factor for the early implant fracture (odds ratio 1.07, p<0.01). The cut off value of MP joint flexion calculated with ROC curve was 60 degree (sensitivity 0.48, specificity 0.91). Our study suggested that postoperative flexion angle correlates with the early implant fracture of AVANTA silicone implant. The flexion angle should be limited no less than 60 degrees.

The Thompson procedure for treating chronic mallet finger with swan neck deformity

List of authors:
Yan Chen*, Danmou Xin¹, Zhiming Zhao¹
¹ Affiliated Puai Hospital of Tongji Medical College (Wuhan)

Objectives / Interrogation: To evaluate the outcomes of treating chronic mallet finger with swan neck deformity with Thompson procedure.

Methods: Eighteen cases of chronic mallet finger with swan neck deformity were treated with the Thompson procedure from June 2013 to December 2017. Ranges of motion of the distal interphalangeal (DIP) and proximal interphalangeal (PIP) joints were measured both pre-and postoperatively. The treatment outcomes were evaluated using Abouna and Brown criteria.

Patients characteristics
Thompson procedure for mallet finger
Results and Conclusions: Results: All the patients were follow-up for 4 to 22 months with an average of 12.5 months. At the final follow-up the average extension lag of the DIP joint was -6° (range, -10° to -5°), while that of the PIP joint was -4° (range, -30° to 0°). Flexion was 61° (range, 45° to 85°) for the DIP joint and 90° (range, 80° to 110°) for the PIP joint. The swan neck deformity was corrected in all the cases. 2 cases were seen mild Boutonniere deformity and a dimple at the proximal tied end of the tendon graft was seen in 1 case. Assessment by Abouna and Brown criteria revealed that 15 of 18 patients were recognized as cured and 3 as improved.

Conclusions: Thompson procedure provides a predictable method for correcting loss of DIP joint extension with PIP joint hyperextension. It is an effective technique for treating chronic mallet finger with a swan neck deformity.

Traumatic Brachial Plexus palsy: How Accurate is the Pre-operative Diagnosis?

List of authors:
Peter Murray*, Yan Chen, Michael Wood
1 Mayo Clinic (Jacksonville)
2 Affiliated Puai Hospital of Tongji Medical College (Wuhan)

Objectives / Interrogation: Brachial plexus injuries are devastating injuries and the pre-operative diagnosis can be difficult despite current imaging techniques and other diagnostic modalities. Purpose of this study was to assess at the individual nerve root level the accuracy of pre-operative diagnosis following evaluation by physical examination, imaging (CT, MRI) and electrophysiologic (EMG).

Methods: Consecutive patients with non-penetrating traumatic brachial plexus injury requiring surgery by the same surgical team between 2005 to 2016 were included in the study. Pre-operative assessments of nerve root injury were made at individual nerve root levels using physical examination, MRI, CT myelogram, and EMG. The results were compared to intraoperative findings. Patient demographics were also recorded.

Patient characteristics

Results and Conclusions: Results: Sixty patients were included in the study. Fifty-four patients had CT myelogram, MRI or both. Fifty-five patients had EMG. All patients had a physical examination. Overall, the accuracy of CT myelogram/MRI was 77.8%, physical examination was 76.7% and EMG was 73.1%. The greatest accuracy of each of the tests was for injury diagnosis at the T1 nerve root: CT/MRI 88.9%, Physical Examination 81.7% and EMG 76.4%. CT/MRI and EMG were least accurate at C5 (64.8% and 69.1) while physical examination was least accurate a C7 (60.7%). When considering combinations of tests, the greatest accuracy was again seen at T1. Injury status of the T1 nerve root was also the most accurately diagnosed level among patients with a BMI > 30. CT myelogram/MRI and physical examination were equally accurate in the pre-operative diagnosis among the >30 BMI subgroup.

Discussion and conclusion: Based on the results of this study, CT myelogram/MRI is more reliable in the pre-operative assessment of patients with brachial plexus injuries than either physical examination or EMG. The pre-operative status of the C8 and T1 nerve roots were more accurately assessed in this study compared to other nerve roots regardless of the type of testing performed suggesting that lower trunk abnormalities were easier to diagnose.

Treatment of scaphoid non-unions by an anterior graft of the 1,2-intercompartmental supraretinacular artery vascularized bone graft

List of authors:
Camilo Chaves*, Ghada Asmar2, Fanny Billac3, Marc-Oliver Falcone4
1 Université Paris XI (Le Kremlin-Bicêtre)
2 Ramsay Generale de Santé - Hôpital privé Paul d’Egine (Champigny sur Marne)
3 Université Paris 5 (Paris)
4 Ramsay Generale de Santé - Hôpital privé Paul d’Egine, Clinique Internationale du Parc Monceau (Champigny sur Marne)

Objectives / Interrogation: Scaphoid non-union is a frequent complication that affects up to 15% of scaphoid fractures and leads to loss of strength and mobility which burdens the healthcare system directly and indirectly. One of the available treatments is the vascularized bone graft from the distal radius, pedicled on the intercompartmental supraretinacular artery 1-2 (1,2 ICSRA), and grafted on the scaphoid by a dorso-radial approach as described by Zaidemberg. This technique is however limited to the treatment of non-unions of the proximal pole, without significant bone loss or carpal collapse.
This thesis evaluates the feasibility and the functional and radiological outcomes of a palmar graft of the vascularized bone graft pedicled on the 1,2 ICSRA for the treatment of non-unions of the neck, waist, or body of the scaphoid.

Methods: An anatomical study on eleven wrists evaluated the feasibility by measuring the pedicle length and the arc of rotation between the radial donor site and the palmar graft site on the scaphoid.
A monocentric, retrospective, clinical study included patients presenting a non-union of the neck, waist or body of the scaphoid operated between 2011 and 2018. The primary outcome measurements were the union rate and the simplified "disabilities of the arm, shoulder and hand questionnaire " (QuickDASH).

Results and Conclusions: The average length of the pedicle was 20.4 mm (16-26 mm). The arc of rotation of the graft was 122° (91-155°).
Eighteen patients were included with an average follow-up of 33.9 months (6-75 months). The average QuickDASH score was 10.4 (0-45). The union rate of the grafts was 88.9% without any displacement or failure of fixation.
Several vascularized bone grafts have been described for the treatment of scaphoid non-unions but there is no consensus on the best therapeutic choice.
The palmar graft of the vascularized bone graft pedicled on the 1,2 ICSRA is feasible and offers good clinico-radiological results for the treatment of non-unions of the neck, waist or body of the scaphoid. By expanding the classical indications of the vascularised bone graft described by Zaidemberg, this thesis provides new elements for the understanding and treatment of scaphoid non-unions.

Risk Factors of Carpal Tunnel Syndrome for Male Patient Undergone Carpal Tunnel Release

List of authors:
Jun-Ku Lee*, Soo-Hong Han
1 Seoul Paik Hospital, Inje University (Seoul)
2 CHA Bundang Medical Center (Seongnam-si)

Objectives / Interrogation: Although the major cause of carpal tunnel syndrome (CTS) remains idiopathic, many male CTS patients are clinically different from female patients and often have specific risk factors associated with their conditions. An accurate analysis of such propensity has yet to be established. The purpose of this study is to compare male and female patients by analyzing the risk factors associated with CTS patients who underwent surgical treatment, with focus on their occupation.

Methods: retrospective chart review of 818 patients with CTS was performed to identify the associated risk factors. Patients were stratified by gender: female (n = 707, 86.4%) and male (n = 111, 13.6%). The mean patient age was 54.5 (range: 16-85 yr.) for all groups. The medical history and risk factors of each patient was thoroughly reviewed by medical charts and telephone survey. We categorized the risk factors of CTS into 7 categories: anatomic, neuropathic, inflammatory, alteration of fluid balance, distal radius fracture associated, occupational risk factor related, and idiopathic. Occupations of CTS patients were divided into high-risk occupations (vibratory tools, assembly jobs, and food processing and packaging jobs, and other occupations of repetitive wrist motion and forceful gripping) and non-risk occupations. All variables were analyzed with chi-square or Fisher's exact test for differences between men and women.

Results and Conclusions: The number of individuals with known risk factors of CTS was greater in male, compared to that of female patients; 97 (87.4%) male patients had the risk factors of CTS, while 361 (51.1%) female patients (p < 0.001) did. In subgroup analysis of risk factors, male patients had frequent risk factors in neuropathic, inflammatory, and alteration of fluid balance (p < 0.001). Occupational risk was strongly associated with male gender (p < 0.001).

Male CTS patients who underwent surgery are more likely to have a reason and have many occupational risk factors than women.

Combination foot flaps for digit reconstruction: A prospective analysis of 37 cases

List of authors:
Guangliang Zhang*, Jihui Ju, Ruixing Hou
1 Ruihua affiliated hospital of Soochow University (Suzhou)

Objectives / Interrogation: Traumatic digit amputations could compromise pinch and grasp functions of the digits. Combination foot flaps for digit reconstruction was previously introduced by our group as an alternative method for toe-to-hand transfer[1]. The aim of this study was to analyze our experience with the combination foot flaps and to present the surgical refinements that were introduced.

Methods: Between 2009 and November 2017 a total of 37 combined flap digit reconstructions were performed on 37 patients with a median follow-up of 27.4 months (range 11 - 78). Of the 37 combined flap digit reconstructions, thumbs were reconstructed in 23 patients, index fingers in 8 patients, middle fingers in 3 patients, ring fingers in 2 patients and small finger in one patient. 21 combination flaps were based on one pedicle while the others were on two pedicles (Finger1). 12 cases were done in the first stage and the remaining 25 in the second stage. The median operation times were 6.7 (range 3.5 - 13) hours.

Results and Conclusions: The shape and size of the reconstructed thumbs or fingers were comparable to the corresponding thumb and fingers on the uninjured side, except for two, which required debulking. The MHQ score of the repaired hand was 80.3 ± 5.2 points. The sensation of the reconstructed digital pulp was 10.0 ± 3.1 points. Partial necrosis occurred in three flaps (4.1%). Two palmar flaps (2.7%) were bulky. Contracture of first web occurred in two cases (2.7%). Wound dehiscence of donor site was observed in three patients (8.1%). Toe nail deformity occurred in one case (2.7%). The combination foot flap is a good option for digit reconstruction with minimal donor-site complications.

Suspension of the humerus to the acromion provides stability to the shoulder following a brachial plexus palsy

List of authors:
Rudolf Rosenauer¹, Hanno Millesi², Robert Schmidhammer²
¹ Trauma Hospital Lorenz Böhler, Millesi Center (Vienna)
² Millesi Center (Vienna)

Objectives / Interrogation: Upper or complete brachial plexus lesions can lead to a severe weakness of the shoulder muscles. Following the denervation and atrophy of these muscles, the maximum range of motion, especially abduction, is impaired. Inferior subluxation of the humerus head in the resting position of the shoulder develops consequently, leading to a flail shoulder. Unfortunately, there are limited therapeutic options to improve this condition. We have developed a surgical procedure for the re-suspension of the humerus head to the acromion, and this study aims to evaluate the efficacy of this method retrospectively.

Methods: Between 2008 and 2014, 13 patients suffering from a paralysed upper limb and, consequently, flail shoulder were treated with this procedure. The humerus head was re-suspended from the acromion using an artificial ligament. In 6 patients, an additional supraspinatus to trapezius muscle-tendon transfer was performed due to complete supraspinatus wasting. The mean age was 30 years (±11) and the mean follow-up was 36 months (±14). All patients were male, and the right side was affected in 85%. The grade of subluxation was determined by measurement of the distance between the lower border of the acromion and the upper border of the humerus head clinically. Abduction was measured as the maximum possible thoraco-humeral angle using a goniometer, with the patient standing upright in front of the investigator. Pain was measured using a visual analogue scale. Furthermore, the ASES, the UCLA, and the Simple Shoulder Scores were obtained postoperatively.

Results and Conclusions: Abduction was improved from 11° (±18) preoperatively to 54° (±17) postoperatively, p<0.05. Pain was reduced from 3.3 (± 3.8) preoperatively to 1.7 (± 2.8) postoperatively, p<0.05. The grade of subluxation was improved from 3.9cm (±0.6) preoperatively to 0.5cm (±1.2) postoperatively, p<0.05. The mean postoperative ASES, Simple Shoulder and UCLA Shoulder Score were 60.8 (±13.7), 2.6 (±0.9), and 18.2 (±3.6), respectively. All patients reported a highly satisfying stability of their shoulder. No foreign-body reactions or wound healing disorders occurred.

In this article, we present a novel procedure to suspend the humerus head from the acromion in the case of inferior subluxation of the humerus head. Subluxation can be reduced with this procedure, and existing muscle strength can be used exclusively for movement. Restoring dynamic shoulder stability can treat the pain arising from a flail shoulder as well.

Comparison among plate fixation, K-wire pinning, and conservative treatment for distal metacarpal fractures

List of authors:
Yuki Fujihara*, Hideyuki Ota, Kentaro Watanabe
1 Nagoya Ekisaikai Hospital (Nagoya)

Objectives / Interrogation: Although several treatment options have been reported for distal metacarpal fractures, no definitive superiority or inferiority among the various treatment options were identified to date. This study aimed at comparing the outcomes of treatments for distal metacarpal fractures, such as conservative treatment, K-wire cross pinning or intramedullary fixation, and plate fixation.

Methods: We evaluated 50 fingers of 48 patients with distal metacarpal fractures who were treated at our hospital between April 2009 and September 2018. We compared the outcomes of three representative treatment options for these fractures; conservative treatment, K-wire fixation, and plate fixation. We defined the active range of motion (AROM) of the metacarpal phalangeal (MCP) joint at the final follow-up as the primary outcome, as well as compared the degree of volar or lateral angulation of the distal part of the fractured fragment before surgery and at the last follow-up among the three cohorts.

Results and Conclusions: The sample sizes for conservative treatment, K-wire fixation, and plate fixation were 19, 20, and 11 fingers, respectively. Although these cohorts included 7 open fractures and 18 intraarticular fractures, their distribution ratio did not significantly differ depending on the treatment. The average MCP joint AROM after plate fixation was 59°, which was significantly lower than that after conservative treatment (78°) and K-wire fixation (77°). Three of 11 patients with plate fixation underwent plate removal and stereoarthrolysis. Although preoperative volar and lateral angulation did not differ depending on the treatment option, postoperative volar angulation after conservative treatment was significantly larger than that after other treatments.

Conclusions
We compared the three representative treatments in our study, and suggested characteristics associated with each. Although postoperative reduction in position after plate fixation was better than that after conservative treatment, our study identified a negative effect of plate fixation on postoperative MCP joint AROM. As functional outcome is far more important than radiographic reduction, the indications of plate fixation for distal metacarpal fractures should be limited and other treatment options should be chosen instead.

study of muscle redistribution technique in signal recognition of intelligent bionic hand

List of authors:
Yong Yang*, Qining Wang2, Liying Sun1, Shanlin Chen1, Wen Tian1
1 Beijing Jishuitan Hospital (Beijing)
2 College of engineer, Peking University (Beijing)

Objectives / Interrogation: To investigate the value of muscle redistribution technique (MRT) in the recognition of human motion intention by intelligent bionic hand.

Methods: Between December 2016 and April 2017, 3 patients with upper limb amputation were treated with muscle redistribution technique procedure. All patients were males, average age were (42.7±4.5) years. The amputation levels were located at the distal 1/3 of the forearm, midcarpal joint and carpometacarpal joint. In MRT, 4-6 muscles and tendons in the stump of upper limb were transferred and the tendons were anchored in different areas of the skin. When the muscle actively contracted, the tendon pulled the skin resulting in obvious skin deformation in different areas. The evaluating indicators included skin deformation, capacitive signal data and postoperative complications.

Results and Conclusions: All the 3 patients were followed up averaged (5±2) months. There were 14 MRT procedures site. 3 months after surgery, patients were able to actively control the transferred muscle contraction and produce skin deformation. At the final follow-up, the effective deformation rate was 85.7%. Two kinds of classifiers were identified by linear discriminant analysis (LDA) and quadratic discriminant analysis (QDA) respectively. The overall recognition accuracy were 97.27% and 100% respectively, and the recognition accuracy of each action was 100%.

Conclusion MRT procedure can effectively output the motion intention of human body and increase the number and intensity of motion signals. The procedure provided a novel way for better control the intelligent bionic hand.

Trans-scaphoid perilunate dislocation in a pediatric patient: a 10-month follow up

List of authors:
Francesca Teodonno*¹, Marta Olmeda Lozano¹, Armando Macera¹, Daniel López Dorado¹, Hugo Garlito Díaz¹, Raquel Serrano Serrano², Rocio Mascaraque Ortiz¹, Juan Carlos Márquez Ambite³
¹Hospital Universitario Infanta Elena (Valdemoro)

Objectives / Interrogation: Transcarpal fractures and dislocations are uncommon in the pediatric population, although studies suggest that the incidence is increasing.
Both conservative treatment and surgery are described in these particular cases.
To the best of our knowledge, no clear guidelines exist to treat these injuries in pediatric patients, due to its uncommonness.

Methods: We present the case of a 12-year-old boy who sustained a trans-scaphoid perilunate dislocation due to fall on the outstretched hand from a motorbike.

The patient was sedated in the ER and a closed reduction was accomplished. The wrist was immobilised with a closed cast including the proximal phalanx of the thumb and with the wrist in slight flexion.
A radiography and a CT scan post-reduction were performed, validating a correct alignment of the carpal bones. The CT clarified the fracture pattern, showing an undisplaced fracture of the waist of the scaphoid and a marginal fracture of the radial proximal pole of the triquetral bone.

**Results and Conclusions:**

The cast was removed at six weeks. At 8 weeks, the patient started the rehabilitation program. At 12 weeks, radiography showed a dorsal intercalated segment instability (DISI) of the scaphoid, with a scapholunate angle of 76° and a normal radiolunate angle of 37°. At 7 months follow up, the patient presented an asymptomatic non-union of the scaphoid fracture. Physiotherapy was prescribed. At final follow up of 10 months, the fractures healed well with a full return of good wrist function.

Modified abdominal flaps for reconstruction of degloving injuries of multiple fingers

List of authors:
Guangliang Zhang*, Jihui Ju, Guangzhe Jin, Ruixing Hou
1 Ruihua affiliated hospital of Soochow University (Suzhou)

Objectives / Interrogation: Treatment of multiple finger degloving injuries is one of the most difficult problems in hand surgery. Although many methods of reconstruction that preserve function and reduce deformities have been described, none provide a satisfactory solution to this problem. The purpose of this report was to explore the results of treatment of degloving injuries of multiple fingers using modified random abdominal flaps.

Methods: From 2009 to 2016, five patients with hand degloving injuries were treated using modified random abdominal flaps. Based on Yamada's technique[1], the flap was designed over the abdomen with the fingers separated and marked on the abdominal skin. The skin was incised transversely at the basal border, which initiated the growing process of the finger flap. The dissection was done on superficial fat above Scarpa's fascia and a pocket was created for each finger separately (taking utmost care not to tunnel into the undersurface and into Scarpa's fascia). This created a tunnel in the superficial fascia layer into which each finger was inserted separately (Figure 1).

Results and Conclusions: All the flaps survived. Wound unhealing occurred in one finger in case One and in case Five. All the wounds healed well after full-thickness skin grafts were used. The modified method required 1-2 operations and the duration of time was 2.5-3.5 months (Average, 3.1 months). All the patients were followed for more than 8 months. The appearance of the repaired fingers in modified group was not bulky without defatting. All the fingers were shorter than the normal fingers without finger nails. The thumb could be opposed to all of the fingers except the small one. The repaired hand gained grip and write function, and could be used for daily life activities (Figure 2). Unfortunately, the sensation of the repaired finger was poor and was graded as S3.

Reconstruction of the dorsal and palm defects of hand with anterolateral thigh flaps from one donor site

List of authors:
Guangliang Zhang*1, Jihui Ju1, Ruixing Hou1
1 Ruihua affiliated hospital of Soochow University (Suzhou)

Objectives / Interrogation: The anterolateral thigh flap is becoming the flap of choice for reconstruction of soft tissue defect with primary donor-site closure. The purpose of this report was to review the reconstruction of dorsal and palm defects of hand by the anterolateral thigh flaps from one donor site.

Methods: From 2016 to 2017, eight patients with dorsal and palm defects of hand were reconstructed with the anterolateral thigh flaps from the one donor site. At least two separate cutaneous perforator vessels are identified on Doppler before the operation and dissected in a retrograde fashion back to the descending branch of the lateral circumflex femoral artery. The skin paddle is then divided between the two cutaneous perforators to give two separate paddles. The cutaneous perforators of the two paddles were from a common vascular supply in seven cases. One cutaneous perforator was anastomosed to the branch of the other cutaneous perforator of the paddle to make a common vascular supply in one case.

Results and Conclusions: All flaps survived completely. There were 16 flaps. The area of the flap was from 18cm×8cm to 7cm×4cm. Arterial crisis occurred in one case and finally the flaps survived after another surgery. The flap was bulky in 2 cases. The contracture of first web and flap bulky both occurred in three cases. These five cases were satisfactory with the functional and appearance results after another surgery. The sensation of the flaps was S2. All of the donor sites healed well in one stage.

It is a good method to use the anterolateral thigh flaps from one donor site to repair the dorsal and palm defects of hand with minimal donor site morbidity.

Flexor Digitorum Superficialis Tendon Transfer for Multiple Finger Extensor Tendon Reconstruction

List of authors:
Jung-Hsien Hsieh*, Hao-Chih Tai
1 National Taiwan University Hospital (Taipei)

Objectives / Interrogation: Tendon transfer and tendon graft reconstruction are the surgical procedures used for extensive tendon injury with difficulty in repair of proximal and distal tendon ends primarily. Tendon transfer is favored by some surgeons for only one tendon repair site with less chance of tendon adhesion and tendon rupture. For multiple finger extensor tendon rupture with poor quality of proximal musculotendinous units, tendons of wrist flexor and finger flexor digitorum supercials (FDS) could be used for tendon transfer reconstruction. FDS tendon is used for finger extensor tendon reconstruction in patients of rheumatoid arthritis and radial nerve palsy. It is rare to use FDS tendon transfer in traumatic extensor tendon injury reconstruction. We will report three cases of multiple finger extensor tendon reconstruction using FDS tendon transfer in special situations.

Methods: Three patients suffered from severe multiple finger extensor tendon injury which could not be repaired primarily. The causes of injury including extensive mycobacteria tuberculosis infection and traffic accident injury. Tendon transfer reconstruction using long finger FDS tendon was performed. The donor finger FDS tendon was transferred to forearm dorsal aspect via radial side at sub-muscle fascia layer. Splint protection for 3 weeks and rehabilitation program for 2 months were undertaken after the surgery.

Results and Conclusions: < Results >
The patients received regular follow up at our clinic. The patients could extend finger completely. The donor finger of FDS tendon could flex well. There were no complications during clinic follow up.

< Conclusions >
FDS tendon transfer could be used for multiple extensive finger extensor tendon injury reconstruction. After meticulous rehabilitation and regular follow up, the patient could have good finger extension function recovery with no obvious donor site morbidity.

Tendon Transfer, Flexor Digitorum Superficialis, Extensor Tendon
Half Extensor Digiti Minimi Transfer for Thumb Extension Reconstruction

List of authors:
Jung-Hsien Hsieh*, Hao-Chih Tai
1 National Taiwan University Hospital (Taipei)

Objectives / Interrogation: Tendon transfer is the favored surgical procedure when extensor pollicis longus (EPL) rupture is chronic or poor quality of ruptured tendon ends. The extensor indicis proprius (EIP) is the most common used donor tendon for EPL reconstruction. Several other tendon transfer donors have been reported; including extensor pollicis brevis (EPB), extensor carpi radialis longus (ECRL), and palmaris longus. We reported a successful reconstruction of thumb extension by half extensor digiti minim (EDM) transfer in a patient with traumatic loss of EPL and EIP. A literature review failed to identify any English reports regarding thumb extension reconstruction using half EDM transfer. Only two total EDM transfers have been reported previously.

Methods: The 66-year-old lady suffered from left wrist crush injury. Painful sensation and swelling without superficial wound was noted. She went to local traditional Chinese medicine hospital for treatment. Lack of left thumb extension was noted after pain and swelling subsided. She came to our clinic 2 months after the injury. Ultrasonic examination showed EPL complete rupture and partial tear of EIP. Surgical reconstruction with tendon transfer was undertaken 2.5 months after injury. The patient had past history of Sjogren's syndrome with immunosuppression medication usage. During surgery, EPL total rupture and EIP almost total rupture was noted at metacarpal bone level. EDC to small finger was very small and no small finger extension during traction of the EDC. Other donor tendon was not used due to the need of tendon graft and poor soft tissue condition of the patient under immunosuppression medication. We transferred ulnar half of EDM (for preserving extension function of small finger) to EPL using Pulvertaft technique. Splint protection for 3 weeks and rehabilitation program for 2 months were undertaken after the surgery.

Results and Conclusions: < Results >
The patient received regular follow up at our clinic. The patient could extend her left thumb interphalangeal and metacarpophalangeal joints completely. The small finger extension function is intact. There were no complications during clinic follow up.

< Conclusions >
Half extensor digiti minim (EDM) transfer in a patient with traumatic loss of EPL is an alternative option for EPL reconstruction if no other potential tendon donors is suitable. After meticulous rehabilitation and regular follow up, the patient could have good thumb extension function recovery.

Objectives / Interrogation: Trapezo-metacarpal and scapho-trapezotrapezoid arthroplasty based on pyrocarbon resurfacing implants is known as “burger arthroplasty”. This technique was proposed in 2014 for the treatment of early stages of symptomatic and debilitating peritrapezial osteoarthritis. This study presents the mid-term clinical results of the initial series.

Methods: This prospective monocentric study included consecutive patients who underwent a “burger arthroplasty” between 2009 and 2017. The surgical technique followed the original description. The epidemiological data of the population was analyzed. Results were evaluated according to the standardized QuickDASH and the PRWE functional scores at the time of the last follow-up. Thumb mobility, strength (pinch and grip), rest pain and maximum pain were assessed by standardized means.

Results and Conclusions: Thirteen patients were included. Ten women (77%) and three men (23%). Their average age was 60 (50-70 years). Average follow-up was 53.3 months (9-95 months). QuickDASH and PRWE scores were respectively 28.8 (2.3-72.7) and 27.8 (0-63.5) at the last follow-up. Average grip strength was 25.2 kg (15-42 kg). Average pinch strength was 5.9 kg (2.7-10 kg). Average pain at rest was 0.7 / 10 (0-3) and the average maximum pain was 4.7/10 (0-10) according to the visual analogue scale. Kapandji's thumb mobility averaged 9.9 (9-10). At the last follow-up, no displacement or instability of the implants was demonstrated either clinically or radiologically.

"Burger arthroplasty" is indicated for early peritrapezial osteoarthritis with no trapezoidal collapse or significant structural bone involvement. This is a conservative and minimally invasive technique compared to conventional trapeziectomy. It reduces pain, preserves pinch and grip strength, and improves thumb mobility.

This arthroplasty is a promising surgical technique for the treatment of early stages of peritrapezial osteoarthritis and should be find its place in the arsenal therapeutic of hand surgeons.

Availability of radiographs in suspected hand fractures - a tertiary referral center experience.

List of authors:
Dominika Michno¹, Prateush Singh¹, Ravina Tanna¹, Naghmeh Naderi¹
¹ Royal Free Hospital (London)

Objectives / Interrogation: This is a retrospective study assessing the availability of adequate radiographic views of suspected phalangeal and metacarpal fractures in a busy emergency plastic surgery clinic. Furthermore, the study demonstrates how significant improvements in the availability and quality of radiological investigations available at the time of assessment in clinic can be obtained with a few simple interventions.

Methods: Patient data was retrospectively collected from electronic medical records over a two separate one-month periods - December 2017 and January 2018. The suspected diagnosis and availability of adequate radiological investigations were recorded. After the first month of data collection the results were presented at a departmental meeting and interventions were introduced to improve the quality of the service. The second data collection cycle was performed one month later to establish if the interventions improved the quality of the radiological investigations present at the time of outpatient assessment.

Results and Conclusions: In December 2017, 95 patients were seen in the trauma clinic with suspected phalangeal (68) and metacarpal (27) fractures of which 75% and 52%, respectively, had inadequate radiographic views for the correct examination of the underlying pathology. Furthermore, 62% of all XRs taken had inappropriate views.
In January 2018, 81 patients were seen in clinic with phalangeal (61) and metacarpal (20) fractures of which 48% and 45% respectively had inadequate XR views (mean 47%). 37% of XRs taken this month had inappropriate views.
X-rays are indispensable in hand fracture assessment and their absence leads to inadvertent delays in patient management. A significant number of patients attending the clinic who need radiographs for accurate assessment either do not have them taken in referring center or they are not sent on time. These situations lead to preventable delays in patient care by waiting for the transfer of images or result in unnecessary irradiation as the radiographs are repeated. Our study demonstrates that significant improvements in the availability and quality of radiological investigations at the time of the preoperative assessment can be made by introducing two simple interventions.

Trapezium bone resection arthroplasty and suspension with suture-button for the treatment of trapezium-metacarpal osteoarthritis: long-term follow-up in a Colombian cohort

List of authors:
Carlos Gonzalez*, David Suarez¹, Daniel Vanegas², Camilo Restrepo², Ana Milena Herrera¹
¹ Clínica del campestre (Medellín)
² Clínica del campestre, Facultad de Medicina. Universidad Pontificia Bolivariana (Medellín)

Objectives / Interrogation: Objective: Osteoarthritis of the trapezium-metacarpal thumb joint, the most common and debilitating degenerative osteoarthritic condition of the hand, occurs in approximately 25% of postmenopausal women; it requires management in case of severe pain and decreased function. Surgical options include arthrodesis versus arthroplasty; the latter uses complete or partial trapeziectomy. However, the tendency to collapse hinders prompt rehabilitation. The suspension with suture-button avoids the use of tendon grafts and favors early rehabilitation.

Methods: Methods: Retrospective study of clinical results of a cohort of patients with osteoarthritis of the trapeziometacarpal joint of the thumb, treated with a trapezium resection arthroplasty plus suspension with suture-button. In the study, we included a total of 25 patients (30 thumbs). Functional recovery and pain level were assessed objectively through the grip and pinch strength tests, the range of motion, Quick DASH and Kapandji scores, and visual analog scale (VAS) of pain.

Results and Conclusions: Results: The average age was 62.2 ± 8.3 years; 23 women and two men; there was bilateral involvement in 5 patients. The preoperative Eaton classification was II in six, III in thirteen, and IV in eleven thumbs. The medians of follow-up times and Quick DASH scores were 24 months (range, 6-96) and 20.5 (range, 0-61.4), respectively. The grip and pinch strengths were 90% and 96.3%, of the non-surgical side, respectively. The average of palmar and radial abduction was 84.1% and 92.3%, of the non-operated thumb, respectively. The average Kapandji score for all operated thumbs was 9.25. Three cases presented long-term complications; there was one case of sensory branch neuroma, one of regional pain syndrome, and one fracture of the second metacarpal.

Conclusions: In our population, trapeziometacarpal arthroplasty with suture-button provides good functional results for patients with osteoarthritis of the trapeziometacarpal thumb joint, especially in pain relief, satisfaction, and early reincorporation to work and daily activities.

Manufacture of PDA/ RGD coated graphene loaded PCL nanoscaffold via integration multilayered printing

List of authors:
Čunyi Fan*, Yun Qian
1 Shanghai Sixth People's Hospital (Shanghai)

Objectives / Interrogation: The nerve guidance conduit can connect two nerve ends, guide axonal regeneration and offer a neurotrophic environment to Schwann cell aggregation and proliferation. Two major factors are involved in fabricating an excellent nerve conduit, material selection and surface modification. As a conductive nanomaterial, graphene has huge potentials in nerve function restoration by promoting electrical signal transduction and metabolic activities with unique topological properties. Polydopamine (PDA) and arginylglycylaspartic acid (RGD) are peptides that can improve cell adhesion in tissue engineering. We intend to evaluate the surface-modified graphene nanoscaffold in the restoration of severe peripheral nerve defects.

Methods: We evaluated single-layered graphene (SG) and multi-layered graphene (MG) in the peripheral nerve repair. We used polycaprolactone (PCL) as the substrate scaffold and fabricated the PDA/RGD-SG/PCL and PDA/RGD-MG/PCL nanoscaffold using layer by layer casting (LBLC) method. We examined the surface morphology and conductive capacity. We performed in vitro assays to evaluate Schwann cell (SC) proliferation, adhesion, neural expression on different nanoscaffolds. For in vivo studies, we created a 15-mm sciatic nerve defect model in Sprague Dawley (SD) rats. We evaluated their functional, electrophysiological, morphological performances at 6, 12 and 18 weeks after injury.

Results and Conclusions: The inner-most and outer-most layers of RGD and PDA were beneficial to cell adhesion and proliferation. The graphene/PCL double layers intensified the tubular structure and allowed certain stiffness in vivo. Our multi-layered macroporous nerve conduit allowed exchanges of nutrients and oxygen via excellent permeability, strong mechanical support, appropriate biodegradation rate, and flexibility for complete nerve regrowth. The glial fibrillary acidic protein (GFAP), beta tubulin (Tuj1) and S100 expression of Schwann cells was enhanced by graphene nanoscaffold, indicating the beneficial effects in improving neural activity. The number of myelinated axons, thickness of myelin sheath, regenerated axon area and average myelinated axon diameter of the regenerated nerves from graphene conduit were significantly higher than pure PCL conduit group. Nerve conducting velocity, distal compound motor action potential and sciatic function index were also better in the graphene conduit group. In addition, PDA/RGD-SG/PCL and PDA/RGD-MG/PCL conduits also promoted myelin sheath and axonal regeneration.

Regulation of neural stem cell fate by three-dimensional gold nanocomposite channels

List of authors:
Çunyi Fan*, Yun Qian

1 Shanghai Sixth People’s Hospital (Shanghai)

Objectives / Interrogation: Peripheral nerve injury (PNI) is a common origin of motor and sensory dysfunction and leads to discontinuity of electrical conductivity. Nerve guidance channels are invented for large nerve gaps as alternative implants. New trends have shifted to a more completed and faster nerve regeneration, calling for a thorough investigation into conductive materials. Gold is investigated widely concerning its potential roles in promoting peripheral nerve repair. Bone marrow mesenchymal stem cells (BMSC) are increasingly significant for PNI. They were highly proliferative and capable of promoting sensory and motor system recovery, axon sprouting as well as Schwann cell (SC) proliferation and migration. In this study, we intend to evaluate BMSC and SC loaded gold nanocomposite channels in severe PNI repair.

Methods: We fabricated a polydopamine (PDA) coated gold/polycaprolactone (PCL) nanoscaffold via multilayer molding method. We examined the surface morphology and elastic modulus. We evaluated the proliferative, adhesive and neural differentiation potential of gold nerve channel for BMSCs and SCs in vitro. We established a 15-mm sciatic nerve defect model of Sprague Dawley (SD) rats. We thoroughly investigated the functional, electrophysiological and morphological performances in BMSC loaded gold/PCL conduit, SC loaded gold/PCL conduit, gold/PCL conduit, PCL conduit and autograft.

Results and Conclusions: We fabricated nerve scaffolds via 3D multilayer molding method. A multilayer structure of PDA coated gold/PCL nanocomposite channel increased rigidity of the scaffold wall. Multiporous and multilayer design improved biodegradation because pores and space between layers allowed body fluid to enter the internal channel freely. Macropores permitted oxygen and water exchange for nutrition supply. BMSCs and SCs were cultured on different nanoscaffolds and their proliferation, adhesion and viability were greatly improved by gold nerve channels. In addition, BMSCs were induced into Schwann-like cells on PDA-gold/PCL nanosheets and the neural expression was evaluated in vitro. The supportive ability of two cells were believed to diffuse growth factors, oxygen and other nutrients. We noticed morphological, functional nerve recovery, and angiogenesis at 6, 12 and 18 weeks postoperatively. CD34 expression was significantly higher in gold conduit groups than PCL group. The myelin sheath and axonal regrowth was also markedly elevated by gold nanoparticle application, which was further enhanced using BMSC seeding.

open arthrolysis on tuberculosis oriented elbow stiffness

List of authors:
Čunyi Fan*, Yun Qian
1 Shanghai Sixth People's Hospital (Shanghai)

Objectives / Interrogation: In the past decades, tuberculosis (TB) has posed a great threat to people worldwide, especially in developing regions. Bone and joint TB is one of the most common types of extrapulmonary TB, with elbow TB comprising a small proportion of these cases. The treatment for elbow stiffness associated with TB has been rarely reported.

Methods: We retrospectively analyzed six patients (four females and two males) with tubercular elbow stiffness during a 7-year period. All of them received open arthrolysis and hinged external fixation to restore functional extension, flexion, supination and pronation. Mayo Elbow Performance Score (MEPS) and range of motion (ROM) were evaluated preoperatively and at final follow-up.

Results and Conclusions: At final follow-up after surgery, we evaluated the average active ROM, which was 111.7° (90°-135°). The average extension was 11.7° (0°-30°), while the average flexion was 123.3° (115°-135°). At the same time, the average supination was increased to 70° (40°-90°) and the average pronation was increased to 68.3° (45°-80°). The MEPS was elevated to 92.5 (85-100). Three patients displayed complications and were treated and cured with dressing changes and antibiotics.

We conclude that open arthrolysis and hinged external fixation are useful for the treatment of nontraumatic elbow stiffness with tuberculosis.

The Effect of Age on Healing of Fractures in the Adult

List of authors:
Ronit Wollstein¹, Ilene Staff², Daniel Mastella², Duffield Ashmead², Lois Carlson², Benjamin Robichaux², Tina Simpson²
¹ New York University School of Medicine (Huntington Station)
² The Hand Center (Glastonbury)

Objectives / Interrogation: Studies in animals suggest that older mice and rats heal fractures more slowly. In adults, as opposed to the pediatric population, the effect of age on fracture healing is unclear. With increasing population age, it is imperative to understand differences in healing according to age for optimal fracture treatment including surgery, immobilization, and therapy.

The purpose of this study was to evaluate metacarpal fractures for age related differences in healing time.

Methods: A retrospective review of patients treated for metacarpal fractures was performed. Patients with incomplete charts or inadequate follow-up were excluded. One-hundred and ninety-eight charts were analyzed. Demographic information and patient factors were documented including background disease, smoking status, hand dominance, and occupation. Fracture characteristics and treatment type were documented. Outcome variables were time to healing and complications. Plain radiographs and clinical examination were used to determine fracture stability and healing.

Results and Conclusions: Age was not associated with fracture healing as a continuous and categorical variable (p=0.09, 0.58 respectively). Minimally displaced and comminuted fractures healed faster than oblique, spiral or transverse fractures (p = 0.05). Patients undergoing surgery healed faster than those without surgery (p = 0.05). Renal failure was negatively associated with fracture healing p=0.03. Diabetes, hypothyroidism and gender were not associated with healing time.
Complications were not associated with age or other patient or fracture related factors.
Conclusions:
1) Age does not affect clinical fracture healing/stability in the adult.
2) Older patients do not require distinct treatment of fractures.
3) Other fracture related factors and considerations such as functional demand and availability of support systems might influence treatment decisions in fracture care.

Denervation of the MCP and the PIP joint - An effective treatment of osteoarthritis in the hand

List of authors:
Rebekka Rath*, Christina Ampofo¹, Wan Konur², Tobias Del Gaudio³, Max Haerle¹
¹ Orthopädische Klinik Markgröningen, Klinik für Handchirurgie und Plastische Chirurgie (Markgröningen)
² Zahnärztliche Oralchirurgische Praxis Dr. R. Gehl (Esslingen)
³ Schwarzwald-Baar Klinikum, Klinik für Plastische-, Hand- und Ästhetische Chirurgie (Donaueschingen)

Objectives / Interrogation: In many cases, patient see us with relatively moderate pain in finger osteoarthritis (OA). Arthrodesis or joint replacement are often refused by these patients as too invasive. We have investigated on the effectiveness of selective denervation of these joints as a cost-effective, simple soft tissue procedure which preserves mobility.

Methods: Between 2005 and 2018, 23 metacarpophalangeal and 129 proximal interphalangeal joints were treated by denervation at our hospital. We investigated on pain, mobility, patient satisfaction, subsequent operations and complications.

Results and Conclusions: Preliminary results show full pain relief in 68.4 % of denervations of MCP or PIP joints. If we consider that a pain reduction of more than 50 % pain relief is a relevant reduction, then 87.5 % success rate could be found. Mobility has been unchanged or improved in 77.9 % of cases compared to preoperative range of motion. We observed for 14.8% of cases sensory disturbances. 4.6 % of joints needed subsequent operations such as arthrodesis or joint replacement. Finally, 82.3 % of patients are satisfied with the results of the operation.

Denervation of the metacarpophalangeal and proximal interphalangeal joint of the hand is an effective and low risk alternative for treatment of osteoarthritis. It preserves mobility and reduces pain. Furthermore, a denervation operation does not limit further treatment options.

denervation, osteoarthritis
Endoscopic Assisted Exploration of the Axillary Nerve through a Posterior Open Approach: first clinical experience

List of authors:
Andres A. Maldonado*, Florian Neubrech¹, Robert J. Spinner², Michael Sauerbier¹
¹ BG Unfallklinik Frankfurt (Frankfurt)
² Mayo Clinic (Rochester)

Objectives / Interrogation: We present the first two cases using an endoscopic assisted approach to explore the whole AN through a posterior approach.

Methods: Two patients with a potential AN injury were included. Dry arthroscopy was performed through a standard posterior approach in an attempt to visualize all segments of the AN. Photographs and videos were performed in order to evaluate the intraoperative visualization of the AN and provide long-term clinical follow-up.

Results and Conclusions: The whole AN was visualized with the scope avoiding the deltopectoral approach. No AN injury was found during the nerve exploration. A more proximal injury (upper trunk) was visualized in both patients during the standard supraclavicular dissection and a triceps branch to AN transfer using the previous posterior approach was performed. After 9 months both patients achieved a shoulder flexion and abduction above 140º. The endoscopic assisted exploration of the AN through a posterior open approach was a useful strategy to visualize the whole AN without the combination of a deltopectoral approach. We believe this technique has a role in selected cases of AN injury.

Ossification of a Dupuytren's Cord Following Xiapex (collagenase clostridium histolyticum) Injection. A Case Report

List of authors:
Robin McManus¹, Kevin McGarry², Phil Grieve¹
¹ Blackrock Clinic (Dublin)
² Department of Plastic Surgery, Ulster Hospital (Belfast)

Objectives / Interrogation: In this case we present a previously unpublished outcome in Dupuytren's disease following collagenase treatment - ossification of the Dupuytren's cord, complicating secondary redo surgery.

Methods: A 67 year old right hand dominant male presented to the hand clinic with a seven year history of Dupuytren's contracture affecting his left index, middle and ring fingers. For primary management he was offered collagenase injection to the little finger. Despite initial improvement he had an early relapse prompting formal dermofasciectomy. Intraoperatively an ossified cord was identified complicating the resection process.

Results and Conclusions: To our knowledge this is the first reported case of Dupuytren's cord ossification following collagenase injection. On literature review no causal link was identified between the treatment and the pathology. However given the increasing use of collagenase in primary Dupuytren's management it is possible further cases may present.

Keywords: dupuytrens ossification collagenase
Addition-subtraction osteotomy with ligamentoplasty for symptomatic trapezial dysplasia with metacarpal instability: a 10-year follow-up.

List of authors:
Gilles Thuysbaert*¹, Jean Goubau²
¹ University Ghent (Gent)
² AZ Sint-Jan Brugge (Brugge)

Objectives / Interrogation: Symptomatic trapezial dysplasia with metacarpal instability can lead to a disabling condition, which is characterized by pain, decrease in mobility and strength. Radiographic changes are initially often absent. Different techniques have been described based on soft tissue balancing or osteotomies around the joint. In dysplastic joints a bony correction is required, because soft tissue correction is insufficient to stabilize the trapeziometacarpal joint.

Methods: We combined two techniques described in the past, an abduction/extension osteotomy of the first metacarpal and an opening wedge osteotomy of the trapezium, to which we added a ligament reconstruction with the hemi Flexor Carpi Radialis. This combination corrects the anatomy and the forces acting across the joint. Between 2003 and 2007 we have done this procedure 21 times in 18 patients. The operation was only done when conservative treatment was unsuccessful (night splinting and nonsteroidal anti-inflammatory medication). Seventeen thumbs were reviewed prospectively with a mean follow-up of 12,2 (+/-0,94) years (range: 10,9 - 14,4). 3 patients were lost to follow-up.

Results and Conclusions: In our results we found very good mobility, strength, pain-relief, function and radiographic evolution. There was an improvement of the key pinch with 1,1 kg (+/-1,8) (range: -2 - 5) and of grip strength with 4,5 kg (+/-7,4) (range: -6 - 18) after 10 year follow-up. Key pinch of the operated thumb is similar to the preoperative situation. The QuickDASH improved by 43,9 points (+/- 19,1) (range: -5 - 68,1). Radiographic evaluation showed a significant correction of the so called Dévers angle (slope of the trapezium), with a mean correction of 9,1° (+/-6,7) (range: 2 - 22). When comparing the postoperative radiographs with those made more than 10 years ago, there was a stable Dévers’ angle. One patient had a trapeziometacarpal arthroplasty one year after the previous operation. One other patient had to be operated on twice more for pseudarthrosis due to entrapment of the ligament into the osteotomy. There was no damage to the articular surface due to iatrogenic fracture or other perforation into the joint. Even in this long-term follow-up no complications were observed.

This technique has a positive long-term effect on symptomatic trapezial dysplasia with metacarpal instability. It protects the trapeziometacarpal joint from further wear and allows other techniques to be used if painful arthritis develops in the long term.

Examination of soft tissue tumors in the hand

List of authors:
Michio Sano*
1 Shizuoka City Hospital, Dpt. of Orthopaedic Surgery (Shizuoka City)

Objectives / Interrogation: [Introduction] The bone and soft tissue tumors that occurred in the hand may be troubled with deciding whether to send to the facility specializing bone and soft tissue tumors or hand surgery. Our hospital has doctors specializing in bone and soft tissue tumors and hand surgery, so there are many opportunities to treat tumors and tumorous lesions that occurred in the hand. Characteristics of the lesion, results of treatment and so on will be examined.

Methods: [Patients and Method] Of the 837 bone and soft tissue tumors who underwent surgical treatment at our hospital during the 10 years from 2008 to 2017, 168 tumors in the hand of 160 cases that occurred beyond the wrist joint were examined. We analyzed the site of occurrence, pathological diagnosis, local recurrence, complications.

Results and Conclusions: [Results] The age was 1 to 83 years old, and the average was 54.0 years old. There were 69 males and 99 females. The right hand was 80 and the left was 88. The site of occurrence was a wrist joint 6, a palm 55, a hand dorsal 9, and a unique finger part 98. Malignancy was only one case of finger nerve metastasis of malignant melanoma, other than that were benign (99.4%). The postoperative observation period was 17.4 months on average. Pathological diagnosis is most frequent in GCTTS 36, ganglion 35, fibromatosis 22, epidermal cyst 16, hemangioma 19, Schwannoma 8, glomus tumor 6, fibroma of tendon sheath 6, angioleiomyoma 3, myopericytoma 2, fibroma 2, venous thrombosis 2, and 1 in other cases. Local recurrence was in 4 cases, GCTTS was 3 cases, and epidermal cyst was 1. Postoperative complications occurred in 3 cases with sensory decline and 2 cases with limited joint range of motion.
[Discussion] In the various reports, the occurrence frequency of soft tissue tumors in the hand region is most frequent, in the order of ganglion, GCTTS, epidermal cyst, lipoma, but in our series GCTTS was the most frequent. This is limited to the cases in which surgery was performed, and it was inferred that there were many cases that did not performed surgery at the time of diagnosing as ganglion. Recurrence occurred in 3 cases in GCTTS, and it was considered that GCTTS tends to invasively expand within joints, bones, and tendon sheaths, so recurrence was occurred. Three patients with postoperative sensory decline appeared. They were 2 Schwannomas and 1 GCTTS. Treating GCTTS, we must pay attention to a possibility that postoperative sensation decline may appear even after microscopic operations.

Handsurgery under limited Conditions - Sense or Nonsense?

List of authors:
André Borsche*

1 Plastische Chirurgie, Diakonie Krankenhaus, Bad Kreuznach (Bad Kreuznach)

Objectives / Interrogation: In the last 35 years INTERPAST-Germany, as a non-profit organization for plastic surgery in developing countries, operated on 95,000 patients in more than 1,300 missions all over the world. About 10% of the patients were handsurgery cases with partly extreme burn contractures, syndactilies or other malformations who need more than only a skin graft for correction. Although in many developing countries only limited facilities are available a variety of plastic reconstructive procedures could be performed safely.

Methods: The design of reconstructive procedures will be discussed under the aspect of safety, effectiveness and recurrence of contractures. The therapy management differs from the experience in our country due to the lack of post-op compression and physiotherapy which often could not put into practice.

Results and Conclusions: Longterm results show that even under poor condition improvement could be achieved, but often secondary surgery is necessary to restore better function. The major problem remains the post operative management. Woundhealing of skingrafts, temporary arthrodesis and flap necrosis need specialized after care. Differential immobilisation and mobilisation are usually not under professional control possible. To begin an operation without thinking of the post op care should be avoided.

Regular INTERPLAST camps with handsurgery specialized colleagues are a meaningful help for many patients who get no chance of any operation elsewhere. Repeated camps at the same place allow us to follow up many patients even with severe deformities. Learning from poor results we developed basic principles which we can teach the local surgeons to enable them to help their own people. Humanitarian aid in the field of hand surgery should not only remain a national task. A worldwide collaboration with many other charitable organizations like MSF show us the effectiveness of our efforts.

Keywords: Interplast, humanitarian aid, handsurgery camps, complications
Clinical Manifestation of Symptomatic Fishtail Deformity

List of authors:
Emiko Horii*, Yoshitaka Hamada¹, Katsu Toyama¹, Shukuki Koh², Junko Otuka²
¹ Kansai Medical University, Orthopaedic Dept (Hirakata)
² Japanese Red Cross Nagoya Daiichi (Nagoya)

Objectives / Interrogation: Aseptic necrosis of the distal humerus seldom occurs after pediatric elbow trauma. We experienced five cases, then report clinical manifestation and their surgical outcomes.

Methods: Five cases included 4 boys and 1 girl with an average age of 11.8 years. Past history revealed that all patients had had elbow trauma at an average age of 4.5 years (range 3.0 - 7.4). Three cases of supracondylar fracture had been treated per-cutaneus pinning in two and another was conservatively. Two cases of lateral condyle fracture had been treated by open reduction and fixation. All of them had been dismissed because of smooth recovery. All patients returned clinic with elbow pain and restricted motion and X-rays showed fishtail deformity. One case was treated close observation with restriction of sports activity. Two cases with atypical medial condyle fracture were treated screw fixation. Other two cases which showed osteochondral dissecans of the capitellum were treated by osteochondral bone peg grafting.

Results and Conclusions: An average follow-up is 1.5 year. Range of motion improved in all patients. Pain was subsided all but one case which had shown the radial head subluxation preoperatively. Regardless severity of the initial trauma, aseptic necrosis occurred after pediatric elbow trauma. It became symptomatic several years later and X-ray showed fish-tail deformity. Although short time outcomes were good, all elbows already showed osteoarthritic changes. There is no fundamental treatment for fish-tail deformity. Early detection of aseptic necrosis might prevent severe progress of fishtail deformity.

Keywords:
fish-tail deformity, pediatric elbow trauma
Endoscopic carpal tunnel release with or without a suture. Is there a difference?

List of authors:
Iwein Piepers*, Jean Goubau¹, Francis Bonte¹, Bert Vanmierlo¹
¹ AZ Sint Jan (Brugge)

Objectives / Interrogation: In our department surgical treatment of Carpal tunnel syndrome is performed using, the single incision technique described by Agee. It is a transverse incision of about 1 cm carefully placed into the skinfold of the palmar wrist. In our practice, we faced 2 cases where the skin suture was removed accidently the day following surgery. We left the wound open and protected it with wound closure strips. The skin healed remarkably well. We therefore set up, after approval of the ethics committee, a randomized study to compare the evolution of wound healing with or without skin suture in patients undergoing an endoscopic carpal tunnel release as treatment for carpal tunnel syndrome. Primary outcome is the Manchester Scar Scale (MSS).

Methods: 159 patients were recruited between April 2016 and April 2017. Inclusion criteria were patients with clinical and electrographic confirmation by the Canterbury NCS Scale of a carpal tunnel syndrome. Age, gender, occupation, predominant hand and the side of the operation were noted.

In the first group (64 patients) the skin was not sutured. In the second group (44 patients) the skin was intracutaneously sutured with ethilon 5-0. Data from 108 patients till 3 months postoperatively could be acquired.

Results and Conclusions: Since the data were not normally distributed the analysis was done with the Independent Samples Mann-Whitney U test (MWU).

There is no significant difference in age (p=0.496), gender (p=0.670) and occupation (p=0.725). The scar assessment using the MSS did not differ significantly between both groups: The MWU test is used, p=0.607. In the non-suture group, the MSS was 6.59 (standard deviation 1.294) and in the suture group the MSS was 6.45 (standard deviation 1.088).

Postoperatively wound healing and scar appearance with or without a suture is a topic that has not yet been addressed in the literature. In this study, the outcome of the scar 3 months postoperatively using the MSS is similar in both groups.

Wound closing without a suture can be considered as a valuable option in treating carpal tunnel syndrome using a single portal endoscopic technique

Advances in Ulnar Collateral Ligament Reconstruction of the Elbow: A Biomechanical comparison.

List of authors:
Felix Riano*, Steve Lee
1 Naples Hand Arthr (Naples)
2 Lennox Hill Hospital (New York)

Objectives / Interrogation: Ulnar Collateral Ligament (UCL) tears keep on increasing in overhead throwing athletes. The original and modified docking reconstruction techniques have been used since described by Dr. Jobe. We present a novel and optimized technique, which it might enhance the strength, stability and recovery of the reconstructed ligament. The comparative biomechanical results are discussed.

Methods: Ten matched pairs of human cadaveric elbows were loaded to failure at a flexion angle of 30 degrees and compressive rate of 14 mm/s. The specimens underwent reconstruction with an autologous palmaris longus graft using a standard Tommy John Technique and modified internal brace technique with a forked tip 4.75mm PEEK suture anchor.

Results and Conclusions: The average stiffness of the standard docking UCL technique was 27.3 ± 2.8 N/mm and FiberTape internal brace docking repair using a 4.75mm PEEK SwiveLock was 42.3 ± 8.5 N/mm. The mean stiffness of the FiberTape internal brace docking repair using a 4.75mm PEEK SwiveLock was statistically greater (p=0.044) than the standard docking technique. The average ultimate moment for the standard docking UCL technique was 29.7 ± 7.7 N-m and FiberTape internal brace docking repair using a 4.75mm PEEK SwiveLock was 42.6 ± 11.8 N-m. These biomechanical results are encouraging, with significant improvement of the strength, which they might allowed for a faster recovery without compromise on the stability.

PSYCHOLOGICAL IMPACT OF HAND INJURIES AMONG FOREIGN WORKERS IN SINGAPORE

List of authors:
Ian Dhanaraj¹, Vaikunthan Rajaratnam²
¹ Khoo Teck Phuat Hospital (Singapore)
² Khoo Teck Phuat Hospital (Singapore)

Objectives / Interrogation: Foreign workers are essential to Singapore, contributing to a significant portion of her workforce through a range of vocations. They are mostly low-skilled and face multiple challenges in order to work in Singapore. In addition to these stressors, an injury to the hand, a primary means of interacting with one's surroundings, may have a profound psycho-social impact. Our study, a first in Singapore, aims to shed light on the psychological impact that hand injuries have on an integral, yet vulnerable and neglected population.

Methods: This is a single-centre prospective study evaluating the psycho-social impact and functional outcomes of hand injuries among foreign workers in Singapore. Foreign workers were consecutively recruited from the Hand Surgery clinic. A single encounter interview was conducted for eligible patients. Psychological impact was measured with the DASS-21, symptom severity and limitation of daily function with the Quick DASH score, pain experienced with the VAS. Injury-specific and demographic data were collected as well.

Results and Conclusions: There were 36 foreign workers were recruited into this study. The mean age was 32.6 years [standard deviation (SD) 7.2]. Majority of them were male (94.4%), married (58.3%), and had salary less than SGD1000 per month (58.3%). The most common mechanisms of work-related injuries were cut (58.3%) and crush (25.0%). Stress, anxiety, and depression were positively associated with limitation of daily function (p<0.001). Multivariate analysis found that limitation of daily function was independently associated with stress (95% CI 0.12-0.34; p<0.001), anxiety (95% CI 0.03-0.23; p=0.017) and depression (95% CI 0.04-0.26; p=0.008)

Our study has for the first time shown that there is a significant psychosocial impact of hand injuries among foreign workers in Singapore. In light of this, there is potential for the development of screening and support programmes for at-risk workers to cater to their mental well-being, a basic human right. We recommend that the psychological impact of hand injuries must be factored into the holistic management and rehabilitation with adequate time and resource allocation. An ancillary benefit of this comprehensive strategy is the improvement of productivity and overall contribution to Singapore's economy. For this reason, this data may be useful to employers and the Ministry of Manpower.

Visualizing the pharmacological delay effect of botulinum toxin A on the flap donors by the infrared thermography in a rat pedicled flap model

List of authors:
Xu Gong*
1 The first hospital of Ji Lin University (Chang Chun city)

Objectives / Interrogation: Experimental evidence suggests the positive effect of botulinum toxin A (BTX-A) on pedicled flaps' viability, but few focus on how to identify preoperatively the delay effect induced by BTX-A.

Methods: Fifty-two Sprague-Dawley rats were divided into the control and delay groups. A pedicled flap of 11×3 cm was marked on the rat unilateral dorsum. In the delay group, 15 IU of BTX-A was injected subcutaneously along the flap boundary and then the flaps were elevated at 2, 3 and 4 weeks after BTX-A injection, respectively. Before flap harvest, both the infrared (IR) thermal imaging and temperature of the flap donors were recorded, and both the number of the dilated choke vessels and microvessel density in the choke zones were evaluated by postmortem arteriography and CD31 staining. The survival area of the flaps was measured on postoperative day 7.

Results and Conclusions: After BTX-A injection, IR thermography of the flap donors showed that the independent white hotspots of the angiosomes enlarged and fused; both the temperature of the flap donors and number of the dilated choke vessels in the choke zones increased significantly within 3 weeks, but no significant difference was detected between the 4-week delay group and the control. The microvascular density manifested a continuously increased trend over time. No significant difference was detected in the survival area of the flaps among the delay groups, although it increased significantly when compared to the control.

Combined use of IR thermography and temperature of the flap donors can identify preoperatively the maximal delay effect of BTX-A.

Visualized identification of the maximal surgical delay effect in a rat flap model

List of authors:
Xu Gong*
1 The first hospital of Ji Lin University (Chang Chun city)

Objectives / Interrogation: Currently, experimental evidence suggests that the surgical delay can increase flap survival area, but its effect may decrease if the optimal delay period is missed. The aim of this study is to establish a sensitive and objective modality based on the visualized and individualized infrared thermography for identifying the maximal surgical delay effect.

Methods: A rectangular three-angiosome flap was designed on the unilateral dorsum of the rat. Ninety-six rats were randomly divided into 6 groups according to the various delay time. Both the relative temperature and the relative temperature ratio were measured by the infrared thermography. Arterial density, number of vessels >0.1mm in diameter, microvessel density, VEGF concentration, and flap viability were measured. Receiving operating characteristic (ROC) curve with the highest Youden-Index was used to detect and identify an optimal cut-off point of the relative temperature ratio in the maximal surgical delay effect.

Results and Conclusions: The criteria for identifying the flap maximum delay effect based on the visualized and individualized infrared thermography imaging were that included (1) the surface of the post-delayed flaps presented white color (higher temperature) instead of the red and white pattern of the normal red area representing colder temperatures between the adjacent angiosomes was converted into the white area representing warmer temperature, and the surface of the post-delayed flaps formed a larger white area; skin and (2) the optimal cut-off point of the relative temperature ratio was more than 1.17 with a sensitivity of 84.6% and a specificity of 77.3%. Instead, the sensitivity and the specificity of the conventional method of based on the conventional delay time for identifying the maximum delay effect were 38.5% and 90.9%, respectively.

Infrared thermal imaging can accurately identify the flap maximum delay effect when combined with the relative temperature ratio.

Role of Anconeus in the Stability of a Lateral Ligament Deficient Elbow: An In Vitro Biomechanical Study

List of authors:
Armin Badre*, David Axford1, Sara Banayan1, Jim Johnson1, Graham King1
1 Roth-McFarlane Hand & Upper Limb Centre, St. Joseph's Health Care (London)

Objectives / Interrogation: The role of anconeus in elbow stability has been a long-standing debate. Anatomical and electromyographic studies have suggested a potential role as a stabilizer. However, to our knowledge, no clinical or biomechanical studies have investigated its role in improving the stability of a lateral collateral ligament (LCL) deficient elbow.

Methods: Seven cadaveric upper extremities were mounted in an elbow motion simulator in the varus position. An LCL injured model was created by sectioning of the common extensor origin, and the LCL. The anconeus tendon and its aponeurosis were sutured in a Krackow fashion and tensioned to 10N and 20N using a transosseous tunnel placed through the lateral epicondyle. Varus-valgus angles and ulnohumeral rotations were recorded using an electromagnetic tracking system during simulated active elbow flexion with the forearm pronated and supinated.

Results and Conclusions: Results
During active motion, the injured model resulted in a significant increase in varus angulation (5.3°±2.9°, P=.0001 pronation; 3.5°±3.4°, P=.001 supination) and external rotation (ER) (8.6°±5.8°, P=.001 pronation; 7.1°±6.1°, P=.003 supination) of the ulnohumeral articulation compared to the control state (varus angle -2.8°±3.4° pronation, -3.3°±3.2° supination; ER angle 2.1°±5.6° pronation, 1.6°±5.8° supination).

Tensioning of the anconeus significantly decreased the varus angulation (-1.2°±4.5°, P=.006 for 10N in pronation; -3.9°±4.0°, P=.001 for 20N in pronation; -4.3°±4.0°, P=.0001 for 10N in supination; -5.3°±4.2°, P=.0001 for 20N in supination) and ER angle (2.6°±4.5°, P=.008 for 10N in pronation; 0.3°±5.0°, P=.0001 for 20N in pronation; 0.1°±5.3°, P=.0001 for 10N in supination; -0.8°±5.3°, P=.0001 for 20N in supination) of the injured elbow.

Conclusions
In the highly unstable varus elbow orientation, anconeus tensioning restores the in vitro stability of an LCL deficient elbow during simulated active motion with the forearm in both pronation and supination. These results may have several clinical implications. Our results suggest that strengthening of the anconeus may play a role in improving the varus and posterolateral instability of an LCL deficient elbow and reducing the "sagging" of the elbow in patients with radiographic drop sign after an elbow dislocation. Finally, in the surgical approaches used in the management of patients with pre-existing elbow instability secondary to LCL injury, the origin of the anconeus and its innervation should likely be protected.

Percutaneous stabilization of scaphoid fractures with headless compression screw fixation

List of authors:
Sabrina Holzer*, Gabriel Halát¹, Bernhard J. Maier¹, Gerhild Thalhammer¹, Irena Krusche-Mandl¹
¹ General Hospital of Vienna, Department of orthopedic and trauma surgery, Division of Trauma Surgery (Vienna)

Objectives / Interrogation: Scaphoid fractures, being the most common carpal fractures, are associated with functional deficiencies of the wrist in a generally young population. In the treatment of those fractures, percutaneous scaphoid stabilization with headless compression screw fixation is a well-established procedure allowing early mobilization, shortened time away from work combined with high consolidation rates.
Our aim was to evaluate our clinical, radiological and functional results of percutaneously stabilized scaphoids.

Methods: We applied a set of in- and exclusion criteria, such as a minimal age of 15, no relevant other wrist lesions, no perilunar luxation mechanism (B4 fractures) and a minimal follow-up time of one year. Out of 107 consecutively treated scaphoid fractures with a headless compression screw (Acutrak ™) in the years 2000-2017, a total of 81 patients was incorporated in the study. Following parameters were analyzed: time of consolidation, immobilization time, return time to work, pinch and grip strength, radiological classification, Disability of the Arm and Shoulder Score (DASH) and the Patient Related Wrist Evaluation (PRWE).

Results and Conclusions: A mean age of 26 years (range: 15-79) was observed in a predominantly male (84%) population. Mean follow-up time was 4.5 years (range 1-17). With 63.8% the B2 fracture was the most commonly observed fracture. We achieved a consolidation rate of 98.8% with only one case of scaphoid nonunion. Three additional cases of delayed union were observed, yet all of those cases achieved full consolidation within 4-7 months after surgery. Mean consolidation time was 12 weeks with an average DASH of 0.98 and a PRWE of 0.2.

The treatment of scaphoid fractures with percutaneous headless compression screw fixation is a convenient treatment option, allowing satisfying consolidation rates with good functional outcome.

Open reduction and internal fixation for dorsal fracture dislocation of the proximal interphalangeal joint: a series of 35 cases

List of authors:
Masayoshi Ikeda*, Yuka Kobayashi², Ikuo Saito³, Ayuko Shimizu², Takayuki Ishii², Daisuke Nakajima², Masahiko Watanabe²
¹ Tokai University School of Medicine, Shona Central Hospital (Isehara, Kanagawa)
² Tokai University School of Medicine (Isehara, Kanagawa)
³ Tokai University School of Medicine, Isehara Kyodo Hospital (Isehara, Kanagawa)

Objectives / Interrogation: We describe a surgical technique for unstable fracture dislocations of the proximal interphalangeal (PIP) joint using a low-profile mini-plate, review of 35 patients treated by this technique, and discuss the factors affecting patient outcomes.

Methods: After reducing the dorsal subluxation of the PIP joint, the depressed articular surface was reduced and the volar fragment was fixed using a low-profile mini-plate through the volar approach. Postoperative motion exercise was started after a few days. Active motion of the PIP joint, total active interphalangeal joint motion, and Strickland's scoring scale, and Gaine's outcome assessment were used to evaluate the results. Clinical assessments were considered satisfactory when they were either excellent or good. Analysis of the categorical factors was performed using Fisher's exact test with p-values set at 0.05.

Results and Conclusions: Bony union was obtained in all cases. Twelve patients had persistent postoperative swelling of the PIP joint, which was managed with short-term steroids. Dynamic splints were applied 4 weeks postoperatively for patients with delayed recovery. The articular involvement was averaged 54.6%. Six patients had concomitant injuries. The mean age was 38.1 years (range, 13-82 years). The mean periods from injury to operation was 11.3 days (range, 1-60 days) and postoperative follow-up period averaged 11.5 months (range, 6-24 months). Active motion of the PIP joint averaged 85.5° (range, 45°-104°), flexion contracture averaged 10.8° (range, 0°-40°), and total active interphalangeal joint motion averaged 81.0% (range, 41.7%-100%) after surgery. Overall, 22 patients had satisfactory outcomes and 13 had unsatisfactory outcomes. Patient age, the time from injury to surgery, and concomitant injuries, such as an associated mallet injury, were found to be significantly associated with outcomes. Additionally, the control of persistent postoperative swelling was important for joint function. This technique catches the volar fragment rigidly between the dorsal cortex and the mini-plate, allowing the possibility for early joint motion. Several factors were associated with poor functional results, including older age, delayed surgery, and concomitant injuries. Additionally, the management of early PIP joint swelling improved joint motion.

Collateral ligament injuries of the metacarpophalangeal joint in long fingers. Results of a series of 20 patients. Presentation of a new clinical test.

List of authors:
Gero Meyer zu Reckendorf*, Mylene Kientzi¹, Jean Claude Rouzaud¹
¹IMM, Clinique St Roch (Montpellier)

Objectives / Interrogation: Collateral ligament injuries of the metacarpophalangeal (MP) joint in long fingers are rare conditions and mostly treated conservatively in comparison to the thumb. Clinical examination is essential to diagnose the gravity of the ligamentous injury. The aim of our study was to report results of surgical management of a series of 20 patients and to focus on a new clinical test.

Methods: 20 patients, mean age 48 years (22-70), were managed surgically for grade 3 injuries of the radial collateral ligament (RCL) of the middle finger (9), ring (4) and small finger (7). The mean delay between accident and surgery was 59 days (0-180). Preoperatively the new laxity test (Meyer's test) was positive in all cases. Surgical intervention found 2 Stener lesions. Postoperatively the MP joint was protected by an extension orthoses for one month, followed by a syndactyly for two months. Patients were reviewed by an independent examiner with a mean follow of 20 months (6-34). Total active motion (TAM) was measured, comparative MP laxity tests were performed at 0°, 30° and 90° of flexion, the Meyer and Bellemere tests were compared to the normal hand and strength measurements were realized.

Results and Conclusions: 15 patients were reviewed for clinical examination. One complication was noted (CRPS type 1). Mean Quick Dash was 16.2 (0-61). Mean TAM was 251° (218-308°) with mean active MP flexion-extension of 86-11° (72-99°/0-29°). The mean radial MP laxity at 0°, 30° and 90° of the injured digit was respectively of 22°, 15° and 13° compared to the normal side 18°, 17° and 14°. The mean ulnar MP laxity at 0°, 30° and 90° of the injured digit was respectively of 30°, 25° and 12° compared to the normal side 31°, 22° and 12°. Meyer's test shows a mean MP laxity of 17° (7-34°) of the injured digit and 13° (9-16°) on the normal side. Bellemere's test to radial and ulnar side on the injured digit shows a mean MP laxity of 12° and 11° compared to 24° and 10° on the normal hand. The mean global strength (Jamar) of the operated hand was 29 kg and 35 kg on the opposite side. Distal and lateral pinch measurements on the injured digit revealed a mean strength of 7 kg and 3 kg compared to 9 kg and 3 kg on the normal side.

Clinical results after RCL repair on the MP joint of long fingers are good despite some residual ligament distension demonstrated by our laxity tests measurements. Our new laxity test is a simple and painless clinical test allowing to diagnose grade 3 RCL injuries necessitating surgical repair.

Application of a Porcine SIS Nerve Cap for Prevention of Neuromas and Associated Pain

List of authors:
Shahryar Tork*, Jennifer Faleris, Anne Engemann, Erick DeVinney, Ian Valerio
1 The Ohio State University Wexner Medical Center, Department of Plastic and Reconstructive Surgery (Columbus)
2 AxoGen (Alachua)

Objectives / Interrogation: Painful neuroma formation is a common and debilitating sequela of traumatic or oncologic nerve amputation. Studies suggest that isolating the nerve-end within a protective cap either at the time of amputation or during revision procedures may assist in the prevention of nerve-end neuromas. This study evaluated the local effects of novel porcine small intestine submucosa (pSIS) nerve caps with internal chambers on a terminal nerve end in an animal model.

Methods: The tibial nerves of fifty-seven (57) Sprague Dawley rats were transected, transposed and secured in a subcutaneous pocket of the lateral hindleg. The nerves were treated with a pSIS Nerve Cap (NC), pSIS Open Tube (OT), or were non-treated Surgical Controls (SC). Weekly pain response testing was performed by observing animals and assigning a semi-quantitative score (0-2) after mechanically stimulating transposed nerve ends, where zero was no response and two was a brisk withdrawal or vocalization. Samples were explanted at 8 and 12 weeks and stained with Hematoxylin and Eosin, Masson's Trichrome, or Neurofilament-200. Sample analysis included axonal swirling, axon optical density (OD), nerve width, cap remodeling, and tissue response.

Results and Conclusions: The NC group had significantly lower axonal swirling and pain response scores compared to the SC and OT groups. Nerve width was notably greater in the SC group compared to the NC group. The nerve caps and open tubes were considered non-irritants and exhibited similar remodeling. The SC group showed significantly lower axon optical density compared to all other groups. A lower axon optical density suggests a higher concentration of collagenous tissue, which is a characteristic of neuromas. Application of pSIS nerve caps in this animal model demonstrated increased axon optical density and decreased axonal swirling, distal nerve stump width and behavioral pain response. This suggests that nerve caps with internal chambers may support fibrin cable formation to facilitate axonal alignment; therefore, more reliably reducing the likelihood of painful neuroma formation.

Clinical outcome of the radial head and neck fracture treated by headless screw fixation

List of authors:
Koichi Yano*, Yasunori Kaneshiro¹, Ryo Sasaki¹, Seungho Hyun¹, Hideki Sakanaka¹
¹ Seikeikai Hospital (Sakai City)

Objectives / Interrogation: We treated the combined fracture of the radial head and neck by headless screw fixation only. The purpose of this study is to report the clinical and radiographic outcome.

Methods: This study included the patients who were suffered combination of the radial head and neck fracture, treated by headless screw fixation only, followed more than nine months. They are four men and four female. Average age at surgery was 40 years-old (19-62), Average number of the radial head was 3.3 (2-5). Associated injuries were none in four patients, ulnar styloid fracture in one, lateral collateral ligament injury of the elbow in one, olecranon fracture in one, scapholunate dissociation in one. In surgical treatment, the multiple fragments of the radial head was taken to the outside and fixed by screws. When the bone defect was found at radial neck, the bone graft was harvested form proximal ulna. After then, radial head was fixed to the radial neck by screw. Immobilization of the elbow and forearm was performed for two weeks postoperatively. From third week postoperatively, the elbow and forearm were started to exercise. Clinical outcome was examined by the range of the elbow and forearm motion at final follow-up. Mayo elbow performance score was also assessed. Radiological examination was performed for bone union, arthritic change. Postoperative displace of the bony fragment was assessed by the angle between bony axis of the proximal metaphysis of the radius and articular surface of the radial head.

Results and Conclusions: Average postoperative follow-up period was 418 days. Bone graft was performed in 2 patients. Average range of motion was as following; elbow flexion: 139° (130-145), elbow extension: -4° (-15-0), forearm supination: 88° (80-90), forearm pronation: 84° (60-90). Average Mayo elbow performance score was 98.1 (85-100). On radiographical examination, bony union was obtained in all patients and arthrosis was found in none. Postoperative displace was minimal because there was no significant difference in the angle between just after operation and final follow-up. Our study showed that the headless screw fixation for radial head and neck fracture maintained reduced position of the fracture site and did not cause the limited motion of the forearm rotation significantly. For the case with good quality of bone, the headless screw fixation could be one of the surgical fixations.

The Threat of Longitudinal Cracking after Distal Radius Fracture Treatment with Volar Locking Plate

List of authors:
Nasa Fujihara*, Yuki Fujihara
1 Aichi Cancer Center Hospital (Nagoya)
2 Nagoya Ekisaikai Hospital (Nagoya)

Objectives / Interrogation: Despite the increasing prevalence of longitudinal crack following volar locking plate fixation in our clinical experience, research on the topic remains sparse. The aim of this study was to examine the occurrence rate of the fine cracks and associated characteristics following volar locking plate fixation of the distal radius.

Methods: Using case records from Shizuoka Saiseikai General Hospital dated between March 2008 and March 2015, a total of 419 eligible adult distal radius fracture patients were identified. Standard anteroposterior postoperative radiographs were evaluated to classify longitudinal crack occurrence. The following data were recorded: plate type, surgeon experience at the time of surgery, patient age, sex, fracture type, and postoperative complications from the crack. Fractures were classified according to the AO/OTA classification system. Documented variables were compared between patients with longitudinal cracking and those without. Univariate analyses were conducted among each plate group.

Results and Conclusions: There were 38 confirmed cases of cracking (Acu-Loc: n=25, Acu-Loc 2: n=11, VA-TCP: n=2). Acu-Loc and Acu-Loc 2 were most common with rates of 13.0% and 27.5% respectively. Neither patient age nor gender was significantly associated with a particular type of plate. Along with patient age and sex, plate type was significantly associated with the occurrence of a longitudinal crack (p<0.05). Surgeon experience level did not affect the fine crack rates. All cracks healed within 4 to 6 weeks after the operation without any symptoms. Although we observed no severe complications following longitudinal cracks after volar plate fixation, surgeons and manufactures should still be cognizant of the potential complication. Intervention may not be necessary, but rare, severe implications may exist. Further study is required to understand the mechanism of the fine cracking and implement appropriate prevention techniques.

Treatment of Prolonged Chronic Monteggia Lesion by Corrective Osteotomy of Ulna with Radial Shortening

List of authors:
Hiroo Kimura\*\(^1\), Atsuhito Seki\(^2\), Naoto Inaba\(^2\), Kazuki Sato\(^3\), Shinichiro Takayama\(^2\)
\(^1\) Nasu Red Cross Hospital (Tochigi)
\(^2\) National Center for Child Health and Development (Tokyo)
\(^3\) Keio University School of Medicine (Tokyo)

Objectives / Interrogation: Chronic Monteggia lesion in children is often treated by open reduction of the radial head and corrective osteotomy of the ulna. However, the treatment of long-standing radial head dislocation may possibly cause poor outcomes of re-dislocation, limited forearm rotation and restriction of elbow flexion. The treatment of chronic radial head dislocation remains controversial. Despite the risk of complications, surgery is recommended for active children. In these cases, we designed radial shortening along with corrective ulnar osteotomy. The purpose of this study is to assess the clinical outcomes of our procedure.

Methods: All cases were retrospectively reviewed. Six elbows in 6 patients who were diagnosed with chronic Monteggia lesion were included in this study. All the elbows showed valgus instability and anterior radial head dislocation. The mean age at the time of operation was 13 years (range 6 to 19 years). The mean period of dislocation was 7.5 years (range 4 to 13 years and 2 cases uninjured). As surgical procedure, radial shortening at the level of proximal diaphysis and anterior capsulotomy for intracapsular observation were carried out first through anterior approach to the proximal forearm. Then corrective ulnar osteotomy and posterolateral capsulotomy if necessary were conducted through posterior approach. Finally, the annular ligament and capsules were tightened and repaired.

Results and Conclusions: In all cases, dislocated radial heads were reduced and osteotomized sites were united, and there were no cases of re-dislocation of radial head during mean follow-up periods of 17 months (range 9-36 months). Compared to preoperative conditions, all the elbows obtained good stabilities and a mean of 12 degrees of elbow flexion (range -5 to 30 degrees). Mayo elbow performance score was increased from a mean of 87 (range 70 to 90) to a mean of 97 (range 80 to 100). Meanwhile, the patients lost a mean of 13 degrees of elbow extension (range 10 to 28 degrees), 12 degrees of pronation (range -20 to 20 degrees) and 8 degrees of supination of the forearm (range 0 to 20 degrees), respectively. There were no major surgical complications. In this study, we demonstrated the short-term results of corrective ulnar osteotomy with radial shortening for long-standing chronic Monteggia lesion. Radial shortening made it easy to reduce and keep radiocapitellar congruity. Although further investigation should be needed to prove long-term effectiveness, it appears to be one of the surgical options.

The Learning Curve in Arthroscopic Scaphoid Resection and Midcarpal Arthrodesis

List of authors:
Markus Pääkkönen*, 1, Aleksi Vihanto1, Tero Kotkansalo1

1 Department of Hand and Upper Limb Surgery, COE TYKS ORTO (Turku)

Objectives / Interrogation: Scaphoid resection and arthrodesis of the midcarpal joint is traditionally performed from an open dorsal arthrotomy. More recently an arthroscopic procedure has been introduced. The artroscopic approach is time-consuming and technically challenging. We wanted to find out the incidence of complications during the learning phase in a single surgeon case series.

Methods: We retrospectively identified 8 patients with 9 cases of arthroscopic scaphoidectomy and midcarpal arthrodesis (6 cases of scapholunate advanced collapse, one case each of Preiser disease, radioscaphoid or capitolunar osteoarthritis) in 2014-2017. All patients were operated by the same surgeon (Level of expertise 3; >10 years of experience in wrist arthroscopy). Osteosynthesis was performed with cannulated screws placed under fluoroscopic guidance. The follow-up time was 5-14 months.

Results and Conclusions: Results
The operating time for the first surgery was 198 minutes. For the last surgery in the series, the operating time was 132 minutes. Fusion was achieved in all patients. Three (33%) patients required a reoperation: scaphoid remnant removal for impingement and two cases of screw removal due to screw malposition. In one of the latter cases a tendon repair was also performed due to tendon laceration caused by a retracted screw. One patient suffered a superficial radial nerve injury.

Conclusions
There is a steep learning curve associated with demanding arthroscopic procedures. We observed a high rate of complications and reoperations among patients operated by an experienced and motivated wrist surgeon. Some of the findings of this study should be taken into consideration when arthroscopic wrist fusion is adopted in an institution for the first time. Performing both total scaphoidectomy and the midcarpal arthrodesis via arthroscopy may lead to long operating times in the first procedures, but the operating time will eventually decrease. It is an option to perform an open scaphoidectomy from a volar incision in the first procedures to reduce operative time, but this was not utilized in this series. To avoid complications relating to hardware, we recommend special attention to the placement of the cannulated screws. Meticulous removal of the scaphoid may reduce the risk of impingement. A structured wrist surgeon training protocol with live surgical demonstrations might be useful in reducing complications.

Preservation of metacarpophalangeal joint function in traumatic defects by metatarsophalangeal osteochondral transplantation

List of authors:
Steffen Löw*, Marion Papay2, Christoph Eingartner3
1 Praxis für Handchirurgie und Unfallchirurgie (Bad Mergentheim)
2 Caritas-Krankenhaus, Klinik für Orthopädie und Unfallchirurgie (Bad Mergentheim)
3 Caritas-Krankenhaus Bad Mergentheim, Klinik für Orthopädie und Unfallchirurgie (Bad Mergentheim)

Objectives / Interrogation: The integrity of the metacarpophalangeal (MCP) joints is essential for finger and hand function. Preservation of range of motion is one of the aims in reconstruction of complex injuries to these joints. Avascular transplants of whole joints are prone to resorption and deterioration of function, whereas osteochondral transplants have shown to be reliable in reconstruction of various joint defects. This series presents three patients with traumatic injuries to four MCP joints, which were reconstructed by seven avascular osteochondral transplants of metatarsophalangeal (MTP) joints. The joints were examined for radiographic signs of resorption or joint space narrowing, and if this would affect the joints' function.

Methods: Between 09/2009 and 01/2015, in three patients (age of 40, 45 and 48 years) with complex injuries to their MCP joints (one milling, two saw injuries), four joints were reconstructed by seven osteochondral transplants of their toe MTP joints. Thereby, three metatarsal head and four osteochondral transplants of the base of the proximal toe phalanges were used. Beside the joint itself, various soft tissue defects were to be reconstructed in each patient. The patients were clinically and radiographically examined after 3, 6, respectively 9 years.

Results and Conclusions: None of the patients complained of pain, neither in the involved joint of the reconstructed finger, nor at their toes. All patients were satisfied with the result of reconstruction. DASH score was 13, 29, and 24, respectively. Range of motion in the four affected joints were 25, 60, 75, respectively 90°. Radiographic examination revealed moderate joint space narrowing in one of the four joints. In another patient, localized osteolysis was found around the screws heads, so that the screws were removed seven years post-op.

Osteochondral transplants for reconstruction of MCP defects are able to preserve function in severely injured joints in the mid and long-term. Joint space narrowing may occur, but this does not cause pain. Since localized osteolysis can cause screw head prominence, midterm radiographic follow-up is necessary to prevent further damage to the joint. In the long-term, remaining bone stock may be adequate for total joint replacement.

Single-stage radialization and pollicization for radial longitudinal deficiency with thumb hypoplasia

List of authors:
Pobe Luangjarmekorn*¹, Pravit Kitidumrongsook¹
¹ Department of Orthopaedics, King Chulalongkorn Memorial Hospital, Chulalongkorn University (Bangkok)

Objectives / Interrogation: For children who had radial longitudinal deficiency with thumb hypoplasia, problems of unable to afford cost of multiple follow-up, transportation, and multiple operations, lack of distraction device or small-size external fixator and poor patient's compliance for taking care these devices made us develop surgical procedure that combine multi-stage reconstruction into single-stage radialization and pollicization. The advantages of this technique was to reduce number of surgical operations and anesthesia, shortening time for wound recovery, reduced frequency of follow-up, and decrease cost of transportation for patients.

Methods: Surgical technique for single-stage radialization and pollicization was explained steps-by-steps. Medical record in 2 patients who treated by this technique were reviewed.

Results and Conclusions: Two children with radial longitudinal deficiency and unreconstructable thumb hypoplasia were operated by single-stage radialization and pollicization without postoperative complication. At 1-year follow-up, wrist positions were improve from 95° to neutral and 90° to 15° radial-angulation. Both pollicized thumbs stayed in proper opposition and started function. Special considerations for this technique were 1.) Dorsal vertical midline incision was used for radialization because benefit in proximal extension for ulnar osteotomy and less interfered with pollicization incision, 2.) Ulnar shortening osteotomy should be done in case of difficulty in reposition carpus over distal ulnar, overlapping bone, or wrist flexion deformity after complete soft tissue released, 3.) Recommended K-wire technique including pre-drill and retrograde insertion should be followed for easy osteotomy fixation, 4.) Exit point of K-wire at the palmar site of base index metacarpal bone was less interfered with pollicization procedure, and 5.) Preserved dorso-radial skin bridge between pollicization incision and radialization incision for adequate venous draining and prevent postoperative swelling.

In conclusion, single-stage radialization and pollicization can be done in severe radial longitudinal deficiency (Bayne and Klug type III and IV) with unreconstructable hypoplastic or absent thumb (Blauth and Schneider-Sickert type II, IV, V) to reduce number of surgical operation and risk of multiple anesthesia.

Keywords: Radialization, Pollicization, Radial longitudinal deficiency, Thumb hypoplasia
Outcome of Proximal Row Carpectomy in a cohort study with 12 months follow up

List of authors:
Freek Lötters*, Ton Schreuders1, Hans Pieter van Not3
1 Hand en Pols Revalidatie Nederland (Goes)
2 Hand en Pols Revalidatie Nederland, Erasmus University Rotterdam (Goes)
3 Hand en Pols Revalidatie Nederland, Admiraal de Ruyter Ziekenhuis (Goes)

Objectives / Interrogation: Proximal Row Carpectomy (PRC) is a surgical salvage procedure for treatment of severe pain in e.g. a SLAC or SNAC wrist. After the PRC procedure patients were submitted to a standardized rehabilitation protocol. The objective of this study was to monitor functional outcomes of PRC and the subsequent rehabilitation in a 12 months follow up period.

Methods: Fifty patients (30 male, 20 female) underwent a PRC. The mean age was 56±12.1 years, and the side of operation was right (56%) and left (44%). The SLAC/SNAC wrists were due to primary radio-carpal osteoarthritis (46%), trauma in the past (18%), wrist fracture (16%), scaphoid fracture (14%) and other (6%). The primary outcome of the study was pain (NRS 0-10), secondary outcomes were wrist mobility (goniometry), grip strength (JAMAR), disability in daily live (DASH/PRWHE 0-100) and patient satisfaction with the operation (0-24;the higher the better). Differences over time were analysed with a Paired T-test (pre-operative-12months follow up). We applied an intention-to-treat analysis. Effect sizes (EF) and the corresponding confidence intervals (CI) were calculated using Cohen-d.

Results and Conclusions: The primary outcome showed a strong statistically significant (p<=0.001) decline in pain intensity at 12 months of 4 points (62%) in comparison with the initial pre-surgery measurement (EF(d)=2.3, CI=-2.9-2.4). On the disability/participation scales patients showed a statistically significant (p<=0.001) improvement of 42.9 points (75%) (EF(d)=3.5, CI= 0.1-6.9) with the initial pre-surgery measurement. Both the improvement on pain and disability/participation can be considered clinically important.
For mobility (EF(d)=0.6, CI=-4.4-5.6) and grip strength (EF(d)=-0.3, CI=-2.9-2.4) no statistical significant differences with pre-surgery status were detectable after 12 months follow up.
The mean post-operative rehabilitation time was 8.1±3.1 hours, and patient satisfaction with operation after 6 months was very high (20.6±4.0). Re-operation was needed in 4 patients, with one arthrodesis and 3 carpal tunnel releases within 12 months follow up.

PRC surgery and the subsequent rehabilitation resulted in a strong decline in pain in patients with a SLAC or SNAC wrist. Additionally, patients clearly perceived less disability problems in daily life after 12 months follow up. Gradually improvement and relief of symptoms occurred during the first 6 months follow up period, and stabilized or slightly further improved in the subsequent 6 months.

Keywords:
The experience of psychological distress in hand injured patients

List of authors: Ingrid Kieran*, Lukas Vaclavek, Matthew Stone, Elizabeth George

1 Pinderfields general hospital (Wakefield)

Objectives / Interrogation: The two aims of this study were to 1) identify levels of distress in patients presenting with hand injuries 2) assess what access patients have to a psychologist nationally in UK plastic surgery units.

Methods: Methods:
1) To identify the level of distress experienced by hand trauma patients, 163 patients attending a tertiary referral centre were surveyed using a distress thermometer. Patients were asked about their experience of distress secondary to their hand injury a) at time of presentation and b) at 4 months follow up.
2) A national survey of all plastic surgery hand units in the UK was undertaken to identify availability of a psychologist for patients with hand injuries.

Results and Conclusions: Results:
1) Over half of surveyed hand trauma patients reported that they experienced distress levels at time of first presentation. Of those reporting distress, 57% reported a significant level of distress. The four month follow up survey demonstrated varying responses in distress levels with a majority of patients experiencing a reduced distress level whilst a smaller number experienced the same or worse levels of distress.

2) The vast majority of UK units have access to a psychologist for hand trauma patients.

Conclusion:
Hand injuries can cause significant distress secondary to inability to work, sudden loss of income and worry. A significant proportion of patients in our unit reported high levels of distress associated with their hand injuries with a smaller number reporting continued or worse levels of distress at four months follow up. Such psychological burden can in turn lead to prolonged consultations between patients and their consultants and hand therapists leading to inefficient use of time and resources. This study highlights the need for the availability of access to psychology services for hand trauma patients. Availability would likely improve affected patient outcomes and service efficiency.

USE OF BOTULINUM TOXIN A IN MANAGEMENT OF A COMPLEX VOLAR THUMB WOUND IN A SYSTEMIC SCLEROSIS PATIENT: CASE REPORT

List of authors:
Ayana Crichlow*¹
¹University of the West Indies (Bridgetown)

Objectives / Interrogation: Patients with systemic sclerosis endure poor wound healing especially in the hand and digit fingertip wounds are a common problem. This disease process typically is associated with immune-mediated vascular injury and unopposed vasoconstriction of the hand's small vessels. There is limited data on the efficacy of botulinum toxin A in the non-surgical treatment of digit fingertip wounds. But, it is still thought of as a viable pharmaceutical option. Its use in systemic sclerosis patients for healing of digit wounds not on the fingertip is undocumented. This case report showcases botulinum toxin A unconventional use for a thumb wound in a systemic sclerosis patient.

The objective was to assess wound healing and monitor for immediate, early and late effects of botulinum toxin A use on digit wounds in a systemic sclerosis patient.

Methods: Informed consent was taken. A median nerve block was performed. 100u of botulinum toxin A was reconstituted and 20u was injected around the thumb radial and ulnar digital nerve(10u each), at the level of the right thumb A1 pulley.

Right thumb SpO2 was taken before and immediately after the procedure. The patient was followed clinically for wound healing and side effects of Botulinum toxin A over the next 9 months.

Results and Conclusions:
This patient presented with a 3 x 2.5cm wound over the volar aspect of her right thumb interphalangeal joint and an exposed flexor pollicis longus tendon was seen in the base of the wound. SpO2 before and immediately after botulinum toxin A injection was 88% and 94% respectively. The patient experienced pain relief in 24 hours. Complete wound healing was noted 25 days after injection. 54 days after injection full thumb range of motion with Kapandji score 10 was noted. No side effects of botulinum toxin A were identified.
Right thumb wound before (A-C), 21 days postop (D,E), and 29 days post op/ injection day (F-H). Healed wound 25 days (I,J) and 9
Botulinum toxin A may be used as an alternative treatment option in healing of wounds to the digits of systemic sclerosis patients where:
1) Surgery is contraindicated
2) Delay in surgery is expected
2) A salvage option where amputation is highly likely.

Analysis of Carpal Malalignment in Distal Radius Fractures Following Volar Locking Plate Fixation

**List of authors:**
Kentaro Watanabe*
1 Department of Orthopaedic Surgery, Nagoya Ekisaikai Hospital (Nagoya)

**Objectives / Interrogation:** PURPOSE: To clarify whether postoperative carpal alignment recovered anatomically after open reduction and internal fixation with a volar locking plate for the treatment of distal radius fractures, the change in carpal alignment, more specially dorsal displacement of the capitate, was evaluated.

**Methods:** METHODS: Sixty-three patients (mean age, 59 years) underwent volar locking plate fixation with a single type of plate (DVR plate; Zimmer Biomet) within 1 week after injury. The fracture type according to the AO/OTA classification was A3 in 16 patients, C1 in four, C2 in 29, and C3 in 14. Radio-capitate distance (RCD), defined as the relative position of the capitate to the radius, was measured in addition to volar tilt (VT), radio-lunate angle (RLA), radial inclination (RI), volar prominence height (VPH), and volar cortical angle (VCA) using standardized radiographs of the uninjured and postoperative wrists. Each variable was compared statistically.

**Results and Conclusions:** RESULTS: Mean values of the variables for the uninjured wrists were, respectively, 1.4 mm for RCD, 8.5° for VT, 6.9° for RLA, 29.3° for RI, 9.9 mm VPH, and 50.0° for VCA. RCD for the uninjured wrists was not correlated with age and sex or laterality. RCD was moderately related to VPH, RLA, and VT, weakly related to VCA, and not related to RI. Mean values of the variables for the postoperative wrists were, respectively, -1.2 mm for RCD, 4.8° for VT, 1.6° for RLA, 27.2° for RI, 9.2 mm for VPH, and 34.7° for VCA. Each variable decreased significantly, which indicated a persistent dorsal shift of the distal carpal row. The change in RCD was strongly related to that in VPH, moderately related to that in VCA and RLA, weakly related to that in VT, and not related to that in RI.

CONCLUSIONS: Anatomical recovery of carpal alignment was not routinely achieved with the use of a single type of plate. RCD should be further evaluated as a parameter for use in distal radius fracture treatment because of its comprehensive association with the parameters such as VPH, VCA, and VT which indicate displacement of the distal fragment.

Three-dimensional MRI-CT fusion images of osteochondritis dissecans of the elbow: A novel technique for preoperative evaluation and surgical planning

List of authors:
Sho Kohyama*, Yasumasa Nishiura², Yuki Hara¹, Takeshi Ogawa³, Akira Ikumi¹, Eriko Okano¹, Masashi Yamazaki¹
¹ Department of Orthopaedic Surgery, Faculty of Medicine, University of Tsukuba (Tsukuba)
² Tsuchiura Clinical Education and Training Center, Tsukuba University Hospital (Tsuchiura)
³ Mito Medical Education and Training Center, Tsukuba University Hospital (Mito)

Objectives / Interrogation: In osteochondritis dissecans (OCD) of the elbow, severity of the lesion affects prognosis and selection of treatment. It is difficult to precisely evaluate lesions even with magnetic resonance imaging (MRI) or computed tomography (CT). We developed a novel technique to construct three-dimensional (3D) MRI-CT fusion images. It enables the detailed evaluation and surgical simulation of OCD of the elbow. We aimed to validate the fusion images against intraoperative findings to clarify their usefulness.

Methods: We enrolled 10 patients with OCD of the elbow who underwent surgery. For preoperative CT, a 320-row detector imager (TOSHIBA©) was used to obtain 1-mm thick slices and to generate a 3D model of the humerus. A 3 Tesla imager (SIEMENS©) was used for preoperative MRI. Images were obtained using a 3D double-echo steady sequence, with 0.4-mm thick slices. 3D models of the humerus and articular cartilage were constructed. To widen the humeroradial joint space and clarify the articular cartilage outline, 7 kg of axial traction was applied to the elbow during MRI. Images were fused for further evaluation and surgical simulation, using software manufactured by Materialise©. The International Cartilage Repair Society (ICRS) classification was predicted based comprehensively on articular cartilage shape (normal or irregular), and the existence of cartilage fissure or defect and segmented subchondral bone lesion. Average distance error of fusion images was examined. Preoperative ICRS classification expected from fusion images was compared with intraoperative ICRS classification. The applicability of preoperative simulation of surgery was evaluated.

Results and Conclusions: Average distance error of the fusion images was 0.87 (range 0.74-1.00) mm. The expected ICRS classifications were classes II, III, and IV in 1, 4, and 5 cases, respectively. Intraoperative ICRS classification accurately matched the imaging-based predictions in all patients. As operative planning, subchondral drilling for a class II and class IV case, free body removal in a class IV case, and costal osteochondral autograft for 4 class III cases and 3 class IV cases were simulated. Surgeries were conducted based on the simulations.

The 3D MRI-CT fusion images provide the exact positional relationship between bony and cartilaginous lesions, an accurate evaluation of lesion severity, and a precise simulation of the surgical procedure. In conclusion, this is a novel and useful technique for the treatment of OCD of the elbow.

Clinically relevant outcome thresholds to enhance indication quality in patients with thumb carpometacarpal osteoarthritis

List of authors:
Miriam Marks*, Cécile Grobet¹, Laurent Audigé³, Daniel B. Herren¹
¹ Schultess Klinik (Zürich)

Objectives / Interrogation: In order to enhance indication quality, it is useful to know at which level of symptoms patients should be operated to achieve the potentially best postoperative result. The objective of this study was to define clinically relevant preoperative thresholds at which patients with thumb carpometacarpal osteoarthritis (CMC I OA) have the greatest chance to achieve a relevant symptom improvement and an acceptable symptom state after surgery.

Methods: In a prospective study, 151 patients with CMC I OA and indication for surgery were included. Patients were examined before and 3, 6 and 12 months after surgery. The Minimal Important Difference (MID), Minimal Important Change (MIC) and the Patient Acceptable Symptom State (PASS) for pain at rest, pain during activities and the brief Michigan Hand Outcomes Questionnaire (brief MHQ) were determined as well as the preoperative thresholds, which are predictive to achieve the MIC and PASS. Anchor-based approaches and receiver operating characteristics (ROC) curves were used.

Results and Conclusions: The MID for pain at rest, pain during activities and the brief MHQ was 1.4, 1.0 and 12 and the MIC was 1.9, 3.9 and 16, respectively. The PASS was 1.5, 2.5 and 70. Regarding the preoperative thresholds, patients with baseline pain at rest of 3.5 or greater were most likely to achieve the MIC, and patients with a preoperative score of 5.5 or less were most likely to achieve a PASS. For pain during activities, the thresholds were 6.5 for achieving the MIC and 7.5 for the PASS. For the brief MHQ, the threshold to achieve the MIC and PASS was equal with 47 points.

We suggest that patients should be operated if they have preoperative pain values between 3.5 and 5.5 at rest and between 6.5 and 7.5 during activities and a brief MHQ score of about 47. Within these reference values, patients have the greatest chance to achieve a subjectively relevant improvement and an acceptable symptom state.

Giant cell tumors of the tendon sheaths in the hand

List of authors:
Ryuta Iwanaga* 1
1 1-1-1 (Ube)

Objectives / Interrogation: Giant cell tumor of the tendon sheath (GCTTS) is the second most common tumor of the hand after ganglion cysts. However, the local recurrence after excision has been reported in 5-30% of cases. The purpose of this study is to evaluate the clinical results of patients and to determine the risk factor of recurrence.

Methods: From 2002 to 2017, 32 patients [17 males, 16 females, mean age 50, ranging from 13-77 years] underwent excision of GCTTS of the hand. The average follow-up time was 15 months (3-180), the disease duration was 19 months (1-60), and the size of tumor was 14.5 mm (11-25). We always used the operating microscope during resection of tumors. We evaluated size of tumor, disease duration, bone erosion, pseudocapsule, and tumor-occupying factor.

Results and Conclusions: Recurrence was noted in only one case, who was successfully managed by a second excision. 2 cases were recurred after resection in other hospitals. Recurrence group (n=3) and control (n=29) were compared, but we could not find the risk factor for recurrence with a statistically significant difference. 2 cases were recurred in the proximal interphalangeal (PIP) joint.

Discussion: The local recurrence of GCTTS was caused by incomplete resection or satellite lesion. GCTTS in or around PIP joint was difficult to remove adequately, because the neurovascular structures are quite close to tumor margins. To prevent recurrence, some literatures suggested postoperative radiotherapy or use of imatinib. However, they have been still controversial. We guess the pre-operative planning and microscopic resection are important to prevent recurrence.

Conclusion: GCTTS in the hand are a common benign soft tissue tumor. Incomplete resection and satellite lesion seem to be the main factors influencing the rate of recurrence.

Keywords:
Robot-Assisted of Volar Percutaneous Scaphoid Screw Placement: initial clinical experience

List of authors:
Yang GUO*¹
¹Beijing Jishuitan hospital (beijing)

Objectives / Interrogation: To investigate a robot-assisted technique for volar insertion of a percutaneous scaphoid screw and compare insertion time, accuracy, and radiation exposure to the traditional technique. We hypothesize that robot-assisted navigation of volar percutaneous scaphoid screw placement would improve accuracy, require less time, and diminish radiation exposure when compared to the free hand technique.

Methods: 16 patients with acute Herbert B2 scaphoid fracture were randomized to computer-assisted versus traditional volar percutaneous scaphoid screw placement. Time of the overall procedure, set-up time, time for ideal guide wire placement, and radiation time were recorded. Number of guide wire attempts was also recorded. Finally, accuracy of planned screw axis and actual screw axis were compared. Student’s t-tests were used to determine whether the differences in outcome variables between computer-assisted and free hand techniques were significant. Postoperative outcome measures included time to union based on computed tomography, patient-reported pain and range of motion.

Results and Conclusions: Results Sixteen screws were placed in 8 patients in the robot-assisted group and 16 screws in 8 patients in the freehand group; no postoperative complications or revisions were reported. The overall time of the 2 procedures and the set-up time were not different between the 2 groups, the time for placement of the K-wire was 60% in the robot-assisted percutaneous scaphoid fixation group, and the number of K-wire attempts needed for accurate screw placement approached clinical significance. Although the radiation exposures of set-up time were higher in robot-assisted group, the radiation exposures for global time of the procedure and guide-wire placement were clinically lower in robot-assisted group. Conclusions Robot-assisted navigation of volar percutaneous scaphoid screw placement takes no more time that traditional methods and significantly reduces the amount of radiation exposure to the patient. This technique also significant reduced the number of incorrect placement of the guide wire compare to free hand guide wire insertion.

Comparison of extension splint and temporary pinning for acute tendon mallet injury

List of authors:
Shigeki Nagura¹, Taku Suzuki¹, Takuji Iwamoto¹, Ruriko Iigaya¹, Noboru Matsumura¹, Masaya Nakamura¹, Morio Matsumoto¹, Kazuki Sato¹
¹Department of Orthopaedic Surgery, Keio University School of Medicine (Tokyo)

Objectives / Interrogation: Purpose: This retrospective study was designed to evaluate conservative and surgical treatment for acute closed tendon mallet injury.
Methods: Methods: A total of 59 patients with acute closed tendon mallet injury were enrolled in this study (29 patients in conservative treatment and 30 patients in surgical treatment). Conservative treatment was performed using two types of splinting and surgical treatment was conducted with oblique K-wire fixation of the distal interphalangeal (DIP) joint. The DIP joint was immobilized for eight weeks in both treatments. Active ranges of motion of the affected finger and clinical results from Miller’s classification were evaluated postoperatively.
Results and Conclusions: Results: The mean extension lag of the DIP joint in the surgical treatment group was significantly better than it was with conservative treatment (2.1° vs 13.8°, p < 0.001). The surgical treatment group also showed significantly better results on Miller’s classification (p = 0.007). Three patients who were noncompliant with the splint showed poor results, while no patients in the surgical treatment group had a poor result.
Conclusions: Surgical treatment with temporary K-wire fixation leads to satisfactory postoperative results for acute tendon mallet injury.

Current algorithms for obstetric palsy are too aggressive. A practical and conservative approach using triceps and wrist extension assessment.

List of authors:
Michael Solomons¹, Aude Bommier¹, Duncan McGuire³, Michelle Maree¹
¹ Groote Schuur Hospital (Cape Town)

Objectives / Interrogation: Current algorithms for surgical indications for obstetric brachial plexus injury (OBPI) use recovery of biceps at 3 months or 4 months. We know the plexus is damaged sequentially with downward traction. Therefore C5 and 6 are more affected than C7 which is worse than C8 etc. C7 can be assessed by measuring triceps and wrist extension. If there is no C7 at 4 months then the chance of C5/6 recovering is slight. Surgery is indicated. If there is good wrist extension and triceps at 4 months then the decision can be delayed to 6 months as some infants will still recover.

This study will compare our algorithm to those in the literature that advise surgery at 3 months if there is no deltoid or biceps recovery.

Methods: All babies referred to our OBPI clinic over a 9 year period were assessed. Those that presented after 3 months were excluded from this study as were those that were complete palsies and those that had good biceps at 3 months. 57 met the inclusion criteria.

Follow up was monthly with assessment of muscle recovery.

We performed a retrospective review comparing the outcome of babies managed by our algorithm (operative and non-operative), to those in the literature that would have received surgery at 3-4 months where there was no recovery of deltoid/biceps.

Results and Conclusions: Our results show that 52.6% of our infants managed to avoid surgery and have a good outcome, that would have been performed at centers using recovery of biceps/deltoid at 3 months.

31.6% of our infants avoided surgery that would have been performed at centers using 4 months as the surgical trigger.

We believe that current algorithms are too aggressive and present our algorithm where triceps and wrist extension are assessed at 4 months. Those that do not have these functions are booked for surgery. Those that do are observed for a further two months. If partial recovery of biceps is observed then a cookie test is performed at 9 months. If there is no biceps at 6 months or they fail the cookie test at 9 months then surgery is booked.

Long-term (5-15 years) clinical outcome after titanium lunate arthroplasty for Kienböck’s disease

List of authors:
Martti Vastamäki\(^1\), Timo Viljakka\(^2\), Kaj Tallroth\(^2\)
\(^1\) Research ORTON, ORTON Foundation (Kuusisto)
\(^2\) Research ORTON, ORTON Foundation (Helsinki)

Objectives / Interrogation: Titanium lunate arthroplasty (TLA) for Kienböck’s disease was introduced in 1984 to address the silicone-wear particle problem common to silicone lunate implants. We sought to study the outcome of TLA.

Methods: We identified 11 patients who had undergone TLA between 2001 and 2010. All subjects were male, age at surgery 47.3 (31-65) years and were followed for mean 11.0 (5.4-15.3) years. Seven patients had suffered traumatic low energetic sprains. Time from the onset of symptoms to surgery ranged from 5 to 45 (median 19) months. Seven patients had the disease in the right, eight in the dominant hand. Six patients had Stage IIIA and five stage IIIB disease. All patients had fracture or fragmentation of the lunate bone. We evaluated pain, ROM, function, and radiological outcome at a mean 11 years after surgery. We compared preoperative ROM and radiological findings to final follow-up in the ipsilateral wrist and made comparisons to the contralateral wrist.

Results and Conclusions: No implants were removed, and no wrist joints were fused. Pain on the visual analog scale averaged at rest 0.5, at night 0.3, and during heavy exertion 2.7. Seven patients had no pain at rest and 9 had no pain at night, but only two had no pain with exertion. None had tenderness to palpation or swelling. When compared with the contralateral wrist, the preoperative range of motion reached in extension 65%, in flexion 63%, in radial deviation 45%, and in ulnar deviation 70% that of the contralateral side, but grip strength was only 55%. After mean 11 years, extension, flexion, and radial deviation of the affected wrists reached 71% of that of the contralateral wrists, and radial deviation 62%. These differences between affected and unaffected wrists were significant for all, p < 0.05. Grip strength was significantly better than before surgery, p<0.05, but still significantly inferior (81%) in the operated hand, p<0.05. DASH score averaged 9.6, optional DASH 9.7, and Mayo wrist score 67.7. Radiologically, only Ståhl, and arthrosis indexes differed significantly between affected and unaffected wrists. Two patients had a dorsally dislocated implant, meaning that around 20% of our cases probably meet the criteria for failure. The results of titanium lunate arthroplasty for Stage III Kienböck’s disease are promising. More study is needed to improve the implant stability.

Keywords: Kienböck’s disease, lunatomalacia, titanium implant arthroplasty, outcome, complications
International comparison of the current practices of the management of post-axial accessory digits on a stalk

List of authors:
Sarbjit Kaur*, Sami Al-Ani1, Kerstin Oestreich1, Ruth Lester1, Andrea Jester1
1 Birmingham Women's and Children's Hospital, Plastic Surgery Department (Birmingham)

Objectives / Interrogation: Background
Birmingham Children's Hospital has an established service for referral of all children with post axial accessory digits at the time of birth. The service is a one stop clinic, where the child is seen and if suitable immediately treated with a surgical resection under local anaesthesia. A comprehensive literature review was carried out and does not advocate any clear recommendations.

Aim
To compare the current clinical practice in the management of post axial accessory digits on a stalk internationally.

Methods: We have distributed a standardized online questionnaire's via 'survey monkey' to pediatric hand surgeons in Europe and the US to compare the current practice in the management of post axial accessory digits across other units.

Results and Conclusions: There are various techniques used, we will present the results of the survey monkey and discuss advantages and disadvantages.

Revisiting "Sandwich" Plating of AO type C3 Distal Radius Fractures - Our Friend or Foe? A case series.

List of authors:
Siew Khei Liew¹, Ikhwan Abdul Samad², Manohar Arumugam¹
¹ University Putra Malaysia (Kajang)
² Serdang Hospital (Kajang)

Objectives / Interrogation: In complex distal radius fractures, combined volar and dorsal plating has been a less favourable option historically to many due to its complications. Our goal was to evaluate radiological and functional outcome of combined dorsal and volar "sandwich" plating of distal radius using low-profile, titanium, fixed angle locking plate system (Variable angle LCP two-column volar/volar rim distal radius plate, DePuy Synthes;Acu-Loc dorsal distal radius plate,Acumed) in AO type C3 fractures.

Methods: 5 patients with closed distal radius fractures AO type C3 due to motor-vehicle accidents from September 2016 to September 2017 were managed surgically via combined dorsal and volar plating using the above implants (single volar and broad dorsal plate engaging radial and intermediate columns of the distal radius). Patient with brain injury was excluded. All cases were done by a single senior hand surgeon. Pre-operative CT wrist were performed. Pre- and post-operative wrist X-rays were evaluated. Clinical assessment of range of movement of the wrist, grip strength, QuickDASH questionnaire, Patient-rated Wrist and Hand Evaluation(PRWE) and Modified Mayo Wrist Score(MMWS) were done at 12 months post-op.

Results and Conclusions: Median age was 37 years (range 32 to 53). There were 4 males and 1 female. Mean follow up was 16.8 months. Mean time from trauma to surgery was 20.2 days. Mean pre-operative radial height was 3.6mm, radial inclination 8.8°, sagittal tilt -0.4°, intraarticular step was 3mm. Mean post-op radial height was 11mm, radial inclination 22.4°, sagittal tilt 1°, intra-articular step was 0mm. No patient required bone grafting. Mean wrist movements post-op 1 year were flexion 62°, extension 58°, radial deviation 14°, ulnar deviation 15°, supination 78°, pronation 87°. Mean grip strength was 82% of the unaffected hand, corrected according to the 10% rule. QuickDASH score was 4.96. PRWE was 16.6. MMWS was 81 (good). At 1 year follow-up, there was no loss of reduction noted. No hardware-related complication was reported and thus none required removal of implant. Patient self-reported average return to work with similar intensity was 6 months, mean self-reported satisfaction on visual analogue scores(0-10) was 7.4 (Good).

We recommend "sandwich" plating for complex AO type C3 distal radius fractures. Both these plates provide excellent stability in maintaining the normal alignment of distal radius. We believe this is the first series reporting the "sandwich" technique using these two different plates.

\textsuperscript{2} Klinik und Poliklinik für Orthopädie und Unfallchirurgie, Schwerpunkt für Unfall-, Hand- und Ellenbogenchirurgie, Uniklinik Köln (Köln)

Objectives / Interrogation: Several surgical approaches to the medial elbow have been described however it remains unclear which exposure provides the optimal view of relevant medial elbow structures. The purpose of this anatomic study is to determine the visible surface area of the coronoid process, distal humerus and radial head through five described approaches to the medial elbow; the muscle splitting approach to the ulnar collateral ligament of the elbow, the medial "Over the Top" approach, the extended medial elbow approach, the floor of the ulnar nerve approach, and the Taylor and Scham approach.

Methods: Eight fresh frozen cadaveric upper extremity specimens were dissected. Five surgical approaches were performed on each specimen, the muscle splitting approach to the ulnar collateral ligament of the elbow, the medial "Over the Top" approach, the extended medial elbow approach, the floor of the ulnar nerve approach, and the Taylor and Scham Approach. The sequence was standardized, moving from least to most invasive. After completing each exposure, the intervals were closed prior to the next interval being exposed. The muscle splitting approach to the ulnar collateral ligament was performed first, followed by the medial "Over the Top" approach, the extended medial elbow approach, the floor of the ulnar nerve approach, and the Taylor and Scham Approach. After each surgical approach was performed, standard retractors were placed and imaging of bony visualization was performed using a laser surface scanning system (Artec Space Spider, Artec 3D, Santa Clara, California) and digitized. The radius, ulna and humerus were then stripped of all soft tissue and laser surface scanned in the same manner. The scans were then segmented using commercially available digital software (Geomagic Wrap, 3D Systems Corporation, Rock Hill, South Carolina) and the surface area visualized was determined.

Results and Conclusions: The extended medial elbow approach showed the highest proportion of the total elbow joint (coronoid, distal humerus and radial head) from the medial side, with a surface area of 13.9cm\(^2\), or 15\% of the joint. It also provided the best visualization of the coronoid (3.2cm\(^2\) or 26\% of the surface area), and distal humerus (9.9cm\(^2\) or 15\%), while the medial "Over the Top" approach was best at visualizing the radial head (0.8cm\(^2\) or 7\%). In conclusion, the extended medial elbow approach provides the greatest surface area visualization of the distal humerus and coronoid process from the medial side.

Prothetic Arthroplasty of the proximal interphalangeal joint using a modular surface gliding implant: A retrospective study

List of authors:
Stefan Meuser*, Martin Richter, Thomas Brockamp, Nico Schwalfenberg
1 Klinik für Hand- und Plastische Chirurgie, Malteser Krankenhaus Bonn (Bonn)

Objectives / Interrogation: To evaluate the postoperative outcome after prothetic arthroplasty of the proximal interphalangeal (PIP) joint regarding improvement of range of motion, reduction of pain and postoperative function of the hand.

Methods: 20 Patients (16 female, average age 64 years) with primary osteoarthritis of 1 or 2 PIP joints were assessed preoperatively and postoperative after prothetic arthroplasty of the proximal interphalangeal joint using a modular surface gliding implant (CapFlex, Fa. KLS Martin, Tuttlingen).
Considered factors were improvement of range of motion, postoperative pain using the visual analog pain scale (VAS) and clinical outcome of the hand judged by the quick disabilities of the arm, shoulder and hand score (quickDASH).

Results and Conclusions:
Results:
A total of 25 joints were evaluated after a mean time of 11.3 months postoperative. The mean active range of motion of the joint improved from 56° to 72°. Patients reported a good reduction of pain to VAS 1 (during rest) and VAS 3 (during stress). The average postoperative quickDASH was 18, showing a good condition of the hand. There were no signs of postoperative lateral instability, axial deviation or implant fracture. All implants showed complete osteointegration without radiological evidence of migration.

Conclusion:
Prothetic Arthroplasty of the proximal interphalangeal joint using a modular surface gliding implant is a good option for patients with primary osteoarthritis to improve the range of motion with an acceptable pain relief, decent stability and good clinical outcome of the hand.

osteoarthritis, proximal interphalangeal joint, arthroplasty
Arthroscopic treatment for isolated traumatic lunotriquetral ligament injury without triangular fibrocartilage complex lesion

List of authors:
Byungsung Kim*, Keonhee Yun¹, WhiJe Cho¹
¹ Soonchunhyang University (Bucheon-si)

Objectives / Interrogation: To evaluate the clinical results of patients treated by arthroscopic debridement and thermal shrinkage of the isolated traumatic lunotriquetral (LT) ligament tear without triangular fibrocartilage complex (TFCC) tear.

Methods: We retrospectively reviewed the results for 12 patients (10 men, 2 women; mean age, 30 years) who underwent arthroscopic debridement and thermal shrinkage for the treatment of isolated traumatic LT ligament membraneous portion tear at our hospital.

The patients were followed for a mean of 9 months. The patients had isolated traumatic LT ligament tear caused by: sprain (N=6); falls (N=5); and boxing (N=1). All the patients underwent MRI. The radiographs for ulnar variance (UV), ulnar dorsal subluxation, and function of the wrist using grip power, DASH score, and Mayo wrist score were examined in all the patients both preoperatively and postoperatively.

Results and Conclusions: For the preoperative MRI, LT ligament tear was not definitely observed in all cases excepting distal radioulnar joint (DRUJ) subluxation in 8, lunate bony contusion in 2, ulnar styloid bony contusion in 1 and occult ganglion of dorsal scapholunate ligament in 2. The average duration from trauma to surgery was 5 months. Preoperative ulnar stress test was positive in 8, DRUJ stress in 7, ballottement test in 7 and supination limitation in 1 case. The average values for the preoperative simple radiographic findings were: UV, 2.6 mm; and dorsal subluxation at the distal ulna, 1.0 mm. Arthroscopically LT tear type was flap tear in 10 and bucket handle tear in 2. In all the cases, the pain improved postoperatively (VAS: from 4 to 1.5). Grip power (compared to the uninvolved limb) was 66% preoperatively and 81% postoperatively. The DASH scores were 36.8 points preoperatively and 7 points postoperatively. The Mayo wrist scores were excellent in 3 cases, good in 8 cases, and fair in 1 cases, and the average score improved significantly from 68 points preoperatively to 87 points postoperatively. Two patients experienced ECU tendinitis.

LT ligament tear should be differentiated from TFCC lesion when the patients is presented with ulnar wrist pain because MRI cannot detect LT ligament tear. Arthroscopic debridement and thermal shrinkage for the treatment of isolated traumatic LT ligament tear can reduce pain.

Keywords: lunotriquetral ligament, triangular fibrocartilage complex, arthroscopic debridement, thermal shrinkage
Arthroscopic wafer resection for ulnar impaction syndrome

List of authors:
Byungsung Kim*, Keonhee Yun¹, Whije Cho¹
¹ Soonchunhyang University (Bucheon-si)

Objectives / Interrogation: To evaluate the clinical results of patients treated by arthroscopic wafer resection for ulnar impaction syndrome

Methods: We retrospectively reviewed the results for 16 patients (5 men, 11 women; mean age, 48 years) who underwent arthroscopic wafer resection for ulnar impaction syndrome at our hospital. The criteria for inclusion were: 1) persistent ulnar-sided wrist pain after conservative treatment over a 3-month period; 2) more than 6 months of follow-up postoperatively. Associated condition was radial head old fracture in 2, triangular fibrocartilage complex (TFCC) foveal avulsion in 2, scapholunate ligament injury in 1, carpal tunnel syndrome in 1, cubital tunnel syndrome in 1, and lateral epicondylitis in 1.

The patients were followed for a mean of 19 months (6~48). The patients symptom was caused by: repetitive overuse (N=8), slip down (N=4), falls (N=3); and sprain (N=1). All the patients underwent MRI. The radiographs for ulnar variance (UV) and ulnar dorsal subluxation and function of the wrist using grip power, DASH score, and Mayo wrist score were examined in all the patients both preoperatively and postoperatively.

Results and Conclusions: For the preoperative MRI all patient had TFCC central wear, a lunate high signal change in 6, triquetrum high signal change in 1. We checked follow up MRI in 3 and CT in 7. The average duration from symptom onset to surgery was 15 months. Preoperative ulnar stress test was positive in 14, fovea sign in 2. For working portal, 4-5 portal was used in 12 and distal radioulnar joint portal in 4. In 5 cases ulnar shortening osteotomy (USO) was needed for persistent pain. UV was changed from 1.7 mm preoperatively to 0 mm postoperatively. Dorsal subluxation of the distal ulna was changed from 2.3 mm preoperatively to 1.5 mm postoperatively. Difference in postoperative dorsal subluxation of the distal ulna was significant between wafer only (0.2mm) and secondary USO (2.7mm). Grip power (compared to the uninjured limb) was 72% preoperatively and 74% postoperatively. The DASH scores were 46 points preoperatively and 35.3 points postoperatively. The Mayo wrist scores improved from 70 to 86 points, excellent in 2, good in 12 and fair in 2. 2nd look arthroscopy was performed in 4 cases and showed fibrocartilage regeneration in resected ulnar head distal pole. Arthroscopic wafer resection is useful procedure for ulnar impaction syndrome. However patients with postoperative dorsal subluxation of the distal ulna may require secondary USO.

Distal Radio-ulnar Joint Configurations in Patients with Idiopathic Ulnar Impaction Syndrome: A New Classification System

List of authors:
Yeun soo Kim*, Jihyeung Kim1, Kee Jeong Bae2, Hyun Sik Gong3, Goo Hyun Baek3
1 Seoul National University Hospital (Seoul)
2 Seoul National University Boramae Medical Center (Seoul)
3 Seoul National University Bundang Hospital (Seongnam)

Objectives / Interrogation: Development of arthritis in the distal radioulnar joint (DRUJ) is a major concern after ulnar-shortening osteotomy. The configuration of the DRUJ is an important predisposing factor for arthritis. Here we suggest a new classification of the morphology of the DRUJ.

Methods: We retrospectively reviewed 26 wrists of 26 patients diagnosed with idiopathic ulnar impaction syndrome and assessed their preoperative three-dimensional computed tomography (CT) findings. We measured the slopes of the sigmoid notch and ulnar head in the middle of the DRUJ. We also simulated the changes in the joint space in the DRUJ after 2 mm ulnar shortening.

Results and Conclusions: The average ulnar variance was 3.4 mm. The slope of the sigmoid notch and that of the ulnar head were not parallel. The slope of the sigmoid notch ranged from -23.9° to 19.3° and that of ulnar head from -24.0° to 17.0°. There was a significant correlation between the slope of the ulnar head and the changes in the joint space of the DRUJ at the center of the sigmoid notch after 2 mm ulnar shortening.

The slope of the ulnar head might be as important a predisposing factor as that of the sigmoid notch for the progression of DRUJ arthritis after ulnar-shortening osteotomy. In our new classification system, we considered the slope of both the sigmoid notch and ulnar head.

Keywords: Sigmoid notch; Slope; Ulnar head; Ulnar impaction syndrome
Volar transfer of the lateral band with transverse retinacular ligament is effective for the correction of swan-neck deformity caused by volar plate injury of the PIP joint.

List of authors:
Masahiro Sato*, Taku Suzuki¹, Takuji Iwamoto¹, Noboru Matsumura¹, Shigeki Nagura¹, Kazuki Sato¹, Masaya Nakamura¹, Morio Matsumoto¹
¹ Department of Orthopaedic Surgery, Keio University School of Medicine (Tokyo)

Objectives / Interrogation: Several surgical methods have been performed for the correction of swan-neck deformity. We introduce a novel surgical method for swan-neck deformity caused by volar plate injury of the proximal interphalangeal (PIP) joint.

Methods: A 61-year-old woman presented with swan-neck deformity of her right little finger. She injured her little finger 45 years ago and was diagnosed with volar plate injury of the PIP joint. Snapping of the lateral band was observed when she flexed her finger. Active range of motion was 25° extension of the PIP joint and 20° extension loss of the distal interphalangeal joint (DIP). Passive correction of the deformity was possible and intrinsic tightness test showed no contracture of the lateral band. Conservative treatment with brace was not effective for the correction of the deformity and surgical treatment was selected.

A dorsal incision is made on the PIP joint and both lateral bands were released from the central slip. Bilateral transverse retinacular ligaments were released from the dorsal attachment and elevated with volar base flap. Lateral bands were transferred to the volar side and transverse retinacular ligaments were sutured slightly volar to the original attachment. Intraoperatively, improvement of snapping was confirmed with active flexion of the finger. The PIP joint was immobilized and active motion of the finger was initiated 2 weeks postoperatively.

Results and Conclusions: One year postoperatively, snapping of the lateral band improved with no appearance of swan-neck deformity. Active range of motion of the little finger was 0° of extension and 100° of flexion at the PIP joint, and 0° of extension and 70° of flexion at the DIP joint.

Transfer of the lateral band using transverse retinacular ligament is minimally invasive surgery and effective for swan-neck deformity caused by volar plate injury of the PIP joint.

DISPLACED DORSAL LUNATE FACET FRACTURE TREATED WITH A VOLAR LOCKING PLATE. IS IT ADVANTAGEOUS TO CAPTURE THE FRAGMENT WITH A FULL LENGTH LOCKING SCREW?

List of authors:
jesse jupiter*

* Massachusetts General Hospital, Harvard medical school (Boston)

Objectives / Interrogation:

PURPOSE
Stability of fixation of an extraarticular distal radius fracture using a volar locking plate can be achieved with screw lengths 75% of the height of the bone avoiding dorsal tendon problems. Is this valid with dorsal lunate facet fragment displacement? This study will demonstrate the safety and efficacy of capturing the displaced fracture with a full length screw using variable angle implants

Methods: MATERIAL AND METHODS
From the ICUC data base of 203 distal radius fractures, we identified 10 cases of intraarticular fractures featuring a displaced dorsal lunate facet which was stabilized with a full length locking screw through a variable angle volar plate. Eight patients were female and 2 male with an average age of 66.5 yrs (range 50-85). All fractures were analyzed by both preoperative and postoperative CT specifically documented the placement of the volar ulnar screw, the alignment of the sigmoid notch, and the position of the volar plate. Patient follow up emphasized forearm function and stability of the distal radioulnar joint.

Results and Conclusions: RESULTS
The average follow up was 104.6 weeks (range 26-343). The postoperative CT scans demonstrated stable reduction and fixation of the dorsal lunate facet in all but one case. The sigmoid notch reduction was within 1mm step off in all but one which had 1 mm impaction and 1.5 mm gap. The position of the plate was Soong 0 in 7 and Soong 1 in 3. There were no dorsal or volar tendon problems noted. The forearm rotation was full in all 10 patients

CONCLUSIONS:
The angular stable plate construction allows the fixation of a dorsal lunate facet fracture as well as the sigmoid notch while maintaining the plate in a safe position and without extensor tendon irritation.

1 Massachusetts General Hospital, Harvard medical school (Boston)

Objectives / Interrogation: PURPOSE
The seminal investigation by Soong et.al. identified radiographic criteria for the risk of tendon irritation post volar plate application. Using the ICUC data base of consecutively treated distal radius fractures with volar plate treatment, we evaluated both standard x-rays and postoperative CT scans to address several questions:
(1) Which critical point on the volar rim of the radius should be used?
(2) Is loss of the normal volar tilt a risk factor?
(3) Should prominent plates be removed even without symptoms?

Methods: Material and Methods
203 consecutive patients treated for a distal radius fracture with a volar plate identified 6 with flexor pollicis injury (4 complete and 2 incomplete rupture). Four patients were female and 2 male with an average age of 62.5 years (range 55-80 yrs). 3 surgeons independently evaluated the x-rays and CT scans.

Results and Conclusions: Results
The average time from plate placement to tendon disruption was 115 weeks (range 29-251 weeks). Of note, 3 patients presented very late at 116, 168, and 251 weeks respectively. Two of the 6 patients were asymptomatic prior to rupture. The CT scan proved more accurate than standard x-rays when measuring the Soong criteria due, in part, to two volar points of the volar rim of the radius with Soong 2 seen in each CT while the x-rays were rated as Soong 1 in 3 and 2 in 3. Three patients had 0 deg volar, 1 8 deg, and 2 dorsal of 2 and 10 deg.

Conclusions
Plate prominence especially combined with loss of volar tilt should be a warning sign of risk of tendon rupture and we believe those patients should have elective plate removal.

Spasticity-reducing hand surgery for patients with upper motor neuron injuries: a prospective study of 30 patients with a one-year follow-up

List of authors:
Joakim Stromberg¹, Ulla Bergfeldt², Therese Ramström², Katarzyna Kulbacka Ortiz², Carina Reinholdt²
¹ Department of Hand Surgery, Sahlgrenska University Hospital, Department of Orthopedics, Alingsås lasarett (Gothenburg)
² C.A.R.E., Sahlgrenska University Hospital (Gothenburg)

Objectives / Interrogation: Spasticity is common in patients with upper motor neuron injuries, with a prevalence reported between 30 to 90% in patients with stroke, traumatic brain injury, incomplete spinal cord injury and cerebral palsy. While pharmacological spasticity therapy has been applied for decades, surgical procedures remain fairly uncommon in adults with spasticity. The objective of this prospective cohort study was to evaluate the outcome of spasticity-reducing surgery in the upper extremity.

Methods: Thirty patients suffering from spasticity in the upper extremity with transient or little effect of BoNT-treatment were included in the study. Between March 2015 and January 2017, all patients had spasticity reducing surgery, which included a tailored set of procedures including lengthening of tendons, tenotomies and correction of deformities according to the specific spasticity pattern in each patient. Active motion exercises were initiated the first day postoperatively with splints used between exercises for three weeks, and patients were also taught a home-training program. All 30 patients were assessed after three weeks, three and six months and after a year.

Results and Conclusions: At one-year follow-up all outcome measures had improved significantly compared to baseline. Spasticity as measured by the modified Ashworth scale (0-5) had decreased by a mean 1.4 (p<0.001), and all but two patients were found to have reduction in spasticity by at least one scale unit. Pain and general hand function (as measured by VAS-scale) had decreased by 1.3 (p<0.05) and 2.1 (p<0.001) respectively. The patients prioritized activity as measured by Canadian Occupational Performance Measure (COPM) had also increased significantly (performance by 3.4 and satisfaction by 3.6 (p<0.01). Passive range-of-motion had increased significantly.

Spasticity-reducing surgery combined with immediate postoperative functional rehabilitation can reduce spasticity, reduce pain and improve hand function in patients with upper motor neuron injuries. The beneficial effects of these surgical procedures are consistent one year postoperatively, and surgery should be considered a treatment option for this large group of patients.

Needle fasciotomy for Dupuytren's contracture- a prospective cohort study of 58 fingers with a median follow-up time of 6.5 years

List of authors:
Anna Zachrisson*1, Allan Ibsen Sörensen2, Joakim Stromberg3
1 Department of Orthopedics, Kungälv hospital (Kungälv)
2 Department of Hand Surgery, Sahlgrenska University Hospital (Gothenburg)
3 Department of Hand Surgery, Sahlgrenska University Hospital, Department of Orthopedics, Alingsås lasarett (Gothenburg)

Objectives / Interrogation: Needle fasciotomy (NF) is a well-established, minimally invasive treatment option for mild to moderate Dupuytren contractures (DC). The procedure requires limited resources, and multiple contractures can be treated during the same session. However, long-term results have indicated a high recurrence rate. This prospective study was initiated to monitor the safe introduction of NF in a context where limited fasciectomy had been the only treatment option for DC, and to investigate the long-term results.

Methods: The inclusion criterion was a palpable cord with an MCP and/or PIP contracture in one or more fingers. 58 fingers in 43 patients were treated by needle fasciotomy between November 2010 and March 2012, and were followed for a median of 6.5 years. Four patients (with 8 treated fingers) died during the follow-up period, and two patients (with two treated fingers) declined follow-up. At the final follow-up of the remaining 52 patients, 29 fingers had had no further treatment for Dupuytren contracture. Nineteen had undergone another (10) or were scheduled for a secondary procedure of the finger (9).

Results and Conclusions: The median total passive extension deficit (TPED) decreased from 52° (range 20-166°) to 10° (range -25°-119°) postoperatively. No severe adverse events such as nerve or tendon injuries were reported. At final follow-up the median TPED was 20° (range -35° - 135°) for all fingers.
A total of 12 fingers (20%) had a recurrence of the contracture defined as an extension deficit of >20° in a previously straightened finger. Six patients had had or were planned for secondary procedures in the same MCP joint, one by partial fasciectomy, five by another NF treatment as preferred by the patients. The median TPED in the remaining 29 fingers was 6° (range -35° - 105°).

Needle fasciotomy is a simple and safe procedure for Dupuytren's contracture, with excellent immediate reduction of the joint contracture but with a recurrence rate that has to be taken into account. However, 29 fingers retained a straight finger at the final follow-up, and repeated NF was preferred in all but one of the patients with recurrence.

Functional reinnervation of the lower limb after contralateral lumbar to sacral nerve transfer for hemiplegic patients

List of authors:
Yan-Qun Qiu*¹, Mao-Xin Du², Bao-Fu Yu³, Wen-Dong Xu³
¹ Huashan Hospital Jing'an Branch, Fudan University, Huashan Hospital, Fudan University, Jing'an District Central Hospital, Fudan University (Shanghai)
² Huashan Hospital Jing'an Branch, Fudan University, Jing'an District Central Hospital, Fudan University (Shanghai)
³ Huashan Hospital, Fudan University, Huashan Hospital Jing'an Branch, Fudan University, Jing'an District Central Hospital, Fudan University (Shanghai)

Objectives / Interrogation: Contralateral C7 nerve transfer has been successfully applied to improve upper-limb motor function for patients who had arm paresis that had ceased to improve after rehabilitation. Similar strategy possibly exists in the lower limb. This study was designed to explore a new procedure for unilateral lower limb dysfunction due to stroke and traumatic spinal cord injury.

Methods: Four patients were enrolled in the study. The first suffered from permanent muscle weakness in his left leg after right cerebral infarction. The second had spasticity and hemiplegia in both upper and lower limbs on the right after a left cerebral hemorrhage. The other 2 patients are with incomplete lower limb paraplegia due to traumatic spinal cord injury caused by spinal fracture. After spinal canal decompression procedure, these two patients mainly manifested as unilateral lower limb dysfunctions. All four patients underwent contralateral lumbar to sacral nerve transfer to improve lower-limb motor function. The procedure mainly consists of transferring 50% of the proximal contralateral lumbar ventral L5 to 50% of the distal ventral S1 nerve (or S1+S2). Selective posterior rhizotomy was performed together in 1 patient with spastic lower limb paralysis. Motor function of lower limb was assessed preoperatively and postoperatively.

Results and Conclusions: Results: 20 months after surgery, all these patients experienced significant improvement in ambulatory status. Motor function of unaffected lower limb was not impaired by transferring 50% of the proximal lumbar ventral L5.

Conclusions: This pilot study demonstrates the possible benefits of contralateral lumbar to sacral nerve transfer for hemiplegic patients. This surgical approach could provide a new means for lower-limb motor functional recovery. Further research, including long-term follow-up and a randomized controlled trial, is required.

Keywords: Hemiplegia, Nerve Rerouting, Nerve Transfer, Spasticity, Stroke
Results of finger extension reconstruction in hemiplegic patients after stroke by transferring the flexor carpi radialis branch to the posterior interosseous nerve

List of authors:
Yan-Qun Qiu*, Yun-Dong Shen2, Guo-Bao Wang2, Wen-Dong Xu2
1 Huashan Hospital Jing'an Branch, Fudan University, Huashan Hospital, Fudan University, Jing'an District Central Hospital, Fudan University (Shanghai)
2 Huashan Hospital, Fudan University, Huashan Hospital Jing'an Branch, Fudan University, Jing'an District Central Hospital, Fudan University (Shanghai)

Objectives / Interrogation: Transfer of contralateral C7 nerve has been successfully applied to reconstruct motor function of affected upper limb in chronic central neurological injury. However, in certain patients, finger extension still remains difficult. One possible mechanism is the fiber distribution of C7. The flexor carpi radialis (FCR) is mainly innervated by C7 nerve. The FCR muscle branch can be used to transfer the posterior interosseous nerve (PIN) to increase the independent control of the finger extensor muscle group. This study was designed to test the effectiveness of FCR branch transfer to PIN.

Methods: Two patients were enrolled in the study. The first is a 48-year-old man who had severe spasticity and hemiplegia in both upper and lower limbs on the right, 29 months after a left cerebral hemorrhage and 17 months after contralateral C7 transfer. The second patient is a 19-year-old man who suffered from permanent muscle weakness in his right wrist and finger extension 8 years after left cerebral arteriovenous malformation rupture, with little spasticity. Both patients underwent right FCR branch to PIN transfer to improve finger extension 1 year after contralateral C7 nerve transfer. Motor function of lower limb was assessed preoperatively and postoperatively.

Results and Conclusions: Results: one year after surgery, the first patient experienced transient significant decrease of wrist and finger spasticity lasting for 2 months, and gradually back to the baseline. Both patients regained finger extension in an extremely relaxed state but failed in tension state. Motor function of wrist flexion was not impaired by transferring FCR branch. Conclusions: Although more nerve fibers from contralateral C7 nerve entered PIN, the functions of the finger extension were not significantly improved. It suggested that improving the independent control of finger extension for hemiplegic patients may require more attention to the inhibition from the tensor of flexion.

Denervation of the thumb carpometacarpal joint in the case of osteoarthritis: results of a controversial treatment option

List of authors:
Rebekka Rath*, Christina Ampofo¹, Wan Konur², Tobias Del Gaudio³, Max Haerle¹
¹ Orthopädische Klinik Markgröningen, Klinik für Handchirurgie und Plastische Chirurgie (Markgröningen)
² Zahnärztliche Oralchirurgische Praxis Dr. R. Gehl (Esslingen)
³ Schwarzwald-Baar Klinikum, Klinik für Plastische-, Hand- und Ästhetische Chirurgie (Donauwörth)

Objectives / Interrogation: If conservative treatment is not sufficient in thumb carpometacarpal (CMC1) joint osteoarthritis trapeziectomy is a valid procedure to reduce pain and gain back functionality. These operations destroy the carpal anatomy and some lead to reduced power and loading forces. This is a relevant problem especial for younger manual workers. Wrist denervation has shown to reduce pain relevantly in radiocarpal osteoarthritis. Therefore, we investigated on the effect of denervation in CMC1 osteoarthritis.

Methods: Between 2005 and 2018, 51 patients suffering from CMC1 (44) and STT(11) joint osteoarthritis underwent a denervation procedure which consisted in a total denervation (Wilhelm 1966) extended to the CMC1 joint (Lorea 2003). Pain (VAS), strength (grip and pinch), mobility (Kapandji index, range of motion), DASH score, complications and overall patient satisfaction were determined.

Results and Conclusions: The preliminary follow-up assessment showed a significant decrease in pain. 6 weeks post operation the pain reduction was 56.5 % and long-term pain reduction was 66.8 %. The postoperative strength of the pinch was 0.6 kg lower than on the other hand. Additionally, the postoperative mobility as measured by the Kapandji score was 9.3 of 10. Overall, 61% of patients are satisfied with the results of the denervation.

The results of our study implicate that a denervation can be an alternative treatment option for patients suffering from symptomatic osteoarthritis. A major advantage is pain reduction through a soft tissue procedure. Furthermore, other more invasive operative treatments are still an option after this operation. However, the long term pain reduction and the overall satisfaction rate is far inferior to the results of simple trapeziectomy. This is why we preserve this operation to patients with special physical requirements.

2 Assaf Harofe Medical Center (Zerifin)
3 Hadassah Medical Center (Jerusalem)
4 Meir Hospital (Kfar Saba)

Objectives / Interrogation: Lateral epicondylitis is a tendinopathy of the common extensor origin at the elbow. When traditional conservative treatment fails, more effective therapies are needed. Vergenix™ Soft Tissue Repair Matrix is an injectable gel composed of cross-linked bio-engineered recombinant human type I collagen combined with autologous platelet-rich plasma (STR/PRP). The complex forms a collagen-fibrin matrix, which promotes cell migration and tissue repair. Based on positive outcomes from preclinical trials, this study is the first clinical trial of STR/PRP on tendinopathy. We hypothesize that STR/PRP is a safe and effective treatment for lateral epicondylar tendinopathy.

Methods: Patients with chronic lateral epicondylitis underwent treatment with STR/PRP. Outcome assessment included grip strength, functional disability and changes in sonographic tendon appearance for up to 6 months following treatment.

Results and Conclusions: Forty patients were enrolled in the study. No systemic or local severe adverse events were reported. Clinical evaluation revealed an improvement in mean PRTEE score from 64.8 prior to treatment, and showed a 59% reduction at 6 months. The SF-12 questionnaire showed improvement from a mean score of 30.7 to 37.7 at the final follow up. Grip strength rose from 28.8 Kg at baseline to 36.8 Kg at 6 months. Improvements in sonographic tendon appearance were evident among 68% of patients.

We conclude that STR/PRP is a safe treatment that effectively induces clinically significant improvements in elbow symptoms and general well-being as well as objective measures of strength and imaging of the common extensor tendon within 6 months of treatment of elbow tendinopathy recalcitrant to standard treatments.

What are the ultrasound features of the trigger finger that may guide management?

List of authors:
Xue Ling Chuang\textsuperscript{1}, Zeus Lim\textsuperscript{2}, Duncan Angus McGrouther\textsuperscript{1}
\textsuperscript{1} Singapore General Hospital Hand Surgery Department (Singapore)
\textsuperscript{2} Biomechanics Laboratory, Singapore General Hospital (Singapore)

Objectives / Interrogation: To determine dynamic ultrasound features of the trigger finger that may guide the management of the trigger finger. Dynamic imaging was conducted to determine the presence of adherence around and between the flexor tendons.

Methods: 30 trigger fingers and 30 controls from the contralateral hand were examined using high-resolution ultrasound. At a pre-determined anatomical point, the static study investigated the A1 pulley thickness. The dynamic study explored the presence of adhesions around and between the tendons.

Results and Conclusions: The dynamic study yielded findings not previously recorded in medical literature. Firstly, the static study showed that trigger fingers had a thicker A1 pulley as compared to normal fingers. The dynamic study demonstrated that trigger fingers had more adhesions around and between tendons, as compared to normal fingers. Patients with adhesions around the flexor tendons were also more likely to lose differential tendon movement due to adhesions between the tendons. Conversely, those without adhesions around the tendons, were also unlikely to suffer from adhesions between tendons. The dynamic study suggested that the severity of finger stiffness may be reflected by the number of sites with adhesions present, and this may guide future management of the trigger finger.

Fixation of Dorsal Ulnar Corner Fractures of the Distal Radius Through an Anterior Approach A Prospective Study with CT Documentation

List of authors:
jesse jupiter*

1 Massachusetts General Hospital, Harvard medical school (Boston)

Objectives / Interrogation: Articular fractures of the distal radius involving a displaced dorsal ulnar corner are problematic and may impact both radiocarpal and/or distal radioulnar joints. Operative treatment may require both volar and dorsal approaches. In this prospective single surgeon study approaching all fractures through only an anterior incision, we have documented the accuracy of reduction comparing preoperative and postoperative axial CT scans and clinical documentation at 12 months post surgery.

Methods: 61 patients with an intraarticular distal radius fracture featuring a splint lunate facet or isolated dorsal lunate facet were treated operatively within 10 days of injury. The surgical approach was the standard FCR exposure without additional release of the tendon. The fracture was reduced using ligamentotaxis, manual manipulation, and a specific radiolucent bone reduction clamp over the dorsal lunate facet. The fixation in each case was done with a 2.4mm Variable Angle Distal Radius Plate System®. Pre and early postoperative axial and sagittal CT scans were used to measure the fracture gap at the sigmoid notch, intraarticular step off, degree of ulnar subluxation, and any screw penetration into the joint.

Results and Conclusions: The CT scans revealed a significant correction of the fracture gap from a mean 2.0mm pre-op to a mean of 0.48mm postoperatively. The mean fracture step was corrected from 1.4mm to 0mm. The mean ulnar subluxation was corrected in each instance with minimal residual subluxation in a limited number of patients. Grade I arthritis changes were found in 14 patients and grade II in 7.

Clinically at an average follow up or 12.6 months, the mean range of motion compared to the opposite wrist was 95% of flexion; 92% of extension; 99% of both supination and pronation.

Conclusion

Using a standard volar approach with the important inclusion of a radiolucent reduction clamp which puts direct pressure over the dorsal lunate facet, we have demonstrated successful reduction of the articular fracture including the sigmoid notch

Long term outcome of open reduction and internal fixation of distal humeral nonunions in the older age patient.

List of authors:
jesse jupiter*1
1Massachusetts General Hospital, Harvard medical school (Boston)

Objectives / Interrogation: While arthroplasty offers an alternative in the treatment of complex nonunions of the distal humerus in the older age patient, its longevity remains a concern. In contrast, restoration of the articular anatomy with a successful ORIF may offer a more predictable outcome.
In order to explore this hypothesis, we elected to obtain long term follow-up in a cohort of patients 48 years and older at the time of their operative treatment to gain union.

Methods: Out of a total of 95 patient seen and treated for a distal humeral nonunion by a single surgeon, 23 patients 48 years and over at the time of their index procedure to gain union (range 48 to 67 years). Seventeen were female and 6 male with the dominant limb involved in 15. Five patients were found to have deceased and at the time of writing, 6 were still unable to be located leaving twelve patient available for follow up at an average of l8 years (range 13-24 years) Four nonunions were at the supracondylar level; 7 were combined intra and extraarticular nonunions; and one primarily involved the articular surface of the lateral column. All but two had major capsular contracture with 7 substantial ulnar nerve dysfunction requiring neurolysis and transposition.
Internal fixation required 3 contoured plates in 10 patients with 4 plates and 2 plates in one each. Autogenous iliac crest bone graft was used in 9 patients with a vascularized fibular graft in one to bridge a bony defect.

Results and Conclusions: At an average follow up of 18 years (range 13-24 years), all but one remained united after the index procedure with the one converted to a total elbow arthroplasty after one year. One other patient required a repeat capsular release. The average age at follow up was 76 years (range 61-99 years). Examination revealed an average elbow flexion of 115 degrees with average flexion contracture of 36 degrees. The average Quickdash was 26 and average PROMIS 39.5. The average Mayo elbow score was 84 (range 55-95). The follow up radiographs demonstrated in the majority of patients evidence of mild to moderate arthrosis.
While some residual functional deficits exist with some radiographic changes over time, the results of this group of patients would suggest that a successful ORIF of a distal humeral nonunion including those involving the articular surface will remain durable and offer the patient a functional outcome.

DISTAL RADIOULNAR JOINT REPLACEMENT WITH WRIST ARTHRODESIS A LONG TERM FOLLOW UP

List of authors:
jesse jupiter*¹
¹Massachusetts General Hospital, Harvard medical school (Boston)

Objectives / Interrogation: Radiocarpal or midcarpal arthritis can occur in association with arthritis of the distal radioulnar joint (DRUJ). Surgical correction may include partial or total wrist arthrodesis as well as simultaneous or staged reconstruction of the DRUJ. While the semi-constrained total DRUJ prosthesis has been proven successful for a number of problems of the DRUJ, prior or even simultaneous wrist arthrodesis may present additional technical problems. These include the need for further interosseous membrane release in order to gain better access to the medullary canal of the ulna. If simultaneous procedures are to be considered, which should go first and will the added exposure create risks for soft tissue healing.

Methods: From 1998-2012 15 patients had an arthrodesis of the wrist either followed by or together with a total DRUJ prosthesis. Eight male and 7 female patients were retrospectively reviewed with the dominant limb involved in 11. The average age of the patients at the time of the DRUJ procedure was 45 years with 11 involving posttraumatic conditions and 4 rheumatoid arthritis. The average number of surgical procedures prior to the DRUJ implant was 9. Twelve had the wrist fusion before and 3 after total wrist arthrodesis.

Results and Conclusions: The average follow up was 7 years (range 1-15 yrs) All patients had statistically significant improvement in forearm rotation with 11 having complete forearm function. All patients had a significant decrease in pain at rest and during exercise. The mean DASH score improved from preoperative 77 to postoperative 24 (p<0.01). Complications included later surgery for ulnar sided wrist pain including pisiform excision (3) and triquetrum excision (2). Superficial infection occurred in 2 patients treated with oral antibiotics and one deep infection requiring implant removal and staged reinsertion without recurrence.

Conclusion:
While technically challenging, total semi-constrained DRUJ prosthesis can be effective either after or before total wrist arthrodesis.

The Dorsal Barton Fracture Revisited

List of authors:
jesse jupiter*¹
¹Massachusetts General Hospital, Harvard medical school (Boston)

Objectives / Interrogation: Background: The anterior shearing fracture-dislocation long termed the "Bartons"" or "Reversed Barton's" fracture of the distal radius by definition involves the carpual subluxation inferiorly along with a wedge segment of the volar aspect of the radius. The dorsal aspect of the radius will be intact and the radiocarpal ligaments will have ruptured but their volar components remain attached to the carpus. Given that the volar ligaments are considerably stronger than their dorsal counterparts, can the same really be the case with the dorsal equivalent or rather are those lesions truly radiocarpal fracture dislocations?

Methods: We evaluated over 500 consecutive distal radius fractures treated operatively as part of the ICUC APP. All fractures were documented with pre and postoperative radiographs and CT scans and followed for a minimum of one year.

Results and Conclusions: We were unable to locate any instance of a case fulfilling the descriptive criteria of a dorsal Barton lesion (AS/ASIF classification 23-B-2). These criteria being a dorsal marginal distal radius fracture including a posterior subluxation of the carpus and an intact volar cortex. Those cases which at first may have appeared consistent with such a injury will be found to have a component of the volar articular surface displaced with maintenance of some continuity of the volar capsular ligaments from the fracture fragment onto the subluxated carpus. These cases without a volar fracture component should be considered radiocarpal fracture-dislocations which are more complex injuries.

Conclusion: The term "Bartons" fracture should be confined to the volar injury with the apparent dorsal equivalent rather a complex intrarticular fracture or a radiocarpal fracture-dislocation.

Radiocapitellar prosthetic arthroplasty: short-term to midterm results of 19 elbows

List of authors:
Amir Reza Kachooei¹, Nicole Heesakkers², Andras Heijink³, Bertram The⁴, Denise Eygendaal⁵
¹ Orthopedic Research Center, Ghaem Hospital (Mashhad)
² Department of Orthopaedic Surgery, Sint Maartenskliniek Nijmegen (Nijmegen)
³ Department of Orthopaedic Surgery, Academic Medical Center Amsterdam (Amsterdam)
⁴ Upper Limb Unit, Department of Orthopedic Surgery, Amphia Hospital (Breda)
⁵ Department of Orthopaedic Surgery, Amphia Hospital, Academic Medical Center, University of Amsterdam (Amsterdam)

Objectives / Interrogation: Few studies have discussed the short-term results of radiocapitellar (RC) prosthetic arthroplasty (PA). In this study, we assessed the short-term to midterm functional and radiographic results of elbows after RC PA. Our secondary aim was to assess the survival of the RC PA.

Methods: We included 19 elbows in 18 patients with a mean follow-up of 35 months (range, 12-88 months). Patients were examined for instability and range of motion and were assessed using Mayo Elbow Performance Index and Oxford Elbow Score at any subsequent visits. RC PA was the primary treatment in 16 elbows, and 3 were revision radial head arthroplasty with concomitant capitellar resurfacing.

Results and Conclusions: Results: Range of motion, pain, and functional scores improved significantly from the preoperative to the final follow-up visit. Categoric grouping of the final Mayo Elbow Performance Index outcome scores showed 9 excellent, 5 good, 3 fair, 0 poor, and 2 missing data. However, stability of the elbow remained unchanged. There was no pain in 11 patients, mild pain in 5, and moderate pain in 3. Radiographic assessment showed no significant progress in ulnohumeral arthritis, although 3 elbows showed osteoarthritis progression to a higher grade. There were no major complications, including infection, revision, disassembly of the components, or conversion to total elbow arthroplasty. Survival of the RC PA was 100%.
Conclusion: Elbow arthritis seems to become stationary after RC PA. Symptomatic RC osteoarthritis would probably benefit from RC PA regardless of the etiology

4 e Hand and Upper Extremity Service, Massachusetts General Hospital (Boston)
5 f Department of Orthopaedic Surgery, Academic Medical Center Amsterdam (Amsterdam)
6 Dell Medical School , The University of Texas at Austin (Texas)

Objectives / Interrogation: PURPOSE:
This study tests the hypothesis that there are no factors associated with removal or revision of a radial head prosthesis. A secondary analysis addressed the time to removal or revision

Methods: METHODS:
We reviewed the database of two large hospitals from 2000 to 2014 and identified 278 patients that had radial head replacement after an acute fracture or fracture dislocation of the elbow: 19 had removal and 3 had revision of the radial head implant within the study period. Explanatory variables including demographics, the type of injury, prosthesis type, surgeon, medical centre, and associated injuries were evaluated. Survival analysis using Kaplan-Meier curves evaluated time to removal/revision

Results and Conclusions: RESULTS:
After adjustment for potential confounders using Cox regression multivariable analysis, hospital was the only factor independently associated with removal or revision (Hazard ratio=2.4, Confidence interval: 1.03-5.8, P value=0.043). The highest proportion of removal/revision was during the first year after implantation and decreased by half each year over the second to fourth years. The most common reason for removal of the prosthesis was to facilitate removal of heterotopic ossification (the majority with proximal radioulnar synostosis) rather than technical error or problems with the prostheses.

CONCLUSION:
These findings suggest that the decision to remove a radial head prosthesis may depend more on surgeon or hospital preferences than on objective problems with the prosthesis. Until clarified by additional study, removal of a prosthesis should not be considered an objective outcome in research. In addition, patients offered removal of a radial head prosthesis, might get the opinion of more than one surgeon at more than one hospital before deciding whether or not to proceed.

clinical trial of comparing the effects of active and passive rehabilitation on flexor tendons repair outcomes in Zone 2

List of authors:
mohammad javad Fatemi*, tooran bagheri, roohollah sobhani, leila mirzaei

1 burn research center, Iran university of medical sciences (Tehran)

Objectives / Interrogation: The present study aimed to compare early passive and active mobilization on restoration of zone II flexor tendon injuries.

Methods: This was a prospective randomized, controlled trial including 21 patients, 28 fingers with zone II tendon injuries scheduled for tendon repair and rehabilitation who were randomly assigned to receive treatment either with passive motion (PM group) or with early active motion (AM group) rehabilitation. Patients between 15 to 60 years of age, with sharp rapture of zone II flexor tendon, time of injury before 72 hours, residence in Tehran and suburbs, and informed consent forms were included in the study. Total active range of motion (TAM), power of hand griping and pinching were all measured at six, eight, and twelve weeks of follow-up by a blinded independent hand therapist. Early and delayed complications were also recorded by a blinded evaluator. Patients in the both study groups underwent 24 sessions of rehabilitation therapy.

Results and Conclusions: No significant differences were observed between the two groups regarding the demographic characteristics (P > 0.05). None of the patients in the both groups have had tendon rapture, hematoma and infection. Two patients in AM group had flap necrosis which was not significantly different compared to the PM group (P= 0.476). At the first and second follow-up, 95% of patients in both groups (91% and 100% in AM and PM groups, respectively) had edema which was limited to the fingers area and one patient had edema in the hand. The results of wound healing rates were as follow; in the AM group, nine patients excellent and three patients good; in the PM group, eight patients excellent, one patient good and another one fair. The adhesion formation was reported in 8 cases of PM group which was significantly higher than the AM group (one case) (P = 0.003). Extension lag and flexion contracture were not significantly different between the studied groups. Six weeks after surgery, the mean TAM in the Am group was 189.15 ± 51.84 degrees and in the PM group was 144.87 ± 47.32 degrees which was significantly different (P = 0.026). The means of TAM eight and twelve weeks after surgery were not significantly different between the two studied groups (P = 0.207 vs. P = 0.949, respectively).

Adaptive 2 plate used as a monoaxial locking plate has sufficient fixation stability for osteoporotic distal radius fracture equal to Acu-Loc 2

List of authors:
Yusuke Sogabe¹, Takeshi Egi², Yukiko Morimoto¹, Masato Shigi², Akira Kawabata¹, Kiyohito Takamatsu¹
¹ Yodogawa Christian Hospital (OSAKA)
² Osaka Saiseikai Nakatsu Hospital (Osaka)

Objectives / Interrogation: APTUS Adaptive 2 Distal Radius Plate (Adaptive 2, Medartis AG, Basel, Switzerland) is a poly-axial locking plate (PLP) with a variable angle of 15° and is suitable for use in the double-tiered subchondral support procedure. However, it can also be used with an attached drill guide block as a monoaxial locking plate (MLP).
In this study, we compared the initial fixation stabilization of Adaptive 2 used as an MLP with the Acu-Loc 2 Wrist Plating System (Acu-Loc 2, Acumed, Hillsboro, OR, USA).

Methods: This study included 42 patients aged >60 years who were followed-up after surgery for 3 months. In total, 25 cases (mean age, 72 years) were treated using Adaptive 2 (Group AD) and 17 (mean age, 73 years) were treated using Acu-Loc 2 (Group AC).
In the third month after surgery, we took X-rays to compare the reduction loss of radial inclination (RI), volar tilt (VT), and ulnar variance (UV) between the groups.
We defined the distance from the most radial screw tip to the radial styloid process tip as the R-value on the front view of the X-ray immediately after the surgery and the distance from the most ulnar side screw?s superior border to the lunate fossa as the L-value level on the lateral view of the X-ray immediately after the surgery.

</tbody>
</table>

Age, sex, and fracture type based on AO classification, all items regarding reduction loss, and L-value were not significantly different between the groups.
Only R-value was significantly smaller in group AD than in group AC (p=0.005); however, there was no correlation between RI reduction loss and R-value.

Adaptive 2 is capable of repairing the radial styloid with just one locking screw and was comparable to Acu-Loc 2 in radial side fixation repair. Adaptive 2 used as an MLP had good initial fixation stabilization that was not inferior to Acu-Loc 2.

The effects of Adipose derived stem cell on optimizing Achilles tendon repair in rat

List of authors:
mohammad javad Fatemi¹, fatemeh khodaei¹, hossein salehi¹, tooran bagheri¹, mitra niazi¹, seyed Aboozar Hosseini²
¹ burn research center, Iran university of medical sciences (Tehran)

Objectives / Interrogation: Most important factor in having more favorable outcome is strength of repaired tendon and lack of adherence to the adjacent tissues. Various methods have been proposed to improve the process of repair and prevent adhesion. The aim of this study is to survey the effects of adipose derived stem cells on optimizing Achilles tendon repair in rat.

Methods: In this research 36 Sprague-Dawley male rats weighing approximately 250 to 300 grams, were randomly divided into three groups. Autologous fat derived stem cells were prepared from inguinal fat pad of 12 rats. Achilles tendon was cut in all 3 groups. Autologous stem cell was injected into the both cut ends of tendon before repair in the first group. In the second group normal saline and in the third group culture medium without cell was injected in the cut ends of the tendons. Strength and quality of repair were surveyed by tensometry and histopathology evaluation after 30 days of repair.

Results and Conclusions: Results showed that the group of stem cell had the most tendon strength with statistically significant difference to other groups (p-value=0.017). The histopathology indices such as the amount of collagen, fibroblasts and else were not significantly different. Although, metaplasia was more common in culture and normal saline groups than stem cell, but the difference was not significant. (p-value= 0.02). This study showed that stem cells could improve biomechanics of tendon repair without any pathologic changes. Although, it was unexpected to have metaplasia in control and culture groups which necessitates more studies in this field.

OUTCOME OF A CONSTRAINED ARTHROPLASTY OF THE DISTAL RADIOULNAR JOINT

List of authors:
ilse Degreef*, Verena Wijnen
1 University Hospitals Leuven (Leuven)

Objectives / Interrogation: This study reports the results of 20 patients who have had a replacement of the distal radioulnar joint (DRUJ).

Methods: Between 2010 and 2018 28 patients received an Aptis prosthesis. 20 out of these 28 patients were willing to undergo a final evaluation. We examined the functional outcome and evaluated the DASH, PRWE and VAS score.

Results and Conclusions: The average results of these questionnaires were 33.5 for the DASH score, 38.7 for the PRWE and 4 for the VAS score. The mean flexion and extension were 68° and 57° respectively. The grip strength recovered to 59% and pinch strength even to 71% after surgery compared to the non-operated side. One prosthesis was removed because of persistent pain and synovitis which brought our survival rate to 96.4%.

Since the introduction of this prosthesis good results. In our study we were able to find comparable results with high satisfaction rates.

A nationwide registry study on the epidemiology of scaphoid fractures in Sweden.

List of authors:
Elin Sward*, Thorsten Schriever¹, Mikael Andersson Franko¹, Maria Wilcke¹
¹ Karolinska Institute (Stockhom)

Objectives / Interrogation: The epidemiology of scaphoid fractures is described only in limited populations and incidence reports are inconsistent. We investigated the nationwide incidence of scaphoid fractures in Sweden 2006-2015.

Methods: Registry data on 34377 patients with a reported scaphoid fracture were evaluated regarding diagnosis, age, sex and treatment. The data was validated by assessing radiographs and medical journals of 300 random patients and incidence rates were adjusted accordingly. The risk for a diagnosed nonunion up to 5-9 years after a scaphoid fracture was analyzed in patients with a scaphoid fracture 2006-2010.

Results and Conclusions: Results: A large proportion (41%) of the recorded scaphoid fractures could not be confirmed (i.e. had a false positive diagnosis). The overall adjusted incidence rate was 22 per 100 person-years. The incidence peaked at 15 years of age in both gender. There was a small but statistically significant decrease in the overall incidence rate in men during the study period. Particularly, the incidence rate decreased in men 20-24 years. 5,3% of the scaphoid fractures had acute surgery, so the vast majority was treated with a plaster cast. Men received surgical treatment to a greater degree than women (6,4 vs. 2,9%). The rate of surgery did not change during the studied period. The risk for a diagnosed nonunion within 5-9 years after a scaphoid fracture was 4,7% for men and 1,4% for women.

Conclusions: The proportion of false positive diagnoses of scaphoid fractures in the Swedish national patient register is high. Scaphoid fractures have decreased in young men. The rate of surgical treatment of scaphoid fractures is higher in men compared to women. Men are more likely to develop a scaphoid nonunion than women.

Can the radiologic progression during 1st follow-up visit after closed reduction of distal radius fracture predict the radiologic outcome?

List of authors:
Hyun Il Lee*
1 Ilsan Paik Hospital (Goyang)

Objectives / Interrogation: Distal radius fracture (DRF) is usually treated with cast immobilization followed in short-interval to observe any reduction loss. However, there is little information whether radiological collapse at 1st follow-up will be associated with further deterioration of radiological results. Purpose of current study is to follow up the radiological results of DRF in two different groups according to radiologic progression at 1st follow-up visit.

Methods: A retrospective study involving non-operative treatment of DRF in 60 patients was conducted. Displaced fractures underwent closed reduction with immobilization. Radiographs were obtained after reduction, at 5–12 days (1st follow-up) and after union. If the radial inclination was decreased more than 5mm, volar tilt was decreased more than 10°, or ulnar variance was increased more than 2mm at the 1st follow-up visit, compared to post-reduction radiograph, we assumed these patients as radiologic collapse (RC) group. We analyzed the amount of change in radiologic parameters and final ratio of unacceptable radiologic results. Displacement involving volar inclination of > 20°, dorsal inclination of > 10°, or positive ulnar variance of > 2mm were considered as radiologically un-acceptable.

Results and Conclusions: At initial presentation, 39-patients (65%) has unacceptable radiologic parameter and this was improved to 30% after reduction. At 1st follow-up, the number of patients with unacceptable reduction was similar compared to immediate post-reduction (28%). However, we could observe the progression of radiologic collapse in 21-patients (35%) and assigned to RC group At 1st follow-up, 33% of of patients had unacceptable radiological outcome in RC group and it was 26% in non-RC group (P=0.6).

At last follow-up, 62% of patients in RC group had resulted in unacceptable radiologic outcome (29%-increase) and in non-RC group, it was 41% (15%-increase). This difference was not statistically significant (P=0.2). Odds ratio for finally unacceptable radiographic results according to the presence of radiologic collapse was 1.7.

Patients, who had radiologic collapse at 1st follow-up, had resulted in higher prevalence of radiologically-unacceptable union, although there was no statistical significance. Data also showed that even if there was no reduction loss at 1st follow-up, substantial number of patients (28%) had continuing collapse of fracture. These knowledge can be used to explain prognosis.

Factors Associated with Conversion to Wrist Fusion after Proximal Row Carpectomy or Four Corner Arthrodesis

List of authors:
Jan Jonas van Hermen\textsuperscript{1}, Jonathan Lans\textsuperscript{1}, Neal Chen\textsuperscript{1}
\textsuperscript{1}Massachusetts General Hospital (Boston)

Objectives / Interrogation: This study aimed to investigate the rate of conversion to total wrist fusion (arthrodesis or arthroplasty) in patients that underwent either proximal row carpectomy (PRC) or four-corner arthrodesis (FCA). Additionally, we evaluated the factors associated with conversion to wrist fusion and progression of radiographic arthrosis for patients treated with PRC or FCA.

Methods: We retrospectively identified patients that underwent a PRC or FCA using ICD-9 procedure and CPT codes and verified these by chart review. We included all adult patients (n=266) that were treated at a single institutional system from 2002-2016. The median age was 54 (IQR:45-62) years, and the median follow up was 8.1 (IQR:5.1-11.7) years. Eighty patients underwent FCA, and 186 underwent a PRC. We performed a multivariable logistic regression to evaluate factors associated with wrist fusion, including all explanatory variables with a p<0.10 in bivariate analysis.

Results and Conclusions: There was an increased progression of lunate fossa osteoarthritis in the PRC cohort (20% vs. 2%, p=0.005). The median time to wrist fusion was 16 months (IQR:12.1-37.7) for PRC and 32 months (IQR:19-45) for FCA. Intraoperative posterior and anterior interosseous neurectomy was associated with a lower rate of conversion to wrist fusion (p=0.004) after PRC. Smoking was independently associated with a higher rate of conversion to wrist fusion (OR: 30.9, p=0.017) after FCA.

Although PRC and FCA appear to have similar rates of arthrodesis at mid-term follow-up; PRC appears to demonstrate more radiographic arthritis. A partial denervation of the wrist may delay conversion or lower the rates of conversion to arthrodesis after PRC.

Recurrent Compressive Neuropathies Treated with Neurolysis and Porcine Extracellular Matrix Nerve Wrap

List of authors:
Loukia Papatheodorou*, Dean Sotereanos
1 University of Pittsburgh Medical School, Orthopaedic Specialists -UPMC (Pittsburgh)

Objectives / Interrogation: This study evaluated the short- and mid-term results of revision neurolysis and wrapping with porcine extracellular matrix (PECM) (AxoGuard® Nerve Protector, AxoGen Inc.) as an alternative technique for the treatment of recurrent compressive neuropathy after one previous surgical decompression.

Methods: Between 2009-2017, 86 patients, 49 with recurrent carpal tunnel and 37 with recurrent cubital tunnel syndrome, were treated with decompression and PECM nerve wrap. All patients had recurrent symptoms after having previously undergone one surgical decompression. The mean patient age was 56.7 years. The surgery consisted of revision median or ulnar nerve neurolysis and PECM nerve wrapping. All patients were noted to have extensive cicatrix formation around the median or ulnar nerve at the time of revision surgery. A hypothenar fat pad flap was performed as a supplementary procedure in cases of recurrent carpal tunnel, and a minimal medial epicondylectomy was performed in 15 of 37 cases of recurrent cubital tunnel.

Results and Conclusions: The mean follow-up period was 49 months (range, 6-108). Mean patient VAS pain scores significantly improved from 8.4 preoperatively to 1.4 postoperatively. The mean grip strength was significantly increased to 85.4% of the unaffected arm, compared with 41.3% preoperatively. The mean pinch strength improved from 63.2% of the unaffected arm before surgery to 81.6% after surgery. Static two-point discrimination improved from a mean 10.2 mm preoperatively to 7.3 mm postoperatively. 79 of 86 patients demonstrated 2 mm or more improvement in two-point discrimination postoperatively. Electro-diagnostic findings in those evaluated also improved, although not to normal values. There were no postoperative infections or wound complications. One patient with persistent elbow pain but normal electro-diagnostic findings needed further surgery 32 months after the revision cubital decompression and PECM nerve wrap. This patient was treated with revision ulnar nerve neurolysis and autologous saphenous vein nerve wrap after removal of the PECM. Based on our short and mid-term results of 86 patients, secondary decompression combined with PECM nerve wrapping is an effective and safe alternative technique for the surgical treatment of the symptomatic patient with recurrent carpal or cubital tunnel syndrome. This technique may eliminate the possible morbidity associated with autologous tissue coverage for failed nerve decompression.

Comminuted Jersey's finger (flexor digitorum profundus avulsion fracture) treated by plate fixation

List of authors:
JEONGHWAN KIM*, YEONTAEK CHOII
1 Seoul Medical Center (SEOUL)

Objectives / Interrogation: Avulsion fracture of flexor digitorum profundus (FDP) tendon is relatively rare fracture at the distal phalangeal base than avulsion fracture of terminal extensor tendon. Terminal extensor avulsion fracture, known as bony mallet finger, could be successfully treated by closed reduction and pinning, such as extension block technique. However, most of FDP avulsion fracture, known as Jersey's finger, needed open reduction, because of the proximal migration of fracture fragment and difficulty of pin fixation. We designed a new surgical technique for comminuted FDP avulsion fracture to treat with plating fixation.

Methods: A 16-year-old male patient visited our out-patient clinic with pain on his right ring finger with limitation of motion. He got a direct injury at finger tip during playing a baseball. On the plain radiograph, large avulsed fragment of distal phalanx was shown at the volar side of middle phalangeal level. And there was another small fragment was shown at the volar side of distal interphalangeal joint level. Magnetic resonance imaging (MRI) had revealed a comminuted FDP avulsion fracture in the ring finger. We performed open reduction. Under digital nerve block, volar zigzag incision was made from distal phalangeal level to proximal interphalangeal joint level. After dissection, A4 pulley was partially injured during proximal migration of FDP avulsion fracture fragment. The comminuted small fragment was too small to be fixated directly. However, the large fragment was large enough to be fixed by plate and screws. We performed internal fixation of large fragment with a two hole plate and two 1.2mm screws (Jeil medical, Korea). And we fixed small fragment by sutures.

Results and Conclusions: After two weeks from surgery, gentle flexion exercise was started. After six weeks from surgery, the range of motion was recovered fully. At the one-year follow-up, the patient had no pain and he had full range of motion. And there was no irritation sign or discomfort at the plate insertion site.
Up to date, most of FDP avulsion fractures were successfully treated by open reduction and internal fixation by suture button or suture anchor technique. However, in some cases with large or comminuted avulsion fragments, fixation with suture button or anchor might be impossible. And if fixation might be possible, their fixation power might be too low to allow early range of motion exercise. Therefore, we designed a new surgical technique to fix with a plate system, and we achieved good result.

Keywords: avulsion fracture, flexor digitorum profundus avulsion, Jersey's finger
HAND INJURIES OF COAL MINERS IN SOUTHERN WEST VIRGINIA WITH A FOCUS ON INJURY LOCATIONS AND DISTANCE ANALYSIS TO TREATMENT FACILITIES

List of authors:
RAVI VIRADIA*, Frank Annie¹, John David Hayes²
¹ West Virginia University-Charleston (Charleston)
² CAMC (Charleston)

Objectives / Interrogation: The implementations of coal mining safety policies have helped to decrease the injury rate and fatalities in miners significantly. However, hand injuries remain commonly observed in coal miners. Therefore, this study aims to review ten years of data and describe the incidence rate, prevalence and patterns of hand injuries in coal miners, as well as investigate the specific areas in WV where coal miners have been injured.

Methods: We evaluated patient demographics, coal mining locations, and patient outcomes. This study is a retrospective review of coal mine workers with coal mining hand injuries included in our level-1 trauma database from a study period of January 1, 2005, through March 31, 2015. Data was collected in an Excel-Spreadsheet.Stata-11.2 which was used to conduct a multinomial logistic regression. A hub analysis was performed to understand the overall distance associated with injury site and care using quantum geographic information systems.

Results and Conclusions: Variables collected are as follows:

- The sample size was 104 coal miners.
- Age of the miners ranged from 19-62. Coal mines are registered on our map with relevance to injury based on location; severity scale is presented in our graphic diagram.
- Most common injuries were fractures at 42.3%-47/104 followed by amputations 26.9%-28/104.
- The index finger had an overall higher rate of injury at 28.8%-30/104.

To understand the overall impact of specific injuries of coal miners based on the location, we looked at the number of injuries sustained at particular sites over the 10-year period.

- Within this, the average distance per injury to a medical center that was able to assist with hand injuries was 46.1 Miles.
- The shortest distance was within one mile of the center; The most prolonged distance was 83.3 miles
- To our level-1 center the average time for a patient to be transported to or from injury was one hour

We found that particular coal mines seem prone to more coal mining hand injuries. This analysis will better clarify which coal mines in Southern WV have been able to promote safety awareness and which continue to harbor a dangerous environment.

Persistent Medial Subluxation of the Ulna with Radiotrochlear Articulation

List of authors:
Amir Reza Kachooei¹, David Ring²
¹ Orthopedic Research Center, Ghaem Hospital (Mashhad)
² Department of Surgery and Perioperative Care, Dell Medical School, The University of Texas at Austin (Texas)

Objectives / Interrogation: Two patients—one with a terrible triad fracture dislocation and one with an anterior olecranon fracture dislocation—were treated for maltracking of the elbow (medial subluxation). The radial head articulated with the lateral trochlea while the ulnar trochlear notch was perched over the medial trochlea. The late revision surgery could not correct the subluxation because the joints were accustomed to the new alignment, however the overall function was reasonable.

Methods: Two patients—one with a terrible triad fracture dislocation and one with an anterior olecranon fracture dislocation—were treated for maltracking of the elbow (medial subluxation). The radial head articulated with the lateral trochlea while the ulnar trochlear notch was perched over the medial trochlea. The late revision surgery could not correct the subluxation because the joints were accustomed to the new alignment, however the overall function was reasonable.

Results and Conclusions: Two patients—one with a terrible triad fracture dislocation and one with an anterior olecranon fracture dislocation—were treated for maltracking of the elbow (medial subluxation). Magnetic Resonance Imaging Correlate Clinical Features of Medial Epicondylitis

List of authors:
Chulhee Park*¹, Che ho Lee¹, Young Ju Chae¹, Yeun soo Kim¹, Sehun Kim¹, Hyun Sik Gong², Kee Jeong Bae¹, Ji hyeung Kim¹, Goo Hyun Baek¹
¹ Seoul National University College of Medicine (Seoul)
² Seoul National University Bundang Hospital (Seongnam)

Objectives / Interrogation: Little is known about the relationship between magnetic resonance imaging (MRI) findings and the clinical features or prognosis of medial epicondylitis (ME). We aimed to evaluate the key MRI findings in patients with ME and whether there are any correlations of MRI findings with the clinical features of ME.

Methods: We retrospectively reviewed 83 patients who had undergone elbow MRI examinations for ME and who were available for follow-up after more than 6 months. We selected five MRI findings for qualitative grading: signal changes of the common flexor tendon (CFT) origin, ulnar collateral ligament insufficiency, ulnar neuritis, bony changes of medial epicondyle, and calcification. We correlated these MRI findings with clinical features, such as symptom, history of steroid injection, ulnar nerve symptoms, and pain level at baseline and follow-up.

Results and Conclusions: The most common positive MRI finding was the signal changes on the CFT (66%), and the least common finding was bony changes (18%). Signal intensity of the CFT was found to be correlated with follow-up pain level ($P = 0.008$) and the number of steroid injections ($P = 0.042$). Signal intensity of the CFT was independently associated with follow-up pain level.

This study demonstrates that the changes in signal intensity in common flexor tendon origin is the most common MRI finding in ME. It also shows that the severity of the signal changes can predict follow-up pain level. This suggests that MRI examinations can be helpful in consulting on the prognosis of conservative treatment in patients with ME.

The Choice of Operation for Young Patients of Kienböck's Disease: A Case Series.

List of authors:
Daisuke Kaji*, Kenji Kawamura, Hiroshi Yajima, Keiichi Murata, Shohei Omokawa, Yasuhiro Tanaka

1 Nara City Hospital (Nara)
2 Nara Medical University (Nara)

Objectives / Interrogation: Kienböck's disease is a rare condition in children or adolescent patients, and incidence of these is reported to be less than 1% of the whole of cases. Because of age-related potential for spontaneous remodeling and revascularization, surgical method for young patients should be different from for adult cases. For children, temporary fixation of the scaphotrapezio-trapezoidal (STT) joint would be not only effective but also simple and less invasive, but for late teenagers with epiphyseal closure, radial shortening osteotomy (RSO) would be more reliable.

Methods: We treated 6 cases of children or adolescent patients (younger than 20 years old) of Kienböck's disease. All patients presented in Lichtman stage IIIa. As a treatment, temporary fixation of the STT joint were performed in 3 patients (bilateral in 1). The ages of the patients in this group were 11, 14 and 16 years old. A period of fixation ranged from 8 to 12 weeks. RSO was performed in the remaining 3 patients. The ages of the patients in this group were 14, 15 and 18 years old. Shortening length was 3mm and volar locking plate was used as internal fixation. For an evaluation of blood circulation improvement in the lunate, MRI images (T1WI) were compared pre- and postoperatively. Carpal height ratio and Stähl index in AP view of X ray image, the range of motion (ROM) of the wrist and grip strength were also measured and compared pre- and postoperatively.

Results and Conclusions: In 11 and 14 year-old-patients underwent temporary fixation of the STT joint, improving blood circulation of the lunate was confirmed with MRI. But in a 16-year- old patient, intensity change was not confirmed with MRI at the time of 20 months postoperatively. As a second surgery, RSO were performed and improving blood circulation was confirmed at the time of 25 months after second operation. In all patients underwent RSO primarily, improving blood circulation of the lunate was confirmed with MRI postoperatively. Carpal height ratio, Stähl index, the ROM of the wrist and grip strength were improved in all patients except 1 patient who underwent secondarily RSO. The choice of operation for young patients of Kienböck's disease should be decided by having epiphyseal plate closure or not. Temporary fixation of the STT joint can be useful in the patients before the epiphyseal closure. In contrast, RSO is recommended after the epiphyseal closure.

Aesthetic reconstruction of thumb or finger partial pulp defect with free lateral great toe flap

List of authors:
Zhangjun Pan*1
1 Yixing People’s Hospital, Jiangsu University Affiliated Yixing Hospital (WUXI YIXING)

Objectives / Interrogation: We retrospectively reviewed the outcomes of reconstruction of thumb or finger partial pulp defect with free lateral great toe flap, and evaluated the outcomes of esthetic and sensory free toe flap reconstructed the digital pulp defects.

Methods: We performed 31 free toe pulp transfers for thumb or finger partial pulp reconstruction in 30 patients from May 2012 to October 2016: 10 men with 11 digits and 20 women with 20 digits. Their mean age was 36 years (21 - 54 years). The defects involved 15 thumbs, 8 index fingers, 4 long fingers and 4 ring fingers. The sizes of the free pulp flaps ranged from 21mm×12mm to 40mm×25mm. The artery and vein were anastomosed in an end-to-end pattern to the recipient vessels. The donor site of great toe was closed primarily or with a full-thickness skin graft from the groin. We used the Semmes-Weinstein monofilament test and the static two-point discrimination test to measure sensory recovery in the transferred pulps and donor sites of toes. We evaluated the esthetic appearance of the reconstructed digits using the Michigan Hand Outcomes Questionnaire. We also measured digital range of motion in the fingers without concurrent bone or tendon injuries.

Results and Conclusions: A total of 30 patients were all reconstructed in a second stage and followed for more than 12 months (average, 18.5 months). All of flaps were survived completely. One patient suffered local infection. Semmes-Weinstein sensitivity score was 2.43 to 3.78 (mean, 3.17) at the flap and 3.78 to 5.86 (mean, 4.93) at the donor sites of toes. The mean static two-point discrimination score was 6.71 mm. The mean esthetic appearance score was 16 according to Michigan Hand Outcomes Questionnaire. We found that 23 digits had extension deficits ranging from 5° to 25° (average, 13°) which compared with the contralateral uninjured digits. The free lateral neurovascular bundles great toe pulp flap is an efficient and reliable flap for the reconstruction of digital partial pulp defects.

In vivo kinematics of the thumb carpometacarpal joint during flexion and abduction

List of authors: Kaoru Tada*, Tadahiro Nakajima1, Mika Nakada1, Masashi Matsuta1, Hiroyuki Tsuchiya1
1 Department of orthopaedic surgery, Kanazawa University (Kanazawa)

Objectives / Interrogation: Screw-home torque rotation is known to occur on carpometacarpal joint of the thumb during the final phase of opposition, but there is no criterion for quantitative measurement of the opposition of the thumb. Therefore, we evaluated the opposition by dividing it into flexion and abduction movements and examined when the movement occurs using CT images.

Methods: The subjects were 10 healthy males aged 23-65 years (mean, 37.3 years). CT images were obtained in 4 equally divided positions during the motion from maximum extension to maximum flexion of the thumb using a supportive device made of Styrofoam. Similarly, images were obtained in 4 positions during maximum adduction to maximum abduction. A three-dimensional model was constructed from the obtained images, and the models of each position were superimposed with reference to the trapezium. A straight line connecting the extension line of the bone axis of the first metacarpal bone at each position with the shortest distance was defined as the rotation axis, and we hypothesized that the first metacarpal bone is translated while rotating around the rotation axis and the bone axis. A movement section from the first limb position to the second limb position is defined as I, from the second limb position to the third limb position as II, and from the third limb position to the fourth limb as III. The amount of angular change around the rotation and bone axes and the translational movement between each position were evaluated.

Results and Conclusions: The amount of angular change around the rotation axis increased as the flexion angle increased during flexion and decreased as the abduction angle increased during abduction. The angular change around the bone axis involved internal rotation in both flexion and abduction, which increased as the flexion angle increased during flexion and was constant during abduction. In terms of translational movement, the first metacarpal bone shifted toward the palm side with respect to the trapezium during flexion, but then moved toward the dorsal side as maximum flexion was approached. During abduction, the first metacarpal bones moved toward the ulnar side with respect to the trapezium regardless of the abduction angle.
In this study, as the flexion angle increased, flexion of the first metacarpal bone and angular change in internal rotation also increased. Hence, the screw-home torque rotation appears to be more prominent in flexion than in abduction.

Donor site morbidity after sural nerve graft harvesting

List of authors:
Kaoru Tada¹¹, Tadahiro Nakajima¹, Mika Nakada¹, Masashi Matsuta¹, Daisuke Yamauchi², Kazuo Ikeda¹, Hiroyuki Tsuchiya¹
¹ Department of orthopaedic surgery, Kanazawa University (Kanazawa)
² Department of orthopaedic surgery, Fukui-ken Saiseikai Hospital (Fukui)

Objectives / Interrogation: At present, autologous nerve graft is considered the best option for peripheral nerve defects. However, sensory disturbance and the pain associated with the harvesting of uninjured nerves are unresolved issues, and reports of donor site morbidity are limited. The purpose of this study was to evaluate donor site morbidity after sural nerve graft harvesting.

Methods: Ninety-one patients underwent autologous nerve graft by harvesting the sural nerve for peripheral nerves defects at our hospital and related facilities. The current address of these patients was determined from the medical records, and 15 patients (10 males, 5 females; mean age at surgery was 47.6 (range, 22-70) years) agreed to participate in a questionnaire-based survey. The time from surgery to the present was 18.5 (range, 1-37) years. The injured nerves included nine mixed nerves, such as the median nerve, and six sensory nerves, such as the digital nerves. The length of the harvested sural nerve was 111 (range, 20-250) mm. Evaluation was carried out using a questionnaire with a 10-point scale. The evaluation items were: 1) sensory disturbance of the feet immediately after surgery and in the present state (0 = no disturbance, 10 = extreme disturbance), 2) pain immediately after surgery and in the present state (0 = no pain, 10 = extreme pain), 3) current functional impairment (0 = no functional impairment, 10 = extreme functional impairment), 4) recovery of nerve defects (0 = unsatisfied, 10 = completely satisfied), and 5) satisfaction with autologous nerve graft (0 = unsatisfied, 10 = completely satisfied).

Results and Conclusions: Sensory disturbance improved from 3.0 ± 3.0 (mean ± SD) immediately after surgery to 2.4 ± 2.5 at present, and pain improved from 2.7 ± 3.6 immediately after surgery to 2.4 ± 3.1 at present, but these differences were not significant. The functional impairment score was 1.8 ± 2.9, while the recovery of nerve defects score was 6.9 ± 2.4, and satisfaction with the autologous nerve graft was 6.9 ± 3.2. Satisfaction with the autologous nerve graft and the recovery of nerve defects were strongly correlated (r = 0.88).
Though donor site morbidity after sural nerve graft harvesting persisted for a long time period after the operation, functional impairment was mild. Moreover, satisfaction was strongly correlated with the recovery of nerve defects. Autologous nerve graft was considered to still be a useful method for cases where a good recovery can be expected.

Comparative study on two models of arterialized venous flap in minipigs

List of authors:
ZHENG LI*, ZHENWEI ZHANG
1 Baoan District Shajing People hospital (SHENZHEN)

Objectives / Interrogation: Comparison of two models of arterialized venous flap in minipigs with dissecting the cutaneous vessels in minipigs, in order to provide anatomical foundations for arterialized venous flap research.

Methods: Deep superior epigastric artery (DSEA) of minipig was probed by PeriCam PSI System with Laser Speckle Doppler Perfusion Imaging techniques, and two types of arterIALIZED venous flap models were established on the torso integument of minipigs with anatomical techniques. Twenty healthy minipigs were randomized into two groups with self-control bilateral contrast test method, experimental groups(A group): end to side anastomosis was done between DSEA and cutaneous vein of flap; end to end anastomosis was control groups(B group). The area of the flaps were designed approximately 8cm*6cm. Blood flow perfusion (PU) of all the flaps in two groups were probed by PeriCam PSI System at different times.

Results and Conclusions: According to the measurement data of blood flow perfusion, A groups were 83.62±3.14; and B groups were 98.14±6.54. A groups significantly lower than B groups in early postoperative period, especially within 72 hours, that meant the preload of flap of control groups were higher than experimental groups. This study describes the good results obtained with two types of arterialized venous flap models in minipigs, and shows the significant difference between these two types of models in blood flow perfusion. In conclusion, these operative procedures are suitable for set up arterialized venous flap models in minipigs which can provide anatomical basis for the research of arterialized venous flap.

Randomized controlled trial of limited fasciectomy with injection of lipoaspirate adipose graft in the treatment of Dupuytren's disease

List of authors:
Marina Tommasini Carrara de Sambuy, Hugo Nakamoto, Marília Sandalo Trevelin Pimentel, Raul Bolliger Neto, Maurício Pinto Rodrigues, Marcelo Rosa Rezende, Teng Hsiang Wei, Maria Virginia Arranz Abreu, Rames Mattar Jr.

Objectives / Interrogation: Dupuytren's disease (DD) is caused by the proliferation and differentiation of myofibroblasts. It is believed that the pluripotent property of stem cells present in adipose tissue would inhibit myofibroblast proliferation. The primary objective of this study was to evaluate the effect of stem cell rich fat graft in patients with DD who underwent limited fasciectomy.

Methods: A total of 45 patients, divided into two groups, were studied in a single blind, prospective and randomized clinical trial. All patients underwent limited fasciectomy. In the control group, only limited fasciectomy was performed. In the fat group, limited fasciectomy was performed and a fat graft was injected at the resected cord site. Outcomes were assessed by Total Passive Extension Deficit (TPED) and Brief Michigan Hand Questionnaire (BMHQ) functional score.

Results and Conclusions: Compared at 6 weeks postoperatively, there was a significant increase in pain in the group with fat graft (p = 0.045). The results of the TPED did not show a significant difference between the groups. The BMHQ had worse outcome measures at 6 months and 1 year postoperatively in the group with fat (p = 0.040 and p = 0.047, respectively). Fat group had 43% complications compared to 8% in the control group (p = 0.019).

The use of fat grafting associated with limited fasciectomy promotes worse functional results compared to conventional limited fasciectomy in the short term. However, there remains doubt as to what the long-term results and recurrence rate will be in the future.

Restoration of elbow active flexion via monopolar latissimus dorsi transfer in patients with arthrogryposis

List of authors: Olga Agranovich*, Evgenya Kochenova¹, Svetlana Trofimova¹, Ekaterina Petrova¹, Dmitry Buklaev¹

¹ The Turner Scientific Institute for Children's Orthopedics (St.-Petersburg, Pushkin)

Objectives / Interrogation: One of the main causes of restriction in daily-living activities in patients with arthrogryposis is severe hypoplasia (or aplasia) of biceps brachii. The aim of this research was to estimate the possibility of restoration of elbow active flexion via monopolar latissimus dorsi transfer in patients with arthrogryposis.

Methods: From 2011 to 2018 we performed restoration of elbow active flexion via latissimus dorsi transfer to biceps brachii in 30 patients with arthrogryposis (44 upper limbs). We used clinical examination, EMG donor and recipient sites, CT chest wall and shoulder in different regimes.

Results and Conclusions: The patients were a mean age of 4,0±2,4 years. The follow-up period was 3,2±1,9 months. The follow-up results were estimated in 26 patients (30 upper limbs). The active postoperative elbow motion was 90,5±14,9°. Limitation of elbow extension was in 51% cases (12,8±4,3°) without problem in daily living. Good results were in 55,6%, satisfactory in 33,3%, poor in 11,1% cases.

Our results of latissimus dorsi transfer were comparable with other authors. Transposition of latissimus dorsi to the biceps brachii allows to restore sufficient flexion of the elbow without severe elbow flexion contractures.

Conclusions: We suggest pedicle monopolar latissimus dorsi transfer as a reliable therapeutic option to restore active elbow flexion in patients with arthrogryposis in cases with passive elbow flexion 90° and more before operation and donor muscle strange grade 4 and more.

Keywords: arthrogryposis, elbow, flexion, muscles transfers.
A new way to screw the scaphoid?

List of authors:
Matthew DeWolf*, Lance Warhold1, Alexander Hartov1
1Dartmouth-Hitchcock (Lebanon)

Objectives / Interrogation: Create customized 3-D printed apparatus for percutaneous retrograde screw fixation of scaphoid fractures (the Fixation Approaches to Scaphoid Trauma, FAST, Procedure) is more accurate, faster, and has less radiation exposure to the surgical team than fluoroscopy-guided percutaneous fixation. We describe in this presentation our process development of this guide.

Methods: We devised a complete system that allows the surgeon to define an optimal insertion point and trajectory on 3D renditions of CT data, and then to construct a guide to position a k-wire in the desired trajectory in cadaver arms. After defining the intended insertion point and trajectory, a 3D printer is programmed to produce the components that perfectly guides a K-wire into the intended position. We developed 4 different models during the process. With this system, we conducted experiments in which orthopedic residents placed casts outfitted with special openings (windows) designed to accommodate the k-wire guides on 7 cadaver arms. Following casting, pre-op CTs were acquired and treatment planning to define the k-wire trajectory was done. Custom guiding inserts were designed based on 3D models of the skeleton and stereolithography (STL) files suitable for 3D printing were produced and made into guide blocks. Finally, the residents placed the blocks into the windows and inserted the k-wires in place. Post-op CTs were used to verify the correct placement of the k-wires and we were able to confirm correct position in all 14 cases.

Results and Conclusions: We first developed an optimal model. We then tested this with resident surgeons. We found that:
FAST is Faster (30 seconds versus 21 minutes)
FAST is More Accurate (all within central axis of the scaphoid)
FAST has no radiation exposure to the surgeon
FAST Procedure planned trajectory courses along the exact planned path (Figure 1)

The FAST Procedure is a faster, more accurate, and more reliable way to perform percutaneous pinning for orthopaedic residents. We present the steps that we took to produce this technique.

Pharmacologic Prevention of Contractures in Neonatal Brachial Plexus Injury

List of authors:
Roger Cornwall*1, Athanasia Nikolaou1, Liangjun Hu1
1 Cincinnati Children’s Hospital (Cincinnati)

Objectives / Interrogation: Contractures in neonatal brachial plexus injury (NBPI) are caused at least in part by impaired growth of denervated muscle, but the mechanism of this impaired growth is unknown. This study uses a mouse model of NBPI to assess muscle protein imbalance (synthesis vs. degradation) as a novel potential target to prevent contractures in NBPI.

Methods: Unilateral C5-T1 NBPIs were surgically created in 5-day-old mice, which reliably causes shoulder and elbow contractures 4 weeks post-NBPI. Protein synthesis was measured in denervated and contralateral control elbow flexor muscles 1-4 weeks post-NBPI by puromycin incorporation and by RNA and protein levels of major muscle proteins. Protein degradation was measured by K48-linkage specific polyubiquitin and RNA levels of protein degradation markers. Bortezomib, a 20S proteasome inhibitor, was then administrated systemically for 4 weeks post-NBPI to inhibit protein degradation. Contractures were measured 4 weeks post-NBPI, and muscles were assayed for proteasome activity and growth.

Results and Conclusions: NBPI did not reduce muscle protein synthesis, either in overall puromycin incorporation or in RNA and protein levels of specific major structural and contractile proteins. However, NBPI increased protein degradation, with a doubling of polyubiquitination and increased expression of MurF1, a driver of proteasome-mediated protein degradation. Bortezomib effectively prevented shoulder and elbow contractures following NBPI (p<0.001, Figure 1). Bortezomib also blunted the denervation-induced increase in proteasome activity (p<0.001), and rescued muscle growth in volume (p<0.0001), cross-sectional area (p<0.001), and length (p=0.03).

Keywords:
Brachial Plexus, contracture, denervation, muscle growth

Figure 1: Prevention of contractures with bortezomib+[Gly14]-humanin. A) Representative images of elbow and shoulder contractures (left side denervated) in mice treated with saline and bortezomib. B) Contractures measured as difference in degrees of range of motion between denervated and contralateral control limbs, blinded to treatment group. [Gly14]-HN, given to limit bortezomib toxicity, had no effect alone. *p<0.001

Thus, contractures in NBPI are caused by increased muscle protein degradation counteracting normal protein synthesis. Proteasome inhibition improves growth of denervated muscle and prevents contractures. This study therefore identifies the pathophysiology of contractures in NBPI and demonstrates the first successful pharmacologic strategy to prevent these contractures by targeting a causative molecular mechanism.

A Unique Retractable Guide Block Used in Volar Locking Plate Fixation for Distal Radius Fracture

List of authors:
Chieko Kadoma*1, Isao Sasaki2
1 Itabashi Chuo Medical Center (Tokyo)
2 Clark Hospital (Sapporo)

Objectives / Interrogation: Volar locking plate fixation is one of the most common surgical treatments in distal radius fracture. Careful attention during placing the plate and fixating the fracture needs to be payed not to injure soft tissues, especially median nerve, radial artery and flexor pollicis longus (FPL) tendon. To make sure the soft tissues are protected, we use a unique retractable guide block (RGB). The aim of this study is to introduce this guide block and the clinical results.

Methods: The retractable guide block has each screw and Kirschner - wire holes, covers the whole plate except distal ulnar screw hole, and has enough height to retract from the bone level to the skin level. The subjects were 84 wrists of 84 cases that underwent volar locking plate fixation for distal radius fracture with a retractable guide block. 24 were male and 60 were female, the mean age was 69 years old (range 19 - 91), 42 were right hands and 42 were left hands. According AO classification, type A2 were 17, type A3 were 21, type B3 were six, type C1 were eight, type C2 were 26, and type C3 were six. The median observation periods were 364.5 day (187.5 - 407 day), the mean operation time was 65.4 minutes (SD 20.8), and the median loss of correction on X-ray was 0 degree (range 0 - 13). The number of surgeons of clinical fellow year were 10 in first year, 14 in second year, 16 in third year, 12 in fourth year, and 32 in fifth year and older. Each year of surgeon treated any AO type fracture with no difference statistically. We retrospectively examined the difference of operation time, the loss of correction on X-ray, and complication according to AO classification.

Results and Conclusions: Results: Neither operation time or loss of correction was statistically different among AO classification. One complication was observed, which was one screw protrusion into articular surface during the time course. Conclusion: Owing to the shape of RGB, the risk of injuring soft tissues such as median nerve and FPL tendon is very low. In addition, the data of the operation time and the loss of correction indicated the probability of stable performance regardless of AO classification. Conclusion: We introduced a unique retractable guide block that has potential for safety and stability in surgical performance.

Single incision for tendon transfer in Radial Nerve Palsy

List of authors:
Govindasamy Balakrishnan*¹
¹ Right hospitals (CHENNAI)

Objectives / Interrogation: One of the drawbacks of the tendon transfer surgery for radial nerve palsy is the resultant multiple scars of the forearm. To overcome this problem we have adopted a single incision technique by harvesting all the tendons and performing the tendon transfers.

Methods: This improves the aesthetic outcome of the tendon transfer surgery. The functional results of the tendon transfer surgery are not compromised by the single incision. The patients were satisfied with the end results of our modification.

Results and Conclusions: We are describing the planning and execution of the tendon transfer surgery using our modified technique and presenting our results of the procedure.

Keywords:
Single incision - tendon transfer - radial nerve palsy
Making five fingered hand in Type III B thumb hypoplasia

List of authors:
Govindasamy Balakrishnan*¹
¹Right hospitals (CHENNAI)

Objectives / Interrogation: Pollicisation remains the gold standard of thumb reconstruction in Type III, IV & V thumb hypoplasia worldwide. Due to cultural differences, Asian parents prefer to have a five fingered hand in Type III B thumb hypoplasia.

Methods: To satisfy these parents, we have developed a novel method to reconstruct the existing hypoplastic digit. A free toe phalangeal bone from third or fourth toe is used to reconstruct the thumb metacarpal in the first stage and a opponensplasty using abductor digiti minimi is performed in the second stage to provide opposition.

Results and Conclusions: We are presenting the technique of thumb reconstruction in Type IIIB thumb hypoplasia and discuss the functional results of our reconstructive procedure and future options.

Keywords: -
A novel method of finger tip reconstruction with composite graft

List of authors:
Govindasamy Balakrishnan*
1 Right hospitals (CHENNAI)

Objectives / Interrogation: Finger tip amputations remain a challenge to the reconstructive hand surgeon to restore the lost nail bed. Reimplantation is ideal but may not be possible in all occasions of amputation at terminal phalangeal level.

Methods: A novel method of finger tip reconstruction was performed using a composite graft of nail bed and sliver of terminal phalanx with a cross finger flap. The procedure was carried out in a series of patients and the results were analysed.

Results and Conclusions: We would like to present our indications for the procedure, technical considerations of the reconstructive surgery and discuss the results and functional outcome of this reconstructive option.

Percutaneous needle fasciotomy in Dupuytren disease: A follow up of the direct outcomes considering recurrence and complications

List of authors:
Holger Erne1
1Klinik für Plastische Chirurgie und Handchirurgie, Technische Universität München (München)

Objectives / Interrogation: Background: The treatment of Dupuytren's contracture with needle fasciotomy is subject of controversial debates due to the high recurrence rate. The present study evaluates the results of a technique of percutaneous needle fasciotomy as a less invasive, less time-consuming and less risky alternative to conventional fasciectomy and found ways to reduce the recurrence rate significantly.

Methods:
Patients and methods: In 2008 to 2018, 81 rays in 64 patients with Dupuytren's contracture were treated using the technique of the 'Percutaneous Needle Fasciotomy' (PNF). With the Classification of Tubiana 38 rays Stage I, 29 Stage II, 12 rays Stage III and 1 Stage IV were categorized. PNF was performed using without local anesthesia at several levels in the palm.

Results and Conclusions:
Results: Within the retrospective study 53 patients (68 rays) were reviewed. The mean age of the patients was 63.65 years. The recurrence rate was 18.86. 49 patients with 62 rays had a totally free extension in the follow up (92.4%). All patients, except one who was jobless were able to return to their job in an average of 5.5 days.
Conclusion: The technique of 'Percutaneous Needle Fasciotomy' (PNF) is reliable and relatively simple to perform, when compared to the open aponeurectomy. The rate of complications is low. The time of operation and period of recovery is shorter than for the conventional technique. The recurrence rate of this study is significantly less compared to the literature.

The economic impact of anaesthesia methods used in hand surgery: global costs and operating room's throughput

List of authors:
Olivier de Boccard*1, Camillo Mueller2, Thierry Christen2, Wassim Raffoul2
1 CHUV, service de chirurgie plastique et de la main (Villars-sur-glâne)
2 CHUV, service de chirurgie plastique et de la main (Lausanne)

Objectives / Interrogation: There are now growing interests worldwide for the wide awake approach to hand surgery. We hypothesized that using the "wide awake, local anaesthesia and no tourniquet" (WALANT) approach would result in lower global costs and in an increase of the operating room's efficiency when compared to other types of anaesthesia: axillary brachial plexus block and intravenous regional Anaesthesia

Methods: All cases of single carpal tunnel release and trigger finger release performed between January 2016 and December 2017 in an ambulatory surgery center in Switzerland were divided into three groups, depending on which anaesthesia method was used. Total operating room occupation time, surgical time and the "all but surgery" time were analysed. A common minimal bill per anaesthesia was generated using multiple bills sent to insurance companies.

Results and Conclusions: WALANT allows for an increase in the operating room's throughput by having shorter occupation times than other methods (17.5-33% depending on the procedure and anaesthesia). Costs of the two procedures are reduced by 21-31% when using WALANT. Preferring WALANT for some procedures in hand surgery has a notable beneficial impact on the costs and on the operating room's efficiency. This effect is more evident on short surgical procedures where the surgical time is only a small portion of the total operating room's occupation time.

**A new computational approach for fully automatic 3D preoperative planning of forearm osteotomies**

**List of authors:**
Fabio Carrillo¹, Simon Roner¹, Andreas Schweizer¹, Ladislav Nagy¹, Jess Snedeker², Philipp Fürnstahl¹
¹ Balgrist University Hospital (Zürich)
² ETH Zurich, Balgrist Campus (Zürich)

**Objectives / Interrogation:** Despite available technologies for planning of surgical treatments, definition of an optimal preoperative plan for complex forearm osteotomies can take up to 6 hours, requiring several adjustment iterations. Existing automatic approaches often fail to provide surgeons with ready-to-use solutions that can be implemented without further adjustments. Thus, clinical times and costs of computer-assisted planning remain too high, limiting its clinical use. A new computer algorithm has been developed to provide surgeons with complete preoperative planning solutions encompassing the position and orientation of the osteotomy cut, the required reduction of the bone fragments, and optimal positions of the fixation plate and screws. Goal of this study was to evaluate the capability of our approach to generating planning solutions that can be directly used in the clinical setting, without requiring further manual tuning.

**Methods:** 38 patients who underwent corrective osteotomy (14 distal radius, 24 shaft) were included in the study with baseline data: affected side: 19 left, 20 right; gender: 20 males, 19 females. The developed algorithm was based on artificial intelligence and statistical shape models. Additionally, bone density of each patient was considered for the automatic implant optimization. A clinical validation compared solutions generated by the algorithm (OA) against manually generated 3D preoperative planning by expert surgeons, considered as the gold standard (GS). Both solutions were blinded and presented to 6 expert hand surgeons, who had then to choose the better operative plan for each case. A technical evaluation was also done, comparing reduction accuracy, position of implant relative to the bone fragments and screw purchase.

**Results and Conclusions:** Clinical validation showed that surgeons favored OA solutions to be better than the corresponding GS solutions in 60% of the tested cases. Subsequent technical evaluation indicated an improvement of 40% on the reduction accuracy, 60% on the implant position and 80% on the screw purchase, in comparison to GS solutions. OA solutions particularly outperformed the GS in cases with a difficult fixation, further improved when considering variable-angle screws.

The presented computer approach allows generating complete solutions for patient specific pre-operative planning of distal and shaft radius osteotomies, which can improve planning times and help assist surgeons on better surgical decisions.

Radial head Resection and Hemi-interposition vs "functional radial head resection" with a computerized ring fixator in patients with chronic missed Monteggia pathology: a prospective analysis.

List of authors:
Konrad Mader*, Sinef Yarar-Schlickewei¹, Mark Flipsen², John Ham², Sebastian Klötzer³, Karl-Heinz Frosch⁴
¹ Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, Sektion Hand-, Unterarm- und Ellenbogentraumatologie, UKE Hamburg (Hamburg)
² Orthopaedic Department, OLVG (Amsterdam)
³ Asklepios Klinik Altona, Sektion Obere Extremität, TOC (Hamburg)
⁴ Klinik für Unfall-, Hand- und Wiederherstellungschirurgie, UKE Hamburg (Hamburg)

Objectives / Interrogation: Chronic "missed" Monteggia pathology is characterized by mild flexion deficit due to abutment of the radial head, progressive cubitus valgus with/without ulnar neuropathy, radiocapitellar arthrosis and pain. In a prospective patient series in 2 tertiary reference centers for this pathology in adolescents and young adults, i.e. in chronic Monteggia lesion with deformity and hypertrophy of the radial head either a radial head resection and hemi-interposition with local capsule tissue or a "functional radial head resection" after Slongo with a computerized ringfixator programmed for angular correction and concomittant lengthening of the ulnar with transfixation of radius and ulna were performed and prospectively evaluated.

Methods: 20 patients (14 M, 6 F, ∅ age 16 years, range 14-25 years), all with the diagnosis of chronic Monteggia with clear deformity and arthrosis of the radial head were included in the study. After thorough clinical assessment and counselling of the Patient and the family one of the afore mentioned procedures (14 resection hemi-interpositions vs 6 "functional radial head resections") were performed by 2 senior upper extremity reconstructive consultant surgeons. At FU and final FU (minimum 2 years, ∅ 5 years, range 2-8 years), function, RUJ- and DUJ stability, q-DASH, PRWE, 2 quality of life scores and and cost analyis were performed.

Results and Conclusions: There were no procedure related complications in the resection hemi-interposition group i.e. no damage to the deep branch of the radial nerve or postoperative instability. There were 2 fixator related complications, one pinsite infection resolving by antibiotics and one aseptic loosening of a radial halfpin treated by resiting of the pin, both occurring during the consolidation period. In all computerized corrections the preplanned goal was reached. 2 patients in the resection group reported mild problems at the distal radioulnar joint (moderate ulnar head abutment) and 1 patient did experience pain at the proximal end of the radius. At final FU elbow function and forearm rotation improved equally, most significant in flexion and pronation. ∅ q-Dash and PRWE improved in both groups, all patients did have better quality of life score at final FU. All patients but one (resection group) would undergo the procedure again.

Both resection interposition and computerized "functional radial head resection" can be performed to alleviate the symptoms and treat the motion deficit in patients with chronic Monteggia pathology.

Changes in joint distance during flexion and abduction of the thumb carpometacarpal joint

List of authors:
Mika Nakada*, Kaoru Tada, Tadahiro Nakajima, Masashi Matsuta, Hiroyuki Tsuchiya
1 Department of Orthopaedic Surgery, Kanazawa University (Kanazawa)

Objectives / Interrogation: Although osteoarthritis of the thumb carpometacarpal (CMC) joint is common, the effect of thumb movement at the joint surface remains unclear. The purpose of this study was to examine the changes in joint distance during flexion and abduction of the thumb by computed tomography (CT) at multiple positions.

Methods: The subjects were 5 healthy men (mean age 44.4±14.9 years). CT images of one hand of each subject were obtained during motion of the thumb from maximum extension to maximum flexion, taken at 4 equally divided positions using a supportive device made of Styrofoam. Similarly, images were obtained in 4 positions during movement from maximum adduction to maximum abduction. A three-dimensional model was constructed from the images, and the joint distance at each position was measured. Solidworks was used as the analytical software, and a measurement perpendicular to the metacarpal joint surface was used as the joint distance.

Results and Conclusions: The minimum joint distance became smaller as the joint flexed from the extended position. The mean minimum joint distance was decreased from 0.66 mm in the extended position to 0.51 mm in the flexed position, but this change was not statistically significant. In the flexed position, the joint distance became smaller on the volar and ulnar sides of the metacarpal joint surface. The minimum joint distance also became smaller as the joint abducted from the adducted position. The mean minimum joint distances was significantly decreased from 0.71 mm in the adducted position to 0.34 mm in the abducted position (p<0.05). In the abducted position, the joint distance became smaller on the volar side of the metacarpal joint surface. Movement of the thumb CMC joint consists of a complex balance of a saddle joint, ligaments, muscles, and tendons. However, its specific movement has been under-investigated. Some studies report that wear of the thumb CMC joint occurred on the volar side of the metacarpal joint surface. However, in our study, as the thumb joint flexed or abducted, the joint distance decreased. Moreover, in the flexed and abducted positions, the joint distance on the volar side was smaller. Importantly, this movement is involved in the occurrence and progression of osteoarthritis of the thumb CMC joint.

Motor innervation pattern of C7 nerve root and clinical study of its reinnervation in BPAI

List of authors:
Su JIANG1, Guobao WANG1, Aiping YU1, Wendong XU2
1 Department of Hand Surgery, Huashan Hospital (Shanghai)
2 Department of Hand Surgery, Huashan Hospital, The National Clinical Research Center for Aging and Medicine, Dept of Hand and Upper Extremity Surgery, Jingan DC Hospital (Shanghai)

Objectives / Interrogation: Contralateral C7 (CC7) nerve root has been utilized as a more prevailing procedure for treating not only disastrous peripheral nerve injuries such as brachial plexus avulsion injury (BPAI), but also spastic arm paralysis in central hemiplegic patients, with promising results reported from many centers. The premise of this procedure is that harvest of C7 nerve root would not cause permanent functional loss in the healthy extremity. However, the relative motor contribution of C7 innervation to the overall function of the upper limb remains unknown, as well as the recovery assessment of specific muscles. In the present study, cadaveric and clinical investigations were combined to delineate the motor innervation pattern of C7 nerve root and to ascertain the extent of functions that can be regained by reanimation of the C7 myotome through CC7 nerve transfer in a completely paralyzed limb suffering from BPAI.

Methods: In the anatomical study, we dissected C7 nerve root in eight embalmed adult cadavers bilaterally, and traced its branches to the muscles. In clinical study, CC7 to C7 nerve transfer was performed on eight patients with BPAI. Outcomes were evaluated by electromyography study and the muscle strength.

Results and Conclusions: Anatomically, consistent and predominantly C7-derived nerve fibers were found in the lateral pectoral, thoracodorsal and radial nerve. The average distance from the C7 nerve root to the lateral pectoral nerve entry point of the pectoralis major was 10.7 ± 1.5 cm which was the shortest. In the clinical study, for the electromyography study, compound muscle action potentials were recorded in all the muscles mentioned above. After an average follow-up of 37 months, it was found that seven out of eight patients regained M3 or higher power for shoulder adduction and elbow extension. Three patients regained M3 wrist extension. All patients were recorded the recovery of finger extension but the muscle strength was not stronger than M2. C7 nerve root provides consistent and dominant contributions to the lateral pectoral nerve, thoracodorsal nerve and long head of triceps branch of radial nerve. For BPAI patients, after successful reinnervation of C7 nerve root, satisfying shoulder adduction and elbow extension could be anticipated, while the recoveries of wrist and finger extensions are poorer.

Bilateral Elbow Extension Contracture in a Child with Arthrogryposis A VERY RARE OCCURRENCE

List of authors:
Neeraj Godara*1
1 Ganga Hospital & Medical center (coimbatore)

Objectives / Interrogation: Arthrogryposis is characterized congenital contractures of two or more joints1,2. The term arthrogryposis multiplex congenita is used to describe a large heterogeneous group of disorders, and it has been subdivided into syndromic arthrogryposis, distal arthrogryposis, and classic arthrogryposis (amyoplasia). The degree of stiffness and weakness ranges from mild to severe and is not progressive. Elbow dysfunction poses a substantial functional limitation for these children2,9-11. With the elbow stiff in extension, they cannot bring the hand to the mouth to feed them or attend to facial hygiene. The goal of treatment for children with arthrogryposis is to improve their quality of life by facilitating functional independence.

Methods: 1.5yr old female child born out of non consanguineous marriage came to our OPD with parental concerns of bilateral upper limb deformity. Though she had almost 90° of range of motion in her right shoulder but no movement was possible at elbow. The X-Ray findings revealed normal elbow joint and MRI showed Normal alignment of bilateral elbow joint with complete atrophy of muscle in anterior compartment both arm. Posterior capsulotomy with triceps lengthening (v-y) was performed for both elbow joints.

Results and Conclusions: Result: Posterior capsulotomy with triceps lengthening (v-y) was performed first on right side and followed by similar surgery on left side after 3 months. The duration of follow-up was 3 years in this case. The arc of motion of elbows improved from 0° preoperatively to 110° at the time of final follow-up. The child was able to reach the mouth without passive assistance and is able to feed herself independently. The child do not underwent any subsequent tendon transfer surgery.

Conclusions: Elbow capsulotomy with triceps lengthening successfully increases elbow flexion and the arc of elbow motion of children with arthrogryposis, enabling hand-to-mouth activities. From this our main emphasis is that one can be benefited to very extent with elbow capsulotomy and triceps lengthening and one should be little careful while doing or selecting tendon transfer for example in this case Latissimus Dorsi was not working, and we could not use pectoralis major, while performing triceps to biceps could result in flexion contracture deformity which is more cumbersome for patient as it restrict free out reach of hand and table top activity such as use of computer which has become a necessity in today’s world.

Shorter Rehabilitation after Extensor Pollicis Longus Reconstruction Combining Modern Suture Technique and New Rehabilitation Protocol

List of authors:
Tim Cordier*, Silvia Schibli
1 Kantonsspital Graubünden (Chur)

Objectives / Interrogation: Reconstruction of Extensor pollicis longus (EPL) function is realized by transferring the tendon of the Extensor indicis (EI) to the distal part of the EPL. Common suture techniques combined with established rehabilitation protocols have proven to achieve good results. However, patients regularly experience an impairment of the operated hand for three months. In addition established rehabilitation protocols tend to be complex and depending on substantial support from hand therapists.
Compared to common suture methods newer Side-to-Side (STS) suture techniques provide improved strength and have been successfully implemented for tendon transfers.
Hypothesis of this prospective study is that the combination of a Side-to-Side suture technique with a straightforward active rehabilitation protocol based on the increased suture stability simplifies and shortens time of rehabilitation after EPL reconstruction.

Methods: Between 11/2015 and 04/2017 we treated a series of 10 patients, median age 56 (range 18-70) after spontaneous EPL-rupture using STS suture technique for EI to EPL transfer. For postoperative rehabilitation we implemented a simplified Controlled-Active-Motion protocol. Clinical follow up was at 2, 4 and 8 weeks postoperatively and additionally one year later by phone. Primary endpoints were the unrestricted use of the operated hand and major complications, defined as tendon rupture or relevant tendon elongation. We reported on patient satisfaction and pain. As objective parameter active range of motion of the thumb and index finger as well as pinch and grip strength were measured.

Results and Conclusions: Results: All 10 patients underwent surgery and postoperative rehabilitation without complication. All patients were satisfied with the treatment 8 weeks and one year postoperatively. All were back to work after 8 weeks or could use the operated hand without any restriction. At 8 weeks all patients achieved a powerful active extension of the IP-joint of the thumb. Pinch- and grip- strength reached on average 83% and 81% of the contralateral side. There was no lost to follow up.
Conclusion: Despite the small patient group and the relative short follow up the results suggest that the Side-to-side suture technique in combination with an adapted active rehabilitation protocol provides a safe and successful method for EPL-reconstruction. Compared with the current literature this concept shortens time of rehabilitation by a third.

Management and outcome of acral soft tissue sarcoma

List of authors:
Benjamin Dean¹, Paul Critchley¹, Lucy Cogswell¹, Henk Giele¹, Harriet Branford-White¹, Nick Athanasou¹, Max Gibbons¹
¹Nuffield Orthopaedic Centre (Oxford)

Objectives / Interrogation: Aim
The aim of this study was to evaluate the surgical management and outcomes of patients with acral (peripheral extremity hand or foot) soft tissue sarcomas.

Methods: Methods and Patients
We identified 63 patients with acral soft tissue sarcomas who presented to a tertiary referral sarcoma service (27 hands and 36 feet). Mean age was 49 (35 males and 28 females). The commonest sarcoma subtypes were epithelioid in the hand (8 patients) and synovial in the foot (11 patients).

Results and Conclusions: Results
In 41 patients (65%) the tumour size was less than 5cm in its largest dimension (median size 3cm). 27 patients (43%) were diagnosed after inadvertent excision prior to their referral to the specialist sarcoma unit. After biopsy and staging, primary surgical intervention at the sarcoma unit was excision and limb salvage in 43 (68%), partial (digit or ray) amputation in fourteen (22%) and more proximal amputation in six (10%). At final follow up, local recurrence had been treated by one partial amputation and six amputations, resulting in a partial amputation rate of 24%, and the proximal amputation rate to 19%.

The rate of local recurrence was 19% and the 5 year survival was 82%. Patients who underwent inadvertent excision demonstrated no statistically significant difference in survival or local recurrence, but underwent a higher rate of amputation (p=0.008). Large tumour size (>5cm) was associated with lower survival (p=0.04) and a higher risk of local recurrence (p=0.009).

Conclusions
The majority of acral soft tissue sarcomas are smaller than 5cm at presentation, indicating that whilst size can be a useful prognostic factor, it should not be used as a diagnostic threshold for referral. Increased tumour size is associated with a higher rate of local recurrence and reduced survival. Sarcoma excision with limb preservation does not result in an increased risk of local recurrence.

sarcoma, acral, soft tissue, hand, foot
List of authors:
Armin Badre*, David Axford, Sara Banayan, Jim Johnson, Graham King
1 Roth-McFarlane Hand & Upper Limb Centre, St. Joseph's Health Care (London)

Objectives / Interrogation: Previous biomechanical studies of LCL injuries and their surgical repair, reconstruction and rehabilitation have primarily relied on gravity effects with the arm in the varus position. The application of torsional moments to the forearm manually is not reproducible; hence studies to date likely do not represent forces encountered clinically. The aim of this investigation was to develop a new biomechanical model to quantify posterolateral stability of the elbow.

Methods: Six cadaveric arms were mounted in an elbow motion simulator in the varus position. A threaded screw was inserted on the dorsal aspect of the proximal ulna and a weight hanger was used to suspend 400g, 600g, and 800g of weight from the screw head to allow torsional moments to be applied to the ulna. An LCL injured (LCLI) model was created by sectioning of the common extensor origin, and the LCL. Ulnohumeral rotation was recorded using an electromagnetic tracking system during simulated active and passive elbow flexion with the forearm pronated and supinated.

Results and Conclusions: During active motion with the forearm pronated, the addition of weights did not significantly increase the external rotation (ER) of ulnohumeral articulation (10.0±7.0°, P=.268 400g; 10.5±7.1°, P=.156 600g; 11.0±7.2°, P=.111 800g) compared to the LCLI (8.4±6.4°). However, with the forearm supinated, the addition of 800g but not 400g and 600g significantly increased the ER (8.2±5.7°, P=.083 400g; 8.7±5.9°, P=.054 600g; 9.2±5.9°, P=.038 800g) compared to the LCLI (5.9±5.5°). During passive motion with the forearm pronated, the addition of 600g and 800g but not 400g resulted in a significant increase in ER (9.3±7.8°, P=.103 400g; 11.2±6.2°, P=.004 600g; 12.7±6.8°, P=.006 800g) compared to the LCLI (3.7±5.4°). With the forearm supinated, the addition of 400g, 600g, and 800g significantly increased the ER (11.7±6.7°, P=.031 400g; 13.5±6.8°, P=.019 600g; 14.9±6.9°, P=.024 800g) compared to the LCLI (4.3±6.6°).

Conclusion
This novel biomechanical model demonstrates that the application of even small amounts of torsional moment on the forearm with the arm in the varus position exacerbates the rotational instability seen with the LCL deficient elbow. This new model allows for a more provocative testing of elbow stability after LCL repair or reconstruction, allowing smaller sample sizes to be used while still demonstrating clinically significant differences. Future biomechanical studies evaluating LCL injuries, repair and rehabilitation should consider using this testing protocol.

Polyaxial Locking Plating for Volarly Displaced Intra-articular Fractures of the Distal Radius

List of authors:
Kozo Morita*1
1 International Goodwill Hospital (Yokohama)

Objectives / Interrogation: Volarly displaced intra-articular fracture of the distal radius with volar lunate facet fragments are very difficult for internal fixation. The object of this study is to evaluate the results following polyaxial locking plate fixation of the fractures.

Methods: A retrospective study was conducted to identify patients who had been treated with polyaxial locking plates (Aptus2.5 plate, Medartis, Basel) for unstable volarly displaced intra-articular fracture of the distal radius. 49 patients 51 wrists were identified with an average age of 63.3 years old and with an average follow-up period 12.3 months. Fracture types were classified type B3 30 cases, C2 7 cases, C3 14 cases in AO classification. We evaluated various parameters with X-rays included calcral translation, size of volar lunate facet fragments and coverage rate of locking plate with CT, range of motion, and Mayo modified wrist score.

Results and Conclusions: All fractures were united. Final ulnar variance averaged 0.6mm, radial inclination was 21.7º, and volar tilt was 13.4º and carpal translation was corrected except initial 2 cases. The average range of motion were: flexion-extension 124° (94.8% of the opposite extremity); pronation-supination 172° (95.1%); grip strength was 12.4 kg (72.1%). There were no complications. Mayo modified wrist score were averaged 88 points.

This study for unstable volarly displaced intra-articular fracture of the distal radius, resulted in union, good to excellent alignment and wrist motion. Especially, polyaxial locking plate fixation enabled to place plate distally by changing of the screw direction. This feature leaded to stabilize volar lunate facet fragments by buttress effect. Polyaxial locking plate fixation were very useful for the fractures.

Aging Affects Tenogenic and Chondrogenic Gene Expression in Mouse Intrasynovial Tendons

List of authors:
Masanori Hayashi, Hiroko Iwakawa, Yo Kitamura, Shigeharu Uchiyama, Hiroyuki Kato
1 Department of Orthopaedic Surgery, Shinshu University (Matsumoto)
2 Department of Orthopaedic Surgery, Okaya city hospital (Okaya)

Objectives / Interrogation: It is well known that aging alters the musculoskeletal system, resulting in tissue degeneration and age-associated injury and disease. Tenosynovitis is also considered to be an age-associated intrasynovial tendon disease. However, little is known about the pathogenic mechanism of tenosynovitis and its relation to tendon degeneration during the aging process. Senescence accelerated mouse (SAM) P6, a strain with low peak bone density, is an osteoporosis and senescence model mouse. The purpose of this study is to investigate age-related changes in SAMP6 mouse intrasynovial tendon.

Methods: Eighty hind paws were obtained from forty mice: ten 8-week SAMR1 mice, ten 8-week SAMP6 mice, ten 24-week SAMR1 mice, and ten 24-week SAMP6 mice. SAMR1 mice were used as controls for SAMP6 mice. The right side hind paws of each mouse were used for real-time PCR. Relative expression levels of scleraxis, tenomodulin, collagen type I, Sox9, Sox5, Sox6, and aggrecan were compared. The left side hind paws were used for histological analyses and immunohistochemical analyses with anti-tenomodulin and anti-aggrecan antibody.

Results and Conclusions: Gene expression analysis for tenogenic marker showed decreased expression of tenomodulin and collagen type I and slightly increased expression of scleraxis in DDF tendons of 24-week SAMR1 and SAMP6 mice compared with 8-week SAMR1 and SAMP6 mice. There was no statistical difference between SAMR1 and SAMP6 in each week. Analysis for chondrogenic marker showed that Sox9 and Sox6 expression in DDF tendons of SAMP6 was higher than in SAMR1 in both 8- and 24-week mice. The expressions of Sox5 and aggrecan were higher in 8-week SAMP6 mice than in SAMR1 mice and increased in 24-week SAMR1 mice. Histological analysis showed no changes in DDF tendon and surrounding tissues of both 8- and 24-week SAMP6 and SAMR1 mice. Immunohistochemical analysis showed the expression of tenomodulin was reduced in DDF tendons of 24-week SAMR1 and SAMP6 mice compared with 8-week SAMR1 and SAMP6 mice. The trend was much stronger in SAMP6 than in SAMR1 mice. Immunostaining of aggrecan showed no difference between 8- and 24-week SAMP6 and SAMR1 mice. This study demonstrates decreased expression of tenogenic marker and increased expression of chondrogenic marker in intrasynovial tendon with aging. Chondroid metaplasia has also been found in the A1 pulley in adult trigger fingers (Sbernardori et al., 2007). This may be associated with the pathogenesis of tendon degeneration and tenosynovitis.

Keywords: tenosynovitis, intrasynovial tendon, aging
Artery-only fingertip replantation distal to lunula: A retrospective analysis of clinical results

List of authors:
yasunori kaneshiro*, Koichi Yano¹, Sengho Hyun¹, Hideki Sakanaka¹
¹Hand and Microsurgery center, Seikeikai Hospital (Sakai)

Objectives / Interrogation: Both arterial and venous repair are crucial for optimal results in digital replantation. However, anastomosis of veins becomes challenging in very distal fingertip amputation because of small vessel diameter or unavailability by damage. The purpose of this study is to investigate the clinical results of artery-only replantation without vein repair for very distal fingertip amputation.

Methods: We performed a retrospective review of 47 digits of 39 patients who had undergone fingertip replantation between 2015 and 2017. All patients in this study had complete fingertip amputation distal to the lunula. By Ishilawa's classification, 12 digits in subzone I, and 35 digits in subzone II. Only one central artery repair distal to arch was performed. All patients received the postoperative protocol including external bleeding with or without the use of medical leech, and anticoagulation therapy for a week until physiological outflow was restored. Clinical outcomes including range of motion, grip strength, and sensory recovery assessed by modified Highet scale at the final follow-up for the patients with the minimum follow-up period of 6 months were reviewed and analyzed.

Results and Conclusions: The mechanism of injury was crush in 16, clean in 10, blunt in 10, and avulsion in 11 patients. The mean ischemia time was 6.0 hours. Complete survival was observed in 30 out of the 47 fingertip replantation (64%). There was statistically significant difference between amputation level and survival rate (91% for subzone I, 54% for subzone II, respectively, p=0.02). There was statistically significant difference between mechanism of injury and survival rate (85% for clean/blunt injury, 48% for crush/avulsion injury, respectively, p<0.01). At the final follow-up, the mean total active motion of surviving digits was 84% of normal side. The mean grip strength was 80% of normal side. Sensory recovery was classified as S1, S2, S3 and S4 for 5, 22, 5 and 0 digits, respectively.

This study suggested that artery-only fingertip for fingertip replantation distal to lunula including many crush/avulsion injuries achieved satisfactory survival rate and good clinical outcomes. Both amputation level of subzone II and crush/avulsion injury were associated with lower survival rate.

3 Hospital Universitario Marques de Valdecilla, Servicio de Cirugia Ortopedica y Traumatologia (Santander)
4 Hospital Universitario Marques de Valdecilla (Santander)

Objectives / Interrogation: An open fracture of the upper extremity in the context of a high energy trauma is in a great risk of developing osteomyelitis of the damaged bones. Chronicity may occur, resulting in a pathological fracture, sequestrum formation and pseudarthrosis. When the distal radius is affected it leads to substantial bone loss that occasionally destroy de radiocarpal joint.
We present 2 cases of wide segmental bone loss at the distal radius affecting the radiocarpal joint due to chronic osteomyelitis, and different techniques to preserve motion at the midcarpal joint.

Methods: Case #1
57-year-old male, who works as policeman, presented in our clinic sustaining a chronic osteomyelitis of the distal radius after 3 months of treatment of an open intraarticular fracture of the distal radius while practicing paragliding as the initial injury. After resecting a segment of the distal radius including a portion of the articular surface, an antibiotic-impregnated cement spacer was placed to fill the gap. One month later, a free vascularized fibula transfer supplemented with a partial arthrodesis (Fibula-scaphoid-lunate) was performed to reconstruct the distal radius while maintaining some motion at the midcarpal level.

Case #2
43-year-old male, who suffered 4 months ago an open intraarticular fracture of the distal radius after a motorbike accident, developed chronic osteomyelitis. In this case, the first row of the carpus was also affected by the osteomyelitis. After 6 weeks of treatment, a free fibula and a free vascularized osteochondral graft from the base of the 3rd MTT was performed to reconstruct the segmental bone loss of the distal radius while keeping some motion at the midcarpal joint.

Results and Conclusions: The follow up of both patients is 2 years and 3 years respectively. The patients have returned to work and leisure activities with little impairment, although motion at wrist level has decreased.
CT scans confirm bone consolidation at both ends of the vascularized bone grafts without radiological defects or shortened bones.
A diverse variety of treatments have been proposed for reconstruction of extensive bone loss at the distal forearm for different conditions such trauma, bone tumours and osteomyelitis, but the vascularized free fibula graft still remains as the gold standard. When distal radius and proximal carpal row are affected motion can still be preserved by the means of either partial arthrodesis or reconstruction of the articular surface with a free vascularized osteochondral graft.

Wide Awake Local Anesthesia No Tourniquet (WALANT) versus General Anesthesia for Plating Distal Radius Fractures

List of authors:
Amir Adham Ahmad*, Mei Yi Liew1, Abdul Rauf Ahmad2
1 International Medical University (Seremban)
2 Hospital Tuanku Ja’afar (SEREMBAN)
3 Hospital Tuanku Ja’afar Seremban (Seremban)

Objectives / Interrogation: Objective: This study aims to compare the outcomes of plating distal radius fractures using WALANT and general anesthesia as we evaluate WALANT as an alternative anesthesia for this type of surgery. Introduction: WALANT is being considered as an alternative anesthesia for fixation of fractures beyond the wrist such as distal radius fractures, which are classically performed under general anesthesia, because patients with acute cardiorespiratory problems or multiple chronic medical illnesses often experienced delay in fracture fixation until they are deemed medically fit for surgery under general anesthesia. As distal radius fracture is very common in the community, fixation of this fracture in a timely manner, is essential to enable patients to regain early full wrist function for continuation of their activities of daily living.

Methods: Methods: Five patients of various ages, comorbidities and with distal fracture requiring plating were recruited for fracture fixation using WALANT whilst another five patients underwent fracture fixation under general anesthesia. Outcomes observed and compared were waiting time for operation, patient’s pain control and hemodynamics, estimated blood loss, occurrence of adverse effects of lignocaine with epinephrine and drugs used for general anesthesia and duration of post-operative stay.

Results and Conclusions: Results: All patients in the WALANT group experienced mild to no pain during surgery and did not require conversion to general or regional anesthesia. None reported any adverse effects from lidocaine or epinephrine during and after surgery. Waiting time to operation was significantly shorter in the WALANT group. Blood losses were comparable to patients who used tourniquet during general anesthesia. Duration of post-operative stay at hospital was relatively shorter for WALANT group.

Conclusion: WALANT approach can be an alternative to general anesthesia for plating of distal radius fracture as it is able to provide patients with adequate pain relief, no adverse effects from lidocaine or epinephrine and good control of bleeding at the operation field thus resulting in a clear operative view for the surgeon. It is also potentially cost saving to both patient and healthcare provider as it obviates the need for pre-operative assessment and post-operative monitoring by the anesthetist and an overall shorter stay at the hospital.

Elbow and Forearm  

Type C distal humerus fractures. A 15-year experience in a demanding surgical issue

List of authors:  
Efstratios Athanaselis*, Dimitrios Deligeorgis, Georgios Komnos, Ioannis Antoniou, Sokratis Varitimidis, Konstantinos Malizos  
1 Orthopaedic Dpt, University Hospital of Larissa (Larissa)

Objectives / Interrogation: In this retrospective study we evaluated long term outcomes of type C (AO classification) distal humerus fracture treated with open reduction and internal fixation with plates.

Methods: From 2002 to 2016, 32 patients with type C distal humerus fracture were treated operatively by plating. Fifteen were males (47%) and 17 females (53%) with a mean age of 53.5 years (18 to 83). Three fractures were open (9.4%), two patients had an ipsilateral olecranon fracture and one patient olecranon and radial head fracture. Fractures resulted from simple fall in 22 patients, fall from a significant height in 6 and motor vehicle accident in 4. All patients were treated operatively by posterior approach and olecranon osteotomy using two plates (preferably precontoured LCP plates, parallel placed) often combined with free screws and K-wires. Olecranon was fixed by tension band technique in 26 patients and by other technique (screw, plate) in 6. Elbow mobilization under protection started after 2 weeks postoperatively. Mean follow-up was 8.7 years (2-15.5).

Results and Conclusions: In 29 patients (90.6%) fracture healed after 8 weeks in average (6 to 10). There were 3 non-unions (9.4%), 9 cases of malunion of varied importance (28.1%), 1 deep infection (3.1%), 1 postoperative ulnar neuropathy, and 1 CRPS treated appropriately. Reoperation rate was 18.7% (6 patients). Postoperative ulnar palsy was present in 3 patients (9.4%). Tension band was removed in 7 patients (21.9%). Carrying angle (average 8o, 5-17o) and posterior angulation (average 45o, 40-56o) of distal humerus were measured. Intercondylar distance was normal in 23 patients (72%). In 9 patients it was 16.7% in average (5-25%) narrower compared with the contralateral. Average ROM was 117o (range 75-150o), extension lag 21o (0-45o) and elbow flexion 141o (120-150o). Mean DASH score was 20 (0-49) and mean MEPS 83.3 (25-100). At final follow up half of the patients (16/32) had some kind of osteoarthritic changes and three had heterotopic ossification. Two-column fixation of type C distal humerus fractures by posterior approach and olecranon osteotomy using plates (preferably pre-contoured LCP) provides satisfactory results. Anatomic reduction and stable fixation are prerequisites for early mobilization, preventing elbow stiffness.

Thumb IP joint arthroplasty with a surface gliding implant: One-year follow-up

List of authors:
Stephan Schindele1, Stefanie Hensler1, Miriam Marks1, Daniel B. Herren1
1 Schulthess Klinik (Zürich)

Objectives / Interrogation: Osteoarthritis of the thumb interphalangeal (IP) joint is a rare condition. Standard treatment of destructed IP joints is arthrodesis, which yields adequate pain relief. However, fine motor skills, especially picking up fine objects and achieving a powerful pinch with the index finger, can be restricted. We hypothesize that joint arthroplasty might lead to better functional results in patients with destructed but preoperatively stable IP joints. Therefore, the objective of our pilot study was to analyze the clinical and patient-reported outcomes in patients up to one year after thumb IP arthroplasty.

Methods: Patients received a surface-gliding arthroplasty (CapFlex-PIP, KLS Martin Group, Tuttlingen, Germany), which was originally designed for the PIP joint, at the thumb IP joint and were assessed preoperatively as well as three months and one year after the intervention. Range of motion (ROM) of the IP joint and key pinch were measured. Patients rated their pain on a numeric rating scale (0-10) and completed the brief Michigan Hand Outcomes Questionnaire (brief MHQ, score 0-100).

Results and Conclusions: Nine patients with a mean age of 67 years were included in this analysis. Pain at rest was reduced from 5 points before the surgery to 4 points after 3 months and to 3 points a year after surgery. The preoperative brief MHQ score of 41 points improved to 67 after 3 months and to 54 points by one year. At final follow-up, ROM could be preserved with 41° and baseline key pinch strength changed from 6 kg to 5 kg and 6.5 kg at 3 months and 1 year, respectively. None of the patients developed lateral instability. In one patient, dorsal luxation of the distal component was observed 7 weeks after surgery, which was finally converted to an arthrodesis. No further complications were documented.

Conclusions: The use of a surface-gliding implant at the thumb IP joint presents as an adequate alternative to the function-restricting arthrodesis, particularly since pinching with the index finger requires high lateral stability at high shear forces. Arthroplasty results in a considerable reduction in pain combined with satisfactory hand function. However, the results of this pilot study have to be confirmed with a larger sample size and longer follow-ups.

Can finger fractures be fixed with a chemical adhesive?

List of authors:
Johanna von Kieseritzky*1, Marianne Arner1, Michael Malkoch2, Viktor Granskog2
1 Department of Hand Surgery (Stockholm)
2 KTH Royal Institute of Technology, Department of Fibre and Polymer Technology (Stockholm)

Objectives / Interrogation: A new chemical adhesive for bone repair based on the thiol-ene coupling (TEC) chemistry was developed. The adhesive is inspired by dental resin composites and self-etch primers. Fracture fixation is achieved by building a patch over the fracture constituted by a primer solution followed by layers of the adhesive with imbedded hydroxyapatite and polyethylene terephthalate (PET) fiber meshes. The layers of the patch are cured by using tissue-friendly high-intensity light. The result is a FRAP (Fiber Reinforced Adhesive Patch) and provides a fixation that can be custom made for every fracture. The objective of the study was to examine biomechanical properties, safety and influence on fracture healing and inflammation of the FRAP.

Methods: Adhesion strength to bone was tested biomechanically in vitro on processed wet bovine bone regarding shear bond strength and compared to commercially available dental adhesives. The rigidity of the FRAP was compared to crossed 1.2 mm K-wires and AO Compact hand 1,5 plates in two fracture patterns, transverse and oblique, on pig metatarsals using 1000 cyclic loads of 10-70 N in a three point bending set up. In vivo studies were performed on a rat femur fracture model investigating adhesion to bone, effect on bone healing and inflammation. A safety evaluation (ISO 10993-1:2009) on FRAP leachables was also carried out.

Results and Conclusions: Shear bond strength in vivo was 55% higher than commercially available acrylate dental adhesive, 9.0 MPa vs 5.8MPa. In comparison between K-wire and plate fixation on pig metatarsal fractures in cyclic loading there was no detectable difference of the fixation between metal plate and FRAP, whereas K-wires showed considerable movement and displacement. Histology studies from in vivo samples on rat revealed no inflammation, and no negative effect on bone healing. Initial adhesion strength and adhesion after 5 weeks in vivo revealed that FRAP had maintained 60% bond strength. No cytotoxicity nor genotoxicity was detected in safety evaluation and neither skin irritation nor inflammation were seen.

Conclusion
The FRAP has promising properties and has potential to become a new versatile technique for osteosynthesis for phalangeal fractures. The fixation material is strong, adheres well to bone, does not cause inflammation and is benign to tissues. Further development to human use is under way.

Delayed surgery for bony mallet finger - a retrospective comparative study -

List of authors:
Masato Okazaki*, Kenichi Tazaki
1 Department of Orthopaedic Surgery, Ogikubo Hospital (Tokyo)

Objectives / Interrogation: It is common for the patient with mallet fracture not coming to the clinic immediately after the injury. Purpose of this study was to investigate the surgical outcome for bony mallet fingers with delayed presentation, and to compare the outcomes between two methods.

Methods: Thirty-one bony mallet fingers treated 35 days or later from the injury with open reduction and internal fixation were included in this retrospective study. Cases with open fractures, multiple finger and/or joint injuries, fracture of the thumb, follow up shorter than 60 days, and reoperation of cases initially treated elsewhere were excluded. There were 18 males/13 females, 5 index/8 middle/11 ring/7 little fingers. Age ranged from 10 to 74 (average 35.3) years old. Intervals from injury to operation were 36 to 122 (average 56.5) days. Fractures were internally stabilized with open Ishiguro's method in 12, and with a hook plate and Kirshner wires in 19.

Results and Conclusions: Active flexion/extension of the DIP joint in open Ishiguro's method and the hook plate group was 44.8±15.2/-12.2±9.7 degrees and 51.8±14.6/-11.9±8.4 degrees respectively. Off set at the DIP joint was 0.63±0.30mm in open Ishiguro's method and 0.39±0.48mm in the hook plate group. The hook plate group tend to be better at active flexion and reduction, however there were no significant differences between two groups. Two cases in the open Ishiguro's group and three in the hook plate group had residual volar subluxation of the DIP joint. All fractures healed at final follow up. Both groups achieved bony union with usable range of motion. Postoperative volar subluxation remains a problem to be addressed. Further study is needed to clarify better solution for the treatment of bony mallet fingers with delayed presentation.

Keywords:

Acute Compartment Syndrome of Upper Limb Requiring Emergency Wide Range Fasciotomy Caused by Suction Injury. A Case Report

List of authors:
Masataka Shibayama*, Jiro Hirayama, Koji Fujita, Hironori Yamazaki, Tsuguo Morikawa
1 Chiba Medical Center, Department of Orthopaedic Surgery (Chiba)

Objectives / Interrogation: Object: Acute compartment syndrome due to absorbing by vacuum hose is a rare injury that requires immediate diagnosis and surgical resolution. We report a case of acute compartment syndrome in the upper limb from shoulder to hand requiring emergency wide range fasciotomy caused by suction injury.

Methods: Materials and Methods: A right-handed 24-year-old man was injured by suctioning his whole upper limb about 30 seconds by the hose of vacuum car which treat factory waste. Initially, he only felt mild pain and observed by himself at home. About 12 hours after the injury, he came to our hospital literally "Walk-in". At the first medical examination revealed diffuse swelling and hardening muscles from shoulder to hand, but there was no rest severe pain, paleness, pulselessness, paresthesia, nor paralysis. He felt disproportionate pain on passive extension of the deltoid, biceps, triceps, flexor and extensor muscles of forearm except intrinsic muscles of hand. From the above, he was diagnosed with acute compartment syndrome of upper limb from shoulder to forearm, and we decided to perform an emergency wide range fasciotomy under general anesthesia. We measured intra-compartmental pressure after anesthesia using an arterial line transducer. The intra-compartmental pressure of each muscles rose from 30 to 70 mmHg, so we performed fasciotomy by the Henry approach extended from the wrist to volar upper arm and independent dorsal upper arm approach. After the procedure, the intra-compartmental pressure of each muscles fell to normal level, and we used shoelace technique with elastic vessel loop. After one week, the swelling of whole upper limb went down, we re-sutured the wound completely.

Results and Conclusions: Results: After eight months, he healed without any disfunction of shoulder, elbow, forearm, hand, and finger.
Conclusion: Acute compartment syndrome of upper limb caused by suction injury is rare, and in some case, the pain is so mild as to pass unnoticed at the initial visit. If the compartment syndrome is missed, it will result in very serious sequela. Therefore, in such case, even if the injury looks light, we need to perform fasciotomy without hesitation.

Keywords: Acute Compartment syndrome, suction injury, vacuum hose, emergency fasciotomy
Primary melanoma of the hand - experiences and review of the literature.

List of authors:
Evi M. Morandini1, Elisabeth Pechriggl1, Christoph Tasch1, Gerhard Pierer1, Eva Maria Baur1, Robert Zimmermann1
1 Plastic, Reconstructive and Aesthetic Surgery, Innsbruck Medical University (Innsbruck)

Objectives / Interrogation: The diagnosis of melanoma of the hand is associated with a poor prognosis. While the surgical management of melanoma is following distinct guidelines, there are no specific considerations regarding functional areas of the hand or subungual melanoma. It was shown by literature, that a wide local resection does not provide any advantage over R0 resection.

Methods: Between 2010 and 2017, 13 patients presented with melanoma of the hand in our clinic. Patient records were reviewed retrospectively and literature was carefully reviewed.

Results and Conclusions: 12 cases were primary melanomas, 7 were subungual tumors. Mean age at presentation was 56 years. The most frequent localization was the thumb. Mean Breslow index was 3,2mm (range 0,2-10). Melanoma in situ was treated with simple excision and full thickness skin grafting. In 5 cases amputation was mandatory.

In this series, amputation was considered in most cases of subungual melanoma. With simple excision, function sparing treatment could be ensured in cases of melanoma in situ with good cosmetic results and sensibility. However, a distinct guideline for treatment of acral melanoma is necessary and desirable.

Keywords:
Multiple flexor tendon rupture in a 34-year old patient with rheumatoid arthritis.

List of authors:
Francesca Teodonna, Juan Carlos Márquez Ambite, Marta Olmeda Lozano, Daniel López Dorado, Hugo Garlito Díaz, Raquel Serrano Serrano, Rocio Mascaraque Ortiz, Cristóbal Suárez Rueda

Hospital Universitario Infanta Elena (Valdemoro)

Objectives / Interrogation: Flexor tendon ruptures in patients with rheumatoid arthritis are an uncommon condition caused by attrition on osseous spurs or by direct invasion of the tendon by hypertrophic tenosynovium. The most common localization of this condition is the carpal tunnel. The flexor pollicis longus and profundus to the index finger are most commonly affected.

Methods: We present the case of a 34-year old patient with seropositive rheumatoid arthritis that suddenly presents hand pain with no prior traumatic event.

The physical examination showed a limited flexion of flexor digitorum superficialis and profundis of all the fingers of the dominant hand as for the fifth. Extension of all fingers was preserved.

An MRI and an ecography were performed showing important synovial proliferation and distension concerning the common synovial sheath of the flexor pollicis longus and flexor tendons at the level of the carpal tunnel and metacarpal region of the hand, as well as partial rupture of flexor digitorum profundis and probable rupture of the flexor digitorum superficialis of 2nd, 3rd and 4th fingers.

A surgical treatment is then performed: A volar approach over the carpal tunnel showed a partial rupture and proliferative tenosynovitis of the flexor digitorum profundis and superficialis of the second, third and fourth finger and of the flexor pollicis longus in flexor zones III, IV and V, as well as an important adhesion of the median nerve.

Consequently, the surgery consisted in an exoneurolysis of the median nerve, identifying both motor and sensitive branches and a reconstruction of the flexor tendons using an autograft of the palmaris longus for the flexor pollicis longus and the radial hemi flexor carpi radialis tendon for the flexor digitorum profundis and superficialis of the second, third and fourth finger. The tenosynovial tissue was excised and sent for histological examination.

The patient was immobilized with a forearm splint in flexion including all fingers.

After two weeks the surgery wounds were in good state with no signs of infection, and the splint was changed to allow phase I of early protected mobilization.

At four-weeks post-operative the splint was changed to advance in the protected mobilization. The analysis of the tissue showed various rheumatoid nodules (nodulosis) and presence of synovitis.

Results and Conclusions: Patients with flexor tendon ruptures present an high disease activity. Prevention of tendon ruptures by early tenosynovectomy is advised, due to poor prognosis.

How Important is the Understanding of Embryology for Parents of Children Born with Congenital Hand Differences?

List of authors:
Andrew D Clelland\textsuperscript{1}, Orla Duncan\textsuperscript{2}, Wee L Lam\textsuperscript{2}
\textsuperscript{1} Edinburgh Medical School (Edinburgh)
\textsuperscript{2} Royal Hospital for Sick Children (Edinburgh)

Objectives / Interrogation: The Oberg, Manske and Tonkin (OMT) system for congenital upper limb anomalies was designed to allow clinicians to reliably classify an anomaly, based on its embryological origin\textsuperscript{[1]}. Despite this, uptake is slow amongst clinicians, largely due to a reluctance to learn embryology. Without discussing embryology, clinicians focused on the treatment plan but often stop short of explaining to parents 'why' congenital hand differences (CHDs) happen. The primary aim of this work was to evaluate the importance of understanding embryology for parents of children born with CHDs. Secondarily we aimed to investigate whether this importance of embryology correlates with disease severity, maternal age or level of education.

Methods: A retrospective, self-administered questionnaire was designed to evaluate the importance of embryology of CHDs for parents within a congenital hand clinic. Parents were given a simple explanation of normal upper limb embryology by a consultant hand surgeon and possible theories of why development 'went wrong', based on current developmental biology knowledge. A questionnaire was then completed, with responses rated on a scale of 1-5 (5 being most important).

Results and Conclusions: Responses were collated from 25 questionnaires. Importance of knowing why CHDs happen was given an average rating of 4.46 ± 0.13 by parents. 84% of respondents believed understanding the embryology of the hand would improve their understanding of why CHDs happen. Parents desired a mean level of knowledge of 3.92 ± 0.22, where 1 represents no knowledge and 5 is of the medical textbook level. Only 52% of parents reported that possible causes of CHDs were discussed with them at time of diagnosis. Overall, 64% believed their questions were adequately answered, and just 40% were aware of specialist support charities.

Analysis of variance (ANOVA) was performed to investigate the secondary aim of the study. Results showed that there was no statistically significant relationship between the importance of understanding embryology and disease severity (p=0.687), maternal age (p=0.161) or maternal level of education (p=0.145).

We have provided preliminary evidence that suggests parents are interested in understanding, to a reasonably high level, the embryology and hence 'why' CHDs happen, irrespective of disease severity, maternal age or maternal level of education. This study further supports the importance of understanding embryology among clinicians, and the use of the OMT in regular clinical practice.

Ulnotriquetral Split Tear Repair: Is It Myth or Fact?

List of authors: Sanjeev Kakar*, Richard Berger, Nick Clark, Nick Munaretto
1 Mayo Clinic (Rochester)

Objectives / Interrogation: To report the outcomes of ulnotriquetral (UT) ligament split tear repairs.

Methods: 228 wrists (142 right and 86 left) in 221 patients (100 males and 128 females, mean age 35 ± 15.5, range 14-77 years) underwent UT ligament split tear repair between 2007 and 2016. Mayo wrist score, Visual Analogue Scale (VAS) pain scores, and objective measures including grip strength and range of motion were obtained. Patients were followed with a mean follow up of 10.3 months.

Results and Conclusions: Ulnotriquetral split tear repair resulted in substantial improvements in pain and function. Mayo Wrist Score for the cohort improved from 56 preoperatively to 82 postoperatively (p<0.0001), and 83% of patients achieved a good or excellent outcome. VAS pain scores decreased from 6.0 preoperatively to 1.4 postoperatively (p<0.0001). Grip improved from 26.1 kg preoperatively to 29.8 kg postoperatively (p=0.003). There was no significant change in range of motion of the wrist. Complications were noted in 13 patients with 8 experiencing continued pain, 4 with dysesthesia of the dorsal sensory ulnar nerve and 1 superficial infection.

Conclusion: Arthroscopic UT split tear repair significantly reduced pain and improved Mayo Wrist Scores.

Keywords: Ulnar wrist pain, arthroscopy, ulnotriquetral split tear
Hook Plate for volar rim fractures of the distal radius: review of the first 45 cases and focus on dorsal radiocarpal dislocation

List of authors:
Giulio Lauri*, Marco Biondi¹, Sandra Pfanner¹, Prospero Bigazzi¹, Massimo Ceruso¹
¹ AOU Careggi (Florence)

Objectives / Interrogation: The volar rim fragment is an attachment site for the short radiolunate and the volar distal radioulnar ligament. Its unstable fixation can lead to articular incongruity, volar or dorsal subluxation of the carpus and distal radioulnar instability. The involvement of this fragment on distal radius fractures is relative common and many studies of Literature have been focused on its treatment.

This study evaluate the clinical and radiological outcome of a new device born to treat marginal articular fractures of the distal radius, focusing on dorsal fracture-dislocations. The device (Aptus Wrist Distal Radius System 2.5, Medartis AG, Basel, Switzerland) represent a fragment-specific fixation system.

Methods: A retrospective review was conducted on the first 45 patients with a mean follow-up of 23 months including postoperative clinical evaluation, grip strength, CT scan and X-ray control.

Results and Conclusions: All fragments, except one, healed and maintained reduced until the final follow-up. The carpus was aligned with the distal radius in all patients presenting with a radiocarpal dislocation.
The Hook Plate stabilizes distal fragments at their bone- ligament interface. In addition to bony reduction, the device permits to stabilize the capsule and ligaments, as volar bony ligament avulsions, in a picture of dorsal radiocarpal dislocation.

Keywords:
The Safety of the Volar Midcarpal Portals in Wrist Arthroscopy

List of authors:
Sanjeev Kakar*¹, Josh Gillis¹
¹Mayo Clinic (Rochester)

Objectives / Interrogation: To describe the safe placement of volar midcarpal portals using the inside out technique and the surrounding anatomical structures at risk.

Methods: Five fresh frozen cadavers were used after institutional approval. Volar midcarpal ulnar (VUMC) and radial (VRMC) portals were placed using an inside out technique. The distance between these portals to surrounding anatomical structures was measured using a caliper, in millimeters.

Results and Conclusions: The VUMC portal pierced the flexor digitorum profundus (FDP) tendon to the long finger in one specimen. The portal was an average 3.7 and 8.4 mm away from the ulnar artery and nerve, respectively. The VRMC portal pierced the palmaris longus in two specimens. It usually was between the flexor pollicus longus, palmaris longus and median nerve. It was an average 1.0 and 1.95 mm away from the median nerve and palmar cutaneous branch of the median nerve, respectively and in one specimen, was in contact with the median nerve.

Conclusion: With increasing use of volar midcarpal arthroscopy, the surgeon needs to have an understanding of the structures at risk when placing the VUMC and VRMC portals.

Outpatient neuromodulation may avert the need for surgery in patients with painful cutaneous neuromas

List of authors:
Abhishek Kumar Das¹, Chye Yew Ng¹
¹ Wrightington Hospital (Wigan)

Objectives / Interrogation: To report the outcome of neuromodulation as an outpatient, non-invasive therapy for painful cutaneous neuromas

Methods: This was a retrospective review of a consecutive series of patients who presented with a painful cutaneous neuroma secondary to a direct trauma or surgery. The diagnosis was made by the presence of neuropathic symptoms in the dermatome of a cutaneous nerve and a positive Tinel sign. Local anaesthetic injection was performed for confirmation of diagnosis. NCS was requested only if there were diagnostic doubts or to exclude superimposed entrapment neuropathy. Each patient was offered optimisation of medical therapy and physiotherapy for scar desensitisation. Neuromodulation was offered as an alternative to neuroma surgery. A course of neuromodulation typically involved six weekly outpatient visits, supervised by a trained nurse. The primary aim of treatment was symptom reduction such that neuroma surgery was no longer required.

Results and Conclusions: Between October 2015 and June 2018, 50 patients (25 females, 25 males) with a mean age of 47 years (range 18-79) presented with a painful cutaneous neuroma. The nerves injured in the order of frequency were superficial radial nerve (16), digital nerve (8), dorsal ulnar cutaneous nerve (7), palmar cutaneous branch of median (4), saphenous nerve (4), sural nerve (2), lateral femoral cutaneous nerve (2), medial antebrachial cutaneous nerve (2), lateral antebrachial cutaneous nerve (2), superficial peroneal nerve (1), posterior cutaneous branch of radial nerve (1) and supraclavicular nerve (1). 3 cases were due to a dog bite, 9 were due to direct trauma and 38 were due to an operation. The index operations included De Quervain release, trapeziectomy, UCL reconstruction, wrist arthroscopy, elbow arthroscopy, carpal tunnel release, cubital tunnel release, ray amputation, distal radius plating, metacarpal plating, CMCJ fusion, trigger finger release and wrist fusion; pelvic surgery, ankle arthroscopy, knee arthroscopy, TKR, high tibial osteotomy, femoropopliteal bypass and Achilles tendon repair. 18 (36%) patients had sufficient symptom relief after neuromodulation such that they did not need to pursue neuroma surgery. Conclusions: Surgery is the commonest cause of a painful cutaneous neuroma. Neuromodulation may offer symptom relief such that neuroma surgery may be avoided in a third of cases. It is a safe and effective therapy for painful cutaneous neuromas.

Autoregulation of Lmx1b during limb development: A role in Nail-Patella Syndrome?

List of authors:
Kerby Oberg¹, Endika Haro², Charmaine Pira¹, Marian A Ros²
¹ Loma Linda University, Div of Human Anatomy (Loma Linda)
² Instituto de Biomedicina y Biotecnología de Cantabria, Universidad de Cantabria (Santander)

Objectives / Interrogation: The LIM homeodomain transcription factor Lmx1b is restricted to the dorsal limb mesenchyme during development and is essential for distal limb dorsalization. In humans, LMX1B mutations cause Nail-Patella Syndrome characterized by nail dysplasia, absent or hypoplastic patellae, and progressive renal disease. In the functional Lmx1b knockout, Lmx1b transcription is reduced 5.7 fold, indicating a role for Lmx1b in its own expression. In this report our goal was to determine whether there are associated enhancers for Lmx1b and whether these play a role in maintaining Lmx1b expression in the limb.

Methods: We used an Lmx1b-targeted ChIP-seq during mouse limb development (E12.5), to identify potential Lmx1b bound regulatory regions. We isolated the Lmx1b bound regions from genomic DNA using PCR and inserted them into a thymidine kinase (tk) basal promoter linked to a GFP reporter. We electroporated the reporter constructs into presumptive chick wings to determine activity of the potential regulatory regions. The role of Lmx1b in the activity of potential regulatory regions was determined by site directed mutagenesis of the Lmx1b binding sites. We also used Chromatin Configuration Capture (3C) to confirm interaction between the Lmx1b promoter and potential regulatory regions. In addition, we performed a targeted CRISPR-cas excision of the potential Lmx1b-associated regulatory regions and examined the phenotypes of the resulting knockout mice.

Results and Conclusions: We identified two Lmx1b-bound noncoding regions 60 and 66 kbs upstream of the Lmx1b locus that were conserved across divergent vertebrate species and active in the dorsal limb coincident with Lmx1b. The two noncoding regions also overlapped with multiple chromatin regulatory marks (p300, H3K27Acetylation, H3K3methylation2, RNAPol II and Med12) suggesting a role as cis-regulatory modules (CRMs). Site directed mutagenesis of the Lmx1b binding sites within these two Lmx1b-associated CRMs abolished reporter activity within the chick wing bioassay. In addition, Chromatin Configuration Capture (3C) confirmed interaction between the Lmx1b promoter and the most distant CRM. Homozygous CRISPR-cas excision of these two CRMs generated mice with nearly symmetrical ventral-ventral limbs.

Our findings indicate that Lmx1b upregulates its own expression through two upstream CRMs. Our data further implies that a threshold level of Lmx1b expression is required to accomplish normal limb dorsalization.

Arthroscopic Suspension Arthroscopy using PL tendon for Osteoarthritis of the Thumb Carpometacarpal Joints

List of authors:
Masaya Tsujii*, Kazuya Odake¹, Haruhiko Satonaka², Akihiro Sudo¹
¹ Mie University (Tsu)
² Ise Municipal Hospital (Ise)

Objectives / Interrogation: Arthroscopic surgery has become a more popular for the treatment of osteoarthritis of the thumb carpometacarpal joints (CMC-OA), since introduction of interposition arthroplasty. However, it is difficult to indicate the arthroscopic interposition arthroplasty for the patients with radial instability in CMC-OA. We reported a new technique of arthroscopic suspension arthroplasty for CMC-OA along with a minimum of 2 years of results.

Methods: Twenty-nine thumbs with were treated by arthroscopic suspension arthroplasty. The procedure included partial trapeziectomy followed by ligamentoplasty using PL tendon similar to Thompson technique. Under arthroscopic visualization, the bone tunnel was made on base of 1st and 2nd metacarpal bone, and PL was passed through the bone tunnels in the order of dorsal diaphysis, articular surface of 1st metacarpal, base of 2nd metacarpal, dorsal capsule and APL tendon. Finally, the tendon was fixed to both metacarpals using interference screws and was tightly sutured to APL. We evaluated pain VAS; DASH; grip and pinch strength; thumb abduction range of motion, and radiographic examination including trapezial space and subluxation ratio preoperatively and every 3 months until 1 year after surgery, and every 6 months thereafter. Besides, these assessments were analyzed in the patients with greater than 1/3 subluxation of the 1st metacarpal base, referred to Menon's classification.

Results and Conclusions: The mean duration of the follow-up was 3.2 years. The mean preoperative pain VAS and DASH were 71 and 45.7, respectively, which were significantly reduced to 7 and 20.0 at the final. Also, strength of grip, tip, and key pinch significantly increased at 9, 9, and 12 months later after surgery, respectively. Abduction motion tended to decrease, although the differences were not significant. Although trapezial space ratio was significantly reduced, there were no significant differences in the results between each follow-up time and the final follow-up. Subluxation ratio was significantly improved and maintained until the final follow-up. Furthermore, the values of clinical and radiographic outcomes, except motion, were significantly improved in patients with greater than 1/3 subluxation of the 1st metacarpal base. In conclusion, the clinical outcomes of this technique were: satisfaction with pain relief, recovery of hand and thumb strength, insignificant decrease of abduction motion, and radiological reduction, even in the patients with radial instability in CMC-OA.

**Abstract no.: IFSSH19-394**

Oral presentation or poster presentation

**Tendon**

**14th IFSSH Congress**

**Objectives / Interrogation:** The purpose of this study is to present secondary trigger finger caused by a neglected partial flexor tendon rupture including discussion of the mechanism and treatment.

**Methods:** We retrospectively reviewed the records of six patients with trigger finger caused by a neglected partial flexor tendon rupture who had been treated with exploration, debridement and repairing of the ruptured tendon from August 2010 to May 2015. The average patient age was 41 years (range, 23-59). The time from injury to treatment averaged 4.7 months. The average follow-up period was 9 months (range, 4-18). Functional outcome was evaluated from a comparison between the Quick-disabilities of the arm, shoulder and hand (DASH) score and the visual analogue scale (VAS) for pain, which were measured at the time of preoperation and final follow up.

**Results and Conclusions:** Four patients showed partial rupture of the flexor digitorum profundus (FDP) tendon and three showed partial rupture of the flexor digitorum superficialis (FDS) tendon. Both the FDP and FDS tendons were partially ruptured in 2 patients, and the remaining patient had a partial rupture of the flexor pollicis longus (FPL) tendon. All patients regained full range of motion (ROM), and there has been no recurrence of triggering. The average VAS score decreased from 3.6 (range, 3-5) preoperatively to 0.3 (range, 0-1) at the final follow up (P=.026). The average Quick-DASH score decreased from 33.6 preoperatively to 5.3 at the final follow up (P=.028).

When we encounter patients with puncture or laceration wounds in flexor zone 2, even when the injury appears to be simple, partial flexor tendon laceration must be taken into consideration and early exploration and repairing of the partially ruptured tendon is recommended.

Dorsal fracture-dislocations of the distal radius: a new classification and proposal of a standardized surgical treatment

List of authors:
Giulio Lauri, Marco Biondi, Sandra Pfanner, Prospero Bigazzi, Massimo Ceruso
1 AOU Careggi (Florence)

Objectives / Interrogation: Dorsal radiocarpal dislocations can be isolated or accompanied with a spectrum of fractures, as bony depressions and marginal articular avulsions of the distal radius. Although isolated dorsal dislocation of the radiocarpal joint is a rare injury, a dorsal fracture-dislocation is more common and often consists in a translocation of the carpus, which treatment and outcomes are not well defined.

In Literature, various methods of operative stabilization and repair have been recommended but the surgical treatment of these injuries is still not well standardized.

Today, a lot of devices of fragment-specific fixation are available to treat these injures properly. We retrospectively reviewed the dorsal radiocarpal dislocations treated in our Institute in the last 5 years in order to propose a new classification and define the proper surgical treatment for each type of lesion.

Methods: We retrospectively reviewed the operative records at our institution for all patients undergoing surgical treatment for a dorsal radiocarpal dislocation or translocation in the last 5 years. We included only patients presenting a preoperative X-ray and CT-scan evaluation of the injury. Information regarding the method of reduction and fixation, type of surgical approach, associated injuries, and complications was recorded. Patients with incomplete clinical and/or radiological records were excluded. Grip strength and range of motion were recorded with the Mayo wrist scores. Two questionnaire as DASH and PRWE were calculated at the last follow-up. Postoperative lateral and A/P radiographs of the wrist were used to look for signs of malunion (or osteoarthritis) and determine whether the radiocarpal joint was unstable.

Patients were classified in IV groups of lesions, each group was subdivided in 2 types of fractures. For each type was proposed a standardized and reproducible surgical treatment.

Results and Conclusions: Clinical and radiological outcome were satisfactory. This classification adequately addresses the spectrum of osseous and soft tissue injuries that occur in dorsal radiocarpal fracture-dislocations. Furthermore, it give a practical guide to surgically treat this various spectrum of lesions.

Bony mallet thumb: Our experience with 9 patients treated surgically

List of authors:
Hidetsugu Suzuki\textsuperscript{1}, Satoshi Usami\textsuperscript{2}, Sanshiro Kawahara\textsuperscript{2}
\textsuperscript{1} Tsuchiura Kyodo General Hospital (Tsuchiura)
\textsuperscript{2} Takatsuki Orthopaedic Hospital (Hachioji)

Objectives / Interrogation: Although a mallet fracture is a common injury, few reports have described bony mallet thumb injuries. We retrospectively investigated bony mallet thumb injuries treated surgically.

Methods: We evaluated 9 patients (6 men, 3 women) who underwent surgery for bony mallet thumb injury between January 2009 and February 2018. The mean age (range) of the patients was 44.9 years (18-80 years), and the surgery was performed 7.2 days (0-18 days) after the injury. The mean follow-up period was 4.8 months (2-14 months).

Results and Conclusions: Based on the Wehbe and Schneider classification of mallet fractures, all patients demonstrated Type I fractures (no joint subluxation). Subtypes A and B were observed in 4 and 5 patients, respectively. Six patients were treated with extension block K-wire pinning using a closed method, and 3 patients were treated with screws. Bone union occurred in 8 patients; however, 1 patient treated with pinning did not show bone union. One patient continued to demonstrate pain with interphalangeal (IP) joint extension. Range of motion and extension lag at the IP joint at the final follow-up were 64.1° (40°-85°) and 3.6° (0°-20°), respectively.

A biomechanical study of mallet fractures has reported that distal phalangeal subluxation is more common with defects involving >40-50% of the joint surface. In this study, although 5 patients demonstrated subtype B fractures (one-third to two-third of articular surface involvement), no patient demonstrated joint subluxation. The retinacular ligament of the IP joint of the thumb (which does not exist in other distal IP joints of fingers) may contribute to joint instability. Bone union did not occur in 1 patient treated with pinning. The fracture fragment observed in bony mallet thumb injuries is relatively larger than that observed with fractures of other fingers. Rigid fixation with screws may be superior to pinning to achieve effective bone union. In conclusion, joint subluxation is rare in bony mallet thumb injuries despite the large area of joint surface defects. Rigid fixation with screws may be effective to achieve bone union.

Severe PIP joint flexion contracture release by External Fixator - importance of post-operative management -

List of authors:
Yoshitaka Hamada*1, Takeyasu Toyama1, Emiko Horii2, Takanori Saito2, Yoshitaka Minamikawa3
1 Center for the Hand Surgery, Kansai Medical University (Neyagawa City, Osaka)
2 Department of Orthopaedic Surgery, Kansai Medical University (Hirakata City, Osaka)
3 Namba Hand Center (Osaka City)

Objectives / Interrogation: Mobilization of proximal interphalangeal joint (PIP) with severe contracture is extremely difficult. We had used the external-fixator, but experienced several complications such as pin site fracture or recurrence of contracture. We modified original technique in order to avoid these complications. Here, we introduce our technique, post-operative management and outcomes.

Methods: Since 2007, we treated 35 fingers with severe flexion contracture of the PIP joint. The patients were divided into 2 groups; the most severe group (12 fingers) showed more than 80° of flexion contracture with long duration (> 3 yrs.), and severe group (23 fingers) showed less contracture with shorter period. Setting of fixator differed depending on each finger condition. At surgery, we only apply the fixator without open soft tissue release. Post-operative management: 1st stage is a distraction phase; PIP was distracted in its flexed position by using strong elastic bands instead of rigid rod to avoid pin site fracture. 2nd stage is a correction phase to spread the range of movement (ROM); PIP was distracted either in extended or flexed position for more than 4 hours a day including sleeping time, respectively. 3rd stage is a stabilization phase to prevent the recurrence; PIP was stretched in extended or flexed position at maximum. Each stage takes a few weeks duration. At the end of the 2nd stage, we evaluated that the central slip was effective or not. Then we reconstructed the attenuated central slip, if necessary. After removal of fixator, night splint was applied at least 6 M.

Results and Conclusions: An average period of applying fixator was 8 weeks. The follow-up ranged 6 M to 97 M. The median active ROM improved from 4° to 32° in the most severe group and from 16° to 54° in the severe group. Nine fingers needed central slip reconstruction. Pin site infection and fracture were observed 4 and 6 fingers, respectively. Recurrence of the most severe cases after long duration (> 3 yrs.) was frequently observed, thereafter we changed the goal setting and strategy of each patient. We will show the changes of our strategy and methods.

The 1st stage is the most important. The joint distraction is achieved in contracted position up to obtaining 2-5 mm of sufficient joint space. In addition, usages of elastic tools (i.e. rubber bands, coil springs) provide safe and reliable traction and correction force.

Despite very severe contractures with various pathologies, we could improve joint motion with minimum complication.

Treatment of acute forearm compartment syndrome after transradial coronary intervention

List of authors:
Young Keun Lee*, Young Ran Jung¹, Kwang Wook Choi¹
¹ Chonbuk National University Hospital (Jeonju)

Objectives / Interrogation: This study documented our experience with acute forearm compartment syndrome after percutaneous coronary intervention via radial artery and suggested caution in order to achieve good results.

Methods: We retrospectively reviewed the records of 4 patients with acute forearm compartment syndrome (ACS) after transradial intervention (TRI) following emergent fasciotomy from 2015 to 2017. The patients included 3 females and 1 male with an average age of 70 years. ACS was diagnosed with clinical symptoms and compartment pressure monitoring and computed tomography angiography to confirm preoperative vascular status was performed in all cases. The time from symptom to operation averaged 5.7 h. The functional outcome was evaluated using a Quick-disabilities of the arm, shoulder and hand (DASH) score, grip and pinch strength at the time of final follow-up.

Results and Conclusions: In three cases, ACS was caused by bleeding from the rupture at the radial artery puncture site, and one case was caused by brachial artery rupture at the level of distal humerus and radial artery rupture at the level of proximal forearm. We obtained satisfactory results without any complications with an average follow-up of 11.5 months (range, 9 to 12). The average Quick DASH score was 15.35. The last follow-up average grip strength was 16 kg and the average pinch power was 1.6 kg. All 4 patients were satisfied with the function of the hand.

We stress that if physicians encounter ACS after TRI, they should be aware of the bleeding from the arterial rupture to confirm the preoperative status of artery and early surgical decompression with minimal injury of soft tissue with satisfactory results even in elderly patients.

Arthroscopic treatment of chronic wrist pain after distal radius fractures

List of authors:
Young Keun Lee*, Young Ran Jung¹, Kwang Wook Choi¹
¹ Chonbuk National University Hospital (Jeonju)

Objectives / Interrogation: The purpose of this study is to report the arthroscopic findings and clinical results of patients with chronic wrist pain after distal radius fracture who underwent diagnostic arthroscopy and arthroscopic-assisted tailored treatment.

Methods: We retrospectively analyzed the records of 11 chronic wrist pain patients after distal radius fracture, who underwent diagnostic arthroscopy and arthroscopic-assisted tailored treatment from 2010 to 2015. Average patient age was 49 years (range 31-68 years), the average time from injury to treatment was 13.8 months (range 3-36 months) and the average follow up period was 17.5 months (range 12-39 months). The functional outcome was evaluated by comparing the range of motion, grip strength, pinch strength, visual analogue scale (VAS) for pain and quick Disabilities of the Arm, Shoulder and Hand questionnaire (Quick DASH score), which were measured preoperatively and at final follow up.

Results and Conclusions: Based on the arthroscopic findings, we could find synovitis in all cases and we could classify the pathologic intra-articular lesions into 4 patterns. TFCC rupture was seen in 11 cases, intercarpal ligament rupture and radiocarpal ligament rupture was in 7 cases, ulnar impaction syndrome was observed in 4 cases, and cartilage defect was noted in 8 cases. In terms of surgical treatment, 11 patients underwent arthroscopic synovectomy, 5 underwent foveal or capsular repair of TFCC, 5 underwent intercarpal K-wires fixation or intercarpal thermal shrinkage, 1 underwent intercarpal ligament reconstruction, 2 underwent Sauve-Kapandji procedure and 1 underwent unlar shortening osteotomy. Postoperatively, the average range of motion, grip strength and pinch strength increased significantly. The average VAS score increased from 6.4 (range 4-8) preoperatively to 1.3 (range 0-3) at the final follow up (P=0.003), while the average quick DASH score decreased from 54.9 preoperatively to 14.7 at the final follow up (P=0.003).

Diagnostic arthroscopy and arthroscopic-assisted tailored treatment of chronic wrist pain after distal radius fracture can provide an accurate diagnosis, significant pain relief and functional improvement.

Operative Treatment of Intra-Articular Distal Radius Fractures With versus Without Arthroscopy: RADAR Trial

List of authors:
Caroline Selles*, Marjolein Mulders, Joost Colaris, Mark van Heijl, Berry Cleffken, Niels Schep
1 Maasstad Hospital (Rotterdam)
2 Amsterdam UMC (Amsterdam)
3 Erasmus MC (Rotterdam)

Objectives / Interrogation: Open reduction and internal fixation (ORIF) for intra-articular distal radius fractures leads to a quicker recovery of function compared to non-operative treatment. However, some patients continue to have a painful and stiff wrist postoperatively. Arthroscopically assisted removal of intra-articular fracture hematoma and debris may improve the functional outcomes following operative treatment of intra-articular distal radius fractures. The purpose of this randomized controlled trial is to determine the difference in functional outcome, assessed with the Patient-Rated Wrist Evaluation (PRWE) score, after ORIF with and without an additional wrist arthroscopy in adult patients with displaced complete articular distal radius fractures.

Methods: In this multicenter trial adult patients with a displaced complete articular distal radius fracture are randomized between ORIF with an additional wrist arthroscopy to remove fracture haematoma and debris (intervention group) and conventional fluoroscopic assisted ORIF (control group). The primary outcome is functional outcome assessed with the PRWE score after 3 months. Secondary outcomes are wrist function assessed with the Disability of the Arm, Shoulder and Hand (DASH) score, post-operative pain, range of motion, grip strength, and complications. Additionally, in the intervention group the quality of reduction, associated ligamentous injuries and cartilage damage will be assessed. A total of 50 patients will be included in this study.

Results and Conclusions: A total of 50 patients were randomized, 25 to the intervention group and 25 to the control group. All patients who had arthroscopic treatment had a hematoma which was removed. All patients had an associated injury consisting of TFCC, SL, LT or damage to the scaphoid or lunate fossa. Median PRWE was not significantly better for the intervention group at 3 weeks (48 [25-67] vs 58 [44-73], p = 0.1), and at 6 weeks (37 [18-63] vs 39 [19-53], p = 0.7). Median PRWE was significantly worse for the intervention group at 3 months (23 [9-44] vs 13 [5-21], p = 0.02). At six months follow-up both groups had a PRWE of 10 (p= 0.3). Complications were equal in both groups; 7 complications in the intervention group and 7 in the control group. Additional arthroscopy after ORIF, compared to only ORIF, does not lead to better functional outcomes in patients with displaced intra-articular distal radius fractures.

Functional outcomes after corrective osteotomy of symptomatic distal radius malunions in children

List of authors:
Caroline Selles*, Marjolein Mulders2, Gert Roukema1, Cornelis van der Vlies1, Berry Cleffken1, Niels Schep1
1 Maasstad Hospital (Rotterdam)
2 Amsterdam UMC (Amsterdam)

Objectives / Interrogation: Closed reduction and cast immobilization of displaced distal radius fractures carries the risk of secondary displacement, which could result in a symptomatic malunion. In patients with a symptomatic malunion, a corrective osteotomy can be performed to improve pain and functional impairment of the wrist joint. The aim of this study was to assess the functional outcomes of children who underwent a corrective osteotomy due to symptomatic malunion of the distal radius.

Methods: All consecutive corrective osteotomies of the distal radius for children younger than 18 years, between 2009 and 2016 were reviewed. The primary outcome was functional outcome assessed with the ABILHAND-Kids score. Secondary outcomes were QuickDASH score, range of motion, complications and radiological outcomes.

Results and Conclusions: A total of 13 patients with a median age of 13 years [IQR 12.5-16] were included. The median time to follow-up was 31 months [IQR 26-51]. The median ABILHAND-Kids score was 42 (range 37-42) and median QuickDASH was zero (range 0-39). Range of motion did not differ significantly between the injured and the uninjured side for all parameters. One patient had a nonunion requiring additional operative treatment. The postoperative radiological parameters showed an improvement of radial inclination, radial height, ulnar variance, dorsal tilt, and dorsal tilt.

Corrective osteotomy for children is an effective method for treating symptomatic malunions of the distal radius.

distal radius, malunion, pediatric surgery, corrective osteotomy, functional outcome
Utility of Image Fusion System for 3D Preoperative Planning in the Osteosynthesis of Distal Radius Fractures

List of authors:
Yuichi Yoshii*, Yasukazu Totoki1, Satoshi Sashida2, Tomoo Ishii1
1 Tokyo Medical University Ibaraki Medical Center (Ami)
2 LEXI Co., Ltd (Tokyo)

Objectives / Interrogation: To reproduce anatomical reduction and appropriate implant placement during the osteosynthesis, image fusion system for the 3D preoperative planning and the fluoroscopy was developed. The objective of this study was to assess the utility of image fusion system by evaluating the reproducibility of preoperative plan in the osteosynthesis of distal radius fractures.

Methods: Twenty-eight wrists of 28 distal radius fracture patients who underwent osteosynthesis using volar locking plates (22 females, 6 males, mean age 62.2 years) were evaluated. The patients were divided into two groups. The image fusion group (n=14) utilized 3D preoperative planning and image fusion system. The control group (n=14) utilized only 3D preoperative planning. The age, sex, and fracture types were matched between groups. All patients had pre- and post-operative CT scans to evaluate the reproducibility of preoperative plan. In both groups, 3D preoperative planning were performed in order to determine the reduction, placement and choices of implants. In the image fusion group, the outline of the planned image was displayed on the monitor overlapping with fluoroscopy image during surgery. Surgeons performed osteosynthesis with the fusion image. Reductions were evaluated by the volar tilt and radial inclination of the 3D images. Plate positions were evaluated with the distance between distal edge of the plate and the distal radius articular surface, and the positions of plate axis relative to the radius axis. Screw choices were recorded for the plan and actual choices for each screw hole. The reproducibility were evaluated by the difference of the parameters between pre- and post-operative image. The differences for reduction shape, plate positions, and screw choices were compared between groups.

Results and Conclusions: The difference of the distance between plate and articular surface were significantly smaller in the image fusion group compared to the control group (0.30+/-0.29 mm and 0.81+/-0.59 mm for image fusion and control groups, respectively, P<0.01). The difference of the distal screw choices were significantly smaller in the image fusion group compared to the control group (0.32+/-0.64mm and 0.64+/-0.92 mm for image fusion and control groups, respectively, P<0.01). There were no significant differences in the reduction shape and the plate axis position. The image fusion system was useful to reproduce the planned plate position and distal screw choices in the osteosynthesis of distal radius fractures.

Treatment of Pyogenic Arthritis with Drainage Sinus in Digits

List of authors:
Sang Ho Kwak*, Jung Yun Bae
1 Pusan National University Yangsan Hospital (Yangsan)

Objectives / Interrogation: In pyogenic arthritis of the digits, when diagnosed lately, drainage sinus may occur. Because of combined osteomyelitis, soft tissue destruction, and cartilage damage, it is difficult to treat this situation. In this study, we reviewed 36 cases of chronic pyogenic arthritis with drainage sinus in digits and (1) reported the result of repeated irrigation and debridement followed by flap surgery, and (2) compared the clinical manifestation between distal interphalangeal (DIP) joint and proximal interphalangeal (PIP) joint.

Methods: 36 patients (16 men and 20 women, 41-80 years of age with a mean age of 60.1 years) were diagnosed with chronic pyogenic arthritis with drainage sinus. The involved joints (21 DIP joints, 12 PIP joints, 2 thumb interphalangeal (IP) joints, 1 thumb metacarpophalangeal (MCP) joint) underwent surgical debridement and followed up for at least 12 months. Combined osteomyelitis in simple radiograph or magnetic resonance image, microorganism, antibiotic therapy, duration of treatment delay, duration of hospital stay, number of irrigation and debridement (I&D), and soft tissue coverage method were analyzed retrospectively. The range of motion (ROM) of the joint and radiologic outcome at final follow up were also analyzed.

Results and Conclusions: Combined osteomyelitis was diagnosed in 30 cases. Microorganisms were identified in 29 cases and 7 were polymicrobial infections. The identified microorganisms were resistant to the antibiotics used before, except one case. In the group analysis between DIP and PIP joint, mean duration of antibiotic therapy (5.9 ± 0.31 weeks, DIP; 7.6 ± 0.66 weeks, PIP; p<0.001) was significantly longer in PIP joints and patients involved their PIP joints had more I&D than those involved DIP joints (2.9 ± 0.84, DIP; 6.5 ± 1.7, PIP; p<0.001). Eight patients (n=0, DIP; n=8, PIP; p<0.001) underwent additional flap surgery. Three patients with involved DIP joint and 10 with involved PIP joint, the joints were fused (p<0.001). The mean ROM was 5.57 degree (8.57±5.51 degree DIP; 0.83±2.88 degree PIP, p<0.001).

Conclusions
Chronic pyogenic arthritis with drainage sinus in digit could be treated with repeated irrigation and debridement. When PIP joint is involved, longer duration of treatment, more I&D, higher need of a flap surgery, and less ROM is expected compared with DIP joint. If empirical antibiotics was used before, the surgeon should perform antibiotic susceptibility test.

Delayed zone 2 flexor tendons repair with less fatigue of the operators had better outcomes than primary repairs: An analysis of 83 fingers

List of authors:
Xiang Zhou¹, Jing Chen², Jun Qin¹
¹ People's Hospital of Jiangyin (Wuxi)
² Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: We compared the outcomes of delayed zone 2 flexor tendon repairs by surgeons with less fatigue and better assistants with those patients repaired in emergency settings in late afternoon or night when surgeons have remarkable fatigue and less qualified assistants.

Methods: We repaired 83 flexor digitorum profundus (FDP) tendons in zone 2 of 68 patients from November 2013 to July 2017. There are 54 men and 14 women. The average age of patients was 36 (range 17 to 65) years old. 36 fingers were repaired after a delay a mean of 4 (2 to 10) days with primary skin closure and later tendon repair. 47 fingers were repaired primarily with 12 hours after injury. The FDP tendon was repaired with the 6-strand M-Tang repair using 4-0 looped suture and sparsely placed simple running peripheral suture with 6-0 or 5-0 nylon. The delayed repair was performed in the daytime with better assistants (1 or 2 junior attending surgeons or residents) and the primary repair was performed during the late afternoon or nighttime with only one general surgery resident to assist. After surgery, the fingers in both groups of patient followed the same rehabilitation protocols of early active motion, with partial range digital active flexion in the first 3-4 weeks and full range of active flexion thereafter. We compared the functional results and demographics and injury factors (gender, age, accompanied injuries, and follow-up lengths) between patients treated with delayed repair or repair in emergency settings.

Results and Conclusions: There are 25 excellent, 7 good, 3 fair, 1 poor in the fingers with delayed primary, and 23 excellent, 13 good, 8 fair, 3 poor outcomes using primary repair with follow-up of 8 to 27 months. There were no tendon ruptures. The mean range of motion of the proximal and distal interphalangeal joints in the 36 fingers with delayed primary repair was 161+/-25 degrees, which significantly better than that of 47 fingers with primary repair of 147 +/- 29 degrees (p = 0.018). We found no significant differences in demographics and injury factors (gender, age, accompanied injuries and follow-up lengths) between the two groups.

A primary repair in the late afternoon or nighttime with inexperienced assistants has worse outcomes than delayed primary repair as a selective procedure with experienced assistants. We conclude that surgeons' fatigue and quality of assistants affect outcomes of zone 2 flexor tendon repair.

Growth of transplanted bone after reconstruction for severely hypoplastic thumb

List of authors:
Ruriko Iigaya*¹, Shinichiro Takayama², Takehiko Takagi², Atsuhito Seki¹, Taku Suzuki¹, Takuji Iwamoto¹, Masaya Nakamura¹, Morio Matsumoto¹, Kazuki Sato¹
¹ Dep. of Orthop. Surg., Keio University School of Medicine (Tokyo)
² National center for child health and development (Tokyo)

Objectives / Interrogation: We have developed a novel two-stage reconstruction for a severe hypoplastic thumb: transplantation of a non-vascularized metatarsal head with epiphysis or metatarsophalangeal (MTP) joint for the first stage and tendon transfers for the second stage. The purpose of this study was to assess the biological attachment, the bone union and the growth of reconstructed first metacarpal bone.

Methods: We retrospectively reviewed the biological attachment and the bone union of 57 hypoplastic thumbs (27 Blauth IIIB and 30 Blauth IV) that underwent the two-staged reconstruction after 1992. The mean age at the first stage of surgery was 3.3 years. Bone union and growth of reconstructed first metacarpal was reviewed up to 5 years after surgery. The length of the reconstructed first metacarpal bone was measured on the AP view of plain radiographs every year. It was compared with the length of the ipsilateral second metacarpal bone.

Results and Conclusions: 42 hands obtained biological attachment. 32 hands obtained bone union without complication and a mean period of bone union was 8.8 weeks. Nine hands needed additional surgeries, and one hand with a bone graft from paralyzed side of the spina bifida had fallen into severe bone absorption. 27 hands (13 Blauth IIIB and 14 Blauth IV) reconstructed after 2000, which excluded these complications, were evaluated up to 5 years after surgery for bone growth of the reconstructed first metacarpal. The mean length of the first metacarpal bone was 23.8mm at surgery and 29mm at 5 years after surgery. On the contrary, the second metacarpal bone was 33.8mm at surgery and 44.6mm respectively. Growth of the reconstructed first metacarpal bone was recognized; however, the growth rate was lower than that of the second metacarpal bone. Subgroup analyses were performed according to the Blauth classification and the type of bone graft (metacarpal head or MTP joint). The growth rate of the first metacarpal bone was 129 % for Blauth IIIB and 118% for Blauth IV cases. There was a statistically significant difference between the two groups. The growth rate of the first metacarpal bone with the MTP joint was inferior to that with the metatarsal head, but there were no significant differences between the two groups.

In our study, the biological attachment and the long-diameter growth of the bone graft were confirmed for 5 years after surgery, although it was transplanted in a non-vascularized fashion. Further long-term follow-up study until epiphyseal closure is necessary.

ANIMAL EXPERIMENTAL ASSESSMENT OF NERVE REGENERATION WITH A PROCESSED HUMAN UMBILICAL VESSEL USED AS A REGENERATION CHAMBER

List of authors:
Aude Griffart*, Laurence Barnouin2, Laurent Obert3, Ludovic Ardouin1
1 institut de la main Nantes Atlantique (Saint Herblain)
2 TBF (Mions)
3 chu (Besançon)

Objectives / Interrogation: Nerve regeneration chambers are used to decrease sites transplant donor morbidity. We propose a safe biomaterial, derived from an inverted umbilical artery from human umbilical cord, included in Wharton jelly which is rich in collagen and hyaluronic acid.

Methods: The biomaterial, with an inner diameter of 1.75 mm, is dehydrated and also secured by a viral inactivating treatment, enabling a hold of its tubular structure. A sciatic nerve section has been performed on 15 rats, with a sleeving and nerve endings suture by nylon points 9/0, in order to create a 1 cm gap. A daily monitoring allowed to assess the motor index of tonus recovery and sensitive recovery, compared to the healthy side. Rats are split in 3 groups and sacrificed at 1,3 or 8 weeks for macroscopic and histological analysis.

Histological staining specific to the myelin (MCOLL) and immunostaining of Schwann cells (S-100) and axonal cells (NF), have enabled to assess axonal regrowth, Büngner bands, the biomaterial integrity and the inflammatory reaction.

Kinetic regrowth compared to contro-lateral nerve has been assessed by histomorphometry.

Results and Conclusions: First sensitive recovery signs appear from D5. The tonus recovery in the emptiness appears from D24, movement against gravity since D28 and continue to evolve until D54. The biomaterial is resorbing progressively since D21 while preserving a regrowth chamber, and disappears completely on D56. The inflammatory reaction is weak since D7.

Staining and immunohistochemistry show a 90% axonal cells recovery since D56, a high density of Schwann cells with an increasing since D21 and an of organisation axonal fibers in the time and biomaterial space, moving from the proximal to distal stump, with an efficient myalination in 8 weeks. Nerve recovery fills quickly the 1 cm gap of the sciatic nerve: 50% at D21 and 100% filling at D56.

Conclusion
The biomaterial shows an efficient axonal regrowth in 8 weeks, after a section of a 1 cm gap. The biological allogenic devitalized structure shows a good tolerance with a complete integration and several physiological proteins that can have enhanced the good kinetic of the nerve regrowth. This new conduit has shown its biocompatibility in rats, with an axonal regrowth. It seems a promising product to consider for human transplants and nerve sutures.

The Patient Specific Functional Scale in Dupuytren's disease; a more responsive outcome measure than standardized PROMS?

List of authors:
Yara van Kooij¹, Ralph Poelstra², Jarry Porsius³, Harm Slijper⁴, David Warwick⁵, Ruud Selles³
¹ Handtherapie Nederland (Utrecht)
² Department of Plastic, Reconstructive and Hand Surgery, Department of Rehabilitation Medicine, Hand and Wrist Centre, Xpert Clinic (Rotterdam)
³ Department of Plastic, Reconstructive and Hand Surgery, Department of Rehabilitation Medicine (Rotterdam)
⁴ Hand and Wrist Centre, Xpert Clinic (Hilversum)
⁵ University Hospital Southampton (Southampton)

Objectives / Interrogation: Due to the wide variety of functional problems of patients with Dupuytren's disease, standardized patient-reported outcome measures (PROMs) may fail to capture all problems these patients experience. Individualized PROMs might overcome this problem by enabling patients to specify and rate those activities with which they have difficulty in daily life. The Patient Specific Functional Scale (PSFS) is such an individualized PROM and is easy and relatively quick to use. The aim of this study is to determine the responsiveness of the PSFS compared to the Michigan Hand Questionnaire (MHQ) in patients with Dupuytren's disease.

Methods: Patients treated for Dupuytren's disease were asked to fill in the PSFS and the MHQ prior to surgery and three months after treatment. For the PSFS, patients were asked to identify and score three to five important activities they experienced difficulties with due to Dupuytren's disease. Activities were scored on an 11-point scale with '0' representing 'unable to perform' and '10' representing 'able to perform at prior-disease level'. At follow-up, the patients are presented with the same activities again and ask to rate the ability for each activity. Cohen’s D effect sizes were calculated to assess the responsiveness to change.

Results and Conclusions: A total of 308 patients was included. Patients mentioned a wide variety of functional problems of which the majority (e.g. computer use) was not covered by standardized PROMs like the MHQ. The mean PSFS score improved significantly from 5.0 at baseline to 7.7 at follow-up. The effect size of the PSFS was 1.0 (95% confidence interval 0.86-1.2), which was significantly higher and almost double the responsiveness of the MHQ (0.58; 95% confidence interval 0.42-0.74) of the MHQ.

This study demonstrates that the PSFS is more responsive to change compared to the MHQ in patients with Dupuytren's disease. Self-generated items and the measurement of such items truly reflect the needs and problems of the individual patient. These characteristics make the PSFS a valuable outcome measure for Dupuytren's disease and this fits well within the current emphasis of patient-centred healthcare.

Online patient information on Hand Transplantation: How reliable is it for facilitating shared decision making?

List of authors:
Stephen Ali¹, Marcus Quinnn², Ioannis Kyriazidis², Samuel Norton¹
¹ Norfolk and Norwich University Hospitals NHS Trust (Norwich)
² North Bristol NHS Trust (Bristol)

Objectives / Interrogation: This study evaluates the quality of online information available for patients considering hand transplantation with vascularised composite allotransplantation.

Methods: Selected key phrases were entered into two popular search engines (GoogleTM, BingTM). These phrases were: “hand transplant”, “hand transplant amputation” and “hand transplant vascularised composite allotransplantation”. The first 50 hits per search were reviewed. Of the 300 identified sites, duplicate (158), irrelevant (26), news (128), academic papers (62) and inaccessible (3) results were excluded. 23 discrete resources were identified for evaluation by two independent assessors using the DISCERN instrument, a set of online criteria by which the quality of patient information websites can be judged.

Results and Conclusions: The median DISCERN score of analysed websites was 40/80 (20.5-55.0). This equates to Fair, bordering on Poor global quality (Excellent = 80-63; Good = 62-51; Fair =50-39; Poor = 38-27; Very poor = 26-15). None of the analysed sites were rated Excellent, 9% (2) rated Good, 48% (11) rated Fair, 30% (7) rated Poor, and 13% (3) rated Very poor. The included websites scored poorly on both reliability of information, including extent to which it can be trusted (18/40; 8.5-25.5), and also quality of information on treatment choices (20.5/35; 8.5-25.5). High quality information is required to facilitate patient-centred shared decision making in patients considering hand transplantation, but is not easily available online, with many available resources being of poor quality. There is a need for focused and reliable online resources to be developed for this patient cohort.

**Computed tomography-based three-dimensional preoperative planning for total wrist arthroplasty**

**List of authors:**
Yutaro Sugiura*, Takuji Iwamoto¹, Taku Suzuki¹, Noboru Matsumura³, Kazuki Sato¹, Masaya Nakamura¹, Morio Matsumoto¹
¹ Keio University School of Medicine, Department of Orthopedic Surgery (Tokyo)

**Objectives / Interrogation:** There have been many reports on the usefulness of three-dimensional preoperative planning (3D planning) using computed tomography (CT) for total knee and hip arthroplasties. However, few reports have described CT-based 3D planning for prosthetic arthroplasty of the upper limbs. We report a case of total wrist arthroplasty (TWA) using CT-based 3D planning.

**Methods:** A 65-year-old female presented to our hospital with weakness of the extensors of the left middle and ring fingers, which had gradually progressed over 2 months. She also had suffered from left wrist pain for 2 years. Having been diagnosed previously with rheumatoid arthritis and systemic sclerosis, she had been treated with methotrexate and tocilizumab since she was 40 years old. On physical examination, her left wrist was swollen, and the range of motion of her wrist joint was restricted: -10 degrees in extension to 40 degrees in flexion. Plain radiography revealed advanced bone destruction of the wrist joint and volar dislocation of the carpal bones, indicating arthritis mutilans. We planned a total wrist arthroplasty and extensor tendon reconstruction. After a 3D digital model of the wrist was reconstructed using CT and software, the computer-aided design models of the implant were superimposed on the wrist; the appropriate size and position of the implant were determined. During surgery, the planned parameters were measured with a slide gauge to reproduce the 3D-planned position of the implant. The size of the implant used at surgery was the same as in 3D planning, and the location of the implant was virtually the same as in 3D planning. Nine months after surgery, the extension and flexion of her wrist improved to 15 degrees and 35 degrees, respectively. Postoperative complications were not observed.

**Results and Conclusions:** It is difficult to place an implant in the proper position during TWA since the procedure is indicated for the treatment of severe wrist deformity due to RA with advanced bone destruction and bone weakness. The size and position of the implant can be appropriately predicted by 3D planning. Our method may contribute to a reduced incidence of complications and improved long-term outcomes after TWA.

Genotype-phenotype insights into familial polydactyly in Chinese people

List of authors:
Gang Han*, Ruiji Guo, Zhengsheng Chen, Li Chen, Wenhai Sun, Bin Wang

1 Shanghai 9th People's Hospital (Shanghai)

Objectives / Interrogation: Polydactyly is a genetically and phenotypically heterogeneous disorder which is the third most frequent congenital anomaly in China. The purpose of this study was to systemically investigate the genotype-phenotype correlations of familial polydactyly in Chinese people.

Methods: A total of 18 Chinese families with polydactyly were included. The family histories were recorded and physical examination of available family members was performed. Genomic DNA was prepared from peripheral blood of affected and unaffected individuals. Whole exome sequencing, Sanger sequencing, CytoScan and qPCR were used to identify the pathogenic mutations. The genotype-phenotype correlations were analyzed. Variants were functionally assessed by luciferase assay or computational simulation.

Results and Conclusions: Pathogenic mutations within HOXD13 and GLI3 were predominantly identified in 17 out of 18 families (94%). Among 11 families with HOXD13 mutations, 10 families had a 7- to 9-alanine expansion of the N-terminal 15-mer poly-alanine region spanning amino acids 57 to 72, and the other one family had a single amino acid substitution, I309F, in the conserved homeobox domain. GLI3 mutated in 6 families, all of which were truncating mutations. Phenotypically, preaxial polydactyly of either hands or feet, frequently Wassel type II and IV, and postaxial polydactyly of the hands were exclusively found in GLI3 mutated families, while postaxial polysyndactyly of the feet was unique for HOXD13 mutated families. In addition, synpolydactyly of 3/4 fingers and 4/5 toes was exclusively associated with HOXD13 mutations, but in GLI3 mutated families, syndactyly could happen between any of two digits and frequently involved multiple digits. Finally, clinodactyly of 4th or 5th fingers and broad thumbs were additional unique feature for HOXD13 and GLI3 mutated families, respectively. Functionally, I309F impairs HOXD13 transcription activity. In conclusion, through the molecular genetics study of the largest cohort of familial polydactyly of Chinese people, we revealed that GLI3 and HOXD13 were predominant mutated genes. Preaxial polydactyly of hands or feet, postaxial polydactyly of the hands, and broad thumbs were exclusively associated with GLI3 mutations, while synpolydactyly of 3/4 fingers or 4/5 toes, and clinodactyly of 4th or 5th finger were unique for HOXD13 mutations. Sanger sequencing of GLI3 or HOXD13 according to specific manifestation could be a cost-effective genetic diagnosis method for patients with polydactyly.

Recurrent Masson’s Tumor of the Finger: A Case Report

List of authors:
Hannah Ng*, Brenton Sio¹, Amir Adham¹, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: To describe a case report of a recurrent Masson’s Tumor of the finger. Intravascular Papillary Endothelial Hyperplasia (IPEH) often referred to as Masson’s Tumor, is an uncommon yet benign vascular disease of the skin and subcutaneous tissues. It usually arises within a blood vessel, but considered to be a non-neoplastic reactive endothelial proliferation commonly associated with vascular injury. Although it is rare, knowledge of this disease is important as it may mimic other benign and malignant tumors, especially angiosarcoma. Typically, IPEHs are asymptomatic and are slow growing soft-tissue masses with extremely low recurrence rates.

Methods: We describe a 19-year-old male with a recurrence of a Masson’s Tumor over the right little finger within 2 months of a routine excision of the lesion. We also present accompanying multimodality clinical, radiological and pathological imaging.
Results and Conclusions: This case illustrates the innocuous nature of the initial lesion easily mistaken for hematoma, thrombus or benign haemangioma. Awareness of the possibility of a recurrence of a Masson's Tumor is important for clinicians to rule out the presence of malignant vascular lesions.

Motor Imagery and Mental Practice as an augment for surgical training

List of authors:
Hannah Ng*, Vaikunthan Rajaratnam
1 Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: The challenges of producing competent surgeons in the shortened training time available requires innovative and easily executable strategies that are evidence based. The working environment of the surgeons for skill acquisition is the operating room (OR) which cannot be the ideal environment for surgical learning both from a quality-of-care, work place efficiency and safety perspective (Arora et al., 2010). There is a need therefore for the design and development of a model for deliberate practice in surgery that is universally accessible and effective in producing learners of expert level performance at the end of the stipulated period of training for a psychomotor skilled task.

Methods: This research shows the methodology to provide a solution for training surgeons with predictable levels of expertise in a standard common surgical procedure using the interventions prescribed in the research model, given the constraints of limited time and unpredictable learning opportunities in the surgical environment.

Results and Conclusions: This new model for deliberate practice in microsurgery designed using Motor Imagery & Mental Practice (MIMP) scripts to produce expert performance among novices will be described together with the theoretical basis for this model and the methodologies of production of the script for other surgical procedures will be presented. The script has shown content and face validity and shown to be effective among surgical interns in a tertiary hospital in Singapore for performing microsuturing with a microscope in a glove model.

This research provides evidence for the use of this new model of motor imagery and mental practice in the microsurgical training domain. It shows that rapid skill acquisition in microsurgery is possible using MIMP training which can be incorporated into residency training programs in Singapore and be utilised for further research work in other settings.

Opinion of surgeons worldwide on management of fingertip injuries

List of authors:
Hannah Ng*, Amir Adham¹, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: Fingertip injuries are common and there are numerous options available for management. The aim is to explore the preferences between how surgeons would want their own fingertip injuries treated compared to how surgeons would treat patients with similar fingertip injuries.

Methods: This qualitative study used a purposeful sampling with an online survey form, distributed to surgeons worldwide via a social media platform. These surgeons were from a community of surgeons on LinkedIn and Facebook. 3 different cases were presented to respondents - case 1 was an Allen 1 injury, case 2 was an Allen 3 injury with 2mm exposed bone, and case 3 was a crush injury of the distal phalanx. Respondents were invited to opine on their management preferences in these scenarios if these were their patients and their own fingertip injuries.

Results and Conclusions: There were 30 respondents. 60% males, 50% practicing in Europe, 36.7% in the Asia-Pacific region. 53.3% had >10 years of experience in surgery, 26.7% had 5-10 years. 36.7% were senior consultants, 43.4% were (associate) consultants.

For case 1, 73.3% would treat both patients and themselves identically, conservatively with toileting and dressing. The remaining would treat both patients and themselves identically, surgically - 6 chose local flaps, 1 a distal flap. 1 respondent chose local flap for his patient, but elected for microsurgical reconstruction with pulp transplant for his own care.

For case 2, 30% would treat both patients and themselves identically, conservatively with toileting and dressing. 4 also chose to shorten the bone. The remaining chose surgical treatment for their patients, of which 66.7% chose surgical treatment on themselves. This respondent elected to treat his own fingertip injury conservatively with simple dressing while treating his patient's with a local flap. Otherwise, the remaining would perform identical surgical treatment on both patients and themselves. 13 respondents chose local flaps, 2 replantation, 2 microsurgical reconstruction with pulp transplant, 1 each for distal flap, terminalization, and grafting.

For case 3, all chose identical treatments for both patients and themselves - 83.3% chose conservative treatment with toileting and suturing the wound followed by dressing. The remaining elected to remove nail with nail bed repair followed by a fingertip splint.

In conclusion, most surgeons would want their own fingertip injuries treated identically to how they would treat patients with similar fingertip injuries.

An early experience on the use of intramedullary headless screws for hand fractures

List of authors:
Hannah Ng*, Amir Adham1, Jane Sim1, Vaikunthan Rajaratnam1
1 Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: The surgical management of metacarpal and phalangeal fractures is commonly with Kirschner wire and plate and screws, which may cause scarring and adhesions leading to poor functional outcomes. Intramedullary headless screw fixation can be a viable alternative with better outcomes. The aim is to present our institution's early experience on the outcomes of metacarpal and phalangeal fractures surgically fixed with intramedullary headless screws.

Methods: We retrospectively reviewed clinical data of patients who had metacarpal and phalangeal fractures fixed with intramedullary headless screws at our institution from January 2018 - August 2018. A total of 6 patients were identified. They were all male, all right handed, all work permit holders with an average age of 31. Five were labourers who were involved in an industrial accident while 1 was a technician who was involved in a road traffic accident.

Results and Conclusions: There were 2 proximal phalanx fractures, 1 middle phalanx fracture and 3 metacarpal fracture, and a single screw was used in all. Two patients had previous fixation of their fracture with plates and screws - 1 patient had removal of implants as his fixation was complicated by painful non-union and poor range of movement, while the other patient had peri-implant fracture. Subsequently, their fractures were surgically fixed with intramedullary headless screws.

At latest follow up, total average range of motion was 128. In 3 patients, fractures were healed and within acceptable radiological parameters. None of the patients have post-operative complications thus far at follow-up.

All patients are still on active follow-up, with ongoing hand occupational therapy. Patient satisfaction, quickDASH score, time to return to normal activities and work have yet to be determined.

Intramedullary headless screw fixation is a reliable alternative to metacarpal and phalangeal fractures.

Hand fractures, intramedullary headless screw
Experience with the use of semi-occlusive dressing and splint caps for the management of fingertip amputation injuries

List of authors:
Hannah Ng*, Amir Adham¹, Cheyenne Rebosura¹, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: Fingertip amputation injuries are one of the most common traumatic hand injuries. These injuries can be treated with surgical intervention such as locoregional flaps, replantation, or with terminalization. However, conservatively treated fingertip amputation injuries have an excellent regenerative ability and can lead to a functional, sensate and cosmetically pleasing fingertip. Our aim is to demonstrate our institution's experience with the conservative management of fingertip injuries with the use of semi-occlusive dressing and splint caps.

Methods: This retrospective study of consecutive patients who have sustained fingertip amputation injuries to the distal phalanx of the finger at our institution from January 2017 - July 2018. All patients attended our day surgery facility. All patients had local anaesthesia, wound debridement to the fingertip injury, followed by dressing with a semi-occlusive dressing, and thereafter the splint cap. We developed a three dimensional thermoplastic splint of the patient's original fingertip contour, termed the splint cap.

Results and Conclusions: There were 20 fingertip injuries in 20 patients who were all male. There were 25% Allen 1, 50% Allen 2 and 25% of patients with Allen 3 injuries. The mean age was 26. The mean follow-up duration was 4 months. The primary semi-occlusive dressing with splint cap was left for an average duration of 2 weeks.

In all our patients, the pulp regains satisfactory tissue cover after 4 weeks. Sensation returns within 6 weeks. 75% of patients had nail involvement. All patients had some degree of deformity of the nail. There were no serious complications such as tissue infections, neuroma, or osteomyelitis. None of the patients required a secondary flap coverage.

In conclusion, conservative treatment with semi-occlusive dressing and splint caps is a viable and cost effective alternative to the management of fingertip amputation injuries with excellent outcomes.

Keywords:
Fingertip injuries, semi-occlusive dressing
Outcomes and impact of fingertip amputation injuries in a local tertiary hospital in Singapore

List of authors:
Hannah Ng*, Aaron Koh¹, Pei Yein Tong¹, Jane Sim¹, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: Fingertip amputation injuries are common with treatment of these injuries by conservative or surgical means, where there has been increasing interest in treatment via conservative techniques. Also, these relatively small injuries also result in a high economic burden due to loss of productivity and disability.

The aim of this study is to demonstrate the outcomes of three different treatment options for fingertip amputation injuries and quantify the economic burden of such injuries in relation to the different treatment modalities.

Methods: This is a combined retrospective and prospective study of patients who received treatment for fingertip amputation injuries at a tertiary hospital in Singapore. These injuries are defined as distal to the distal interphalangeal joint.

In the retrospective arm, 30 case-matched patients received treatment for their injuries from January 2015 to July 2018 were analysed according to the following treatment modalities - semiocclusive dressing and splint cap, tutoplasty or locoregional flap coverage. There were 10 patients in each group.

In the prospective arm, purposeful sampling was used to randomly assign patients to receive treatment to either semiocclusive dressing and splint cap, tutoplasty or locoregional flap coverage.

The clinical and functional outcomes of these treatment modalities were examined and compared. Demographic data, occupation and cost of treatment were also collected and an estimation of economic costs was performed.

Results and Conclusions: Initial results revealed that patients who received tutoplasty took a longer time to heal, while patients who received locoregional flap coverage healed faster. Functional outcomes showed no statistical difference between all three groups.

Despite these clinical outcomes, there were no statistical difference in return to work amongst all three groups. Even though healing was faster in the surgical intervention group, however the costs of treatment was higher. The economic burden remained high for all three groups.

Deeper analysis will be presented.

In conclusion, fingertip injuries are common and although the outcomes are generally acceptable, these injuries result in significant economic burden. Semi occlusive dressing and splint cap is a treatment modality that can potentially reduce healthcare costs and time to return to work.

Flap reconstruction and salvage of the diabetic foot - early results of a single surgeon.

List of authors:
Tina Lee*, Pek Chong Han, Yuan Kong
1 Tan Tock Seng Hospital (Singapore)
2 Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: To evaluate the outcome of diabetic foot reconstruction with free and locoregional flaps.

Methods: Between November 2017 and September 2018, diabetic patients requiring lower limb reconstruction were recruited into our study. All surgeries were performed by a single surgeon. Preoperative risk factors (smoking, peripheral arterial disease, history of angioplasty, chronic renal impairment and cardiac disease), minor and major complications (including need for repeat surgery as well as flap failure) and limb salvage rate were analysed.

Results and Conclusions: Results:
12 patients with diabetes and lower limb wounds received flap reconstruction. There were 7 microsurgical free flaps (1 gracilis, 6 anterolateral thigh) and 5 locoregional flaps. Patient age ranged from 35 to 74 years. There was 1 case of total free flap loss that was subsequently amenable to skin grafting. There were no incidences of life-threatening complications. Limb salvage rate was 100% at follow up.

Conclusion:
Our early results show that flap reconstruction for the diabetic foot has a good success rate and limb salvage rate with careful patient selection. Co-morbidities such as diabetes, peripheral arterial disease and smoking do not preclude lower limb flap reconstruction.

Keywords:
diabetic foot; lower limb; free flap; reconstruction
Triquetral fractures - a retrospective, multi-centre study of incidence, management and outcomes

List of authors:
Alyse Hopkins*, Michael Dowd1, Angelo Preketes1, Sebastian Bowman1, Abdullah Ibrahim1
1 The Nepean Hospital (2747)

Objectives / Interrogation: This study examines triquetral fracture data from 6 hospital centres between 2009 and 2018. This study focused on elements of triquetral fracture management within these 6 centres, including the incidence, the fracture pattern, the short-term and long-term outcomes and the common mechanisms of injury. It is anticipated this will be the largest cohort of triquetral fractures studied to date and will ultimately lead to treatment recommendations for optimal management of triquetral fractures.

Methods: Data was obtained from hospitals within the Nepean and Blue Mountains Local Health district in NSW, Australia. (Nepean hospital ethics approval no: NBM18/805)

Results and Conclusions: Initial analysis has shown the incidence of triquetral fractures is higher than previously reported and may continue to rise as a result of increasing rates of motor vehicle accidents and falls in an aging population. In addition, triquetral fractures can be challenging to identify with plain radiography, and can be commonly identified as lunate fractures. If there are ongoing symptoms and a high clinical suspicion CT may be indicated and, in future practice, may be justified as a first line imaging modality. Particularly, given the increasingly higher resolution imaging available with shorter radiation exposures. For the management of triquetral fractures where there is a small chip fracture and wrist stability is intact a short arm cast with carpal stability is the standard, however a shorter period maybe useful and more easily tolerated by patients who are compliant and can aid in a rapid functional recovery.

Outcomes of flexor tendon repairs of 99 fingers in zones 1 and 2 using a multi-strand core suture repair followed by early active mobilization

List of authors:
Zhangjun Pan*
1 yixing people hospital, Jiangsu University Affiliated Yixing Hospital (WUXI YIXING)

Objectives / Interrogation: We retrospectively reported the outcomes of flexor tendon repairs in zones 1 and 2 using a multi-strand core suture repair followed by early active mobilization, and evaluated the influencing factors on the recovery of flexor tendon repairs, including finger, age, gender, zone, time of surgery and associated nerve injury.

Methods: From January 2014 to August 2017, we performed primary or delayed primary repair for completely divisions of flexor digitorum profundus (FDP) tendon in zones 1 and 2 in 99 fingers (67 patients) using multi-strand core suture repair followed by early active mobilization. The FDP tendons were repaired in 11 fingers in zone 1, 16 in zone 2A, 24 in zone 2B, 35 in zone 2C and 13 in zone 2D. These included 27 index, 26 long, 29 ring, and 17 little fingers in 51 men and 16 women. Their mean age was 36 years (16 - 67 years). Fifty-eight fingers had associated digital nerve or artery injuries. All repairs were performed within 7 days after injury except six patients. We repaired the FDP tendons using either a 6-strand M-Tang or a 4-strand U-shaped Tang core suture with 4-0 looped sutures, followed by a running peripheral suture using a 6-0 nylon suture. We did not repair the superficialis tendon in any patients and vented the entire A4 pulley or a part of the A2 pulley when necessary. A digital extension-flexion test was always performed after tendon repair. Active partial range flexion exercise were initiated from day 3 to 5 after surgery. The outcomes were evaluated with Tang criteria. Kruskal-Wallis test and the Mann-Whitney U-test were used to compare outcomes between zone 1 and each zone 2 subzones.

Results and Conclusions: A total of 99 fingers were followed up from 6 months to 20 months (mean 8.7 months). According to Tang criteria, excellent or good function was achieved in 46 (47%) and 41 (42%) fingers, fair 9 (9%) and poor 2 (2%) at the final follow-up, respectively. The outcomes in zone 2D were significantly superior to those in zones 2C (p=0.002) and 1 (p=0.004). The functional outcomes of women were significantly better than those men (p=0.02). However, the effects of some other demographics and injury factors (different fingers, time of surgery and accompanied injuries) on the recovery of flexor tendon repairs were little. There was no significant difference in outcomes between zone 1 and zone 2 in general.

We conclude that flexor tendon repair in zone 2D has significantly better outcomes than in zone 1 or zone 2C.

Accessory Palmaris Longus causing carpal tunnel syndrome

List of authors:
Ian Dhanaraj¹, Jing Yuan¹, Hannah Ng¹, Vaikunthan Rajaratnam¹
¹ Khoo Teck Puat Hospital (Singapore)

Objectives / Interrogation: The palmaris longus is the most variable muscle of the human upper extremity, and many variations have been describe. One of these variations is the accessory palmaris longus, or more commonly known as the palmaris profundus. In humans, the palmaris longus does not serve any important intrinsic function, however, the clinical applications of this muscle in hand surgery makes it important to recognize and be aware of its normal and variant anatomy.

Methods: We will briefly describe the anatomy and developmental origins of the palmaris longus, and describe the clinical relevance of an accessory palmaris longus by presenting a case report of an 86-year-old female who had right sided carpal tunnel syndrome secondary to an accessory palmaris longus.
Results and Conclusions: Awareness of the normal and variants of the palmaris longus is useful for hand surgeons. Furthermore, the accessory palmaris longus is a rare but important entity for the surgeon to recognize during routine carpal tunnel release surgery.

Keywords:
Palmaris longus, carpal tunnel syndrome, carpal tunnel release surgery
Treatment for flexor tendon tenosynovitis with rare non-tuberculous Mycobacteriosis (M. haemophilum): A case report

List of authors:
Kosuke Saito*, Takuya Yokoi¹, Takuya Uemura², Mitsuhiro Okada³, Ema Onode¹, Hiroaki Nakamura¹
¹ The Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine (Osaka)
² The Department of Orthopaedic Surgery, Osaka General Hospital of West Japan Railway Company (Osaka)

Objectives / Interrogation: Background
We need to keep non-tuberculous mycobacteria for recurrent flexor tendon tenosynovitis with poor inflammatory findings in mind. Mycobacterium haemophilum (M. haemophilum) belongs to the group of non-tuberculous mycobacteria and is rarely reported as a cause of upper extremity and hand infections. Now we report surgical treatment for flexor tendon tenosynovitis due to M. haemophilum.

Methods: Case
A 73-year-old female patient was admitted with chronic flexor tendon synovitis of the left middle finger. She had a history of living renal transplantation and oral administration of immunosuppressant. Three debridements were carried out and wound swabs were taken. In the initial surgery of middle finger, acid-fast bacteria was found. As the swelling gradually appeared on the left thumb, second synovectomy for thumb were carried out and histologically a granulomatous infection with Langerhans cells was revealed. Mycobacterium haemophilum was identified by genetic examination. Medication was started with clarithromycin, rifampicin, moxifloxacin and rifabutin. Six months after second operation, synovitis of middle finger recurred. Third synovectomy was performed, and M. haemophilum was detected again.

Results and Conclusions: Discussion
M. haemophilum infection is very rare. Although there are few reports of pulmonary lesions and skin lesions in immunocompromised patients, M. haemophilum is rarely reported as a cause of flexor tendon tenosynovitis. It is difficult to identify this bacteria by conventional method and standard therapeutic regimen is unknown. The multiple drug combination of acid-fast bacteria is used and the administration period tends to be long term.

Conclusion
We experienced recurrent cases of M. haemophilum of the flexor tendon. It is necessary to keep this bacteria in mind for recurrent flexor tendon tenosynovitis of immunocompromised patient.

Outcomes of Syndactyly Reconstruction using Hyaluronic Acid Matrix

List of authors:
Charles Goldfarb*1, Katherine Velickikv1, Lindley Wall2
1 Washington University School of Medicine, Shriners Hospital For Children, St Louis Childrens Hospital (Saint Louis)
2 Washington University School of Medicine, Shriners Hospital, Saint Louis Childrens Hospital (Saint Louis)

Objectives / Interrogation: Syndactyly reconstruction typically includes full thickness skin grafts for areas of skin deficit after finger separation. Skin grafting requires additional anesthesia time and has donor site morbidity. In 2014, Landi, et al reported favorable outcomes with the use of a hyaluronic acid (HA) scaffold for syndactyly reconstruction instead of skin grafts. The purpose of this investigation was to assess our objective outcomes with HA scaffold use in syndactyly reconstruction.

Methods: All patients who were treated for syndactyly reconstruction with HA scaffold at our institution from 2015-2017 who had at least 1 year follow-up were included. 23 webs in 16 patients were identified including 11 patients with congenital syndactyly, 3 with symbrachydactyly, and 2 with amniotic constriction band. Average age at surgery was 39 months. There were 7 female patients and 5 webs were revisions. All webs were assessed with blinded clinical photos by two congenital hand surgeons. Outcome measures included web creep assessment (range 0-4), Vancouver Scar Scale (0 normal) to characterize scar appearance and a Visual Analogue Scale (VAS) for appearance and satisfaction (range 0-10).

Results and Conclusions: Web creep averaged 0.4, with 15 webs having no creep. Vancouver Scar Scale averaged 1.25 including 19 webs had normal vascularity, 16 with normal pigmentation, 12 with normal pliability and 14 with a flat scar. VAS assessment of appearance was 9 on both surgeon and parent assessment (range 5-10) and VAS for satisfaction averaged 9 (range 7 - 10). There were no post-operative complications.

Conclusions
HA scaffold instead of skin grafts is a reasonable option in syndactyly reconstruction. Our heterogeneous population revealed satisfactory outcomes for both surgeons and families. While no post-operative complications were noted, the maximum deficit able to be covered has not yet been determined.

Age, pathogenesis and the period from onset to surgery significantly affects the severity of cubital tunnel syndrome

List of authors:
Takao Omura*, Takashi Ogawa1, Kaori Sugiura1, Ryo Okabayashi1, Michihito Miyagi2, Tomokazu Sawada3, Hiroaki Ogihara4, Yukihiro Matsuyama1
1 Hamamatsu University School of Medicine (Hamamatsu)
2 Shizuoka Cancer Center (Nagaizumi)
3 Shizuoka City, Shizuoka Hospital (Shizuoka)
4 Hamamatsu Red Cross Hospital (Hamamatsu)

Objectives / Interrogation: Cubital tunnel syndrome (CuTS) is symptomatic ulnar nerve dysfunction at the level of the elbow resulting from a combination of compression, traction, and friction. McGowan's classification is most frequently used to define the severity of CuTS. There are several causes of CuTS including osteoarthritis (OA) of the elbow, valgus of varus deformity after elbow fractures, subluxation of the ulnar nerve and constriction at arcuate ligament of Osborne. The severity of the CuTS is diverse due to the different causes of CuTS. The purpose of this study is to identify the characteristics of patients operated for CuTS, based on their severity of CuTS.

Methods: 107 patients who were operated under the diagnosis of CuTS at a single institute were included in this study. Apart from clinical examination, all the patients were examined with electrophysiological testing and a plain radiograph of the elbow. The analysis of the characteristics of CuTS included the cause of CuTS based on the operative findings, age, gender, time from onset to surgery. These factors were cross compared between different McGowan stages.

Results and Conclusions: According to McGowan's classification, 11 patients were classified as grade I, 59 patients were classified as grade II and 37 were as grade III. The average age of the patients was significantly younger in grade I (47.7±4.3) in comparison with grade II (60.8±1.7) and III(63.3±2.0). As for the causes of CuTS, 45% was due to subluxation of the ulnar nerve and 18% was due to OA in grade I, whereas in grade II, OA was significantly higher in grade II followed by deformity after elbow fracture (11.9%). In grade III, the prevalence of OA also was also significantly higher (83.8%), followed by deformity after fracture (10.8%). The period from onset was significantly longer in patients with grade III (10.1 months) in comparison with grade I (6.7months) and II (6.1).

Our result revealed that patients going under surgery at McGowan stage I are significantly younger and have less incidence of osteoarthritis. Although here is no significant difference in age and cause of CuTS between grade II and II patients, the period from onset to surgery is significantly longer in grade III patients. We conclude that age, pathogenesis and the period from onset to surgery significantly affects the severity of cubital tunnel syndrome.

Anatomic Study of the Endoscopic Carpal Tunnel release

List of authors:
Jorge Quintero*
1Kleinert Kutz Institute (louisville)

Objectives / Interrogation: Our hypothesis is to define the relationship between vulnerable anatomic structures and knife edge of the instrument (Arthrex) in a cadaveric study. Vulnerable structures (ulnar artery, ulnar nerve, digital nerve 3rd and 4th web space, flexor tendons) will be within 10 mm of the knife edge when performing a ECTR using the Arthrex instrument in more than 50% of cadaveric specimens.

Methods: 18 specimens, 44% male, and 50% RHD and 50% LHD, ). The distance between the knife and the nerve for the 3rd web space showed the average distance when in neutral position 2.88 ± 2.18 mm increased to 4.22 ± 3.19 mm when the hand was in extension. When comparing the tip of the instrument to the nerve to the 4th web space, the distance averaged 5.1 ±1.88 mm when the hand was in neutral position, and increased to an average of 6.5 ±1.89 mm when the hand was in extension. The percentage of specimens with structures within 10 mm of the knife edge was statistically higher than expected 50% of specimens for the ulnar artery (P=0.027), the nerve for the 3rd web space (p=0.031) and the nerve to the 4th web space (p=0.039), as well as both in extension (p=0.039), as determined by Fisher’s exact test. An average of 2.6 passes of the knife to completely release the transverse ligament was documented.

Results and Conclusions: In conclusion, the data supported our hypothesis that in the majority of specimens the ulnar artery, commons digital nerves and are all less, and in many cases much less, than 10 mm from the knife edge of the instrument during a carpal tunnel release procedure. A relationship between the flexor tendons and the knife edge was not observed. In wrist extension, the distance from the tip of the knife to the common digital nerve for the 3rd and 4th web space increases, but is still less than 10 mm.

The distally based and free microvascular interosseous anterior flap in the treatment of hand injuries. Our experience.

List of authors:
Elmar Fritsche, Elvira Bodmer, Urs Hug
1 Klinik für Hand- und Plastische Chirurgie (Luzern)

Objectives / Interrogation: In contrast to the distally based and free interosseous posterior flap, the interosseous anterior flap is not very often used. We strongly believe, that this flap should be more often be considered as an ideal flap in the treatment of hand- and especially of finger injuries. The anatomical basis is very constant and the harvesting of the flap, pedicled or free, is easy and straightforward.

Methods: We used the interosseous anterior flap in its pedicled and microvascular variant in 12 cases of hand- and finger injuries. The free microvascular flap was used in 3 cases as a through-flow flap for revascularization and soft tissue reconstruction. In the literature we find hardly no description of the interosseous anterior flap in clinical use for this purpose. We want to show the exact anatomical basis and our clinical experience with this flap.

Results and Conclusions: 11 of our 12 interosseous anterior flaps survived completely. In 1 case we lost one distally pedicled flap. In one case the revascularisation of a thumb was not successful but the flap survived and could be used for covering the amputation stump. We believe that this flap has many advantages and is ideal for revascularisation of severely damaged fingers. This flap is our first choice for harvesting a through-flow flap for finger revascularisation and should be used more often than in the literature mentioned so far.

Mallet finger Treatment with temporal finger arthrodesis

List of authors:
Luis Naquira¹, Juan Ramirez¹, Mariana Perez¹
¹Universidad Ces (Medellín)

Objectives / Interrogation: The mallet finger is a common traumatic disease, can be open or closed injury. The closed injuries can be treated without surgery, but the patient has to use a splint, this kind of treatment is so many times uncomfortable for the patients, and let the patients don't follow and fail this. In our clinic for the closed mallet finger use a temporary transarticular k wire, lock the distal interphalangeal joint and the wire is left under the skin, and the patient doesn't have to use a splint, go back to work in 2 days, and take out the k wire in 8 weeks. This study is for review the functional and clinical outcomes of this technique, and review complications.

Methods: All the patients were examined by a medical doctor, different of the hand surgeon, who performed the surgery, all patient was check the range of motion of the finger, and the pain, and also the days to return to work and describe complications.

Results and Conclusions: The study find 60 patients, only 2 patients lost, 58 was examined, the average lag of extension was 6º (5-12), the pain was 1 (0-3), return to work was 3 days (1-8), we find our results can be compared with other treatments, and our technique can be useful for patients who wants to come back to work, and can be more comfortable for the patients this technique.

Dupuytren’s contracture: Long term results after treatment with excision of the contracted palmar fascia

List of authors:
Ioannis Antoniou*, Efstratios Athanaselis¹, Nikolaos Stefanou¹, Ioannis Maniotis¹, Zoe Dailiana¹, Konstantinos Malizos¹, Sokratis Varitimidis¹

¹ Orthopaedic Dpt, University Hospital of Larissa (Larissa)

Objectives / Interrogation: Operative treatment for Dupuytren’s contracture includes percutaneous division, partial excision or total excision of the palmar fascia. The aim of this study is to present complications and the long term outcome in a large group of patients in whom the disease was treated with resection of the contracted palmar fascia, only in the affected rays.

Methods: From 2000 to 2016, 234 patients with Dupuytren’s contracture were treated with excision of the contracted palmar fascia in the affected rays. Mean age was 68 years (from 37 to 86). The dominant hand was affected in 146 patients. The ring finger was most commonly affected (149 patients). Ninety eight patients presented with two or more finger rays affected. The procedure was performed with axillary block and with a tourniquet application. All diseased tissues (contracted fascia, skin, digital ligaments) were dissected and excised. Excision of the contracted tissues at the proximal phalanx was carried out to restore or improve range of motion. Check rein ligaments in the PIP joint were divided if there was stiffness of the joint. When skin was infiltrated by the disease, it was removed and the wound was left open to close by secondary intention. Non diseased palmar fascia of the adjacent finger rays was not excised.

Results and Conclusions: Mean postoperative follow up was 10 years (from 2 to 16). Preoperatively, average extension deficit in the MCP and PIP joint was 38 and 32 degrees respectively. Postoperative values at the final follow up were 10 degrees in both joints presenting improvement of 28 and 22 degrees. Complications occurred in 61 patients (26%) and included 16 recurrences, 15 patients with complex regional pain syndrome, 1 amputation of the distal phalanx of the finger, 3 arthrodeses, 7 infections, 5 injuries of digital nerves that needed immediate repair, 7 sensory neuroapraxias that resolved after 6 months and 7 patients with cold intolerance which resolved at two years postoperatively. Excision of the affected-contracted palmar fascia is effective in the treatment of Dupuytren's contracture. Although it is technically demanding in the advanced stages, it remains the most effective type of treatment in these late stages. Complications (early and late) are frequent with the most serious being a digital nerve injury, infection, complex regional pain syndrome and recurrence of the disease. Early complications need immediate and appropriate treatment for a satisfactory outcome.

Reconstruction of fingertip injuries using the homodigital island flap

List of authors:
Efstratios Athanaselis*¹, Vasileios Kontogeorgakos², Ioannis Antoniou¹, Dimitrios Deligeorgis¹, Zoe Dailiana¹, Konstantinos Malizos¹, Sokratis Varitimidis¹
¹ Orthopaedic Dpt, University Hospital of Larissa (Larissa)
² Orthopaedic Dpt, University Hospital of Athens “Attikon” (Haidari Attikis)

Objectives / Interrogation: Amputation of the fingertip with loss of the pulp, exposed bone and nail bed injury is a common problem, not infrequently neglected. Fingertip reconstruction requires new pulp glabrous skin coverage with sensitivity buttressed by the nail. Traditional management techniques may leave a much shorter hypersensitive stump, with joint stiffness, cold intolerance and prolonged disability. The aim of this study is the analysis of our experience from the use of homodigital island flap for the reconstruction of amputated fingertips.

Methods: The homodigital island flap was applied in 52 patients (65 fingers), at every level of finger amputation with special indication on fingertip coverage. The procedure was carried out under axillary or wrist block using magnifying loupes. For the index and the middle fingers, use of the ulnar bundle is preferred. For the thumb, ring and little finger use of the radial neurovascular bundle is used. The neurovascular bundle is well dissected from the flap to the base of the finger. After suturing of the flap the donor area is covered with split thickness graft from the hypothenar. The finger is mobilized one week after the procedure.

Results and Conclusions: Follow up ranged from 14 to 94 months (mean 46 months). Postoperatively, range of motion was normal in 50 fingers, 8 fingers had 10 degrees loss of extension at the DIP joint and 7 fingers had loss of motion between 10 and 20 degrees. Two-point discrimination was 4mm (from 3 to 10mm). Three patients had cold intolerance for 8 months. There was no neuroma or sensitive scar formation and no need for a second operation. According to patients cosmesis was acceptable to all fingers.

The use of homodigital island flap provides excellent functional reconstruction of the fingertips after a complex tissue loss in Allen II, III, and IV amputations. It is a straightforward operation that provides very satisfactory results.

Keywords:
homodigital island flap, fingertip amputation, Allen's classification, fingertip reconstruction, split thickness graft
A new non-invasive device in the treatment of severe finger contractures

List of authors:
Andreas Felix Klenner*, Krisztina Klenner
1 St. Barbara Clinics (Hamm)
2 Mariannen Hospital (Werl)

Objectives / Interrogation: Advanced Dupuytrens disease and other pathological conditions can lead to extreme contractures of fingers, which are technically hard to access by surgery. Thus, the effort and the chance of complications in operative treatment are increasing in relation to the level of contracture.

Hence preoperative treatment for those severe conditions, aiming to minimize extension deficit, is desirable.

In this concern, treatment is divided in invasive and non-invasive methods. Invasive treatment can be associated with severe complications and needs good compliance. Non-invasive, ready-to-use splints are useless for severe contractures. Only few technical devices and solutions are described in the literature, most of them are only available at one hospital and not on the European or global market.

We felt the necessity to obtain a non-invasive device, capable of mastering all desired requirements and linked with lowest drop out rate possible.

Methods: We developed a pneumatic splint, which addresses severe contractures of the fingers and is obtainable for everybody.
It is composed of a combination of a hard material splint, a steel frame clip and flexible materials. The splint has a hinge, which can be adjusted and fixed with a lever at any angle. The clip divides an air chamber, allowing to direct the expansion of the flexible materials in two different locations (thenar/hypothenar and fingers) from palmar to dorsal; the device is fixed at the dorsal side of the hand. The combination of the materials interact, thus realizing a stretching force to the fingers, according to the three-point support principle. The splint can be easily adapted and used with one hand and at both sides.

Results and Conclusions: The recently on the market available, innovative device is efficient particularly for the preoperative treatment of severe finger contractures, avoiding the disadvantages of invasive options. It is simple to use, variable and adaptive to even high grade contractures and thus effective, when other splints fail. The acting forces can be fine-tuned at any time and the splint therefore fulfills the need to act smoothly on the tissues. It provides patients with a magnitude of comfort, is very application friendly and highly accepted.

finger contracture, Dupuytrens, splint, extension treatment, pneumatic
The use of titanium miniature plates and screws for the treatment of intra and extra-articular fractures of the hand

List of authors:
Ioannis Antoniou*, Efstratios Athanaselis, Fotios Papageorgiou, Dimitrios Agorastakis, Zoe Dailiana, Konstantinos Malizos, Sokratis Varitimidis
1 Orthopaedic Dpt, University Hospital of Larissa (Larissa)

Objectives / Interrogation: Operative treatment of hand fractures is reserved for unstable, irreducible, comminuted, intraarticular, and open fractures. The aim of this study was to evaluate the outcome of hand fractures treated with titanium, low profile plate and screws.

Methods: 90 patients with 114 hand fractures were treated with titanium mini plates and screws. 46 phalangeal and 68 metacarpal fractures were included. Mean age of the patients was 36 years (from 11 to 75). The dominant hand was injured in 50 patients (55%).
114 fractures involved 113 rays. 32 were open, 27 were intra-articular and 12 were both open and intra-articular. 23 fractures involved combined injuries with damage to tendons or neurovascular bundles.
Fractures were fixed after a mean of 2.9 days (range, 0-28) from injury. Regional anaesthesia was utilized in 85 patients and general anaesthesia in 5 patients. Combined plates and screws were used in 85 fractures, while only screws were used in the remaining 29 fractures. Fixation with screws was selected for condylar or intra-articular fractures, and for long oblique or spiral diaphyseal fractures.

Results and Conclusions: Mean follow-up was 39 months (from 30 to 57). Apart from one case, all fractures were successfully fixed. Grip strength was measured as high as 89% compared to the uninjured hand even in patients of intra-articular fractures. Open intra-articular fractures had the least favorable outcome (67% of the contralateral hand).Regarding tip pinch, open intra-articular fractures had the least favorable outcome (68% of the contralateral pinch strength). DASH score was 8.7 in the intra-articular group and reached 15.6 in the open intra-articular group. Finally, pain measured with the Visual Analog Scale reached a maximum of 2.3 in all groups, except for open intra-articular fracture, which demonstrated a mean of 3.2. There was no statistically significant difference in grip strength (p= 0.25) or Total Active Motion (p= 0.849) between extra and intra-articular fractures. TAM and grip strength were statistically different between open and closed fractures (p= 0.001 and p= 0.013 respectively).

Low profile plates and screws can be used successfully to establish union and restore alignment of the hand skeleton while achieving satisfactory clinical outcome. Factors that influenced the final outcome included the severity of the initial injury and not the anatomic location (intra or extra-articular, metacarpal or phalangeal) of the fracture.

hand fracture, intra-articular comminuted fracture, mini plates fixation
An analysis of patient’s and disease related factors predictive of the outcomes of surgery for carpal tunnel syndrome

List of authors:
Andrzej Zyluk*, Paulina Zyluk-Gadowska¹, Zbigniew Szlosser¹
¹ Pomeranian Medical University (Szczecin)

Objectives / Interrogation: Outcomes of surgery for carpal tunnel syndrome may differ in relation to certain factors like age, duration of symptoms, clinical and electrophysiological severity. The objective of this study was an investigation into the hypothesis that several factors are predictive of results of surgical treatment of the condition.

Methods: The pre- and postoperative records of 1,117 patients: 909 women (81%) and 208 men (19%) with a mean age of 63 years were analysed. The whole group was divided into subgroups, depending on the variables analysed: sex, age, duration of symptoms, clinical and electrophysiological severity of and presence of comorbidities. The effect of these variables on outcomes of surgery at 6 months was investigated by univariate and multivariate analysis.

Results and Conclusions: None of the considered variables had a substantial impact on the results of carpal tunnel release which were sufficiently satisfactory at any circumstances. Slightly poorer outcomes in grip strength were observed in elderly patients, with clinically severest condition and with concomitant comorbidities.

Keywords:
carpal tunnel syndrome; outcome measures; multivariate analysis
An analysis of the course of carpal tunnel syndrome before operation

List of authors:
Piotr Puchalski*, Andrzej Zyluk
1 Pomeranian Medical University (Szczecin)

Objectives / Interrogation: The natural history of carpal tunnel syndrome (course of untreated disease) is not well recognised. Older studies suggested that CTS progressed in time leading to median nerve compromise and subsequent loss of sensation, muscle weakness and functional impairment. However, more recent literature shows that a proportion of patients who were scheduled for surgery, cancelled it due to significant clinical improvement or permanent spontaneous recovery.

Methods: This work reports the results of an analysis into the course of carpal tunnel syndrome before operation in 479 patients, predominantly women, aged a mean of 58 years, who were scheduled for carpal tunnel operation. The patients were asked to characterise in detail the course of the disease and what determined the decision to undergo surgery.

Results and Conclusions: We identified two specific patterns of CTS course: progressive and preservative/mild. Patients with short-lasting disease suffer first of all from symptoms, but the longer the duration, the more pronounced the functional impairment. In a proportion of patients with longer-lasting disease, spontaneous resolution may occur, for up to a year or more. Bilateral involvement is more common than unilateral and the interval between involvement of the other hand is a mean of 10 months. For most patients the primary motivation to undergo surgery is troublesome symptoms (pain and paraesthesia). Functional impairment is of secondary importance, however, its prominence increases in older patients and in those with longer-lasting disease.

Keywords: Carpal tunnel syndrome, Natural history, Clinical course
Familial occurrence of carpal tunnel syndrome

List of authors:
Andrzej Zyluk*, Piotr Puchalski
1 Pomeranian Medical University (Szczecin)

Objectives / Interrogation: The controversy has been considerable regarding the incidence of familial occurrence of carpal tunnel syndrome. Single families have been reported where the most of members have been affected and the results of some population-based studies showed a higher incidence of the condition among relatives of some patients. The objective of this study was to investigate the incidence of familial carpal tunnel syndrome in patients admitted to the authors' institution for carpal tunnel release.

Methods: Questionnaires completed at baseline clinical examination by 120 patients with CTS admitted to the authors' institution between December 2017 and March 2018 (4 months) were reviewed. Informed consent was obtained from all subjects before enrolment. There were 92 women (77%) and 28 men (23%) at a mean age of 56 years (range 33-84). Basic demographic and clinical information was recorded in the questionnaire. All participants were then asked whether they knew of one or more family members with carpal tunnel syndrome. In the event of a positive answer, patients were asked to indicate who of the relatives were affected, when the disease was diagnosed, which hand was involved and how they were treated.

Results and Conclusions: Familial occurrence of the disease was noted in 21 patients (17%): 16 women and 5 men. Three family members were affected in 3 patients, two relatives in 8 patients and one relative in 10 patients, giving a total of 35 affected relatives. The patients' sisters (n=16) were the most commonly involved, followed by mothers (n=12), daughters (n=2), brothers (n=2), grandmothers (n=2) and an aunt (n=1). Bilateral manifestation of the disease was noted in 19 patients (90%) and in 31 (88%) of their affected relatives. The results suggest that carpal tunnel syndrome shows moderate tendency to familial occurrence and if so, it usually manifests bilaterally.

carpal tunnel syndrome; familial occurrence; genetical predispositions
Late outcomes after hand replantation

List of authors:
Andrzej Zyluk*, Ada Owczarska

1 Pomeranian Medical University (Szczecin)

Objectives / Interrogation: The objective of this study was evaluation of functional outcomes in patients whose underwent successful replantation of amputated hands in author's institution at least 4 years before.

Methods: 54 patients who underwent successful replantation of amputated hands or fingers were identified. These patients were mailed a set of questionnaires asking for hand function (DASH questionnaire), quality of life (SF-36), cold intolerance and return to work. 22 completed questionnaires returned (response rate 41%) and these data was a subject of the analysis. This group comprises also 5 patients who were examined directly in the hospital. The group consisted of 22 patients, 20 men and 2 women, in a mean age of 43 years (range 20-82), who had performed hand or fingers replantation a mean of 6.5 years before the assessment (range 5-7). The most patients had amputation of the metacarpus (n=9), followed by fingers II-V (n=8), wrist (n=2), thumb (n=2) and forearm (n=1). The cause of amputation was circular saw in 15 cases (68%) followed by industrial or agriculture machinery.

Results and Conclusions: A mean DASH score for a whole group was 23 (range 2-74) what shown for an average mild dysfunction of the replanted hands. Ten patients (45%) regained very good function (DASH< 20), seven (32%) showed mild dysfunction (DASH 21-40) and five had greater disability (DASH >40). The patients following wrist and thumb replantation showed the best functional outcomes (DASH 4), less favorable had patients after finger II-V replantation (DASH 16) and the poorest showed patients after metacarpus and forearm replantation (DASH 33). The mean score in physical subscale of the SF-36 questionnaire was 61, indicating good quality of life. For mental SF-36 subscale the mean score was 58 indicating moderate quality of life. Twenty patients complained of troublesome symptoms of cold intolerance. Twelve patients (54%) returned to previously performed work.

Conclusion. Results of this study show that most patients regained good function of replanted hands allowing them good functioning in a daily life and return to work in proportion of them.

Successful treatment of paediatric lower limb CRPS by continuous epidural anaesthesia: a report of 2 cases

List of authors:
Andrzej Zyluk*
1 Pomeranian Medical University (Szczecin)

Objectives / Interrogation: CRPS occurs in children less frequently than in adults, but in the last two decades it has become a well-established entity in children and adolescents. The symptomatology, course, responsiveness to treatment and prognosis of the paediatric disease is also different from the "adult" form.

Methods: The paper presents the successful treatment of two cases of paediatric CRPS involving the lower limb, by continuous epidural anaesthesia with bupivacaine. Both patients developed the condition after minor trauma or overuse. CRPS diagnosis was based on clinical grounds. Both patients presented a history of psychological distress, due to familial problems.

Results and Conclusions: In one patient, the initial treatment was lumbar sympathetic block, resulting in immediate and complete recovery. After relapse of the disease at four months, the next intervention included continuous epidural infusion of bupivacaine, with an excellent and rapid response. In the 2nd case, continuous epidural infusion was used primarily with the same, excellent and fast result.
Clinical peculiarities, treatment modalities and other aspects of paediatric CRPS are discussed. Poor awareness of the condition in the paediatric community is emphasized.

Keywords: complex regional pain syndrome; epidural anaesthesia; psychological distress
Three-year (2014-2016) activity report of the Replantation Service for hand amputations in a Mid-European country

List of authors:
Andrzej Zyluk*, Jerzy Jablecki, Anna Chrapusta, Leszek Romanowski, Tomasz Mazurek
1 Pomeranian Medical University (Szczecin)
2 Department of general Surgery and Limb Replantation (Trzebnica)
3 Department of Burns and Plastic Surgery (Krakow)
4 medical University in Poznan (Poznan)
5 Medical University in Gdansk (Gdansk)

Objectives / Interrogation: The paper summarises 32 months (January 2014 - August 2016) of activity of the Replantation Service for hand amputation in a Mid-European country.

Methods: Questionnaires were analysed received form 6 institutions, members of the National Replantation Service. Over the period of 32 months (January 2014 - August 2016) a total of 354 cases of amputations and other complex injuries to the hand were treated. There were 167 total (47%) and 142 subtotal (40%) amputations; 45 patients (13%) had other severe hand injuries. Vast majority of the patients constituted males aged a mean of 39 years. The most common injury was amputation of several digits in one patient, and thumb amputation - a total of 229 cases (65%), followed by transmetacarpal and wrist amputations - 92 (30%) and forearm/arm amputations - 33 cases (9%).

Results and Conclusions: Replantation of amputated extremity was performed in 141 patients (40%), revascularization in 145 (41%) and in 29 (8%) primary repair of the complex injuries. In 27 cases (8%), a coverage of the tissue defects, and in 12 (3%) primary terminalization was performed. Survival rate was of 78% for replantations and revascularizations. Comparing to the period 2010-2012, an increase in number of treated patients (of n=64 cases), in number of amputations (of 96 cases) and in number of amputated digits (of 88 cases) were noted. The activity report shows importance of Replantation Service, an informal structure, in saving limbs of severely mutilated patients.

DORSAL CAPSULOPLASTY FOR POST-TRAUMATIC INSTABILITY OF THE DISTAL RADIOULNAR JOINT

List of authors:
Bernardo Couto Neto*1
1 UERJ (Rio de Janeiro State University) (Rio de Janeiro)

Objectives / Interrogation: Analyze the functional and subjective outcome of patients with posttraumatic Distal Radioulnar Joint (DRUJ) instability treated with dorsal Capsuloplasty.

Methods: We have re-examined 8 patients with chronic posttraumatic instability of the DRUJ who have been operated with a Dorsal Capsuloplasty and reinsertion of the Triangular Fibrocartilage. Their ages varied between 23 and 57, with an average of 42. The duration of the symptoms before surgery varied from 2 to 18 months. Only patients with at least 1 year after surgery were included. We have assessed subjective issues like pain, instability and satisfaction. In the objective assessment we carried out the physical examination of the wrist and potential complications from the surgery.

Results and Conclusions:
All of the patients reported relieve from the pain. Three patients reported local pain for a few months after immobilization and 4 patients reported paresthesia in the dorso-ulnar region of the hand. However, in every case, the symptoms improved before the re-examination for this study, in which all of the patients examined were operated more than 1 year before. In all of the patients the range of the pronosupination motion was normal, although 3 of them have noted that the region of the head of the Ulna was still a bit more protuberant when compared with the contralateral side. Nevertheless, these patients had no complaints. They have all reported not having the previous instability symptoms anymore and have resumed the activities they performed before the trauma, and also, they have all mentioned being satisfied with the treatment. Four patients are high level amateur tennis players that are satisfied with being back to their sport activity.

Conclusion:
The Capsuloplasty of the DRUJ for chronic instability of such articulation is an efficient surgical procedure with few complications.

Outcomes after scaphoid excision and midcarpal arthrodesis for SNAC and SLAC wrist arthritis

List of authors:
Andrzej Zyluk*, Zbigniew Szlosser
1 Pomeranian Medical University (Szczecin)

Objectives / Interrogation: Persistent, long-lasting pseudoarthrosis of the scaphoid or scapholunate dissociation results in arthrosis of the radio-scaphoid joint called "scaphoid nonunion advanced collapse, SNAC" or scapholunate advanced collapse, SLAC", which cause pain, reduction of movement of the wrist and weakness of the hand grip. Scaphoid resection followed by midcarpal "four-corner" arthrodesis is a recognized method of management of this condition. The objective of this study was assessment of long-term outcomes of this technique employed in patients with SNAC and SLAC wrist arthrosis.

Methods: The results of the treatment of 27 patients, 26 men and one woman with SNAC (n=15) and SLAC (n=12) wrist arthritis at a mean of 4 (range 2-8) years after the operation were assessed. The outcome measurements included pain intensity in numeric rating scale, NRS, wrist range of motion, total grip strength, and function of the hand with DASH and Mayo questionnaires.

Results and Conclusions: A mean pain score at wrist movements in numeric scale was 3.6 (range 1-5). A mean wrist active range of movement was (affected vs healthy hand) was: flexion 27O vs 58O (46%), extension 27O vs 52O (53%), ulnar deviation 16O vs 26O (62%), radial deviation 9O vs 17O (53%), total grip strength 22 kG vs 29 kG (76%), DASH scores a mean of 22 (range 4-36) and Mayo scores a mean of 72 (range 65-80). None of the patients required revision surgery. Of the 16 patients employed prior to operation 10 returned to work after a mean of 4 months sick-leave.

Conclusion. The resection of degenerated scaphoid bone followed by midcarpal arthrodesis is an effective treatment of SNAC and SLAC wrist arthrosis, resulting in pain cessation and improvement of hand dexterity, at the cost of mild reduction of wrist movements.

Percutaneous K-wires vs palmar-locking-plate fixation for distal radial fractures: a comparison of the outcomes of two methods used according to the accepted guidelines.

List of authors:
Andrzej Zyluk*, Piotr Janowski¹, Zbigniew Szlosser¹
¹ Pomeranian Medical University (Szczecin)

Objectives / Interrogation: There are several options for the operative treatment of distal radial fractures, but the two most-common forms of surgical fixation are percutaneous K-wire and locking-plate fixation. Although the latter technique has attracted increasing popularity in recent years, the former is still useful for selected fractures. The objective of the study was a comparison of the outcomes of K-wire vs plate fixation for distal radial fractures used according to the proposed institutional algorithm. Fracture configurations A2, A3, B1, B2, C1 and some C2 were operated on with K-wire pinning, whereas B3 and some B2, C3 and some C2 were with locking palmar-plate fixation.

Methods: Four hundred and sixty-seven patients were non-randomly allocated for either K-wire (n=363) or palmar-plate (n=104) fixation. The results were assessed at 3 and 12 months by the same outcome measures.

Results and Conclusions: No statistically significant differences were observed in any of the analysed variables: range of wrist motion, total grip strength, and DASH scores at the final assessment. Statistically significant differences were noted in radiological measures of the palmar tilt (0° vs -5°) and the ulnar variance (0.3 vs 1.4 mm), both favouring the plate-fixation method. Although K-wire fixation provides suboptimal stability and does not guarantee the maintaining of the reduction, it can be effective for selected fracture configurations, which constitute at least 2/3 of their total number. We concluded that being guided by the postulated algorithm in the choice of treatment for distal radial fractures struck a reasonable balance between clinical- and cost-effectiveness.

distal radial fractures; K-wire fixation; outcome measures
Outcome of partial excision arthroplasty of fifth carpometacarpal joint

List of authors:
Michelle Spiteri*
1 Nuffield Orthopaedic Centre (Oxford)

Objectives / Interrogation: Comminuted intra-articular fractures of the base of the fifth metacarpal without carpometacarpal joint dislocation are relatively common injuries. A small proportion of these injuries develop displacement of a bony fragment due to the pull of extensor carpi ulnaris tendon resulting in an intra-articular step, subsequently remaining symptomatic, with pain, weak grip and subsequent inability to return to their previous level of activity at work.

To assess outcome and function in patients who underwent partial excision arthroplasty of the fifth carpometacarpal joint (CMC) with excision of this bone fragment and interposition of a distally based capsular flap.

Methods: Ten patients were identified prospectively. Wrist range of motion and grip strength were assessed pre-operatively, and at six weeks, six months and one year post-operatively. Pre and post-operative pain visual analogue score (VAS), post-operative patient evaluation measure (PEM) score, and return to work were also assessed.

Results and Conclusions: All patients had delayed presentations, between four and six weeks following injury, and involved the dominant hand. Seven were manual workers, three were military personnel. None had fifth CMC joint dislocation or other injuries on computed tomography scan. Wrist dorsiflexion and ulnar deviation were decreased pre-operatively due to pain and returned to normal when compared to the contralateral side within six weeks of surgery. Mean grip strength was 40% of the contralateral side pre-operatively and improved to 68% by six weeks post-operatively and 87% at six months. Mean pain VAS decreased from 8.4 to 3.4 at six weeks post-operative. Mean PEM score was 19.4 six months after surgery. All patients returned to their previous employment, and none required further surgery. There was no significant further improvement at one year and manual workers described discomfort after a full day at work, which they described as minimal when compared to pre-operative level of pain.

Partial excision arthroplasty of the displaced bone fragment to restore articular congruency of the fifth CMC joint and capsular interposition in cases of delayed presentation or fracture fragment displacement provides good pain relief and improved function allowing return to function and gainful employment.

Intramedullary fixation using artificial bone block for comminuted distal radius fractures suppresses the reduction loss after the surgery

List of authors:
Ryosuke Sato*, Syunji Nakano1, Naohito Hibino2, Masaru Nakamura1, Shinji Yoshioka1, Makoto Takeuchi1, Tadahiro Higuchi1, Yoshitaka Hamada3, Koichi Sairyo4
1 Tokushima municipal hospital (Tokushima)
2 Tokushima prefecture naruto hospital (Tokushima)
3 Kansai medical university kori hospital (Osaka)
4 Tokushima university hospital (Tokushima)

Objectives / Interrogation: On the past decade, volar locking plate has become the most popular technique in the treatment of distal radius fractures (DRFs). Rigid fixation using these plates allowed for early mobilization, restoring the wrist function. However, DRFs with cortical comminution at the palmar side makes it difficult to stabilize to anatomical alignment only volar locking plate and that treatment often require additional methods. The object of this study is to assess that surgical fixation using artificial bone block suppressed reduction loss after the surgery by investigating the change of postoperative anatomical alignment of the distal radius.

Methods: A total of 153 patients with the open reduction and internal fixation were seen in this series between March 2013 and June 2018. All patients underwent proximal-type volar locking plate (stellar 2, HOYA technosurgical). Patients were excluded if they underwent fixation using external fixator or distal-type volar locking plate. Of these, 15 patients were added to artificial bone blocks. 10 patients, who belong to the same AO/ASIF classification as artificial bone block used group, were treated without bone block and compared as control group.

Imaging data using preoperative and postoperative radiographs were examined for radial alignment including radial tilt (RT), volar tilt (VT) and ulnar variance (UV) from 0 to 3 months after surgery.

Statistical analysis was done using a student-T test or ANOVA.

Results and Conclusions: At the population of patients by AO/ASIF classification, A3 was one (3), C2 was four (2) and C3 was ten (5). In Postoperative alignment of the cases using artificial bone block, the mean of RT was 21.5° (21.5°), VT was 12.2° (11.1°) and UV was -0.7mm (0.1mm). In Postoperative reduction loss, the group with artificial bone block, RT was 0.6° (2.4°), VT was 1.3° (2.8°) and UV was 0.6mm (2.1mm). () showed control group.

In comminuted DRFs, especially palmar side comminution, those treatment still be challenging. This analysis indicates surgical fixation using artificial bone block is effective for preventing reduction loss after the surgery.

Sonographic diagnosis of closed pediatric finger injuries

**List of authors:**
Marcell Varga*1, Luca Tóth2, Sándor Pintér3
1 Péterfy Hospital, National Trauma Center (Budapest)
2 Péterfy Hospital, National Trauma Center (Budapest)
3 University of Szeged, Department of Traumatology (Szeged)

**Objectives / Interrogation:** Closed injuries of the fingers are very common in childhood. In the majority of cases, targeted two-planes X-rays can exclude or confirm the diagnosis of possible fractures. High frequency ultrasound can have a diagnostic value similar to X-ray. In our presentation we report the results of 200 point of care sonographic examinations.

**Methods:** We included children under the age of 14 with closed, 1-3 days old finger injuries. We excluded children with open physeal plates, open injuries or non-traumatic hand complaints. Sonographic examinations were carried out immediately after physical survey by two orthopaedic surgeons skilled in pediatric trauma and musculoskeletal ultrasound. Fingers were evaluated from four different standard longitudinal planes. A comparative picture from the unaffected side was also made. Ultrasound pictures were saved and analyzed. The examinations were carried out with a 20MHz frequency linear transducer. Standard two-planes x-rays were made immediately after physical and sonographic evaluations. Results of X-rays and sonography were compared.

**Results and Conclusions:** Between 2017 and 2018 we evaluated 200 children. We found 61 (30.5%) finger fractures out of 200 injuries by x-rays. Distribution of fractures diagnosed by X-rays was the following: 20 (10%) basal phalangeal avulsions, 6 (3%) distal phalangeal avulsions, 7 (3.5%) epiphyseolysis, 5 (2.5%) diaphyseal fractures, 21 (9%) torus fractures, 2 (1%) intraarticular displaced fractures. We did not detect any false negative sonographic result. We found five false positive sonographic cases. Regarding bony cortex disruptions we found the following results of ultrasound tests compared to X-ray examinations: sensitivity 1, specificity 0.96, positive predictive value 0.92, negative predictive value 1. Evaluation by examiners showed a minimal difference. Interobserver agreement was 95.08%, Cohen's kappa value: 0.88. In the case of negative sonographic findings X-rays may be omitted. In cases when the exact configuration of the fractures can be established by ultrasound the need for any X-rays should be considered. X-rays are indispensable with positive but uncertain sonographic findings. The use of the ultrasound can provide additional information of a particular injury. Point of care high frequency sonography can be a valuable addition in the diagnostics of pediatric finger injuries. The routine use and the accurately defined professional and legal background of the method are still the tasks of the future.

Scapholunate Ligament Reconstruction with Internal Brace Technique Provides Biomechanically Equivalent Fixation Compared to the Percutaneous Pin Fixation in a Cadaveric Model

List of authors:
Steven Orr*, Kyle Morse¹, Kate Meyers¹, Andrew Weiland¹
¹Hospital for Special Surgery (New York)

Objectives / Interrogation: To compare the in-vitro efficacy of a knotless suture anchor internal brace technique with the percutaneous pin fixation for wrist stabilization in the setting of scapholunate interosseous ligament injury (SLIL) injury.

Methods: 10 cadaveric forearm pairs were randomly assigned to two groups based upon repair techniques, either internal brace reconstruction or percutaneous pinning.
Internal Brace Technique

A) scapholunate interval widening following SLIL transection  
B) anatomic reduction  
C) internal brace fixation  
Radiographs demonstrating three-pin fixation:  
D) posteroanterior (PA) view  
E) lateral view

Figure 1 Images demonstrating internal brace: A) scapholunate interval widening following SLIL transection B) anatomic reduction C) internal brace fixation Radiographs demonstrating three-pin fixation: D) posteroanterior (PA) view E) lateral view

Three-pin Fixation Technique

The SLIL was transected utilizing a dorsal approach. A modified Henry approach was utilized to isolate the flexor tendons, which were secured with #5 Ethibond suture. Kirschner wires were placed in the lunate and scaphoid for use as joysticks to aid in
reduction, which was held with two transscaphoid, transtunate k-wires and one transscaphoid, transcapitate k-wire. In the internal brace group, an Arthrex Swivelock anchor with labral tape was first placed dorsally in the proximal pole of the scaphoid and then secured under tension to the dorsal aspect of the lunate using a second Swivelock anchor. The "V"-shaped construct was completed by bringing the labral tape back to the distal pole of the scaphoid and securing it under tension with a third Swivelock anchor dorsally. For the k-wire repair group, two k-wires were placed percutaneously spanning the scaphoid and lunate and a third was placed spanning the scaphoid and capitate. Retroreflective markers were attached to the distal radius, scaphoid, and lunate to track the 3D motions of each bone. The flexor tendons were loaded to 20lb at 1Hz for 300cycles to simulate physiologic gripping. The change in scapholunate gap (mm) and scapholunate angle (degrees) were calculated after completion of cyclic loading. Paired t-tests were used for statistical comparisons with a p-value < 0.05 considered to be statistically significant. All values reported as mean ± standard error.

**Results and Conclusions:** There was no difference in the increase of the scapholunate gap (0.51 ± 0.14 vs. 0.26 ± 0.18, p>0.05) or angle (0.97 ± 0.23 vs. 1.12 ± 0.33, p>0.05) between repair techniques. The use of an internal brace technique is biomechanically comparable to k-wire fixation in a cadaveric model.

Social Deprivation and Congenital Hand Anomalies - An assessment using PROMIS

List of authors:
Charles Goldfarb*, Lindley Wall, Donald Bae, Suzanne Steinmann, Julie Samora
1 Washington University School of Medicine, Shriners Hospital For Children, St Louis Childrens Hospital (Saint Louis)
2 Washington University School of Medicine, Shriners Hospital, Saint Louis Childrens Hospital (Saint Louis)
3 Boston Childrens Hospital, Harvard Medical School (Boston)
4 Seattle Childrens Hospital (Seattle)
5 Nationwide Childrens Hospital (Columbus)

Objectives / Interrogation: Social deprivation, a measure of socio-economic status, has been shown to negatively affect perceptions of orthopedic conditions and outcomes of treatment. The objective of this study was twofold to assess whether social deprivation would correlate with subjective assessment of function in pediatric patients with congenital hand anomalies.

Methods: All upper extremity (UE) anomalies in patients enrolled in the prospective Congenital Upper Limb Differences (CoULD) registry were classified and subjective function assessed using the Patient Reported Outcome Measurement Information System (PROMIS). PROMIS scores for pain interference, peer relations, anxiety, depression, and UE function were obtained for all patients 5 years and older at initial presentation. Social deprivation was determined by the Area Deprivation Index (ADI) through use of 9-digit zip codes; the index ranges from 0-100 with higher scores being the most deprived. PROMIS scores were correlated with the ADI for all patients.

Results and Conclusions: 375 pediatric patients with congenital UE differences were evaluated. Average age at inclusion was 11 years. 56% were female. 55% of patients had bilateral involvement. There were 247 extremities with a diagnosis of malformation of the entire limb and 261 had a hand plate malformation. 137 limbs had a diagnosis of dysplasia, 4 had a deformation, and 54 had an associated syndrome. Overall, PROMIS scores were within one standard deviation of normal for peer relations, pain, depression, and anxiety. However, PROMIS scores for UE function were more than one SD below the national average (50), both for parent (40) and child (38) scores.

The mean ADI for the cohort was lower than the national average, indicative of less deprivation, with only 14% of patients in the most deprived quartile. Parent PROMIS scores did not vary with ADI scores. In contrast, child reported PROMIS scores for pain, peer relations, and anxiety were statistically different between the highest and lowest quartile. Children with higher social deprivation reported higher pain interference, lower peer relations, and higher anxiety.

Conclusions:
1) PROMIS scores for UE function were one standard deviation below normal for all patients with congenital hand anomalies, but were normal for the psycho-social measures.
2) Child reported PROMIS for pain interference, peer relations, and anxiety scores were statistically worse in more socially deprived areas, suggesting more psychosocial challenges in these children.

Convergent Validity of PODCI and PROMIS domains in Congenital Upper Limb Anomalies

List of authors:
Charles Goldfarb*, Lindley Wall, Donald Bae, Carley Vuillermin, Patricia Miller
1 Washington University School of Medicine, Shriners Hospital For Children, St Louis Childrens Hospital (Saint Louis)
2 Washington University School of Medicine, Shriners Hospital, Saint Louis Childrens Hospital (Saint Louis)
3 Boston Childrens Hospital, Harvard Medical School (Boston)

Objectives / Interrogation: This study evaluates the patient reported functional and psychosocial impact of upper limb congenital anomalies in patients prior to surgical intervention utilizing the PODCI and PROMIS. We hypothesized that patients will have scores that are in the normal range. Secondarily we sought to assess the similarities between the PODCI subscales and PROMIS domains and hypothesize that the two outcomes measures will have strong convergent validity.

Methods: A multi-center prospectively collected database of congenital upper limb patients, the CoULD (Congenital Upper Limb Differences) registry, was utilized for this study. All patients with complete PODCI and PROMIS data prior to surgical intervention were included in this study. Demographic information was collected and all anomalies were classified by the Oberg-Manske-Tonkin (OMT) classification. Scores for PODCI subscales of UE function, pain/comfort, and happiness and PROMIS domain of UE function, pain, depression, anxiety, and peer relations were collected. Ceiling and floor effects were examined and convergent validity for PODCI and PROMIS domains were assess using Spearman’s correlation coefficients.

Results and Conclusions: 359 patients were included in the study. 241 patients had a diagnosis of malformation of the entire limb and 231 had a malformation of the hand plate. Four, patients had a diagnosis of deformation, 118 had a dysplasia, and 45 patients had a syndrome. Median PODCI and PROMIS scores are seen in Table 1.

There was no difference between the PODCI and PROMIS ceiling or floor effects for the upper extremity domains. The ceiling effect for the PROMIS pain domain (46%) was not different than the floor effect of the PODCI pain subscale and there was no difference seen between the floor effect of PODCI happiness and PROMIS depression domains. Convergent validity was achieved between the PROMIS and PODCI upper extremity domains (r = 0.82; 95% CI = 0.78 to 0.85; p<0.001), between the PROMIS pain domain and PODCI pain/comfort subscale (r = -0.60; 95% CI = -0.66 to -0.53; p<0.001), and between the PROMIS depression domain and PODCI happiness subscale (r = -0.53; 95% CI = -0.60 to -0.45; p<0.001).

Conclusion
For assessment of pediatric patient perceptions of congenital upper extremity anomalies, PROMIS domains for the upper extremity function, pain, and depression are comparable to PODCI domain scores. Consideration can be made for replacing the PODCI with the shorter and more widely utilized PROMIS questionnaire.

Radiographic remodeling of the proximal phalangeal head using a stretching exercise in patients with camptodactyly

List of authors:
Seok Woo Hong*, Jihyeung Kim, Hyun Sik Gong, Goo Hyun Baek
1 Ewha Womans University Hospital (Seoul)
2 Seoul National University Hospital (Seoul)
3 Seoul National University Bundang Hospital (Seongnam)

Objectives / Interrogation: The aims of this study were to verify the recovery of proximal phalangeal head after stretching exercise in patients with infantile type camptodactyly and to propose radiographic indices to quantify bony deformities.

Methods: Forty-eight fingers of 20 patients (9 males/11 females, mean age 14.2 ± 12.16 months, age range 1-35 months) with camptodactyly were selected and normal 163 fingers in 66 participants also included to estimate reference values of proposed indices. Patients with camptodactyly were younger than 36-month-old and had no other combined anomalies of the hand. The stretching exercise were instructed to all patients and their parents. The new radiographic parameters, head triangle ratio (HTR) and head angle (HA) were estimated on finger lateral radiographs taken at the initial visit and at the point of 12-month follow up. The extent of proximal interphalangeal joint (PIP) flexion contracture was evaluated to determine clinical outcomes from conservative treatment. The normal group comprised patients who visited our clinic with unilateral hand trauma to verify the reference values of HTA and HA accordance with finger types and age ranges.

Results and Conclusions: Two suggested radiographic parameters showed significant differences before and after intervention. The extent of PIP flexion contracture showed significant improvement. The HTA and HA had excellent validity and reliability. In the normal group, both parameters did not show significant differences accordance with finger types and age ranges. The stretching exercise could not only improve the motion of the proximal phalangeal joint but also have influence on recovery of congruency of proximal phalangeal head in patients with infantile type camptodactyly. The HTR and HA would be useful indices for objectifying the degree of bony deformities in patients with camptodactyly.

The Prevalence of the Linburg-Comstock anomaly in a Multiracial Population Sample.

List of authors:
Leonardo Barreto¹, CARLOS HENRIQUE FERNANDES¹, LUIS RENATO NAKACHIMA², JOAO BAPTISTA GOMES DOS SANTOS³, FLAVIO FALOPPA⁴
¹ Universidade Federal de São Paulo (Sao Paulo)

Objectives / Interrogation: The Linburg-Comstock (LC) anomaly is an anatomical variation characterized by the interconnection between the tendons of the thumb flexor and the deep flexor digitorum muscles. This interconnection is usually asymptomatic and as a consequence of its presence, the flexion of the thumb is accompanied by the simultaneous bending movement of the indicator alone or accompanied by the other long fingers. The prevalence of the Linburg-Comstock anomaly in a multiracial population sample is different from that reported in the literature.

Methods: We evaluated 1008 volunteers, 531 men and 477 women, totaling 2016 hands. The two clinical tests (Linburg and Comstock, 1979) were used for the clinical diagnosis of the anomalous tendon slips from the flexor pollicis longus to the flexor digitorum profundus. In the flexion test, the volunteer was asked to flex her thumb with a flat hand and supine forearm. When simultaneous flexion of one or more long fingers was observed, this was considered to indicate the presence of the anomaly (Image 1A). When the flexion test indicated presence of the anomaly a second test was performed. The volunteer was asked to flex her thumb while the examiner maintained passive extension of the index finger. If the participant reported pain or discomfort in the distal volar region of the forearm and wrist, this was considered symptomatic of an anomalous tendon slip (Image 1B).

Results and Conclusions: The mean age of the volunteers was 38.3 years (18–70 years). The Linburg-Comstock anomaly was observed in 564 individuals (52.63%), p=0.4377, being bilateral in 300 individuals (52.67%) and unilateral in 162 (28.72%), p=0.0016. In the male population, the prevalence was 291 individuals (54.80%) and in the female population, 273 individuals (57.23%), no statistical significance for gender. The pain test was positive in 105 (36.08%) of males and females in 150 (54.94%), p=0.0001.

**Prognostic factors for conservatively treated sagittal band injuries of the metacarpophalangeal joint**

**List of authors:**
Young Hak Roh1, Seok Woo Hong1
1 Ewha Womans University College of Medicine, Ewha Womans University Medical Center (Seoul)

**Objectives / Interrogation:** Most sagittal band injuries can be nonsurgically managed with relative motion extension splintage, especially in the acute setting, although optimal management of subacute and chronic sagittal band injuries remains controversial[1]. The aim of this study was to evaluate the factors that influence the prognoses for patients with sagittal band injuries who were treated conservatively.

**Methods:** A total of 94 patients who had been diagnosed with traumatic sagittal band injury and initially treated with 7 weeks of relative motion extension splintage (5 weeks of full time followed by 2 weeks of part time use, figure 1) were enrolled. The response to treatment, including finger range of motion (ROM), extensor tendon instability, grip strength, and functional outcome measured as Quick Disability of the Arm, Shoulder, and Hand score were assessed at 24-week follow-up. The factors that were assessed for their influence on the outcomes were age, sex, occupation, hand dominance, type of injury, injury severity, time to treatment, and the duration of splintage.

**Results and Conclusions:** After 24 weeks follow-up, 67 (71%) patients achieved resolution of symptomatic tendon translocation with 78% of grip strength and 90% of ROM compared to the un-affected hand, and final mean QuickDASH scores was 15. However, 27 (29%) patients had persistently symptomatic tendon subluxation and of those, 18 (19%) underwent surgical repair. There were significantly more manual laborers in the failure group than in the success group. Subjects in the treatment failure group were older, had longer symptom durations, and were more likely to have grade III injuries than were those in the success group. Multivariable analysis revealed that manual labor (Odds ratio [OR], 3.4), longer symptom duration (OR, 3.9), and grade III injury (OR, 2.4) were associated with a higher likelihood of conservative treatment failure for sagittal band injuries.

Comparison of conservative versus operative treatment of peripheral TFCC tear after acute distal radius fractures.

List of authors:
Tae-Min Kim*, Seoung-Joon Lee¹
¹Konkuk University School of Medicine (Seoul)

Objectives / Interrogation: This study was designed to compare the clinical outcomes and residual instability conservative and operative treatment of peripheral TFCC tear after acute distal radius fractures.

Methods: We reviewed retrospectively patients who treated with volar locking plate for distal radius fractures. We enrolled 39 patients suffering from the distal radius fracture with peripheral tear of TFCC that confirmed with arthroscopy. All distal radius fractures were fixed with a volar locking plate. 26 patients of them were conservatively treated with long arm splint (group A). 13 patients were operatively treated with TFCC repair (group B). We compared the clinical outcomes between the conservative and operative treatments, using their range of motion; Disabilities of the Arm, Shoulder, and Hand score; PRWE score; and grip strength. At final follow-up, we checked DRUJ stability with stress test and recorded the grade of DRUJ instability from 0 to 3.

Results and Conclusions: Results: There was no statistically significant difference in the DASH score, PRWE score, grip strength, and wrist range of motion between two group. At final follow-up, DRUJ stress test showed similar stability in both groups.

Conclusion: We think that the conservative treatment with long arm splinting will provide good clinical results without DRUJ instability.

Comparison of Clinical Outcomes after Ulnar Shortening Osteotomy for Ulnar Impaction Syndrome With or Without Arthroscopic Debridement

List of authors:
Young Hak Roh*1, Seok Woo Hong1
1 Ewha Womans University College of Medicine, Ewha Womans University Medical Center (Seoul)

Objectives / Interrogation: Only a few reports have compared the results of ulnar shortening osteotomy (USO) alone with those of combined arthroscopic debridement (AD) and USO. The purpose of this study was to compare the clinical outcomes after USO for UIS, either with or without concomitant arthroscopic TFCC debridement.

Methods: Forty-four patients who had been diagnosed with ulnar impaction syndrome and who were scheduled to undergo ulnar shortening osteotomy were randomized into two groups, one treated by ulnar shortening osteotomy alone and the other treated by ulnar shortening osteotomy combined with arthroscopic debridement. The response to treatment, including the pain numeric rating scale in an ulnar provocation test and the Disability of the Arm, Shoulder, and Hand score was assessed at 3 and 12 months after surgery.

Results and Conclusions: The mean pain and disability scores showed significant clinical improvement at the 12-month
follow-up in both groups. The pain scores at 3 months of follow-up were significantly better in the ulnar shortening osteotomy with arthroscopic debridement group. However, no significant differences were observed between the two groups in the disability scores at 3 and 12 months, or in the pain scores at 12 month follow-up. We conclude that similar improvements in symptom severity and hand function occurred in the long term in patients both with and without concomitant arthroscopic debridement. This information regarding concomitant arthroscopy could be used in the informed consent discussion with patients scheduled for ulnar shortening osteotomy.

Thumb and finger reconstruction using vascularized half-big toenail flap with minimum donor site morbidity

List of authors:
Katsuyasu FUKASAWA*1, Naoko Masuyama2, Ken Nishimura1
1 Kanto Rosai Hospital (Kawasaki City)
2 Tokyo Takanawa Hospital (Tokyo)

Objectives / Interrogation: The vascularized half-big toenail flap was originally developed by Kuroshima in 1990. This flap is a short-pedicled free vascularized flap of approximately 30 mm in size that contains a fibular half nail with a 5 mm skin edge and partial distal phalanx bone. The fingertip skin of the amputated finger is reflected to cover the skin deficiency. The sensation and function of the donor site are maintained, and primary wound closure of the donor site is possible. We herein report cases of thumb and finger reconstruction using this flap.

Methods: We assessed 16 patients (11 cases of single-digit amputation, 5 cases [8 digits] of multiple-digit amputation) who underwent this procedure among 108 (85 cases of single-digit amputation; 23 cases [47 digits] of multiple-digit amputation) who were indicated for reconstructive surgery between 2007 and 2017. We evaluated the following parameters: digits, amputated level, survival rate, elongated length, feeding artery, vein distribution, width and length of nails, longitudinal and axial convexity of nails before surgery/final follow-up and complications. We used the Mann-Whitney U test to evaluate the significance of differences.

Results and Conclusions: The reconstructed digits were three thumbs, five index fingers, five middle fingers and six ring fingers. The amputated levels were Tamai Zone II to IV. The flap survival was obtained in all cases, including one atrophic case. The elongated length was 14.1 mm (range, 0 to 30), including 4 cases of iliac bone graft. The feeding artery to the flap was the digital artery in 15 toes, anonymous artery in 3, and a branch of the digital artery in 1. We harvested the vein in the first web in 16 toes. The mean width and length and the longitudinal/axial convexity of the transferred nail before surgery and final follow-up were as follows: 8.0 to 9.2 mm (p<0.01), 14.2 to 11.7 mm (p<0.01), 10.8° to 23.1° (p<0.05) and 32.9° to 61.1° (p<0.01), respectively. Complications were partial necrosis of the skin graft and delayed wound healing of the donor site. Multiple-digit defects were more unacceptable to our patients than a single-digit defect, and they preferred cosmetic improvement to functional improvement. This flap restored the thumb's availability to grasp and made the middle finger longer than other fingers with no functional deficits at the donor site. Morphological adjustment of the transferred nail at surgery was unnecessary, as the donor site nail ultimately resembles the finger nail.

Comparison of ultrasound-guided versus blind corticosteroid injection for carpal tunnel syndrome: a prospective randomized trial

List of authors:
Young Hak Roh*, Seok Woo Hong

1 Ewha Womans University College of Medicine, Ewha Womans University Medical Center (Seoul)

Objectives / Interrogation: Although a local corticosteroid injection for carpal tunnel syndrome (CTS) is frequently performed by palpation using anatomic landmarks, ultrasound allows physicians to place the injectate closer to the median nerve without damaging the surrounding tissue, improving the efficacy of the injection. The aim of this study was to compare the effectiveness and complications of ultrasound (US)-guided steroid injections with blind injections for CTS.

Methods: A total of 102 patients with CTS were randomized into 2 groups: blind injection and US-guided injection. The response to treatment, including grip strength, perception of touch with a Semmes-Weinstein monofilament, and the Boston Carpal Tunnel Questionnaires (BCTQ) was assessed at baseline and at four, 12, and 24 weeks after the injection.

Results and Conclusions: The Boston symptom and function scores were similar in the two groups throughout the 24 week follow-up period, with the exception of significantly lower (better) Boston symptom scores at 4 week follow-up in the US-guided injection group than in the blind group. The grip strength and sensory index of Semmes-Weinstein monofilament were similar in...
the two groups throughout the 24 week follow-up period. After 24 weeks, 12 patients (24%) in the blind injection group and 9 patients (18%) in the US-guided injection group had undergone carpal tunnel surgery. With regard to adverse events, symptoms of median nerve irritation were more likely to occur in patients with blind injections than in those with US-guided injection (14% vs. 2%). US-guided steroid injection for CTS reduces steroid-associated complications, but produces similar pain and functional results to those of blind injection.

Acute Loge de Guyon Syndrome in distal forearm fracture - a case report

List of authors:
Daniel Sauter*, Joachim Ganser
1 Klinik für Orthopädie, Kantonsspital (Münsterlingen)
2 Klinik für Plastische und Handchirurgie, Kantonsspital (Münsterlingen)

Objectives / Interrogation: Nerve palsies after closed fractures of the upper arm and forearm are usually treated by expectation. A broadly recognized exception from this rule is acute carpal tunnel syndrome resulting from distal forearm fractures. In this setting, carpal tunnel syndrome is a special form of compartment syndrome and requires therefore the immediate surgical intervention to restore tissue perfusion, thus preventing muscle contracture and permanent nerve palsy. Hand surgeons even know the spontaneous acute entrapment of the median nerve without vascular disturbance of the hand. This atraumatic acute carpal tunnel syndrome requires urgent carpal tunnel release to prevent permanent median palsy. An acute compression of the ulnar nerve in Guyon's canal is not an established entity. But how should you manage a situation when a closed distal forearm fracture is complicated by an acute and complete distal ulnar nerve palsy?

Methods: A 9-year old boy sustained a closed, apex palmar angulated distal forearm fracture, 3 cm proximal the wrist joint. The immediate clinical evaluation registered a classical clawing of the ring and small fingers, a complete sensual loss of the small finger pulp and of the ulnar side of the ring finger pulp, and a partially impaired sensibility of the ulnar-sided dorsum of the hand. After closed reduction and percutaneous pinning of the distal radius and ulna, we revised the ulnar nerve, its dorsal branch, and the ulnar artery in the same operative session. We did not find any signs of injury except a compression mark of the ulnar nerve at the entrance of Guyon's canal. After incising 7 mm of the volar ligament, the entrapment was eliminated, putting aside a formal opening of the whole Loge de Guyon. Three hours after surgery, the ulnar nerve had completely recovered, the sensibility was completely reestablished, the clawing had gone. The whole case is pre-, intra- and postoperatively documented by photographs and x-ray pictures.

Results and Conclusions: Analogue to acute carpal syndrome, we recommend immediate ulnar nerve revision if a distal forearm fracture is complicated by an acute ulnar nerve entrapment. The entrapment at the entrance of Guyon's canal could otherwise cause a prolonged ulnar palsy. This risk justifies the relatively small operative effort even in the case of closed fracture treatment.

Annual trends in surgery for osteoarthritis of carpometacarpal joint of the thumb: Analysis of a national database in Japan

List of authors:
Kosuke Uehara*, Yutaka Morizaki, Takashi Ohe, Nobuaki Michihata, Hideo Yasunaga, Sakae Tanaka
1 Department of Orthopaedic Surgery, The University of Tokyo (Tokyo)
2 Department of Orthopaedic Surgery, NTT Medical Center Tokyo (Tokyo)
3 Department of Health Services Research, Graduate School of Medicine, The University of Tokyo (Tokyo)
4 Department of Clinical Epidemiology and Health Economics, Graduate School of Medicine, The University of Tokyo (Tokyo)

Objectives / Interrogation: There have been no reports to clarify annual trends in surgery for osteoarthritis (OA) of carpometacarpal (CMC) joint of the thumb. The aim of this study was to examine the annual numbers of surgeries related to the CMC joint of the thumb in Japan, using the Diagnosis Procedure Combination database, which is a nationally representative inpatient database of hospital information, discharge abstract, and administrative claims data, including about 55% of all acute-care inpatients in Japan.

Methods: For this study, we extracted data on a total of 2,210 patients who underwent arthroplasty (AP) (n=1,215) or arthrodesis (AD) (n=995) of the thumb CMC joint from July 2010 to March 2016. We examined patients' age, gender, accompanying bone graft, length of stay, total costs (in US dollars), year, and type of anesthesia.

Results and Conclusions: The average and standard deviation of age (years) in the AP and AD groups was 63.7 (10.4) and 63.7 (10.2) years, respectively. Males made up 17% and 31% of the AP and AD groups, respectively (P<0.001). Bone graft was accompanied in 12 (17%) patients in the AD group, and 398 (40%) patients in the AD group (P<0.001). The average length of stay was 11.5 days in the AP group and 10.9 days in the AD group (P<0.001). The average total cost was $5,760 in the AP group, and $6,090 in the AD group. The numbers of surgical patients each year in the AP/AD groups were 157/169, 242/200, 187/155, 221/186, and 264/202 in 2011, 2012, 2013, 2014 and 2015, respectively (P=0.023). General anesthesia was selected in 875 (72%) patients in the AP group, and 775 (79%) patients in the AD group (P=0.002). The AP/AD group ratio gradually increased year by year together with the spread of surgical techniques of arthroplasty. The ROAD study, a large population-based cohort study, revealed that about 50% of all adults, both male and female, had OA of the CMC joint of the thumb on the X ray imaging. This figure was comparable to those in OA of the hip or the knee. However, our study showed that the annual numbers of surgery for OA of CMC joint of the thumb was much smaller than those for total knee replacement or total hip replacement in Japan. This may be because (i) there are fewer recommendable surgical procedures for OA of CMC joint of the thumb than for the knee or the hip, and (ii) pain derived from pinch motion can be less severe than that from gait or getting up.

Revision of trapeziometacarpal prosthesis by replacement with another prosthesis: a report of 8 cases.

List of authors:
Gero Meyer zu Reckendorf*, Jean Claude Rouzaud

1 IMM, Clinique St Roch (Montpellier)

Objectives / Interrogation: Indications for total trapeziometacarpal (TTM) arthroplasty in the management of thumb basal joint arthritis are becoming more and more common. The trapezium in particular is exposed to complications such as aseptic loosening or fracture. Loosening of TTM prosthesis generally leads to simple trapeziectomy. The aim of this study was to present our experience of revision of a failed TM prosthesis by replacing it with a new prosthetic implant.

Methods: Our study involved 8 cases of revision of Elektra metal-metal prosthesis with a 6.5mm impacted cup. Between 2012 and 2018, 8 patients (1 male, 7 female) with a mean age of 63 years (58-72) were operated on by the same surgeon for aseptic loosening of the prosthetic cup including 2 cases of trauma. The mean delay between the initial surgery and revision was 31.8 months (11-87). In all cases the bone scan showed a loosening of the trapezium implant. We found no fractures of the trapezium on the preoperative CT-scan. All cups were surgically revised with implantation of 1 cemented cup, 2 double mobility impacted cups with bone graft and 5 double mobility screwed cups (9 or 10mm) without bone graft. Complications consisted of 1 case of intra-operative fissuring of the trapezium which, however, did not prevent the implantation of a cup, and 1 early mobilization of an impacted cup, although this did not require surgical revision.

Results and Conclusions: At a mean follow-up of 37.3 months (9-73) no patients required reoperation. Residual pain on the VAS was 0.71 with a Quick-Dash score of 21.2. Mean pinch strength was 3.5kg and the key-grip was 4.25kg. Five patients "forgot" their prosthesis and these represented our best results. Radiographic evaluation showed signs of loosening of the cemented cup, but the clinical result remained excellent. No radiologic modifications were noted for the other implants. The particularity of this series was the revision of a small trapezium cup and the absence of preoperative fracture of the trapezium which conditioned preserving this bone. The surgical technique without a bone graft currently represents the preferred procedure during revision surgery of a total TM prosthesis with a conservable trapezium. Preoperative CT-scanning is important to measure the dimension of the loosening cavity of the trapezium which must not go beyond 10mm of diameter. In selected clinical cases, loosening of a total TM prosthesis can be revised by replacing it with another prosthesis leading to stable results at medium-term follow-up.

Direct coaptation in the microsurgical reconstruction of obstetric brachial plexus lesions

List of authors:
Jörg Bahm* 1
1 Franziskushospital (Aachen)

Objectives / Interrogation: Severe upper and total obstetric brachial plexus lesions must be explored and reconstructed within the first months of life. The frequently encountered non conducting neuroma in continuity are routinely excised and grafted by sural interposition fascicles. In specific cases, when the gap is around 1 cm and the mobilisation of the distal plexus is achievable, a direct coaptation of both the proximal and distal nerve stumps after histographic control is feasible- we present those cases among our patient series.

Methods: We performed direct intraplexic coaptations in 22 children between 2013 and 2016, involving 10 combined upper and middle trunk, 12 upper trunk (1 partial rupture). All patients were followed clinically and video documented.

Results and Conclusions: We observed good functional improvement in all cases, comparable to autologous grafts. Six months after surgery, active elbow flexion ranged between 60 and 90 degrees and active abduction was 75°, improving to 90° after 12 months and 124° after 18 months. In upper lesions treated by direct coaptation of the upper trunk, an additional spinal to suprascapular nerve transfer improves passive and active shoulder lateral rotation.

In selected cases with short gap after neuroma resection, the direct stump coaptation is feasible and appealing. Suture tension is reduced by special 6/0 sutures and a more adducted- elbow flexed limb position and immobilisation. Clear advantages are the missing need for sural nerve harvest and the coaptation of thick, fiber rich nerve stumps of good regenerative capacity. Potential drawbacks are the risk of suture rupture and intraneural fibrosis ; also do we observe some more coactivation. So far our clinical results are promising and feared complications are rare.

Nerve transfers for non traumatic diseases in children

List of authors:
Jörg Bahm*
1 Franziskushospital (Aachen)

Objectives / Interrogation: Nerve transfers have become a reliable surgical technique to restore function after severe traumatic nerve lesions, where direct coaptation or grafting is impossible, especially when the proximal nerve stump is unavailable for reconstruction. This technique might be successfully applied to other non traumatic conditions in children, where there have been so far no surgical solutions, like (atypical) arthrogryposis and transverse myelitis.

Methods: We reviewed our patient charts for this indication and found 3 children affected by arthrogryposis and one with severe sequelae from transverse myelitis. All children underwent nerve transfers to improve shoulder and/or biceps function. Postoperative function was analysed looking at the active range of motion scored by the BRMC score from M1 to M4. Videorecordings were added.

Results and Conclusions: We regularly obtained M3 motor function in the targeted muscles in the shoulder and arm, offering useful function in body segments where no other surgical repair technique so far could help. Results are constant in the follow-up period for 3-5 years.

Nerve transfers allow an extension of repair techniques to some non traumatic diseases affecting children's upper limbs. We present clinical cases and update the treatment strategy in these diseases.

Keywords: nerve transfer, arthrogryposis, transverse myelitis
First web-space commissure reconstruction with a precisely designed morphometric free flap

List of authors:

⁸ Department of Orthopedics, Changzheng Hospital, The Second Military Medical University (Shanghai)

Objectives / Interrogation: First web-space contractures have a significant impact on hand function by restricting thumb opposition and abduction. Surgical management utilizing non-standardized free flaps has been reported in the literature with often unpredictable outcomes. We sought to delineate the anthropometric morphological characteristics of first web-spaces derived from cadaveric dissections in an attempt to conceive a configuration algorithm for an individually-proportioned first web-space free flap design and harvest.

Methods: The morphological parameters of cadaveric first web-spaces were measured after pre-defining their cutaneous boundaries. Seven parameters measured from the patient's unaffected hand were selected to precisely calculate the dimensions, size and shape of the requisite free flap.

Results and Conclusions: Clinically, six cases of first web-space contracture were released and reconstructed with precisely designed morphometric free flaps. The appearance of the reconstructed first web-space aesthetically and functionally satisfied the patients. This study demonstrates the technique of precisely designing a patient-tailored first web-space commissure, utilising measurements from the patient's unaffected hand.

It is never late to perform flexor tendon reconstruction for zone 2 injuries

List of authors:
Irina Miguleva*, Irina Miguleva, Aleksei Fain
1 Sklifosovsky Institute for Emergency Medicine (Moscow)
2 Department of Hand Surgery, State Clinical Hospital 29 (Moscow)

Objectives / Interrogation: The problems of flexor tendons reconstruction in patients who present for surgery at many years after laceration are not often discussed in the literature. We would like to share our surgical treatment experience for the very long lasting flexor tendon injuries within the fingers.

Methods: Forty one patients with deep or both flexor tendons laceration in 49 fingers presented for tendon reconstruction at 2 to 30 years after injury and were treated by the same hand surgeon. In 20 cases surgery was performed at the time from 2 to 5 years after laceration, in 11 cases - at the time from 5 to 10 years and in 18 cases surgery was performed at the time from 10 to 30 years after injury.

In each of these patients two-staged reconstruction using passive silicone implants was carried out. Pulley system was carefully preserved, A2 pulley was cut transversely into several parts for to dilate each part separately. Stage 2 procedure - silicone rod removal and grafting from toe extensors - was usually performed at 12 months after rod implantation. Early active motion rehabilitation program in all patients was the same.

Results and Conclusions: The functional outcomes were clinically evaluated at follow-up examination 6 months after grafting in 31 patients to whom deep flexor tendons had been reconstructed in 36 fingers. Eight patients are still having ongoing treatment. Four patients were lost to final follow up, but their midterm results had been favorable. One patient declined stage 2 surgery. The overall outcome was excellent in 17 (47,2%) of fingers, good in 14 (38,9%) and fair in 3 (8,3%) of fingers. Excellent/good results ratio was 1,21. In 1 digit (2,8%) finger flexion contracture was evaluated and in 1 finger (2,8%) graft ruptured. These results are comparable to our general results of two-stage deep flexor tendon reconstruction in 316 cases: 52,9% of excellent results, 25,3% of good, contracture rate at 4% and rupture rate at 10,7%, with excellent/good results ratio at 2,1. Therefore the rate of excellent outcomes seems to be somewhat lower in long-standing lacerations group, but this difference is not statistically significant (t=0,6; P > 0,05).

In this very flexor tendons series the average time from injury was about 10 years. In spite of so long delay of reconstruction two-stage deep flexor tendon grafting provided good enough outcomes with rather low contracture rate. Hence FDP reconstruction should be attempted no matter how late after injury patient presents for surgery.

late flexor tendon reconstruction
Healing of a critical-sized bone defect in the rat with the use of platelet concentrates

**List of authors:**
Irina Miguleva¹, Aleksei Fain¹, Andrey Savotchenko², Nataliya Borovkova¹, Ivan Ponomarev³, Aleksandr Vaza¹, Marina Petukhova¹, Aleksandr Papaninov¹, Gennadiy Berchenko³

¹ Sklifosovsky Institute for Emergency Medicine (Moscow)
² Department of Hand Surgery, State Clinical Hospital 29 (Moscow)
³ Priorov National Center of Traumatology and Orthopaedics (Moscow)

**Objectives / Interrogation:** The purpose of this study was to evaluate the osseous healing of a critical-sized tibia shaft defect in rat model with the use of three platelet concentrates: PRP, defrosted PRP and PRF. The shaft of rat tibia as a model was used because of its subcutaneous position similar to hand phalanges and metacarpals.

**Methods:** Intramuscular anesthesia was used. Critical-sized 5-6 mm-long midshaft defect of the right tibia of 73 male cross-breed rats (weight 420-500 g, age 5-6 months) was created and secured with a pre-bend gauge plate and screws, and a fragment of 22G needle placed intramedullary. In group 1 (24 animals) the bone defect was filled with hydroxyapatite-collagen biomaterial and orthotopic bone chips 1:1 mix, infused with 0,2 ml fresh allogeneic PRP. In group 2 (23 animals) the defect was filled with the same biomaterial - bone chips mix, infused with 0,2 ml cold-stored and defrosted allogeneic PRP. In group 3 (12 animals) allogeneic Choukroun's PRF was added to the biomaterial - bone chips mix. In group 4 (14 animals) the defect received biomaterial - bone chips mix alone and no platelet concentrate was added. Animals were sacrificed at 6 and 12 weeks, at 4,5; 6; 7,5; 9 and 12 months and 2 rats from group 4 - at 24 months. Both tibia and fibular bones were dissected and the presence of new bone formation in the tibia defect was examined. Bones were fixed in formalin and embedded in paraffin after decalcifying and hardware removal. Longitudinal histological sections were stained with hematoxylin and eosin.

**Results and Conclusions:** According to the data from dissection, in PRP group 19 animals of 24, in defrosted PRP group 15 animals of 23 and in PRF group 8 animals of 12 demonstrated new bone formation in the defect. There was no detectable bone formation over the 24 months period in no platelet concentrate group 4. On histologic analysis at 6 weeks to 12 months after surgery 42 of 59 rats (71,2%) from groups 1, 2 and 3 demonstrated more or less mature bone formation in the defect and an increase in calcified bone formation over time. Group 4 showed no histologic evidence of bone formation. Results demonstrate that either of the three platelets concentrates added to hydroxyapatite-collagen biomaterial promotes bone formation and healing of critical-sized segmental bone defect in rat model. Thus PRP, defrosted PRP and PRF autologous techniques may provide other options for reconstruction of hand bones segmental defects in cases where biomaterial alone is not sufficient to heal the defect.

Multidisciplinary neuropathic pain management improves differential diagnosis considering thoracic outlet syndrome

List of authors:
Jörg Bahm* 1
1 Franziskushospital (Aachen)

Objectives / Interrogation: Thoracic outlet syndrome is a rare neuro-vascular compression syndrome affecting the upper limb with various vascular and/or neurologic symptoms, frequently including neuropathic pain. When the vascular or neurologic etiology is unclear and pain the pertinent symptom, patients may be admitted to the hospital for 2 to 3 weeks of interdisciplinary treatment involving anaesthetists, physio- and ergo therapist, psychologist under coordination of the hand surgeon, all together in a specific therapeutic frame recognised by the national health system. We present our 3 years experience with this modality allowing us not only to efficiently treat these patients, but to sort out operative indications in disputed thoracic outlet syndrome cases.

Methods: Between 2016 and 2018, 20 patients were admitted in our hand surgery department for evaluation and multidisciplinary pain treatment. The standardised protocol for pain (VAS) and functional impairment assessment was applied and treatment assumed by all participating disciplines. Our retrospective review concentrated on patient characteristics, comorbidities, pain relief and eventual surgical indication.

Results and Conclusions: Patients were representative of all age groups within the working community. Subjective improvement of pain was reached in all patients, 3 underwent secondary hand surgery, none a surgical decompression for a hypothized TOS syndrome. Patient compliance was high and complication rate low (2 superficial infections at the pain catheter skin insertion).

This treatment modality is a useful tool when sorting out "disputed" TOS patients for a surgical indication, while the interdisciplinary pain treatment allows a lot of new insights and therapeutic actions in a chronic course of severe neuropathic pain and certainly avoids undue or complex surgery in selected patients.

Keywords:
neuropathic pain, thoracic outlet, multidisciplinary
Objectives / Interrogation: Distal radius fractures are the third most common type of fragility fractures, following vertebral and proximal femur fractures. There has been an increasing trend towards surgical fixation, although most fractures are treated non-operatively. Minimally-invasive surgical approaches have been described before. However, a single transverse incisional approach to distal radius fractures has never been published.

Methods: A retrospective case series of patients undergoing distal radius fracture fixation via a single transverse wrist incision. The surgeries were performed by a fellowship trained hand surgeon, between July 2015 and August 2016. All patients underwent the institution-specific standard post-operative rehabilitation regimen for distal radius fractures.

Results and Conclusions: There were 16 patients with a total of 17 fractures. The mean age of patients was 58 years old. 11 out of 16 patients were females. The most common fracture type was the AO 23-A3. At 3 months post-surgery, the mean range of wrist motion showed a flexion of 52 degrees, extension of 60 degrees, pronation of 80 degrees, supination of 83 degrees, radial deviation of 17 degrees and ulnar deviation of 33 degrees. Mean grip strength was 67% of the contralateral side. Radiographic parameters showed a mean post-operative improvement of 6.9 degrees in radial inclination, 2.0 mm in radial height, and 26.9 degrees in volar tilt. All patients returned to pre-injury work within 3 months after surgery. There was one incidence of superficial wound cellulitis, which resolved with oral antibiotics. The patients were satisfied with the appearance of the surgical scar. Clinical and radiological parameters were maintained in the 11 patients that were followed up 1 year post-operatively. Average grip strength at 1 year was 78% of the unaffected side.

The single transverse wrist incision approach to distal radius fractures is a viable alternative which provides an aesthetically pleasing scar which blends with the wrist crease. There was better exposure of the ulnar corner of the distal radius during fracture fixation. Post operative range of motion and radiographic parameters were comparable to published literature of conventional volar approach at 3 months and 1 year post surgery. There maybe a learning curve for this new approach and care should be taken during retraction of the skin.

Hideyuki Mizushima*

*Orthopedic surgery, Sakai city medical center (Sakai city, Osaka)

**Objectives / Interrogation:** Replantation cannot be performed in all cases of fingertip amputation, and in such cases, a pedicle flap is sometimes used to cover the skin and soft tissue defect. Kutler described a technique of bilateral V-Y advancement flap for reconstructing fingertip amputation in 1947. In this study, we show a newly developed bilateral V-Y advancement flap (modified Kutler method) and evaluated the outcomes of this local flap.

**Methods:** Materials: We reviewed 21 cases (men, 21; women, 1; average age, 47 years) of amputation of the fingertip from July 2009 to February 2016. The injury sites were as follows: thumb (1), index finger (6), middle finger (7), ring finger (4), and little finger (3). Nineteen cases were injured in crush, and 2 were in clean cut. The average follow-up period was 188 weeks. Sensory disturbance and pain were examined at the final follow-up. Methods: Inverted triangular flaps, the apex of those were placed on distal interphalangeal joint, were designed in radial and ulnar side of amputated finger. The volar incision was slightly undermined but left attached to subcutaneous tissue, and the dorsal incision was made to periosteum in both flaps. Both dorsal incisions were connected anterior to distal phalanx and volar subcutaneous tissue which include two flaps was separated from distal phalanx. Because of this maneuver, mobility of both flaps was greater than original Kutler method.

**Results and Conclusions:** Results
All flaps survived. numbness, hypersensitivity, or hypesthesia remained in 8, 5 and 10 cases respectively. And pain due to an attack remained in 1 case. Coldness remained in 5 cases. Affected finger were useful in 18 patients and not useful in 3 patients. Of three cases, one was not useful because of pain, one was of hypersensitivity, and remained one was of hypesthesia.

Summary
Our modification allowed much greater mobility of the bilateral V-Y advancement flap than original Kutler method. But in this study, the incidence of numbness, hypersensitivity, or hypesthesia after operation were higher than expected. Otherwise, this flap is very useful method for fingertip injury because affected fingers were useful in most of patients.

Flexor pollicis longus excursion and irritation following plating of distal radius articular volar lip fractures

List of authors:
Michelle Spiteri*1
1 Nuffield Orthopaedic Centre (Oxford)

Objectives / Interrogation: Comminuted intra-articular fractures of the distal radius involving the marginal volar lip often require fixation distal to the watershed line in order to obtain bone purchase and control of these far distal fragments. Despite recent developments and various low profile smooth contoured plate designs, implants sited in this region have been described to cause tendon irritation and rupture.

The aim of this study is to evaluate excursion and irritation of the flexor pollicis longus (FPL) tendon in fractures treated with these implants, as the course of this tendon runs in close proximity to the radial aspect of the plate.

Methods: Patients who underwent fracture fixation using plates designed to be sited at this far distal site were identified from theatre and implant registers. Thumb interphalangeal (IP) joint flexion, and maximal thumb composite opposition were compared with the contralateral side at six and twelve weeks. Ultrasound assessment was performed at the same time intervals, and at six months following surgery.

Results and Conclusions: Thirty patients were identified. Full thumb mobilization was encouraged in all cases. Patients described initial pain and restricted thumb movement which improved over the first six weeks, ranging from a mean visual analogue score for pain of 8.8 for all thumb movement to no pain on IP joint movement and 2.8 pain on full thumb flexion. 37% of cases had sonographic signs of tenosynovitis at six weeks post-operatively. Full IP joint movement was present and maintained at and beyond six weeks of surgery. Full thumb opposition was decreased by a mean of 3 points on the Kapandji score when compared to the contralateral side at 6 weeks, becoming symmetrical in 89% of the cases by twelve weeks. Evidence of tenosynovitis resolved in most cases, with mild persisting tenosynovitis on ultrasound in 23% and discomfort on pinch grip testing in 17% at six months following surgery.

This study shows that the initial postoperative thumb stiffness improves over the first three months after surgery. As movement progresses, mild signs of FPL tendon irritation are present on ultrasound despite patients being asymptomatic during their daily activities. Given the potential for flexor tendon rupture due to irritation from implants inserted distal to the watershed line, the persistence of evidence of tenosynovitis in nearly a quarter of patients at 6 months is concerning, although the clinical relevance and so the implication when advising upon implant removal is unclear.

Chronic Scapholunate Instability in Carpal Anomaly: Proposed Surgery Treatment

List of authors:
Pier Luigi Bonucci, Emanuele Gerace, Marcello Marcialis, Emmanuelle Richard, Guido Cristiani

1 Hesperia Hospital, Hand Surgery unit (Modena)
2 Università di Ferrara, Orthopaedic Clinic (Ferrara)
3 Department of Orthopedics and Traumatology center of Nimes (Nimes)

Objectives / Interrogation: A 47-year-old man presented to Hand Unit, Hesperia Hospital with right wrist pain after recent fall injury at work. Standard X-ray, MRI and physical examination were consistent with scapholunate instability and surgery confirmed carpal dissociation in presence of a lunotriquetral coalition (complete osseous fusion os luno-triquetrum).

Methods: This patient was treated surgically with horizontal proximal carpal row retightening. This unusual case emphasizes the need to reconstruct the carpal alignment and scapho-lunate linkage.

Pre-surgery

Right hand (traumatized hand) presented a type 3 coalition (classification by Devilliers Minnaar 1952) and the left hand had type 1 coalition (incomplete fusion resembling pseudo-arthritis (fibro-cartilage coalition)). Widening of the scapholunate joint space is a common finding in patients with lunotriquetral coalition. This condition poses difficulty in diagnosis scapholunate instability.
Post-surgery
Results and Conclusions: At 2 years follow up, the function of the right wrist was normal. X-ray confirmed a normal scapholunate joint space.

Keywords:
scapholunate instability; luno-triquetral coalition; scapholunate fibrodesis; carpal anomaly

Short to mid-term results of a 360 degree technique for reconstruction of the scapho-lunate ligament

List of authors:
Allan Ibsen Sorensen\textsuperscript{1}
\textsuperscript{1} Sahlgrenska University Hospital (Gothenburg)

Objectives / Interrogation: The aim of this prospective study is to present short to mid-term results of a 360 degree technique for reconstruction of the scapholunate (SL) ligament.

Methods: Patients with a symptomatic SL ligament lesion Geisler type 3 or 4 were included. In the technique for reconstruction a part of Flexor Carpi Radialis or Plantaris tendon was used to stabilize on both the dorsal and volar side of the scapholunate joint. Temporary K-wire fixation was not used in the later part of the study. All the patients had a cast for 6 weeks. All patients were evaluated preoperatively, 12 and 26 weeks postoperatively and then yearly with ROM, grip strength, VAS scores for pain and satisfaction, Quick-DASH and PRWE-questionnaires. X-Ray was performed preoperatively, 3 months postoperatively and thereafter yearly. Forty-seven patients were operated and 2 patients twice, 39 men and 8 woman. Median age 42 years (19-61). Mean values are used.

Results and Conclusions: Median follow-up was 31 months (range 3-89). 6 patients had Geisler 3 and 41 Geisler 4 status preoperatively. Early changes of the cartilage of the proximal pole of the scaphoid was found preoperatively in 20 (43%) patients. Preop. SL distance on x-ray was 5.4mm (1.4-8.3) and at last follow-up (LFU) 3.5 mm (0-9.4) (P<.01). Dorsal/volar flexion was preop. 89% (range 17-185%) of the contralateral wrist and at LFU 72% (31-114) (P<0.01). Radial/ulnar deviation was 85% (23-193%) versus 89% (22-191%) postoperatively (P=NS). Grip strength preop. was 36 KgF (2-60) and at (LFU) 35 (4-67) (P=NS). VAS for pain (mm) was preop. at rest/activity; 28/56 and at LFU; 23/36 (P=NS/<.01). Watsons test was positive in of 39 of 42 cases preop and positive in 13 of 49 at LFU (P<0.01). Radiographic dorsal intercalated segment instability (DISI) was seen in 22 of 47 cases preop. compared with 26 of 47 at last Follow-up. Quick DASH and PRWE preop: 41 and 52 and at LFU; 30 and 35 (P<0.01). Patients VAS of Satisfaction improved from 26 (0-100) Preop. to 62 (0-100) at LFU(P<0.01). Six developed SLAC wrist. Five revisions (10.2 percent) were performed, two with a new ligament with the same technique, one to an arthrodesis of the wrist and one to a proximal row carpectomy and one scheduled to four corner arthrodesis. This 360 degree technique for reconstruction of the SL ligament improved Quick-DASH, PRWE, VAS for pain in activity and patients satisfaction. Revision rate is so fare acceptable low, but longer follow-up is needed to evaluate this technique.

Scapholunate ligament reconstruction, SL-ligament reconstruction
Outcome of Tendon Transfer Around Shoulder with Erb’s Palsy Internal Rotation Deformity

List of authors:
Farouk Hamad*, MUHAMMAD ROMEIH1, MOSTAFA AYOUB1
1 Orthopaedic Department, Faculty of Medicine, Tanta University (Tanta)

Objectives / Interrogation: Background: Obstetric Brachial Plexus Palsy (OBPP) is one of the most severe complications at birth with internal rotation deformity that have significant functional disability. There is a many different methods of tendon transfer that have been descrided to improve the shoulder Range of Motion (ROM).
Objectives of Study: Evaluate the outcome of teres major tendon transfer around the shoulder in children with Erb’s palsy internal rotation deformity.

Methods: Methods: This study was Retrospective and Prospective randomized clinical study carried out on totally (25) patients admitted to Orthopaedic Department of Tanta University Hospital. Ten children represented the Retrospective portion of the study, and fifteen represented the prospective portion. All cases were operated by Modified Sever-L’Episcopo technique. The external rotation, according to Mallet score, was recorded pre-and post-operatively.

Results and Conclusions: Results: The mean follow-up period was twelve months (range 6-18). The Mallet score for the shoulder external rotation, at the end of follow-up periods, was graded as Grade II in two patients (8%), Grade III in nine patients (36%), and Grade IV in fourteen patients (56%). There was a highly significant improvement (p=0.00001) of the external rotation range as the mean pre-operative score was 2.04±0.02, and the mean post-operative score was 3.48±0.65.
Conclusion: The Modified Sever L'Episcopo procedure that compromises of anterior release, then teres major tendon transfer to the tendon of infraspinatus shows a high incidence of good outcome with a promising subjective and objective improvement in almost cases.

Midterm follow up of volar plate fixation for chronic unstable scaphoid nonunion

List of authors:
Philip Schormans*, Jan Ten Bosch¹, Martijn Poeze³, Pascal Hannemann¹
¹ Maastricht University Medical Center (MAASTRICHT)

Objectives / Interrogation: Fixation of chronic unstable scaphoid nonunion with a volar angular stable mini-plate and cancellous bone grafting has shown to be a successful technique in small series. No mid or long term follow-up has been documented ever since. Our objective was to evaluate the midterm follow-up of plate fixation for scaphoid nonunion and to evaluate the necessity for hardware removal in these patients.

Methods: Patients with a chronic unstable scaphoid nonunion were prospectively enrolled and treated with open reduction of the scaphoid fracture using a volar approach and internal fixation using an angular stable miniplate fixation and cancellous bone grafting from the ipsilateral iliac crest. Follow-up included physical examination, functional assessment using the PRWHE questionnaire and multiplanar reformation computed tomography at a three month interval until union was confirmed. For the midterm follow up, (median 31 months after surgery) physical examination and functional assessment will be re-evaluated.

Results and Conclusions: Forty-eight patients with a mean age of 30 years with a mean duration of nonunion of 45 months were included. Eleven patients had previous surgery of the scaphoid fracture, 26 patients had a dorsal intercalated segment instability and 13 patients had a scaphoid nonunion advanced collapse of the affected wrist. Post-operative, 93% of patients showed radiological confirmed healing of nonunion. Average time to union was 4 months. Due to impingement of the plate on the volar rim, 17 patients had the hardware removed during follow up. No significant changes in range of motion and grip strength were found postoperative after 3 months compared to pre-operative function. Functional outcome improved significant after 3 months (PRWHE from 50 to 25 points). Midterm functional outcome after 1-3 years will be evaluated but is expected to improve further, especially after plate removal.

In conclusion, angular stable plate fixation supplemented with autologous cancellous bone grafting is a successful technique for treatment of chronic unstable scaphoid nonunion, resulting in union in the majority of patients within half a year in this large cohort. Impingement of the plate against the volar rim may necessitate a second operation for hardware removal and should be discussed pre-operatively with the patient. Midterm results will determine if functional outcome will further improve.

Collagenase dose related correction of flexion deformity in Dupuytren's contracture: A prospective randomized study

List of authors:
Nash Naam*, Abdel Hakim Massoud

1 Southwestern Illinois Hand Center, Southern Illinois University (Effingham)
2 Al Azhar University (Cairo Egypt)

Objectives / Interrogation:
Collagenase injections have been used in treatment of Dupuytren's contracture. The recommended dose is 0.58 mg per cord. We hypothesized that increasing the Collagenase dose may increase the likelihood of correcting the flexion deformities.

Methods: A prospective randomized study was conducted comparing 2 groups of patients with Dupuytren's contracture. Patients were selected randomly for either injection of 0.9 mg of Collagenase (group I) or 0.58 mg (group II). The injection technique was the same. Patients were seen after 24 hours for the extension procedures under local anesthesia. There were 37 digits in 27 patients in group I and 34 digits in 29 patients in group II. Age averaged 58 years in group I and 61 years in group II. There were 23 males in group I and 24 in group II. Isolated Metacarpophalangeal (MP) joints were involved in 21 digits in group I and 18 digits in group II. Isolated Proximal Interphalangeal (PIP) joints were involved in 4 digits in group I compared to 6 in group II. Both MP and PIP joints were involved in 12 digits in group I and 10 digits in group II. Flexion deformities of MP joints averaged 69 degrees in group I compared to 72 in group II while PIP joint flexion deformities averaged 41 in group I compared to 39 in group II.

Results and Conclusions: All patients in both groups exhibited bruising and swelling of the involved hand after injection with no significant difference. Correction of flexion deformities of MP joints to 0-5 degrees was achieved in 26 digits (79%) in group I compared to 17 digits (61%) in group II which was statistically significant (P=0.01). Correction of PIP joints to 0-5 was achieved in 10 digits (63%) in group I compared to 8 digits (50%) in group II (P=0.02). The mean improvement in MP joints was 40 degrees in group I compared to 28 in group II (P=0.02). The mean improvement of PIP joints was 27 in group I compared with 17 in group II (P=0.02). DASH scores were similar in both groups (P=0.3).

Complications
One patient in group I had axillary lymphadenopathy that improved in one week. 4 patients in group I and one patient in group II had skin tears that healed within 2 weeks.

Conclusions:
Increasing the dosage of Collagenase injections to 0.9 mg increases the effectiveness of correcting flexion deformities with Dupuytren's contractures.
There is no increase of risk or complications.

Dupuytren; Collagenase: Dosage; Deformities; correction
A different perspective on the aetiology of hook of hamate fractures and the high association with other carpal fractures

List of authors:
Matthew Ricks*, Zaid Al-Watter, David Hargreaves
1 University Hospital Southampton (Southampton)

Objectives / Interrogation: Fractures of the Hamate are rare and difficult to diagnose both clinically and radiographically. It was thought that hook of hamate fractures were sustained by either a fall onto an outstretched hand or by direct impact from a racquet or ball whilst playing sport. We have reviewed our series of hook of hamate fractures from a level 1 trauma centre over a ten year period. This was to assess the aetiology and associated injuries of this uncommon yet significant injury.

Methods: A retrospective analysis of all patients who presented with a hook of hamate fracture to the level 1 trauma centre over a ten year period. The patient demographics and mechanism of injury was collected from the patients notes. All patients underwent radiographs and advanced imaging in the form of either Computed topography (CT) or magnetic resonance imaging (MRI). Imaging was examined for classification and associated injuries.

Results and Conclusions: There were 27 patients who sustained 28 hook of hamate fractures between 2007 to 2017. The fractures occurred through the base of the hamate in 16 patients, the body in 11 patients and the tip in 1. The mechanism of injury in 18 Hamate fractures were sustained whilst falling onto an outstretched hand and of these 6 had an associated carpal fracture. 4 of the 28 fractures were sustained from a direct blow with 2 cases having an associated fracture. 6 of the 28 hamate fractures were sustained from gripping a handle (Tennis racquet, Golf club) with no direct blow or fall reported.

We found no evidence to support the current opinion of hamate fractures being sustained from a direct blow against a handle. The authors feel that the fractures in this patient population occurs as a consequence of the tangential force from the adjacent flexor tendons (flexor digitorium profundus of the ring and little fingers) when maximal grip occurs against the handle. There is also a higher association of scaphoid and carpal fractures (28%) with a hamate fracture than what has been previously been reported in the literature. It is our opinion that with the increasing use of CT or MRI imaging more associated carpal injuries would be identified. This has led to an increased rate of identifying both the hook of hamate fractures and any associated injuries. The authors recommend a thermoplastic splint that has been developed to support the wrist and fingers of the little and ring and prevent excessive FDP movement of these fingers.

A Decision Aid Decreases Decisional Conflict in Patients Undergoing Plate Fixation for a Distal Radial Fracture

List of authors:
Sehun Kim*, Hyun Sik Gong, Yeun soo Kim, Kee Jeong Bae, Ji hyeung Kim, Goo Hyun Baek
1 SMG - SNU Boramae Medical Center (Seoul)
2 Seoul National University Bundang Hospital (Gyeonggi-do)
3 Seoul National University Hospital (Seoul)

Objectives / Interrogation: Although a shared decision-making model is emphasized for patient-centered care, patients experiencing acute trauma might have limited time and resource for their involvement in decision-making, which may lead to decisional conflict. The purpose of this study was to evaluate whether a decision aid can reduce decisional conflict in patients undergoing plate fixation for a distal radius fracture (DRF) and to investigate factors that may affect the decisional conflict.

Methods: We prospectively enrolled 50 patients who presented with acute DRF and chose to undergo plate fixation. We randomized these patients into two groups. The test group was given a decision aid in addition to regular information while the control group was only given regular information. The decision aid consisted of purpose, procedure, and effect of the surgery, precautions and complications after the operation, and other treatment options that could be performed if operation was not performed. At 2 weeks after the surgery, we evaluated patients’ decisional conflict during decision-making for surgery by decisional conflict scale (DCS). In addition, we evaluated factors that might affect decisional conflict, such as age, dominant hand, comorbidities, history of previous surgeries, perceived disability, and administration of a decision aid.

Results and Conclusions: The test group showed significantly lower DCS than the control group (19.6 vs. 32.1, P = 0.001). In multivariate analysis for factors affecting the DCS, younger age and administration of a decision aid were independently associated with lower DCS. This study shows encouraging results towards that a decision aid can reduce decisional conflict in patients undergoing plate fixation for DRF. This study also shows encouraging results towards that older patients have more decisional conflict in decision-making for surgery than younger patients, suggesting that they need more careful doctor-patient communication.

The treatment of the chronic lateral epicondylitis by denervation of the lateral humeral epicondyle: technique and results

List of authors:
LUIZ VILELA*, HENRIQUE CHAMON, FABRICIO ABU KAMEL, TIAGO HERINGER, LEANDRO FARIA
1 HOSPITAL MARCIO CUNHA (IPATINGA)
2 HOSPITAL MARCIO CUNHA (Ipatinga)

Objectives / Interrogation: To evaluate the surgical treatment of the lateral epicondyle humerus denervation technique for chronic lateral epicondylitis, which is a frequent pathology and is well treated by conservative ways in most cases, and that for refractory ones, there is no consensus in the literature of which technique would be the most appropriate. We present an unusual surgical technique for this pathology with good clinical results.

Methods: retrospective study in one institution with prospective data collect. All the surgeries were performed by the same surgeon in an outpatient procedure, with local anesthesia and sedation. Magnifying glasses 4.5 x was used.

12 patients, 12 elbows were evaluated.

The inclusion criteria was the response to the nerve block - posterior branch (es) of the cutaneous posterior of the forearm by anesthesia with lidocaine 1.0% without epinefrine, 5 cm above of the epicondyle in a straight line taking with reference of the humerus, in pre operative with complete reduction of the pain; at least 1 year of symptoms and non response to another treatments.

The evaluation of the patients was by Quick Dash score with comparison pre and post operative.

Results and Conclusions: the Quick Dash score was used to measure the results. In all the patients we observed a reduction of the score.

pre operative the average was 78.7 and pos operative average of 28.9.
pre operative the higher score has 91.7 and the lower 60.0
pos operative the reduction were significant with the higher still 86.7, but the lower 5.0 (2 patients)
the worse result was in a patient that as receiving benefits by social security.
half of them were below the 20 points in pos operative
75% showed a good clinical result

we conclude that the denervation of the lateral epicondyle of the humerus in a chronic situation, produces good results, as showed by another authors, being a simple outpatient surgery, low cost (compared to arthroscopy or open surgery), with fast recovery and no need of formal reabilitiation.

Keywords: elbow, lateral epicondylitis, denervation, surgical results
Revision arthroscopic surgery for tennis elbow

List of authors:
Takuro Wada*, Akira Saito, Takashi Oda
1 Saiseikai Otaru Hospital (Otaru)

Objectives / Interrogation: Literature regarding the outcomes of revision arthroscopic surgery for tennis elbow is limited. The purposes of the study were to report clinical outcomes for a cohort of patients with chronic tennis elbow who underwent revision arthroscopic release of the extensor carpi radialis brevis (ECRB) tendon.

Methods: From January 2003 to December 2017, 150 arthroscopic surgeries for chronic tennis elbow were performed by a single surgeon. Among them 5 patients had persisted elbow pain following a primary surgery and underwent revision arthroscopic surgery. Indications of primary surgery included failure of a minimum of 6 months of conservative treatment such as rest, activity modification, counterforce bracing, nonsteroidal anti-inflammatory medications, and corticosteroid injection. Operative treatment consisted of an arthroscopic inspection, debridement of the ECRB tendon origin, and resection of the radiocapitellar synovial plica if interposed in the joint. The mean age of 5 patients was 48 years; four were male and one was female. The average duration between primary and revision surgery was 11 months and the average follow-up period after revision surgery was 18 months. Outcome was evaluated on the basis of visual analogue pain score, range of motion of the elbow, grip strength, Japanese Elbow Society (JES) score, DASH score and patient satisfaction. Arthroscopic findings of the revision surgery were also evaluated. Statistical analysis was performed using a paired Student t test, with statistical significance set at p< 0.05.

Results and Conclusions: Significant improvements were seen in terms of postoperative pain (p < 0.05), active extension and flexion (p<0.05), grip strength (p<0.05), the JES score (p < 0.05), and DASH (p<0.05). All of 5 patients satisfied with the operative results. Arthroscopic findings of the revision surgery included insufficient release of the ECRB origin in three patients and persisted impingement of the posterolateral synovial plica in two patients. Rate of revision arthroscopic surgery for tennis elbow was 3%. Incomplete release of the ECRB origin or synovial plica was considered to be a cause of persisted pain. Revision arthroscopic surgery resulted in reliable pain relief and improvement in elbow function in patients with persisted elbow pain following primary arthroscopic tennis elbow surgery.

Keywords: tennis elbow, revision surgery, arthroscopy
The relationship between positional contracture of proximal interphalangeal joint on trigger finger and metabolic syndrome

List of authors:
Kazuya Odake*, Masaya Tsujii1, Akihiro Sudo1
1 Department of Orthopaedic Surgery, Mie University (tsu city, mie)

Objectives / Interrogation: Trigger finger (TF) is a common hand problem and sometimes leads to positional contracture of proximal interphalangeal (PIP) joint after treatments, especially it is mostly in middle finger (MF), however this has not been proven scientifically. Though several studies reported that the relationship between tendinopathy and metabolic diseases such as diabetes, obesity and dyslipidemia, there were few reports about the relationship with metabolic syndrome (MetS). we herein presented the relationship between positional contracture of PIP joint on TF and MetS

Methods: The study group was composed of 34 fingers in 34 patients (25 women and 9 men; mean age, 67.4 years), treated with corticosteroid injection or open release of the A1 pulley for TF of MF. The survey included age, sex, degrees of PIP joint before treatments(pre-PIP), height, weight, Body mass index (BMI), waist, blood examinations (T-chol, HDL, LDL, TG, FBS, HbA1c) and the prevalence of MetS. We defined -10 degrees of PIP joint after treatments (post-PIP) as positional contracture and assessed between the patients with (group P) and without contracture (group N) at 6 months after treatments.

Results and Conclusions: Thirteen fingers (38.2%) were diagnosed as positional contracture. In group P, the mean of age, waist and degrees of pre-PIP were 72.8 years, 91.0cm and -24.2°, respectively. These were significantly greater than the value (64.0 years, 81.1cm and -7.4° respectively) in group N. Additionally, there was a significant correlation between the degrees of pre-PIP and post-PIP. Besides, in group P, the mean value of HDL (60.8 mg/dL) was significantly lower than group N (74.4 mg/dL) and the those of TG (173.8 mg/dL) was significantly higher than group N (135.3 mg/dL), with significant negative correlation between TG and the degrees of post-PIP. There were no significant differences among the others. Moreover, there was a significant relevant between MetS and the presence of positional contracture.

MetS is responsible for the increase in chronic diseases, diabetes, cardiovascular disease, neurodegenerative disease, and cancer. In addition, a low-grade inflammation may have a role in the pathogenesis of MetS. Favre described that the chronic inflammation would cause an enlargement and/or shortness of tendon and induce the flexion contracture of the PIP joint. From our study, the prevalence of Mets would become the predictor of positional contracture of PIP joint on TF.

trigger finger, positional contracture of proximal interphalangeal joint, metabolic syndrome
Factors related poor outcomes in the extension block pinning of mallet fractures

List of authors:
Takeyasu Toyama*, Yoshitaka Hamada1, Emiko Hori2, Yoshitaka Minamikawa3, Takanori Saito2
1 Kansai Medical University (Neyagawa City, Osaka) (Neyagawa City, Osaka)
2 Kansai Medical University (Hirakata City, Osaka) (Hirakata City, Osaka)
3 MinamikawaNamba Hand Center (Osaka City) (Osaka City, Japan)

Objectives / Interrogation: Percutaneous extension block pinning (pinning) for mallet fracture is simple and less invasive method. However, we occasionally encounter poor outcomes. We reviewed our cases in order to find out the factors causing poor outcomes.

Methods: Patients: From 2012 to 2017, fifty mallet fingers of 50 patients were consecutively operated on by pinning. There were 32 men and 18 women with an average age of 43. The patients followed more than 6 months were involved in this review. The affected fingers were 2 index, 10 middle, 22 ring, and 16 little fingers. The average interval between injuries to surgery was 7.6 days. The surgery was done according to Ishiguro method with some modification. The K-wire was removed at 5 to 6 weeks, then followed by night splint in extension.

The patients were evaluated by DIP joint motion, then divided into good or poor group. Either more than 10 degrees of extension lag or less than 30 degrees of active flexion was rated as poor. Fracture type was divided as avulsion type or axial compression type. The length of the dorsal cortex and the joint surface ratio of the bony fragment were measured on the lateral X-ray.

Results and Conclusions: Results: Thirty-three fingers were resulted into good, and 17 fingers were poor. The average patients' age was 40.1 years in good group and 50.6 years in poor group, which was statistically significant (P<0.05). The involved fingers and the interval to surgery were not significantly difference between two groups. Regarding fracture type, 67% of fingers showed avulsion type in good group, on the other hand 65% showed axial compression type in poor group. Joint surface ratio of the bony fragment was not significantly different between two groups, but the average length of dorsal cortex was 2.4 mm in poor group and 1.8mm in good group, which was significantly different (P<0.05).

Discussion: The average age was significantly high in poor group. Bone quality might be not rigid enough to secure K-wire, or pre-existing osteoarthritic changes caused restriction of DIP joint motion. Regarding fracture type, compression type and long bone fragment caused poor outcomes. The extension block pin aims to decrease traction force by terminal tendon, but it does not effectively prevent rotation deformity of bone fragment. We have to use an additional pin to directly fix bone fragment to the distal phalanx, or small screw would be effective. We should know the limitations of percutaneous pinning.

Objectives / Interrogation: There are many operative techniques to treat mallet fracture when it is larger than one-third of the articular surface of the distal interphalangeal (DIP) joint, including extension block pinning or open reduction and internal fixation and the use of a hook plate. The extension block pinning is a useful surgical procedure for the treatment of this fracture. However, its complications are pin tract infection, flexion contracture of DIP joint and delayed union or nonunion. We have reported good outcome of minimally invasive screw fixation (MISF) technique for mallet fracture on 2013 FESSH, which is combined closed reduction of the mallet fragment by an extension block pining with internal fixation with one or two Leibinger screws through dorsal stab skin incision. We retrospectively compared the clinical and radiographic results of extension block pinning with MISF for mallet fractures.

Methods: Forty patients with a mallet fracture involving more than one-third of the articular surface were reviewed. Twenty cases were treated using extension block pinning (EB group) and 20 were treated using MISF technique (MI group). At the final follow-up (average 18 months), extension lag and range of motion of the DIP joint of the affected digit were measured, and the overall clinical outcomes were graded using Crawford's criteria. Complications, including nail deformity and dorsal prominence, were also assessed. The Mann-Whitney's U test was used to determine the significance of intergroup differences for continuous variables.

Results and Conclusions: At the final follow-up, the mean extension lag in MI group was 2.2°, which was significant different from that of the EB group (mean 12.8°; P<0.01). The mean range of motion of DIP joint in MI group was 74.9°, which was significant different from that of the EB group (mean 51.2°; P<0.01). Outcomes, as assessed using Crawford's criteria, were excellent in 12, good in 2, and fair in 6 in the MI group, and excellent in 2, good in 17, and fair in 8 in the EB group. All the fractures had united by 3 months after injury in both groups. We acknowledge that this is a short-term study of a small series, but patients treated with MISF technique had greater ROM and clinical outcome in the finger than extension block pinning. The current study indicates that adaptation of MISF for mallet fracture may be efficient to minimize soft tissue damage, stabilize the fracture fragment and mobilize the joint at the early stage.

Involvement of the lesser sigmoid notch in elbow fracture dislocations

List of authors:
Amir Reza Kachooei*, Matthew A Tarabochia, Neal Chen, C. Niek van Dijk, David Ring
1 Orthopedic Research Center, Ghaem Hospital (Mashhad)
2 Hand and Upper Extremity Service, Massachusetts General Hospital, Harvard Medical School (Boston)
3 Department of Orthopaedic Surgery, Academic Medical Center Amsterdam (Amsterdam)
4 University of Texas Health Science Center, Fort Worth, TX, USA; and Dell Medical School, The University of Texas, Austin, TX, USA (Texas)

Objectives / Interrogation: This study addressed the primary null hypothesis that there is no difference in the articular surface area of the lesser sigmoid notch involved among Mayo classes. Secondarily, we analyzed the fracture line location and the pattern of lesser sigmoid notch articular surface involvement among Mayo classes.

Methods: Using quantitative 3-dimensional computed tomography, we reconstructed and analyzed fractures involving the lesser sigmoid notch articular surface in 52 patients. Further, we assessed the surface area involved in the fracture, the number of fracture fragments, and the location and direction of the fracture lines. Coronoid fractures were classified according to Mayo types.

Results and Conclusions: Results: There was no significant difference between Mayo types 1 and 2 in any characteristic of the involvement of the lesser sigmoid notch articular surface, whereas Mayo type 3 was significantly different from both Mayo types 1 and 2 in the area involved in the fracture (42% in Mayo type 3 vs. 9% in Mayo types 1 and 2), the number of articular fragments (>3 fragments in type 3 vs. 2 fragments in types 1 and 2), and the direction of fracture line (both horizontal and vertical lines in type 3 vs. only horizontal line in types 1 and 2).

Conclusion: Mayo type III results in a more complex fracture, which might need to be addressed directly or indirectly during open reduction with internal fixation of olecranon fracture dislocations because changes in the geometry of lesser sigmoid notch may affect the radioulnar joint if it remains incongruent.

The utility of the mangled extremity severity score (MESS) for decision-making in treating mangled upper extremities? A meta-analysis

List of authors:
Hidemasa Yoneda¹, Hitoshi Hirata
¹ Nagoya University (Nagoya)

Objectives / Interrogation: The mangled extremity severity score (MESS) is utilized to decide whether to try limb salvage or perform an amputation for the severely mangled extremity, but its utility in the treatment of the mangled upper extremity is not documented. To demonstrate its accuracy, we conducted a meta-analysis of studies comparing the diagnostic accuracy of the MESS in patients with mangled upper extremities.

Methods: We retrieved PubMed and EMBASE. We defined sensitivity as the probability that limbs requiring amputation had the MESS of 7 and above. Specificity was defined as the probability that salvaged limbs had the MESS <7. Cases where reconstruction failed and eventual revision amputation was performed were counted as amputation. The heterogeneity and publication bias were evaluated. Pooled sensitivity and specificity and positive and negative likelihood ratios were calculated using a bivariate random effects model for meta-analysis of diagnostic tests.

Results and Conclusions: Most studies dealt with injuries of lower and upper extremities collectively. Therefore, after full-text reading, we verified the availability of the information associated only with upper extremity injuries from the studies. Ultimately, nine studies (N=285) were included in the meta-analysis. The I-square test showed heterogeneity (I=0.60), caused by the difference in the injury characteristics between studies. Allowing for potential heterogeneity among studies, a hierarchical summary receiver operating curves model and bivariate model were used.

The pooled sensitivity and specificity were 97.7% (95%CI; 72.5% to 99.9%) and 89.2% (95%CI; 75.6% to 95.7%), respectively. The positive and negative likelihood ratios were 9.04 (95%CI; 3.81 to 21.5) and 0.25 (95%CI, 0.00 to 0.38), respectively. The area under the hierarchical summary receiver operating curve was 0.98 (95%CI; 0.97 to 0.99). Deeks' funnel plot asymmetry test suggested a little potential publication bias (p=0.09).

The pooled sensitivity and specificity was not worse than those of the lower extremity; the sensitivity means an extremely high probability of achieving limb salvage in cases where the MESS was under the threshold. The gained specificity suggests that limb salvage was achieved in more than 10% of the patients whose MESS was 7 and above. Limb salvageability of the mangled upper extremity does not depend on the MESS; amputation cannot be justified by the MESS. Development of a new scoring system that has excellent specificity is indispensable for surgeons.

Recurrent and persistent carpal tunnel syndrome: predicting clinical outcome of revision surgery

List of authors:
Pepijn Sun*, Ruud Selles², Miguel Jansen², Harm Slijper³, Dietmar Ulrich¹, Erik Walbeehm¹
¹ Radboudumc (Nijmegen)
² Erasmus Medical Center (Rotterdam)
³ Xpert Clinic (Hilversum)

Objectives / Interrogation: The aim of this study was to evaluate the outcome of revision surgery in patients with recurrent and persistent carpal tunnel syndrome (CTS) and to identify predictors of clinical outcome of revision surgery.

Methods: A total of 114 hands in 112 patients were surgically treated for recurrent and persistent CTS in 1 of 16 specialized hand clinics. As part of routine care, patients were asked to complete online questionnaires regarding demographic data, comorbidities and clinical severity measures. Symptom severity scale (SSS) and function status scale (FSS) were measured with the Boston Carpal Tunnel Questionnaire (BCTQ) at intake and at 6 months postoperatively to evaluate the clinical outcome. Using multivariable regression models, we indentified factors predictive of the outcome as measured by the BCTQ FSS, SSS and total score at 6 months.

Results and Conclusions: RESULTS
Revision surgery significantly improved symptoms and function. Longer total duration of symptoms, a higher BCTQ total score at intake and co-diagnosis of Complex Regional Pain Syndrome (CRPS) were associated with worse outcome after revision surgery at 6 months postoperatively. Respectively 33%, 23% and 30% of the variance in outcome measured by FSS, SSS and BCTO total score could be explained by our multivariable regression models. Although patients with higher BCTQ score at intake have worse outcome, they generally have most improvement of symptoms and function.

CONCLUSIONS
This study identified total duration of symptoms, BCTQ total score at intake and co-diagnosis of CPRS as predictors of clinical outcome and confirmed that revision surgery significantly improves symptoms and function in patients with recurrent and persistent CTS. Patients with more severe CTS symptoms have greater improvement in symptoms at 6 months postoperatively as compared to patients with less severe CTS, but 80% of our patients still had residual symptoms 6 months postoperatively. These results can be used to inform both patient and surgeon to manage expectations on improvement of symptoms.

Isolated limb perfusion beyond 24h - a potential avenue for global organ sharing, limb resuscitation and optimization

List of authors:
Nicco Krezdorn1, Fiona Macleod2, Sotirios Tasigiorgos3, Branislav Kollar3, Elazer Edelmann2, Bohdan Pomahac3
1 Hannover Medical School, Department of Plastic, Aesthetic, , Hand and Reconstructive Surgery (Hannover)
2 MIT (Cambridge)
3 Brigham and Women's Hospital, Plastic Surgery (Boston)

Objectives / Interrogation: The maximum allowable ischemia time of 4-6h for amputated limbs is currently the biggest hurdle for broader application of limb allotransplantation and optimized donor-recipient matching. The safe extension of the allowable ischemia time for transport and or restoration and optimization of tissues prior to replantation may be achieved through extracorporeal isolated limb perfusion.

Methods: Based on the results of our experimental studies of ex-vivo perfusion of porcine forelimbs for up to 24h and beyond, and when compared with conventional cold storage on 4°C ice, extracorporeal perfusion with acellular solution at 10°C is a safe means to preserve amputated limbs.

Results and Conclusions: The implications of this progress are many-fold as its success would potentially allow for global organ sharing as well as treatment of injured limbs with compounds unavailable for systemic therapy prior to replantation.

limb perfusion, ex-vivo perfusion
Allogenic upper extremity transplantations - opportunities and limitations

List of authors:
Nicco Krezdorn*, Peter Vogt
1 Hannover Medical School, Department of Plastic, Aesthetic, Hand and Reconstructive Surgery (Hannover)

Objectives / Interrogation: Two decades ago the first successful hand transplantation has kindled the development of previously unthinkable reconstructive and restorative surgical options. Since then more than 100 of these vascularized composite limb allotransplantations (VCA) have been performed. VCA has moved from an experimental approach to a sound surgical option for patients with upper limb amputations.

Methods: Cumulative data from the international cohort suggest adequate functional and aesthetic outcomes. Patient reported quality of life after these interventions is also favourable. The remaining major limitation towards broader application is the need for continuous life-long immunosuppression. Despite advancements in terms of immunosuppressive protocols, the related infectiology, metabolic, and malignant side effects still remain.

Results and Conclusions: Allogenic limb transplantation is a good option for some amputated patients, although not all. Careful selection and individual risk-benefit evaluation is mandatory prior to considering this novel therapeutic option.

Keywords:
VCA, extremity allotransplantation, limb transplantation
Upper extremity amputations in Germany

List of authors:
Nicco Krezdorn¹, Viola Stögner¹, Kai Megerle², Peter Vogt¹
¹ Hannover Medical School, Department of Plastic, Aesthetic, Hand and Reconstructive Surgery (Hannover)
² Klinikum Rechts der Isar TU München, Klinik und Poliklinik für, Plastische Chirurgie und Handchirurgie (München)

Objectives / Interrogation: Macroamputations of the upper extremity - from the level of the mid-hand to more proximal - are relatively rare in developed countries. This is mostly to high standards of work environments, transportation and traffic. When these amputations occur, they represent a major challenge in terms of the possibility of replantation as well as long term functional results. Specific knowledge on the incidence of macroamputations in Germany is currently lacking and mostly based on case reports.

Methods: We used publicly available data from the summary of quality reports of hospital of the joint German federal committee. We conducted a search query with ICD-10 codes for partial and total upper extremity amputation and OPS codes for limb replantation.

Results and Conclusions: The most recent available database contained data from 2016. A total of 23 traumatic amputations at the level of the wrist, 21 at the level between shoulder and elbow, 9 at the level of the elbow, 14 between elbow and wrist and 23 of not further specified amputations of the upper extremity. A total of 40 replantations of these amputations at various levels has been reported as well. More than 80 major amputations of parts of the upper limb are documented for a single year in Germany with replantation in less than 50%. Among further more detailed studies of these patients, future efforts should be geared towards prevention as well as modalities for optimizing replantation efforts, such as ex-vivo perfusion for example.

amputation, macro amputation
Three dimensional kinematic analysis of scapholunate joint during axial-loaded extended wrist position

List of authors:
Junya Hojo*, Shohei Omokawa2, Hiroshi Ono3
1 Heisei Memorial Hospital (Kashihara)
2 Nara Medical University, Department of Hand Surgery (Kashihara)
3 Nishi Nara Central Hospital, Hand center (Nara)

Objectives / Interrogation: Wrist injuries are most frequently caused by falls on an outstretched hand, resulting in bone fracture or ligament injury when the wrist joint is loaded in an extended position. We hypothesized that kinematic change would occur in the scapholunate joint when the wrist joint is loaded in an extended and pronated position. The purpose of this study was to investigate changes in the lengths of simulated scapholunate ligaments during wrist extension with axial loading and to clarify whether loading changes scapholunate joint kinematics.

Methods: The dominant arms of 9 volunteers with healthy wrists were studied. We mounted a compression device onto the elbows in an inverted position. A 0-kg and 7-kg load each was applied during low-dose radiation CT imaging and a bone model was produced. We marked the insertion sites for the 3 scapholunate ligaments stabilizing the scapholunate joint: proximal scapholunate ligament (P-SL), volar scapholunate ligament (V-SL), dorsal scapholunate ligament (D-SL). Each ligament was virtualized and the length of each simulated ligament was measured.

Results and Conclusions: The length of P-SL was 4.82mm at 0kg and 4.85mm at 7kg. The length of V-SL was 3.66mm at 0kg, and 3.79mm at 7kg. The length of D-SL and V-SL increased under the loaded condition compared with the unloaded condition but this difference was not statistically significant. The length of D-SL was 4.05mm at 0kg, 3.94mm at 7kg. The length of D-SL decreased significantly under the loaded condition compared with the unloaded condition. The dorsal SL ligament is an important ligament stabilizing the scaphoid bone and lunate bone, but it was thought that the compression force is generated on the dorsal side by the load and the length of the D-SL is shortened. Although not significant, the V-SL extends, there is a possibility that the ligament were stretched during axial loading. This results may support that there may be a progressive tearing of the SL ligaments from palmar to dorsal, eventually leading to a complete scapholunate dissociation.

Tendon transfer surgery after contralateral C7 nerve transfer to reconstruct the finger extension function in spastic arm paralysis patients after central neurological injury

List of authors:
Juntao Feng*, Gaowei Lei1, Yundong Shen1, Wendong Xu1
1 Huashan Hospital, Fudan University (Shanghai)

Objectives / Interrogation: Spastic arm paralysis after central neurological injury was difficult to treat. Conventional means such as tendon transfer could not be applied since the forearm muscles were in a high level of spasticity. Contralateral C7 nerve transfer provided a good method for the control and reduction of the spasticity of the paralyzed forearm muscles. Here we reported the use of forearm muscles innervated by the contralateral C7 nerve as the donor for tendon transfer to reconstruction finger extension function in central neurological injury patients.

Methods: Before the surgery, the spasticity of the flexors of the forearm was high, and surface EMG detected persisted contraction waveform in the flexor carpi radialis (FCR). Intuitive control of the spastic arm was not possible; therefore, the patients was not able to perform hand opening tasks. Contralateral C7 nerve transfer surgery was performed firstly, and the spasticity was significantly lower, while intuitive control was better in both of the patients at one-year follow-up. After this, tendon transfer surgery was performed with the following strategy: the FCR transposed to the extensor digitorum communis (EDC) via subcutaneous tunnel. The hand function was evaluated again after the surgery including the range of motion, muscle strength and hand function evaluation (Fugl-Meyer scale).

Results and Conclusions: Results: After the contralateral C7 nerve transfer surgery, the surface EMG detected shows the low-level of spasticity of the FCR. No detectable functional loss was reported from the patients. Three months after the tendon transfer surgery, the finger extension motion range increased from 0° to 0-30° while the mean increase in hand function score in the paralyzed arm was 7 points comparing to the one-year follow-up results after the contralateral C7 nerve transfer surgery. Conclusion Contralateral C7 nerve transfer surgery connected the paralyzed upper limb to the contralesional hemisphere, and provided good intuitive control and reduction in spasticity of the FCR. This provided good donor muscle for tendon transfer to further improve the hand open function and acquired good clinical outcome in our preliminary study.

Keywords: Contralateral C7 nerve transfer; Central neurological injury; Spastic arm paralysis; Tendon transfer.
Is hand dominance and a history of hand injury associated with a higher prevalence of hand pain and osteoarthritis in cricketers?

List of authors:
Karishma Shah*, Dominic Furniss1, Nicholas Peirce2, Nigel Arden1, Stephanie Filbay1
1 Botnar Research Centre (Oxford)
2 England and Wales Cricket Board, National Cricket Performance Centre (Loughborough)

Objectives / Interrogation: Hand osteoarthritis (HOA) is the most common form of OA. However, factors associated with hand pain and HOA in current and former sport participants is poorly understood. We aimed to determine if hand pain and HOA are more prevalent in (i) cricketers with a history of hand-injury (ii) the dominant hand.

Methods: 28,152 current and former cricketers of all playing standards who were registered on a national database were invited via email to complete a questionnaire. 2,598 participants responded and consented to the questionnaire. To be eligible for this study, participants must have played at least 1 cricket season and be aged at least 18 years.

Self-reported explanatory variables included any former cricket-related hand injury leading to more than 4 weeks of reduced participation in exercise/training/sport; and dominant hand used to throw/bowl. Outcomes were current hand pain on most days of the last month; and doctor diagnosed HOA.

Chi-squared test was used to compare outcome prevalence between groups. The association between injury and pain was only assessed in former cricketers (to minimise confounding by acute injury). Other analyses were performed on all cricketers (current and former).

Results and Conclusions: Results
2294 were eligible for this study, mean age 52 +/- 15 (range 18-94) years, mean BMI 27.8 +/- 5, mean seasons played 29 +/- 15 (range 1-68), 65 (2.8%) female, 835 (36.4%) former cricketers.

Former cricketers reporting former hand-injury (n=128, 15%) had a higher prevalence of hand pain, compared to former cricketers reporting no hand-injury (38% vs. 17%, p<0.01). All cricketers reporting a hand injury (n=385, 17%) had a higher prevalence of HOA, compared to all cricketers reporting no hand injury (7% vs. 3%, p<0.01). There was no difference in the prevalence of hand pain or HOA between dominant and non-dominant hands (pain 6.6% vs 5.2%, OA 3.9% vs 2.8%, respectively).

Conclusions
Cricket-related hand injury was associated with a higher prevalence of hand pain in former cricketers and a higher prevalence of HOA in current and former cricketers. Hand pain and HOA prevalence was similar between the dominant and non-dominant throwing hand. This suggests hand injury may be a risk factor for the development of hand pain and HOA.

Suture button suspensioplasty vs Sigfusson-Lundborg ligamentoplasty for basilar thumb arthritis treatment

List of authors:
Pedro Teixeira Mota*1, Ana Ribau2, Cláudia Rodrigues2, Margarida Areias3, Alexandre Pereira2
1 CHTMAD (Chaves)  
2 CHP (Porto)  
3 ULSAM (Viana do Castelo)

Objectives / Interrogation: The purpose of this study is to determine if basilar thumb arthritis treatment using suture button suspensioplasty (SBS) is associated with better clinical and functional outcomes than treatment with Sigfusson-Lundborg ligamentoplasty (SLL).

Methods: We performed a retrospective study that included patients diagnosed with basilar thumb arthritis, submitted to surgical treatment with one of two techniques - SBS vs. SLL - and with a minimal follow up of 6 months. Surgical technique was chosen upon surgeon preference. Functional outcomes were compared using QuickDash Score (QDS) and pain was assessed with Visual Analogic Scale (VAS) in three diferent moments: before surgery and at 3 and 6 months after surgery. We also measured trapezial space before surgery and at last appointment.

Results and Conclusions: Twenty-six patients were included in this study. Thirteen were in SBS group and 13 in SLL group. Mean age was 63 (52-75) and no differences were found between groups (61,6 in SBS vs. 64,5 in SLL). Follow up was similar for both groups, 12,4 months for SBS and 12 months for SLL. Pain was 5,31 for SBS group and 5,46 for SLL group before surgery, which did was not significative (p>0,05). At 3 months, pain was statistically significative inferior in SBS group, 0,77 vs 1,77 (p=0,005). At 6 months, the differences between groups did not maintained (0,69 vs 0,92; p>0,05). QDS improved in both groups, from 36,01 to 12,76 in SBS group and from 37,77 to 12,93 no SLL group. In both times of measurement, we did not find differences between groups (p>0,05). Trapezial space decreased 28,1% in SBS group and 39,4% in SLL group which was statistically significant (p=0,012)
We reported no major complications and we registered two patients, one in each group, that sustained anesthesia in sensitive radial nerve area that resolved after nearly 3 months.
Basilar thumb arthritis can be a disabling condition. There are several surgical options for treatment of this condition and recently, SBS has grown in popularity, presenting as main advantage early mobilization. We think this is the main reason why, in our study, patients submitted to SBS refer less pain at 3 months than patients submitted to SLL.
We conclude that patients submitted to basilar thumb arthritis treatment with SBS recover faster than patients submitted to SLL, but this effect tend to disappear over time.

Keywords: -
Salvage of the proximal scaphoid: A retrospective comparison of Medial Femoral Trochlear Osteocartilaginous graft and Costo-osteochondral graft with a minimum 2 year follow-up

List of authors:
John Galbraith*, Cameron Keating¹, Chris Powell¹, Charlie Bain¹, Anthony Berger¹, David McCombe¹, Eugene Ek¹, Stephen Tham¹
¹St Vincents Hospital Hand Unit, Dandenong Hospital Hand Unit, Hand and Wrist Biomechanics Laboratory/O'Brien Institute (Melbourne)

Objectives / Interrogation: Introduction
The free vascularized medial femoral trochlear (MFT) osteochondral graft and the costo-osteochondral graft (COG) are two options for the salvage of the fragmented proximal scaphoid. The aim of this study was to compare outcomes of these techniques at a minimum of 2 years postoperatively.

Methods: Methods
Institutional ethics approval was obtained to review all patients who had undergone either a MFT or COG for fractures of the proximal third of the scaphoid over the last 20 years. Baseline demographic information was collected, including age, sex, hand dominance and pre-operative procedures. Patients returned for clinical review and outcome measures were recorded (DASH, PRWE and VAS). Range of motion of the wrist and grip strength were measured. Follow-up radiographs were reviewed to identify degenerative changes, carpal height, lunocapitate and radiolunate angles.

Results and Conclusions: Results
There were 12 MFT and 21 COG procedures performed, of which 9 MFT and 12 COG patients presented for review. The MFT group were younger (mean 30.6 Vs 38.3 years, p=0.01) and had significantly shorter follow-up (mean 35 Vs 124 months, p< 0.001). The MFT group had significantly better postoperative VAS (1.4 Vs 3.3, p=0.05), but there was no significant difference in postoperative DASH (15.3 Vs 12.7), PRWE (23.3 Vs 16.5) or Grip strength (41 Vs 35.6 kg)(p >0.05). There was no significant difference in postoperative wrist Flexion/Extension arc (65° Vs 77.7°), Ulnar/Radial arc (36.1° Vs 34.2°) and Pronation/Supination arc (159.4° Vs 158.9°)(p>0.05). In the MFT group there was radiographic evidence of beaking of the radial styloid in 6 wrists. In the COG group all patients had mid-carpal and radiocarpal osteoarthritis. The two groups had a markedly different complication profile. In the COG group 1 patient required a total wrist fusion 2 years postoperatively. There were 2 pneumothoraces, 1 joint infection and 1 radial styloectomy. In the MFT group 1 patient underwent scaphoid excision and four corner fusion at 7 months, 1 patient had notable knee pain and 8 patients complained of some knee discomfort not sufficient to affect their daily activities.

Discussion
The survivability of the COG group is notable at 10 years with good outcomes despite the radiological changes. The intermediate results of the MFT group are promising and potentially will have better long-term outcome, because of the similarity in arc of curvature of the MFT to the proximal scaphoid and the presence of articular cartilage.

Treatment of Fracture-dislocation of hamate-metacarpal articulation with across-joint internal fixation using bridging plate technique

List of authors:
zhongzhe li*
1 Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To introduced the clinical application results and surgical technique of treatment of Fracture-dislocation of hamate-metacarpal articulation with across-joint internal fixation using bridging plate technique.

Methods: From August 2008 to December 2015, 55 cases of Fracture-dislocation of hamate-metacarpal articulation were treated with this kind of method and followed up. According to Cain type, including 8 cases of 1A type, 27 cases of 1B type, 13 cases of 2 type, 7 cases of 3 type. Open reduction and across joint internal fixation was performed to Fracture-dislocation of hamate-metacarpal articulation using a 2.3mm Stryker bridging plate, early motion was allowed. The plate was removed at 4 months after operation.

Results and Conclusions: All the cases were followed up average 2.5 years, all the fractures were union successfully, the average union time were 5.5 weeks. Function evaluation was made according to pain degree and flexor and extensor activity of wrist joint. The overall good-excellent rate was 96.3%, the clinical results were satisfactory. Treatment of Fracture-dislocation of hamate-metacarpal articulation with across-joint internal fixation using bridging plate technique was better than conventional methods. This technique avoids redislocation and instability of the hamate-metacarpal joint, It is allowed to early active motion of wrist joint while still being able to achieve a stable fixation construct strong enough. Minimizing the need for prolonged splinting. It is an effective method in treatment of Fracture-dislocation of hamate-metacarpal articulation

Across joint; Bridging plate interfixation; Hamate-metacarpal articulation
The diagnosis and treatment of aneurysmal bone cyst of the metacarpals and phalanges of the hand

List of authors:
zhongzhe li*
1 Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To analyse the clinical features, imaging Characteristics, differential diagnosis, clinical treatment methods and the recurrence rate of aneurysmal bone cyst of the metacarpals and phalanges of the hand.

Methods: The clinical data of 12 cases of aneurysmal bone cyst of the metacarpals and phalanges from 2002 to 2012 was evaluated, and follow-up information was available. To review clinical symptoms and signs, X-ray and MRI imaging Characteristics, tumor performance, operative methods and bone graft, recurrence rate.

Results and Conclusions: 8 of 12 cases were in metacarpal, 4 of 12 were in phalange. The mean age was 28 years, 7 male and 5 female. Clinical features Characteristics were local inflation and pain. Radiographs typically show a lytic lesion with expansion of the cortex. The lesion is usually well marginated and may have a faint sclerotic rim. MRI show a soap bubble like expensive bone destruction was detected, Bone trabeculae mixed with osseous septae in the lesion and fluid-fluid level was detected. During operation bone cortex became purple and swelling and thin. Treatment is by curettage and bone grafting and resection with reconstruction. 1 case recurrence. The diagnosis was clear by histopathology. 1 cases concurrent Giant cell tumors. Aneurysmal bone cyst of the metacarpals and phalanges of the hand is a infrequent disease, is not familiar to hand surgery surgeon. Early diagnosis is very difficult, should be differentiated from other hand bone tumors. Aneurysmal bone cyst of the metacarpals and phalanges of the hand have some identical clinical features and imaging Characteristics. Combination of X-ray and MRI can distinctly improve the correct ratio of the diagnosis. High-speed burr curettage and bone grafting and resection with reconstruction may reduce recurrence rate.

Keywords:
Scaphoid Fracture Classification: a Three-Dimensional Computed Tomography Analysis

List of authors:
Anne Eva Bulstra*, Arthur Turow2, Miriam Oldhoff3, Batur Hayat1, Job Doornberg2, Gregory Bain2
1 Flinders Medical Centre, Flinders University, University of Amsterdam (Bedford Park)
2 Flinders Medical Centre (Bedford Park)
3 Delf University of Technology (Delft)

Objectives / Interrogation: Traditional scaphoid fracture classifications rely on radiography. Radiography alone can prove challenging for fracture diagnosis and description of fracture characteristics. The aims of this study were to describe acute fracture morphology, to map fracture patterns onto a three-dimensional scaphoid model and to devise a classification system based on computed tomography (CT).

Methods: In this retrospective, multicenter study, 59 adult (>18yrs) patients with an acute scaphoid fracture who had a CT-scan within 6 weeks after injury were included for analysis. Exclusions: pre-existing scaphoid pathology and scans of insufficient quality (such as slice thickness >2mm). CT scans were segmented manually to create 3D surface rendered models. These models were reduced and superimposed onto a 3D standardised template of an intact scaphoid. Fracture lines of all models were then superimposed onto the template.

Results and Conclusions: Preliminary analysis identified four distinct fracture patterns:
1) Proximal pole: 17% of the fractures ran obliquely and proximal to the dorsal ridge. These fractures were more distal than usually described.
2) Transverse waist: 29% of the fractures fractured transversely through the dorsal ridge
3) Oblique waist: 37% of the fractures ran obliquely along the dorsal ridge
4) Scaphoid tubercle fracture: 17% of the fractures constituted 2 types of tubercle fractures - those localised to the Scapho-Trapezial ligaments, and those that went into the STT joint.

The proximal pole and scaphoid tubercle fractures were rarely significantly displaced. Waist fractures were commonly displaced (31%). Most fractures were 2-part fractures (92%). Remaining fractures (8%) were 3-part fractures, which typically involved displaced oblique waist fractures with a third fragment involving the dorsal ridge.
Figure 1. Radial and ulnar view of three-dimensional right scaphoid fracture map

Conclusion:
3D-CT analysis identified four distinct patterns of scaphoid fractures: proximal pole fractures, transverse waist fractures, oblique waist fractures and tubercle fractures. Waist fractures were commonly significantly displaced, whereas proximal pole and tubercle fractures were not.

Soft tissue reconstruction for preserving metacarpophalangeal joints in the rheumatoid hand

List of authors:
Takaaki Shinohara*, Tatsuo Watanabe¹, Kimitoshi Noto², Takamasa Masuda¹, Taiji Iwasawa¹
¹ Hand and Microsurgery Center, Daido Hospital (Nagoya)
² Hand and Microsurgery Center, Daido Hospital (Nagoay)

Objectives / Interrogation: Implant arthroplasty is a popular surgical procedure for correcting metacarpophalangeal (MP) joint deformity in rheumatoid arthritis (RA) patients. However, there are several problems such as infection, implant breakage, limitation of MP joint flexion. This study reports the surgical results of soft tissue reconstruction for preserving MP joints in rheumatoid hand with ulnar drift and extension loss of the fingers.

Methods: We retrospectively reviewed 21 fingers in 6 RA patients with ulnar drift and extension loss of the fingers who had undergone soft tissue MP reconstruction. Our indication for this procedure are: (1) RA well controlled by medication; (2) MP joint not severely destructed; (3) MP joint is passively correctable. The mean age at the time of surgery was 60 years (range, 55-71). The mean follow-up was 36 months (range, 13-72). Soft tissue MP reconstruction was basically performed in accordance with the method previously described by Wood et al.. Crossed intrinsic transfer was done only in 2 fingers that showed severe ulnar drift (more than 65 degrees). The dislocated extensor tendon was sutured on the dorsal base of the proximal phalanx in all fingers. All patients were evaluated for active range of motion of the MP joints and the degree of ulnar drift in maximum active extension preoperatively and at final follow-up. Comparisons between preoperative and final follow-up active range of motion and the degree of ulnar drift were performed. Postoperative complications were also assessed.

Results and Conclusions: The active finger extension of the MP joint was significantly improved from a preoperative average of -42° (range, -80°-0°) to -9° (range, -35°-0°). The active finger flexion of the MP joint did not change from a preoperative average of 93° (range, 73°-110°) to 93° (range, 50°-110°). The degree of ulnar drift was significantly improved from a preoperative average of 35° (range, 10°-80°) to 9° (range, 0°-35°). There were no serious surgical complications. There are several limitations, including small number of patients and short-term results. However, our procedures provides good results without serious complications if the MP joint not severely destructed and is passively correctable.

The evaluation of Dupuytren's contracture with ultrasonography for safety of Collagenase Clostridium Histolyticum injection

List of authors:
Issei Nagura¹, Takako Kanatani¹, Yoshifumi Harada¹, Atsuyuki Inui², Yutaka Mifune¹, Ryosuke Kuroda²
¹Kobe Rosai Hospital (Kobe)
²Kobe University Graduate School of Medicine (Kobe)

Objectives / Interrogation: The technical instruction leaflet for Collagenase Clostridium Histolyticum (CCH) injection recommends a "2-3mm depth" of injection, however, there is little supporting evidence. We consider that CCH injection into the middle of the cord is optimal to avoid the possible complications of skin laceration or flexor tendon rupture. This study investigated using the long axis images of ultrasonography as a tool to determine the appropriate injection depth.

Methods: 32 patients with Dupuytren's contracture with a mean age of 71.4 years (range; 57-87 years) were included in this study. All patients showed fixed flexion contracture (FFC) of the MCP joint caused by a palpable cord. The average FFC of the MCP joint was 51.4 degree (range; 20-80). We marked the CCH injection point on the skin above the cord and added two injection points proximally and distally with a 2mm distance. Then we measured the thickness of the skin and the width of the cord, and the distance from the skin to the middle of the cord as "the appropriate injection depth" by high resolution ultrasonography with long axis images (SNiBLE; Konica Minolta, Tokyo, Japan).

Results and Conclusions: The average distance from skin to the cord was 1.1mm (range; 0.5-2.0). The average width of the cord was 2.7mm (range; 1.5-3.8). The average distance from the skin to the middle of the cord was 2.4mm (range; 1.5-3.0). There was no difference of the distance among the three points.

Injection of CCH to an adequate depth is very important not only to obtain the maximum effect of collagenase but also to avoid possible complications. By using ultrasonography, we demonstrated that the distance from the skin to the middle of the cord was comparable to that described in the technical manual for the CCH injection namely "2-3mm depth injection is recommended". Using long axial images was practical for the measurement of the three injection points at one time. CCH injection could be possible safely not only relying on the feeling of resistance at the injection but also recognizing the actual depth by the ultrasonography.

Late primary FDP tendon repair under walant

List of authors:
THOMAS APARD*, VANESSA COSTIL1, EGEMEN AYHAN2
1 Ultrasound Hand Center, Clinique des franciscaines (Versailles)
2 University of Health Sciences, Diskapi Yildirim Beyazit, Orthopaedics and traumatology (ankara)

Objectives / Interrogation: After 21 days, the flexor digitorum profundis (FDP) tendon is so retracted that the surgeon considers there will be too much traction and a bad vascularization of the sliding system (flexion contracture or tendon rupture) to obtain a good result.
The aim of this clinical study is to blow the myth that you can’t repair flexor tendon after 21 days if the tendon is retracted prior to the palm.

Methods: In 2 Hand Surgery Centers, we repair 4 patients (aged 19 to 49 year-old) with injured FDP tendon with no other complications (no digital nerve injury, no infection, to joint stiffness) : one index finger, one 3rd finger and two 5th fingers. The FDP tendon have been checked at the first phalanx by high resolution ultrasonography with Doppler mode. Every patient have been treated under wide awake surgery with local anesthesia and no tourniquet (walant technique). The Lalonde and Tang guidelines has been respected : vent of the pulley 1,5 to 2 cm proximaly, solid six strand suture with no gap after several active motion, authorization to move it but not to use it, and education of the patient who see the finger at the end of the procedure. Immediate rehabilitation started few days after surgery.

Results and Conclusions: The ultrasonography was possible for every patient. The Doppler mode was not a good exam to attest if the vascularization was correct around the injured tendon.
The walant anesthesia has been performed successfully for all the patients (no sedative drugs or general anesthesia needed). The tendon was repaired with the respect of a part of A2 pulley. The opening of the A4 pulley was done for 3 patients. At one and a half month follow-up, there was no rupture observed. The mean total active motion (TAM) in flexion (MP+PIP+DIP) was 190° and the mean TAM in extension was 5° of flessum.

A late FDP tendon repair has been performed successfully for this short cohort. We recommend to use ultrasonography to check the retracted FDP tendon and to use the walant technique respecting the Lalonde and Tang guidelines to check the suture.

Wide awake ultrasound guided percutaneous anterior interosseous nerve release

List of authors:
THOMAS APARD*, VANESSA COSTIL1, GILLES CANDELIER2, DONALD LALONDE3
1 Ultrasound Hand Center, Clinique des franciscaines (Versailles)
2 CENTRE DE LA MAIN, CLINIQUE SAINT MARTIN (CAEN)
3 Dalhousie University (Saint John)

Objectives / Interrogation: Anterior interosseous nerve (AIN) palsy is a purely motor neuropathy that comprises less than 1% of all upper extremity nerve palsies. The AIN innervates three muscles in the forearm: flexor pollicis longus (FPL), pronator quadratus (PQ), and the radial half of flexor digitorum profundus (FDP).
AIN compression is classically treated under general anesthesia with open surgical release of the median nerve through a long incision above and below the elbow. More recently, Hagert has published good success sectioning the Lacerates Fibrosus (LF) with a less invasive wide awake approach though a 3 cm incision at the elbow crease in a cohort of patient suffering of AIN compression without palsy.
We present 2 cases report of a AIN palsy, treated with minimally invasive ultrasound guided wide awake release of lacertus compression of the proximal median nerve at the elbow with return of function on the operating table.

Methods: 2 patients (30 year old female and a 26 year old male) presented to the outpatient clinic complaining of a 4 months history of complete palsy in the FPL and index FDP for the male and a unique palsy of the FPL tendon for the female. He was found to have a positive scratch collapse test over the median nerve at the elbow. There was no sensory deficit in the median nerve distribution.
Electrodiagnostic studies supported the diagnosis of a compression neuropathy affecting the AIN at the elbow. An ultrasound examination showed no extrinsic tumor or vascular/nervous abnormalities but the dynamic compression of the median nerve between the pronator teres and the LF. The MRI of the wrist showed a denervation of the FPL and the PQ muscles.
The patients underwent wide awake surgical decompression of the median nerve using a technique similar to the technique described by Hagert. We used a 1 cm transverse skin incision 5 mm distal to the anterior elbow crease to cut the LF with a polycarbonate knife.

Results and Conclusions: We performed an intraoperative total active movement examination, and found the index distal interphalangeal joint and the interphalangeal joint of the thumb were able to immediately actively flex against resistance, compared to no movement preoperatively.
The wide awake ultrasound guided AIN release technique allowed intraoperative active motor examination confirming immediate return of strength of muscle groups involved in AIN palsy.

Targeted Muscle Reinnervation at the Time of Amputation Reduces Pain Severity and Behavior in Upper Extremity Amputations

List of authors:
Andrew O'Brien¹, Sumanas Jordan², Julie West¹, Geoffroy Sisk¹, Steven Schulz¹, Joel Mayerson³, Thomas Scharschmidt³, Gregory Dumanian², Ian Valerio¹

¹ Ohio State University Medical Center, Dept. of Plastic and Reconstructive Surgery, Suite 2100 (Columbus)
² Northwestern University, Div. of Plastic Surgery (Chicago)
³ Ohio State University Medical Center, Dept. of Orthopedic Surgery (Columbus)

Objectives / Interrogation: Targeted muscle reinnervation (TMR) is a technique for the management of peripheral nerves in amputees. Regarding pain management, TMR aims to address symptomatic neuromas, which are disorganized ends of severed nerve fibers encased in scar. Neuromas are often responsible for much of the residual limb pain (RLP) experienced by those with limb loss, limiting function and making the use of prostheses uncomfortable, or even impossible. Moreover, neuromas may be a driver of phantom limb pain (PLP), or the feeling of discomfort in the non-existent limb. We have employed TMR as a means to prevent such pain when performed at the time of amputation.

Methods: A retrospective review of patients who underwent upper extremity amputation with concurrent TMR was performed. Pain was assessed using the NIH-funded Patient-Reported Outcome Measurement Information System (PROMIS) Pain Intensity Short Form 3a, and Pain Behavior Short Form 7a, which assess the intensity and outward manifestations of pain over a 7-day recall period, respectively. Our TMR cohort was compared to benchmarked data from an unselected population of upper extremity amputees.

Results and Conclusions: Sixteen patients who underwent upper extremity TMR at the time of amputation were identified and were compared to 55 patients who underwent upper extremity amputation without TMR. Among TMR patients, 25% underwent transradial amputation, 31.2% transhumeral amputation, and 43.8% underwent shoulder disarticulation. Median follow-up time was 13.7 mos, ranging from 3.1 mos to 5.3 yrs. Nine patients (56%) were using a prosthetic at most recent follow-up, and avg time to prosthetic was 4.7 mos. The mean PROMIS PLP intensity t-score for the general amputee population was 47.02 vs 36.6 in the acute TMR population (p=0.001), representing a statistically significant reduction in the TMR cohort. PROMIS pain intensity for RLP trended towards benefit with TMR (44.68 versus 39.8, p=0.133). Additionally, the PLP behavior t-score among general amputees was 52.2 vs 46.7 in the TMR population (p=0.046), demonstrating a reduction in pain behavior among TMR amputees.

In addition to the benefit of TMR for myoelectric prosthetic control, our study demonstrates that TMR performed at the time of amputation is a promising strategy for improving PLP and RLP severity and behaviors in the upper extremity. TMR performed at time of amputation is cost-effective, technically easier, and permits the patient early prosthetic rehabilitation without need for delayed procedures.

**Tendon transfer and wide awake: innovation and high functional result**

**List of authors:**
Giovanna Petrella¹, Roberto Adani²
¹ Hand and Microsurgery Unit Policlinico di Modena (Modena)
² Chief of Hand and Microsurgery Unit Policlinico di Modena (Modena)

**Objectives / Interrogation:** The wide awake anesthesia technique is the new frontier for hand surgeon. Operating patients under local anesthesia, without the discomfort of the tourniquet, allows you to observe the tension given to tendon transfers by active movements and possibly make changes in tension before skin closure. [1]

**Methods:** We present our case studies of 20 patients, aged between 8 and 86 years, operated with this anesthesiological technique, to which we carried out tendon transfers. The tendon rupture was after degenerative disease. Active rehabilitation was carried out for all to obtain high results.

**Results and Conclusions:** In no case we have obtained a deficit of vascularization of the fingers, never used the tourniquet, in no cases we have assisted tendons rupture or deficit of tension in tendon transfer. No patients felt ill during the surgery and were pleased to have participated like active actor during the surgery.

We believe that the wide awake technique is a good innovation for hand surgery and can perform over 80% of the operations. It is a technique that can be applied to all ages, it does not require the suspension of any therapies and introduces the concept of field sterility

⁵ Vall d'Hebron University Hospital, Institut Kaplan (Barcelona)
⁶ Hospital Universitari Dexeus - ICATME, Hospital Universitari Vall d’Hebron (Barcelona)

Objectives / Interrogation: Metacarpal and phalangeal fractures account for 41% of all below-elbow fractures. Despite most of them can be managed successfully conservatively, unstable fractures often need surgical treatment. We sought to compare the three different techniques most used in extra-articular metacarpal and phalangeal fractures: plate-screw, KW and retrograde intramedullary screw (RIS). We aimed to determine whether retrograde intramedullary screw provides better clinical outcomes than plate-screw or KW fixation.

Methods: We conducted a retrospective review of patients who underwent surgical treatment of metacarpal and phalangeal fractures from January 2011 to December 2017. Only patients with displaced short oblique or transverse extraarticular metacarpal and phalangeal fractures were included. Patients were classified into three groups depending on the treatment received: plate-screw, KW and RIS. The duration of each procedure was collected. Clinical assessments included measuring total active motion, grip strength, and evaluation of plain x-ray until healing. Quick-DASH had been performed in all the patients. The data was analyzed by model analysis of variance (ANOVA) or Kurskall-Wallis rank test.

Results and Conclusions: A total of 253 fractures in 230 patients were included, 202 metacarpal and 51 phalangeal fractures. One hundred thirty-five fractures underwent plate-screw fixation (53.3%), 53 KW fixation (20.9%), and 65 RIS fixation (25.6%). Mean surgery time was significantly shorter in KW (20 min [11-36]) and RIS (25 min [17-38]) groups, compared to plate-screw group (32 min [16-48]) (p<0.05). Loss of reduction occurred in 6 patients in KW group, 2 in plate-screw group and 3 in RIS group. A total of 38 patients of KW group, 33 patients of PS group and 2 patients of RIS required hardware removal. No differences between the three groups were observed when evaluating mean grip strength, total active motion, Quick Dash and mean time to radiological union. Mean return to work time was significantly lower in the plate-screw (7.8 weeks, [3-6]) and RIS (8.3 weeks, [4-24]) groups when comparing to KW group (9.2 weeks, [5-20]) (p<0.05).
Surgical treatment should be individualized in patients with unstable metacarpal and phalangeal fractures. RIS has shown lower surgery duration and time to return to work when compared to plate-screw and KW, respectively, and lower hardware removal compared to both. Prospective randomized study should be performed to better define the advantages of retrograde screw technique.

Distribution of sensory nerve endings in the interosseous membrane of the forearm

List of authors:
Susanne Rein*, Mireia Esplugas², Marc Garcia-Elias², Thomas Magin³, Frank Siemers⁴, Hubertus Philipps¹
¹ Klinikum Sankt Georg, Plastische und Handchirurgie (Leipzig)
² Institut Kaplan, Hand and Upper Extremity Surgery (Barcelona)
³ University of Leipzig, Institute of Biology, Division of Cell and Developmental Biology (Leipzig)
⁴ Trauma Center Bergmannstrost, Department of Plastic and Hand Surgery, Burn Unit (Halle (Saale))

Objectives / Interrogation: The role of proprioception in understanding the dynamic stability and neuromuscular control of the forearm is important for the treatment of forearm injuries involving bone, ligaments and joint capsules. Therefore the aim of the study was to investigate types and distribution of sensory nerve endings in the different parts of the human interosseous membrane of the forearm.

Methods: The distal oblique bundle (DOB), the distal accessory bundle (DAB), the central band (CB), the proximal accessory bundle (PAB), the dorsal oblique accessory cord (DOAC), and the proximal oblique cord (POC) were dissected from twelve human fresh frozen cadaver forearms. Sensory nerve endings were analysed in two levels per specimen as total cell amount/ mm² after immunofluorescence staining with low-affinity neurotrophin receptor p75, protein gene product 9.5, S-100 protein and 4,6-Diamidin-2-phenylindol (DAPI) on an Apotome microscope (Carl Zeiss Microscopy, Jena, Germany) according to Freeman and Wyke's classification.

Results and Conclusions: Free nerve endings were the predominant receptor in all six ligaments with greatest density in the DOB followed by POC. The second most sensory nerve endings were unclassifiable corpuscles, followed by Pacini corpuscles. The DOB had the highest amount of Pacini corpuscles followed by the PAB and POC. The DOAC only contained free nerve endings and unclassifiable corpuscles.
The DOB, PAB and POC had the highest density of sensory nerve endings, which indicates, that control of the dynamic stability of the forearm is pronounced at the distal and proximal radioulnar joint due to the closed proximity of the DOB and POC, respectively.

Nailbed trauma: a review of 76 cases

List of authors:
Jefferson Braga Silva*, Amanda Gros¹, Julia Zubaran¹, Pedro Piccinini¹
¹ PUCRS (Porto Alegre)

Objectives / Interrogation: Nailbed trauma is a commonly overlooked part of fingertip reconstruction. To evaluate outcomes of nailbed injuries treated with different reconstructive techniques, we performed a retrospective review of 76 patients who presented with nailbed injuries.

Methods: We conducted a retrospective chart review of 76 adult and pediatric patients who underwent nailbed reconstructions due to trauma between January 2000 and August 2017 at our institution's division of Hand Surgery and Reconstructive Microsurgery; only patients with at least 12 months of follow-up were included. Outcomes assessed were growth (0 = no growth; 1 = partial growth; 2 = normal growth), size (0 = less than 25%; 1 = between 25 and 50% and 2 = >50% of the size of the contralateral nail) and shape (0 = significant deformity on the horizontal and vertical planes; 1 = vertical deformity, 2 = no deformity) of the nail compared to the contralateral finger. The results obtained by the sum of scores were classified as good (5-6), acceptable (3-4) and poor as previously described by Foucher et al. This study was approved by our institution's institutional review board for ethics in research and performed in accordance with the Declaration of Helsinki.

Results and Conclusions: In our series, 32 patients (42.10%) underwent suturing of the nailbed (SNB); 25 patients (32.89%) underwent suturing of the nailbed associated with an osteosynthesis of the distal phalanx (SNBOst); 19 (25%) received a nailbed graft in the ER (NBGE) (Table 2). The results were considered "good" in all patients who underwent SNB and in those who underwent SNBOst associated with an osteosynthesis of the distal phalanx. "Good" results were also achieved in 57.9% of patients who underwent NBGE. "Acceptable" results were obtained in 42.1% of patients grafted in the ER.

In summary, in our series, patients treated with simple suturing of the nailbed - both those with and without associated finger fractures - and patients who underwent reconstruction of the entire nailbed showed improved outcomes compared to those treated with nailbed grafts. Larger prospective, randomized trials stratified by degree of injury may help guide the most appropriate approach to patients with these challenging injuries.

Surgical Outcomes following Syndactyly Reconstruction - using JSSH Evaluation Form

List of authors:
Junko Otsuka*, Emiko Horii1, Shukuki Koh1, Keizo Fukumoto2
1 Japan Red Cross Nagoya Daiichi Hospital (Nagoya)
2 Saimata Hand Surgery Institute (Higashimatsuyama)

Objectives / Interrogation: The purpose of this study is to investigate long term surgical outcomes after syndactyly release by Japanese Society for Surgery of the Hand Evaluation form (JSSH form) and patient-reported outcomes.

Methods: Eleven patients of 15 hands were included in this study. Involved fingers were 3 index/middle finger, 10 middle/ring, 1 ring/little and 1 middle/ring/little. Ten hands were simple syndactyly (6 showed the complete type, 4 the incomplete type) and 5 hands were complex syndactyly. We used dorsal rectangular flap to create the web and volar triangular flap with full-thickness skin graft for 12 hands, and dorsal Y flap for 3 hands of incomplete type. Of 15 hands, eight hands had undergone a revision surgery. All patients were directly assessed and interviewed. JSSH form includes function (joint contracture), cosmesis (web creep, skin pigmentation, nail deformity, finger deformity, scar quality) and subjective assessment (pain, patient satisfaction). Patient-reported outcomes include Quick DASH and HAND 10, then overall cosmetic appearance was rated in five grades.

Results and Conclusions: Result
An average follow-up interval after the first surgery was 13.5 years (range, 7-21 y). JSSH evaluation form averaged 14.1 points; 4 hands were excellent, 3 good, 5 fair, and 3 hands were poor. Q-DASH averaged 0.4 (0-2.27) and HAND10 averaged 1.63 (0-7). The overall cosmetic appearance averaged 2.6 (1-4). Simple syndactyly showed better outcome compared with complex syndactyly. All patients showed functionally good, but cosmetic factors effected on patient satisfaction. JSSH evaluation reflected well both function and cosmesis.

Conclusion
After long-term follow-up, the most of patients maintained good function, but nail and finger deformities caused poor satisfaction. JSSH evaluation form which includes functional and cosmetic factors is appropriate to assess overall patient condition.

syndactyly, JSSH evaluation
Nailbed regeneration in Pediatric Patients

List of authors:
Jefferson Braga Silva*, Amanda Gros, Julia Zubaran, Pedro Piccinini

1 PUCRS (Porto Alegre)

Objectives / Interrogation: Controversy still exists as to the regenerative potential of the nailbed after trauma, with some recent evidence in rodent models pointing to the interplay between periosteal osteogenic cells and epidermis as potential contributors. In this context, we present a review of 31 patients with Allen type 2 to 4 fingertip injuries who underwent surgery using either an island or Atasoy flap.

Methods: We performed a retrospective chart review of 31 patients who sustained fingertip trauma with nailbed injury. Variables analyzed were age, type of injury (Allen classification), follow-up period, time from trauma to surgery and affected finger(s). Outcomes were evaluated based on presence and degree of tissue necrosis (1 - absent, 2 - less than 50%, 3 - greater than 50%), nail deformity (classified using the Result Reconstructed Fingertip Length Appearance of Nail Unit - and joint mobility. Mobility was evaluated in comparison to the contralateral (CL) phalange and classified as 1 - 100% CL, 2 - 75% CL, 3 - 50% CL, 4 - 25% CL.

Results and Conclusions: Complete data were available for all 31 patients. Most (21) had a crush injury, while four presented with a laceration. Injuries were classified as Allen types 2 (9), 3 (8) and 4 (14). Mean patient follow-up was 26 months. Nine patients, all of which had Allen type 2 crush injuries, underwent reconstruction with an Atasoy flap. None presented with postoperative necrosis. Regarding nail appearance, four was considered “excellent” while six were classified as “good”. Joint mobility was 100% CL in two patients, 99-75% in another two and 74-50% in one patient. The 22 remaining patients with Allen types 2 (4), 3 (7) and 4 (11) injuries underwent reconstruction with an island flap. One patient with an Allen type 4 crush injury developed postoperative tissue necrosis, compromising less than 50% of the affected fingertip. In total, one patient developed partial tissue necrosis, none developed necrosis greater than 50% of the tissue area, five had “good”, rather than “excellent” nail appearance and four had decreased joint mobility compared to the contralateral finger.

Nailbed injury continues to be a relatively underappreciated topic of hand surgery, as many patients who sustain trauma or other injuries to the nails do not seek out medical help, and there is currently no consensus as to the optimal treatment of such injuries.

Determination Minimal Clinically Important Differences (MCIDs) in Patient-Reported Outcome Measurement Information System (PROMIS) Physical Function (PF), Upper Extremity (UE), and Pain Interference (PI) in Carpal Tunnel Release

List of authors:
Warren Warren Hammert\(^1\), David N Bernstein\(^1\), Jeff R Houck\(^2\), Bilal Mahmood\(^1\)
\(^1\) University of Rochester Medical Center (Rochester, NY)
\(^2\) George Fox University (Newberg, OR)

Objectives / Interrogation: An uncertainty exists about what change in PROMIS scores represents a true clinically relevant improvement (minimal clinically important difference [MCID]) in hand surgery care. Using a region-specific PRO tool (Michigan Hand Question (MHQ)) and a condition-specific PRO tool (Boston Carpal Tunnel Questionnaire (BCTQ)) as anchors, MCID values were determined for PROMIS PF, UE, and PI among patients undergoing carpal tunnel release (CTR).

Methods: Patients undergoing carpal tunnel release with a single surgeon from November 2014 to April 2017 were asked to complete the BCTQ, MHQ and PROMIS PF, UE, and PI CAT at each visit. Patients who had completed questionnaires both at a preoperative and either a six-week or three-month postoperative visit were included. MCID values were calculated using established methods in the literature with both region- (i.e., MHQ) and condition-specific (i.e., BCTQ) PRO tool anchors. The region-specific anchor was the MHQ Satisfaction domain, while the condition-specific anchor was the average score of the two BCTQ domains.

Results and Conclusions: A total of 70 patients fit our inclusion criteria. The average age was 61 years (range, 27-86 years) and a minority were men (34.3%). Of our sample, 43 patients (61.4%) had a six-week follow-up, while 27 patients (38.6%) had a three-month follow-up. Using MHQ Satisfaction, PROMIS UE and PI MCIDs were 4.60 and -3.90, respectively; PROMIS PF could not be calculated. Using the average of the two BCTQ domains, PROMIS PF, UE, and PI MCIDs were 2.45, 3.50, and -3.90, respectively.

PROMIS UE and PI can be used to determine MCID cut-offs similarly to both region- and condition-specific PRO tools for patients undergoing CTR. PROMIS PF does not perform as well.

Keywords: Patient-Reported Outcomes; PROMIS; Carpal Tunnel; MCID
Comparing the Responsiveness and Validity of the Patient-Reported Outcome Measurement Information System (PROMIS) domains to Region- and Condition-Specific Patient-Reported Outcome (PRO) Tools in Carpal Tunnel Release

List of authors:
Warren Warren Hammert*, David N Bernstein\(^1\), Jeff R Houck\(^2\), Constantinos Ketonis\(^1\), Bilal Mahmood\(^1\)
\(^1\)University of Rochester Medical Center (Rochester, NY)
\(^2\)George Fox University (Newberg, OR)

Objectives / Interrogation: There is a growing trend in surgical care to utilize patient-reported outcomes (PROs) to improve shared decision-making, guide expectation setting, and improve clinical care. We aimed to determine if PROMIS Physical Function (PF), Upper Extremity (UE), and Pain Interference (PI) domains were as responsive and valid in evaluating carpal tunnel release as region-specific (Michigan Hand Questionnaire (MHQ)) and condition-specific PRO tools (Boston Carpal Tunnel Questionnaire (BCTQ)).

Methods: Patients undergoing carpal tunnel release with a single surgeon from November 2014 to April 2017 were asked to complete the BCTQ, MHQ and PROMIS PF, UE, and PI CAT at each visit. Patients who had completed questionnaires both at a preoperative and either a six-week or three-month postoperative visit were included. The effect size index (ESI), a common index of change to judge responsiveness, was utilized. Convergent validity was evaluated using Spearman correlation coefficients.

Results and Conclusions: A total of 70 patients fit our inclusion criteria. The average age was 61 years (range, 27-86 years) and a minority were men (34.3%). All PRO domains demonstrated at least a medium effect size at final follow-up except for PROMIS PF (ESI = 0.25) and MHQ Aesthetic (ESI = 0.02). Within PROMIS, the PI domain demonstrated the best responsiveness (ESI = 0.74), followed by the UE domain (ESI = 0.66). Within the MHQ, the Satisfaction domain demonstrated the largest effect size (ESI = 1.48), followed by the total score (ESI = 1.22). Within the BCTQ, the symptom severity domain demonstrated the best responsiveness (ESI = 1.54), followed by the average of the two BCTQ domains (ESI = 1.27). PROMIS UE and PI demonstrated significant correlations with MHQ Satisfaction and the average of the two BCTQ domains, which are two anchors in the literature; however, PROMIS PF did not.

PROMIS UE and PI demonstrated concurrent validity with the MHQ and BCTQ, while PROMIS PF did not. While PROMIS UE and PI were responsive, the domains were not as responsive as MHQ and BCTQ domains. These findings suggest that PROMIS UE and PI domains are valid and may add value in being universal but that there is a minor trade-off in responsiveness.

Treatment of Proximal Pole Scaphoid Nonunion with Capsular-Based Vascularized Distal Radius Graft

List of authors:
Loukia Papatheodorou*1, Dean Sotereanos1
1 University of Pittsburgh Medical School, Orthopaedic Specialists -UPMC (Pittsburgh)

Objectives / Interrogation: Treatment of proximal pole scaphoid nonunion with avascular necrosis is a challenging issue. We retrospectively reviewed the results of 89 patients with proximal pole scaphoid nonunion, 58 with avascular necrosis, treated with a capsular-based vascularized distal radius graft.

Methods: Seventy-one male and eighteen female patients with symptomatic nonunion at the proximal pole of the scaphoid were included in this study. No patient had a humpback deformity. The mean patient age was 28 years (range, 19-44). In all patients, the vascularized bone graft was harvested from the distal aspect of the dorsal radius and was attached to a capsular flap of the dorsal wrist capsule. The graft was vascularized by the artery of the fourth extensor compartment. After fixation of the scaphoid with a small cannulated screw, the graft was inserted press-fit into a dorsal trough across the nonunion site. Supplementary fixation of the graft with a micro suture anchor into the scaphoid was used in 66 patients. At follow-up each patient was evaluated with clinical and radiographic examination.

Results and Conclusions: At a mean time of 12.3 weeks (range, 6-24) after surgery, solid union was achieved in 76 of 89 patients (49 of 58 with avascular necrosis). Eleven patients had persistent non-union and two fibrous union as determined by CT scan. Sixty-six of the patients with solid bone union were completely pain free and ten complained of slight pain with strenuous activities. Wrist flexion and extension were improved postoperatively. The average grip strength at the final follow-up was 84% of the contralateral arm, compared with 67% before surgery. The mean modified Mayo wrist score significantly improved from 42 to 87. No arthritic changes were noted at the dorsal ridge of the radius. No donor site morbidity was observed.

Results of the use of a capsular-based vascularized bone graft from the distal radius for scaphoid nonunions compare favorably with the results of pedicled or free vascularized grafts. The capsular-based vascularized bone graft from the distal radius is a reliable alternative technique for scaphoid nonunions. It is a simple technique that eliminates the need for dissection of small-caliber pedicle or microsurgical anastomoses. The supplemental fixation with a micro suture anchors eliminates the risk of graft displacement.

Intra-operative Subluxation of the Ulnar Nerve: Use of a Triceps Sling Reconstruction to Avoid Transposition

List of authors:
Loukia Papatheodorou*, Dean Sotereanos
1 University of Pittsburgh Medical School, Orthopaedic Specialists -UPMC (Pittsburgh)

Objectives / Interrogation: Ulnar nerve subluxation may occur in up to 17% of patients after in situ release of the ulnar nerve for the treatment of cubital tunnel syndrome. Several surgical techniques have been described to address the ulnar nerve subluxation, including anterior transposition of the ulnar nerve, and minimal medial epicondylectomy. None of which have been reported to be objectively superior to the other in the literature. We retrospectively analyzed the outcomes of 12 patients who underwent a triceps sling reconstruction for intraoperative ulnar nerve subluxation after in situ decompression of the nerve.

Methods: There were 8 women and 4 men with a mean age of 41 years (range, 33-56 years). The subluxation of the ulnar nerve over the medial epicondyle of the elbow was noted with flexion and extension of the elbow after cubital tunnel release with release of Osborne’s ligament as posterior as possible. In all patients, a distally based small strip of triceps tendon was harvested. The strip was sutured to the posterior aspect of Osborne’s ligament. Thus a “sling” is created between the medial epicondyle and the olecranon preventing the nerve from subluxating. At completion, the elbow was flexed and extended, noting no further subluxation of the ulnar nerve through the entire range of motion. Patients were clinically evaluated preoperatively and postoperatively.

Results and Conclusions: The mean final follow-up was 31 months (range, 24 to 38 months). There was no postoperative subluxation of the ulnar nerve. Mean patient visual analog pain scores significantly improved from 8.6 before surgery to 0.2 after surgery. Static 2-point discrimination was improved by a mean 9.1 mm preoperatively to 5.7 mm postoperatively. Strength significantly improved by a mean of 37% and 34% with grip and pinch, respectively. No patients required additional surgery. No other complications were encountered. All patients returned to full activities.

Triceps sling reconstruction is a safe and effective alternative procedure to anterior transposition of the ulnar nerve in patients with intraoperative ulnar nerve subluxation following in situ decompression. With the triceps sling reconstruction, the blood supply of the ulnar nerve is preserved.

The key clinical symptoms that differentiates cervical radiculopathy from cubital tunnel syndrome

List of authors:
Takashi Ogawa¹, Takao Omura¹, Tomohiko Hasegawa¹, Yukihiro Matsuyama¹
¹Hamamatsu University school of medicine (HAMAMATSU)

Objectives / Interrogation: Ulnar nerve is supplied by fibers originating from C8, T1 roots and it is sometimes difficult to differentiate cubital tunnel syndrome (CuTS) from C8 radiculopathy. The purpose of this study was to retrospectively review cases of C8 radiculopathy that were referred to our hospital that were diagnosed as CuTS at the previous hospital.

Methods: 238 cases who were referred to our department suspected for CuTS were included in this study. All the patients were examined for their neurological symptoms and underwent electrophysiological study. Among the patients with normal conduction velocity (NCV), 22 cases were diagnosed as C8 radiculopathy by MRI. We investigated the clinical symptoms of elbow and cervical spine, radiographic findings, distribution of the paralyzed muscles and the electrophysiological testing results.

Results and Conclusions: The numbness at the ulnar half of the ring and little finger was observed in 18 cases (88%), and in 14 cases (64%) the area of numbness was observed in the forearm, extending proximally to the wrist crease. Positive Tinel's like sign was observed in 5 cases (23%) and positive Froment sign also in 5 cases (23%). However, spurling or Jackson sign of the cervical spine was positive in only 1 case (5%). In radiographic evaluation, 8 cases had osteoarthritis of the elbow (36%), 13 cases had spondylosis change of the cervical spine (59%) and only 1 case had C7/Th1 intervertebral foramen disorder (5%). On manual muscle testing, 17 cases had paralysis of the first dorsal interosseous muscles (IOD (1)) or the abductor digiti minimi muscle of little finger (ADQ) (77%), but a part of these muscles innervated by the ulnar nerve, some cases had paralysis of the extensor digitorum or the abductor pollicis brevis muscle. In all cases, conduction velocity of the ulnar nerve was normal, but the amplitude was decreased to 80% in comparison with the healthy side. After the diagnosis of C8 radiculopathy, 3 cases (14%) received surgical treatment and the rest were treated conservatively.

The most common difference between a typical CuTS and C8 radiculopathy was sensory disturbance extending to the ulnar side of forearm. Also, paralysis was present in the muscles innervated by the radius and the median nerve, so a detailed evaluation of the muscle strength is required. The electrophysiological testing shows normal conduction velocity of the ulnar nerve but reduced amplitude in C8 radiculopathy.

Arthroscopic resection of volar wrist ganglion: surgical technique description and a prospective series of 39 patients

List of authors:
Ricardo Kaempf*1, João Farina Brunelli1, Márcio Aita2, Gustavo Mantovani3, Vicente Carratalá Baixauli4, Pedro J Delgado5
1 Hospital Santa Casa de Porto Alegre (Porto Alegre)
2 Faculdade de Medicina do ABC (São Paulo)
3 Hospital Beneficência Portuguesa (São Paulo)
4 Hospital Quiron Salud (València)
5 Hospital Universitario Monteprincipe (Madrid)

Objectives / Interrogation: To describe the technique and results of arthroscopy for the surgical treatment of volar ganglion cyst of the wrist.

Methods: This study comprised 39 patients that were submitted to arthroscopic treatment of volar ganglion cysts of the wrist during January 2015 to May 2017, with minimum follow-up of six months. The technique was indicated for those patients who presented pain and functional impairment for more than four months, with no improvement with conservative treatment, or for those with cosmetic complaints and the presence of the cyst for over three months.

Results and Conclusions: Mean patient age was 42.4 years; 28 were females (71%), and 23 affected the right side (59%). Mean follow-up from surgery to final assessment was 8.8 months. Two patients complained postoperatively of mild pain, whilst another patient presented slight motion restrictions. The 37 remaining patients reported improvement of cosmetic complaints, along with complete functional recovery, and pain improvement. There were no recurrences or infections. No patient required further surgery. The arthroscopic resection of volar ganglion cyst is a useful and safe technique. It is a minimally invasive procedure, with low morbidity and very few complications, representing a good alternative to the open technique.

Free osteochondral graft from ipsilateral hand for treatment of partial finger joint defects in adult

List of authors:
Hideki TANAKA*
1 Niigata Prefectural Yoshida Hospital, Department of Orthopaedic Surgery (Tsubame-shi, Niigata)

Objectives / Interrogation: This retrospective study was designed to evaluate clinical results of partial finger joint cartilage defects using osteochondral graft taken from ipsilateral hand in adults.

Methods: Since 1996, 9 fingers of 9 patients were reconstructed by free osteochondral graft. There were 5 men and 4 women with an average age of 42 years (rang, 20 - 68years). The affected joints were 2 MP joints and 4 PIP joints and 3 DIP joints (3 index fingers, 2 long fingers, 3 ring fingers, 1 little finger).

The average cartilage defects was 46% (range, 20 % to 60%). Four joints combined 20% to 50% concomitant cartilage damage facing main lesions.

In 8 patients, surgery was performed at 3 days to 12 years after injuries. In a patient with bone tumor, reconstruction was done at the same time of tumor resection.

Damaged lesions were debrided and prepared for the graft. Osteo-cartilage defects of metacarpal head and proximal phalanx head were replaced by a part of capitate or trapezoid which was close to the shape of original joint surface. In patients with defects of proximal phalanx or middle phalanx base, 2nd or 3rd metacarpus base were adopted as the donor. In a particular case with partial loss of DIP joint, osteo-cartilage graft including a part of ECR tendon was transplanted. The graft was fixed by K-wires.

ROM exercise was started at 4 or 5 weeks after surgery.

The postoperative follow-up period ranged from 6 months to 41 months with a mean of 15 months.

Results and Conclusions: There was neither motion pain nor instability on the recipient. Mean ROM of PIP joints increased from 38 degrees to 53 degrees, and mean ROM of DIP joints increased from 0 degree to 17 degrees. In a patient with traumatic partial loss of DIP joint, it failed to ankylosis 9 months after the surgery.

The grafts were all survived, although shrinkage of grafts were detected in 2, and erosive change in 3.

Six donor sites after harvesting of the graft were filled with autogenous bone graft without morbidity.

The requisite shape of joint defects can be reconstructed using a shape-matched portion of cartilage surface of capitate, trapezoid or base of metacarpus within the same surgical field.

Although there is limited indication and technical difficulties, but satisfactory functional results can be expected without donor morbidity.

Relationship between width of volar locking plate and loss of reduction in distal radius fracture.

List of authors:
Masashi Isaji*, Masatoshi Amako, Ryoji Fujimaki, Mao Yamada, Kazuhiro Chiba
1 JSDF Central Hospital, Orthopaedics (Tokyo Setagaya)
2 National Defense Medical College, Department of orthopaedic surgery (Saitama Tokorozawa)

Objectives / Interrogation: Volar locked plating (VLP) is a standard procedure for distal radius fracture (DRF). The width of locking plate is usually decided in accordance with the width of the distal radius, however, the optimal width of the plate is not well known. The purpose of this study was to disclose relationship between the width of the plate and loss of reduction after VLP fixation.

Methods: Forty-three patients with DRF were treated using VLP between 2014 and 2017. There were 28 females and 15 males, with an average age of 62.4 years. The average follow-up period was 8.1 months. According to AO classification, there were 7 type A, 2 type B, and 34 type C. The maximum width of the plate and the distal radius were measured on the radiological frontal view, and the radio-plate ratio were calculated. We also evaluated loss of reduction by changes in three radiological parameters, radial inclination, palmar tilt, and ulnar variance from immediate after surgery to the final follow-up. Correlation coefficient between the radio-plate ratio and loss of reduction were evaluated. We also divided patients into two groups according to the radio-plate ratio: the wider group (more than 0.65), and the narrower group (less than 0.65), and compared loss of reduction and postoperative complications.

Results and Conclusions: The radio-plate ratio were distributed between 0.56 and 0.85, with an average of 0.72. There were no significant correlations between the radio-plate ratio and the three radiological parameters. There were no significant difference in three parameters between two groups. Although, the narrower group had no complication, one patient with tendinitis of the flexor pollicis longus was observed in the wider group.

DRF is usually treated with a wider plate, and all comminuted fragments are fixed by locking screws, however there was no difference in loss of reduction between those treated with wider and narrower plates. Because we experienced one case of flexor tendinitis in patients treated with a wider plate, we believe that most DRFs could be fixed sufficiently with a narrower plate, and with less complications.

Long-term follow-up of partial intercarpal arthrodesis after excision of the lunate for advanced Kienböck disease

List of authors:
Katsumi Takase*, Kengo Yamamoto
1 Tokyo Medical University, Department of Orthopedic Surgery (Tokyo)

Objectives / Interrogation: When the Kienbock’s disease becomes advanced, carpal collapse, joint incongruity, and osteoarthritis develop. For these patients, we have performed the collapsed carpal bone excision, capitate osteotomy and partial intercarpal fusion. At this time, we have formed the newly radio-carpal joint using the articular surface of the proximal capitate. In this study, we report therapeutic results of the procedure on the patients with the advanced Kienbock’s disease.

Methods: The materials were 28 patients, consisting of 18 males and 10 female. The mean age at time of surgery was 44.9 years. The stage of these diseases was stage 3b in 9 and 4 in 19 patients. The mean follow-up period was 142.7 months. Of these patients, 10 to 15 years follow-up was 6 patients, and more than 15 years follow-up was 15 patients. Therapeutic results were evaluated based on the scoring system of Evans et al..

Results and Conclusions: For most patients, pain had disappeared after surgery. For only one patient, the intensity of the pain was reduced to a mild level. On the patients, good were achieved in 20 patients, fair in six, poor in two, and very poor in none. In the range of motion at the wrist joint and the grip strength postoperatively, mean palmar flexion was 42.2 °, mean dorsi flexion was 51.7 °, and mean grip strength was 83.1 % of that on the unaffected side. Postoperative radiographs showed that the carpal bone parameters (carpal height index and radio-scaphoid angle) had improved. Although radiographic osteoarthritic changes occurred in all patients, except for moderate limitation of range of motion at the wrist joint, these findings did not affect their level of pain, grip strength, or activity of daily living.

Lunate excision, capitate osteotomy and intercarpal fusion (the modified Graner procedure) is a reliable form of treatment for patients with advanced Kienböck’s disease for at least ten years postoperatively.

Determinants of subjective and clinical outcomes one year after proximal interphalangeal joint surface replacement

List of authors:
Stefanie Hensler*, Daniel B. Herren¹, Miriam Marks¹, Martina Wehrli¹, Stephan Schindele¹
¹ Schulthess Klinik (Zürich)

Objectives / Interrogation: Predicting the outcome of a medical intervention can help both the patient and surgeon in the decision-making process for treatment. There is little knowledge on the predicting factors for subjective and clinical outcome, especially for proximal interphalangeal (PIP) joint replacement. Therefore, our study objective was to identify the preoperative predictors for subjective and clinical outcome in patients with primary osteoarthritis (OA) one year after PIP joint surface replacement surgery.

Methods: All PIP joint OA patients treated with a CapFlex-PIP implant (KLS Martin Group, Tuttlingen, Germany) were prospectively documented in a clinical registry. Sociodemographic, surgical and radiographic data were recorded at baseline. Patients completed the brief Michigan Hand Outcomes Questionnaire (brief MHQ) and rated their pain at rest and during activities of daily living on a 10-point numeric rating scale before and one year after PIP joint replacement. In addition, PIP joint range of motion (ROM) was measured. In order to identify predictors for the brief MHQ, pain at rest and PIP joint ROM one year after surgery, all baseline variables were entered into three multivariate linear regression models and described with R-square ($R^2$) coefficients.

Results and Conclusions: One hundred and nineteen patients with 119 PIP joints and a mean (± standard deviation) age of 70 (±9) years were included in the analysis. Predictors of a higher brief MHQ score one year after surgery were a better baseline brief MHQ score, higher baseline pain level at rest, greater preoperative PIP joint ROM, less finger axis deviation, and if one of the ulnar sided fingers (i.e. ring and small finger) was affected ($R^2 = 0.24$). However, it was impossible to predict postoperative pain at rest ($R^2 = 0.06$) and PIP joint ROM ($R^2 = 0.10$) using baseline factors.

Subjective hand function measurements are more suitable for the prediction of postoperative outcomes after PIP joint surface replacement. Consequently, the decision for treatment should preferably be based on patient-reported hand function rather than clinical variables. The fit of our models was quite low. Further evaluation of additional predictors seems necessary in order to provide a robust predicting model to support the future decision-making process for PIP joint replacement.

Surgical approach to management of perilunate dislocations - Volar or Dorsal or Combined?

List of authors:
Chaitanya Dodakundi*1, Khalid Alawadi1, Nebojsa Jovanovic1
1 Rashid hospital, Department of Trauma, Hand and Microsurgery Unit (Dubai)

Objectives / Interrogation: Perilunate dislocations are rare injuries of the wrist occurring in high energy trauma and hence missed in the emergency room. Management consists of early closed reduction or open reduction, fracture fixation and ligament repair. Previous studies have used different approaches and the management has been towards fracture fixation and scapholunate ligament repair, however with no clear management of lunotriquetral joint. We highlight upon combined volar-dorsal approach for definitive treatment in perilunate dislocations with or without other carpal bone fractures, their diagnosis and management.

Methods: Patient were included from a tertiary referral center between August 2015 to August 2017 with a minimum follow up of one year. All patients underwent closed reduction in emergency under conscious sedation or external fixation when not reducible as soon as possible considering these were patient with high energy trauma. Once the swelling subsided they were taken up for definitive management with open reduction and fixation with ligament repairs. Intraoperative findings were recorded and patients were followed up at regular intervals. Assessment were made in terms of fracture healing, range of movements, pain, radiological angles and wrist scoring.

Results and Conclusions: There were 22 patients among which 19 were males, all involving high energy trauma with road traffic accidents as the most common cause and fall from a height of more than 3m being the second most common cause. 18 patients had closed reducion in emergency and 4 patients needed reduction and external fixation. All patients underwent combined volar and dorsal approach with fracture fixation and ligament repairs. Grade 3-4 Scapholunate injuries were noted in all 10 patients who had pure ligamentous type of perilunate dislocation which were repaired and stabilized with Scapholunate and Scapho capitate wires. Lunotriquetral ligament was torn in all which was addressed using the volar approach by direct repair and K wire fixation. One patient had scaphoid non union, Average range of motion was 90 degrees in flexion-extension, persistent VISI was seen in 2, DISI in 4 with Grade 4 scapholunate tears and 18 patients had good results using the Mayo wrist scoring.

Conclusion- Using combined volar and dorsal approaches for perilunate dislocations is of paramount importance to address both the scapholunate and lunotriquetral ligaments along with fracture fixation.

PIP joint lateral stability in healthy joints compared to surface replacement and silicone arthroplasty

List of authors: Stefanie Hensler*, Pascal Behm2, Stephen J. Ferguson2, Daniel B. Herren1, Stephan Schindele1
1 Schulthess Klinik (Zürich)
2 Institute for Biomechanics, ETH Zürich (Zürich)

Objectives / Interrogation: To date, there is no objective quantitative data on the natural lateral stability of healthy proximal interphalangeal (PIP) joints or the postoperative stability of different PIP joint arthroplasties. The objective of this study was to quantify the lateral stability of healthy PIP joints using a three-dimensional (3D) motion capture system, and compare it to affected joints after surface replacement and silicone arthroplasty.

Methods: Three study groups comprised healthy participants, patients with PIP joint osteoarthritis treated with a surface replacing implant (CapFlex-PIP, KLS Martin Group, Tuttlingen, Germany) and those with a silicone arthroplasty. All participants were matched for gender and finger, and the two treated patient groups were also matched according to the follow-up time point. For measuring lateral stability, an optical tracking system was used (CamBar B2 C4, Axios 3D GmbH, Oldenburg, Germany). Radial and ulnar stability of the PIP joint was measured as the maximal lateral deflection angle of the intermediate phalanx under a 170 gram load at 20 degrees PIP joint flexion angle. Measurement reliability was evaluated with a test-retest (intraclass correlation coefficient (ICC)) method. Descriptive statistics were presented as median (range) values.

Results and Conclusions: A total of 30 participants (21 female, 9 male; median age 69 years (52-83)) were assessed including 5 index and 5 middle fingers in each of the three groups. Patients had a median follow-up of 3 years (1-5). The median radial deflection angles were 2.8° (0.8-10.0) for healthy joints, 3.1° (0.7-10.5) for the surface replacement group, and 5.1° (1.0-12.6) for the silicone arthroplasty group; the median ulnar deflection angles were 2.9° (0.5-6.2), 2.8° (0.9-11.0), and 3.9° (1.4-6.9), respectively. Test-retest reliability was high with an ICC of 0.93.

Lateral PIP joint stability shows high variability in both healthy participants and patients after PIP joint arthroplasty. Joints after silicone arthroplasty tend to have higher lateral deflection angles than unaffected healthy joints and joints with a surface replacement arthroplasty. Combined with the possibility to quantify lateral PIP joint stability precisely and reliably, we assume that certain healthy joints show natural joint laxity and that PIP surface replacement arthroplasty tends to achieve anatomical baseline stability with higher intrinsic stability compared to flexible silicone implants.

Keywords: Lateral stability, motion capture system, proximal interphalangeal joint, surface replacement, silicone arthroplasty, CapFlex-PIP, osteoarthritis
Risk factors and outcomes of revision trapeziometacarpal arthroplasty

List of authors:
Simo Mattila*, Eero Waris

1 Helsinki University Hospital, Department of Hand Surgery (Helsinki)

Objectives / Interrogation: Although the majority of trapeziometacarpal arthroplasties result in favorable outcomes, 3-5% of patients do not benefit from the procedure at all or develop recurrent symptoms making revision surgery necessary. Outcomes of revision surgery have been reported in rather small patient series. Studies comparing outcomes of revision surgery after conventional resection arthroplasty and implant arthroplasty are lacking and data on risk factors for revision surgery is limited.

Methods: A chart review of the years 2003-2013 identified 1174 trapeziometacarpal arthroplasties. Of these 32 were performed with an implant. Alltogether, 69 patients had had a total of 88 revision procedures. At a clinical and radiologic followup visit subjective analysis was carried out with the Quick disabilities of the arm, shoulder and hand score, patient evaluation measure and visual analog score for pain. Objective assessment included strength and range of motion measurements. Standard posteroanterior radiographs of the hand were obtained. The revision rate, risk factors for revision, factors affecting the outcome of revision and the outcomes of revised patients were analyzed.

Results and Conclusions: The revision rate was 4.6 % for conventional arthroplasty and 59.4 % for implant arthroplasty. Patient age under 55 years was a risk factor (OR 3.3, p=0.00) and an operation on both thumbs at some point in time was a negative risk factor for revision surgery (OR 0.444, p=0.021). There was no difference in revision risk between tendon interposition ligament reconstruction with or without a bone tunnel (p=0.267). No factors affecting the outcome of revision surgery could be identified and there was no difference in outcomes after revision between cases operated on primarily with conventional or implant techniques.

The revision rate is in the same range as previously described. Young age is a risk factor for revision and ligament reconstruction tendon interposition with a bone tunnel does not reduce the risk of revision surgery. Multiple revision procedures do not result in worse outcomes than cases revised only once. The final outcome after revision seems to be the same regardless of the primary surgical method used for trapeziometacarpal arthroplasty.

Trapeziometacarpal, arthroplasty, revision, outcome, implant
Cost-utility analysis of surgery for trapeziometacarpal osteoarthritis

List of authors:
Cécile Grobet*, Laurent Audigé¹, Klaus Eichler², Flurina Meier², Simon Wieser², Daniel Herren¹
¹ Schulthess Klinik (Zürich)
² Winterthur Institute of Health Economics, Zurich University of Applied Sciences (Winterthur)

Objectives / Interrogation: Knowledge about the costs and benefits of hand surgical interventions is important for surgeons as well as social insurances and health policy decision makers. Little is known about the impact of surgery for trapeziometacarpal osteoarthritis (TMC OA) on the quality of life and costs. Therefore, we examined the impact of surgery for TMC OA on the quality of life, direct medical costs and loss of productivity from the societal perspective in the Swiss health care setting.

Methods: Patients with TMC OA indicated for surgery were included in a prospective study. Quality of life (EQ-5D-5L; [index: 0-1]) and hand function (brief Michigan Hand Questionnaire [brief MHQ: 0-100]) were assessed one year before (pre-OP) and up to one year after surgery (post-OP). Their relationship was explored by regression analysis. Eleven major Swiss insurance companies provided direct medical cost data including all health-related diagnoses to consider potential side effects of the surgery. Indirect costs were assessed using the work productivity and activity impairment questionnaire. The year pre-OP served as the control period. Mean total costs to gain one extra quality adjusted life-year (QALY) were estimated by calculating the incremental cost-effectiveness ratio (ICER). Costs are given in 2018 US$ (with a conversion rate of 1.042 from Swiss Francs to US$).

Results and Conclusions: A total of 151 patients (mean age 65.3 years; 77% female) were included and received surgical treatment either as resection or implant arthroplasty. The mean EQ-5D-5L index improved from 0.69 (pre-OP) to 0.88 (post-OP; p < 0.001) and was significantly associated with the brief MHQ (p < 0.001), which improved from 49 (pre-OP) to 83 (post-OP; p < 0.001). Mean total costs were 11,382 US$ in the year pre-OP and comprised the conservative treatment of TMC OA, comorbidities and productivity losses. In the year post-OP, mean total costs including surgical costs and rehabilitation of TMC OA, comorbidities and productivity losses increased to 16,388 US$. The ICER was 25,834 US$ per QALY gained (95%CI: 12,033 to 39,636 US$/QALY) one year post-OP compared to the pre-OP control period.

TMC OA surgery using either resection or implant arthroplasty results in a clinically relevant and statistically significant increase in function and quality of life one year after the intervention. The cost-utility ratio of 26,000 US$ is clearly below the discussed Swiss threshold of about 100,000 US$/QALY.

Keywords: cost-utility, cost-effectiveness, costs, osteoarthritis, trapeziometacarpal osteoarthritis, resection arthroplasty, implant arthroplasty, quality of life, incremental cost-effectiveness ratio
Portal placement in elbow arthroscopy by novice surgeons: cadaver study

List of authors:

Harvard Medical School, University of Amsterdam, Orthopaedic Hand and Upper Extremity Service, Massachusetts General Hospital, Boston (Boston)
Orthopedic Research Center, Ghaem Hospital (Mashhad)
Orthopaedic Hand and Upper Extremity Service, Massachusetts General Hospital (Boston)
Orthotrauma Research Center Amsterdam Resident, University of Amsterdam Orthopaedic Residency Program (Amsterdam)
Sports Medicine Service, Massachusetts General Hospital (Boston)
Shoulder and Elbow Unit, Onze Lieve Vrouwe Gasthuis, Amsterdam, The Netherlands (Amsterdam)
Orthotrauma Research Center Amsterdam Resident, University of Amsterdam Orthopaedic Residency Program (Amsterdam)

Objectives / Interrogation: In this anatomical cadaver study, the distance between major nerves and ligaments at risk for injury and portal sites created by trainees was measured. Trainees, inexperienced in elbow arthroscopy, have received a didactic lecture and cadaver instruction prior to portal placement. The incidence of iatrogenic injury from novice portal placement was also determined.

Methods: Anterolateral, direct lateral, and anteromedial arthroscopic portals were created in ten cadavers by ten inexperienced trainees in elbow arthroscopy. After creating each portal, the trajectory of the portal was marked with a guide pin. Subsequently, the cadavers were dissected and the distances between the guide pin in the anterolateral, direct lateral, and anteromedial portals and important ligaments and nerves were measured.

Results and Conclusions: RESULTS:
The difference between the distance of the direct lateral portal and the posterior antebrachial cutaneous nerve (PABCN) (22 mm, p < 0.001), the lateral antebrachial cutaneous nerve (4.0 mm, p < 0.001), and the radial nerve (25 mm, p < 0.001) was different from the average reported distances in the literature. A difference was found between the distance of the anterolateral portal and the PABCN (32 mm, p < 0.001) compared to previous studies. Three major iatrogenic complications were observed, including: laceration of the posterior bundle of the medial ulnar collateral ligament, lateral ulnar collateral ligament midsubstance laceration, and median nerve partial laceration.

CONCLUSION:
Surgeons increasingly consider arthroscopic treatment as an option for elbow pathology. In the present study a surgical complication rate of 30 % was found with novice portal placement during elbow arthroscopy. Furthermore, as the results from this study have indicated, accurate, precise, and safe portal placement in elbow arthroscopy is not easily achieved by didactic lecture and cadaver instruction session alone. Level of evidence V.

Type of "gloves" - tractional damage of fingers

List of authors:
Mismil Muradov*, Kanat Mukhamedkerim1, Aliya Baiguzeva1, Kymbat Kazantayev1, Daniyar Koshkarbayev1
1 NSC of Surgery named after A.N. Syzganov (Almaty)

Objectives / Interrogation: The choice of tactics of surgical treatment for traction finger damage by the type of "gloves".

Methods: From January 2014 to January 2018 we treated 29 patients with a tractional damage of fingers. Of these, 13 were men, and women 16. For the distribution of damage, we used the classification by J. R. Urbaniak, in the modification R. Adani (1996). Group I patients received only conservative treatment with timely provision of specialized care. Anti-inflammatory treatment was used, including corticosteroid preparations, microcirculatory drugs, anticoagulants, painkillers, physiotherapy and immobilization. Patients of group II were subjected to surgery aimed at normalizing blood circulation, with extensive defects we used "Filatov flap". Damaged vessels were recovered under x8 fold increase. Binocular magnifiers, microsurgical instruments and microsurgical material 9/0-10/0 was used.

7 (35%) patients of this group recovered the patency of one vein, 3 (15%) - two veins, 4 (20%) - one artery, 6 (30%) - one artery and one vein.

In group of II patients dominated venous insufficiency: 66.6% (6 patients), in 3 patients (33.3%) the arterial. When manifestations of venous insufficiency, medical leeches were also used.

Results and Conclusions: In the postoperative period, the dynamics were controlled clinically. Of the 29 examined at 21 (72.4%) was evaluated as a good result, these patients were operated during early after trauma (within 3-4 hours from the time the injury). In 8 (27.5%) cases, the result was assessed as unfavorable and this operation was performed for this group of patients to remove the defect of the fingers' covering tissues with the "Filatov flap".

Traction finger injury of the type "gloves" should be considered as a specific traumatic injury that requires immediate medical care in specialized units.

Which factors affect the rate of surgery performed in patients with carpal tunnel syndrome?

List of authors:
Young Ju Chae¹, Jiheung Kim¹, Hyun Sik Gong², Kee Jeong Bae³, Yo Han Lee³, Li QINGYUAN¹, Goo Hyun Baek¹
¹ Seoul National University Hospital (Seoul)
² Seoul National University Bundang Hospital (Seongnam-si)
³ SMG - SNU Boramae Medical Center (Seoul)

Objectives / Interrogation: Carpal tunnel release is recommended when patients with positive electrophysiologic test remain symptomatic in spite of conservative treatment. However, only some of them eventually undergo surgery. The purposes of this study, therefore, were to evaluate the rate of carpal tunnel release performed among the patients with a positive electrophysiologic test and to identify which factors were associated with the rate of the surgery.

Methods: Subjects of this study were 865 wrists of 495 patients (65 males and 430 females) who were diagnosed with a carpal tunnel syndrome between January 2013 and December 2016. The diagnosis of carpal tunnel syndrome was confirmed by electrophysiologic test, and only the patients who were followed up for more than 1 year were enrolled in this study. The average age at the time of the electrophysiologic test performed was 61.4 years, and the severity of carpal tunnel syndrome was evaluated according to the Bland scale (Gr 1—6) based on the electrophysiologic test. Whether or not the patients received carpal tunnel release was evaluated at the last follow-up visit.

Results and Conclusions: Result
Among the 865 wrists, carpal tunnel release was performed on 528 wrists (61%). Rate of the surgery performed significantly increased in patients with more severe grades on electrophysiologic test. More patients in female (63.3%) than in male (50.3%) and more patients with age under 60 (67.5%) than age over 60 (57.1%) received the surgery. However, there was no significant difference in the rate of carpal tunnel release according to the bilaterality or dominant hand.

Conclusions
The rate of carpal tunnel release among the patients diagnosed and confirmed as carpal tunnel syndrome was not higher than we expected.
We should also pay more attention to the patients who did not undergo carpal tunnel release and investigate the reasons why those patients did not undergo surgery.

Carpal tunnel syndrome, carpal tunnel release, decision making, rate of surgery
Shorter versus longer immobilization after surgery for thumb carpometacarpal osteoarthritis: a propensity score matched study

List of authors:
Jonathan Tsehaie*, Robbert M Wouters, SER Hovius, Reinier Feitz, Harm P Slijper, Ruud W Selles
1 Erasmus MC (Rotterdam)
2 Erasmus MC, Xpert Clinic (Rotterdam)
3 Xpert Clinic (Rotterdam)

Objectives / Interrogation: To investigate if shorter immobilization is non-inferior to longer immobilization after Weilby procedure for thumb carpometacarpal osteoarthritis

Methods: Participants that received short immobilization (3-5 days plaster cast followed by a thermoplastic thumb spica splint until 4 weeks) were compared with prolonged immobilization (10-14 days plaster cast followed by a thermoplastic thumb spica splint including until 6 weeks). All the participants were surgically treated with the Weilby procedure and matched using propensity score matching (PSM) to control for confounders. Primary outcomes were pain measured with a Visual Analogue Scale (VAS) and hand function measured with Michigan Hand Questionnaire (MHQ) at six weeks, three months and twelve months. Secondary outcomes were complications, range of motion, grip and pinch strength, satisfaction with treatment and return to work.

Results and Conclusions: Results: We matched 131 participants with shorter immobilization and 131 participants with longer immobilization. No significant differences were found in VAS pain (effect size 0.03, 95% C.I. -0.21-0.27) or the MHQ (effect size 0.01, 95% C.I. -0.23-0.25) between the groups at three months or at twelve months. Furthermore, no differences were found in complication rate or in other secondary outcomes.

Conclusions: In conclusion, shorter immobilization of 3-5 days of a plaster cast after Weilby procedure is equal compared to longer immobilization for outcomes on pain, hand function and our secondary outcomes. These results indicate that shorter immobilization is safe and can be recommended, since discomfort of longer immobilization may be prevented and patients may be able to recover sooner which may lead to reduced loss of productivity. Future studies need to investigate effectiveness of early active and more progressive hand therapy following CMC-1 arthroplasty.

The structural changes of carpal tunnel and median nerve in MRI before and 2 years after endoscopic carpal tunnel release

List of authors:
Toshimitsu MOMOSE*, Hiroyuki OSHIBA¹, Yukio NAKATSUCHI¹
¹ Department of Orthopaedics, Marunouchi Hospital (Matsumoto)

Objectives / Interrogation: We do not know enlargement of carpal tunnel has maintained for a long time after endoscopic carpal tunnel release (ECTR). We investigated the structural changes of carpal tunnel and median nerve in MRI before and two years after ECTR.

Methods: 28 patients had undergone ECTR for idiopathic carpal tunnel syndrome. The patients included 8 males, 20 females. The mean age was 67 years old. ECTR was performed utilizing Chow's two-portal technique. MRI (Siemens, 1.5T) of carpal tunnel and nerve conduction studies (motor distal latency) was performed before and two years after ECTR. The cross-sectional area of carpal tunnel and median nerve, and palmar bowing (PB) at the hook of hamate level were measured using T2* images. The palmar bowing was the distance to the flexor retinaculum from the line between the hook of hamate and trapezium at the hook of hamate level. The cross-sectional area of median nerve was measured at wrist level. The cross-sectional area of the carpal tunnel and median nerve was outlined digitally. The expansion ratio was calculated by dividing the postoperative cross-sectional area by the preoperative cross-sectional area. Preoperative data was compared with postoperative data using Wilcoxon signed-ranks test.

Results and Conclusions: Motor distal latency was improved from 9.1ms to 4.3ms after ECTR. Detached flexor retinaculum was seen as a linear area of low signal intensity 2 years after ECTR. The cross-sectional area of carpal tunnel and median nerve was 1.16 and 1.2 respectively at hamate level. The cross-sectional area of carpal tunnel and median nerve was significantly increased at hamate level two years after ECTR. PB was significantly increased at hamate level two years after ECTR. The cross-sectional area of median nerve was 0.9 at wrist level. The cross-sectional area of median nerve was significantly decreased at wrist level two years after ECTR. The enlargement of carpal tunnel was maintained two years after ECTR. Flexor retinaculum was released during ECTR. However, a continuous linear area of flexor retinaculum was detected two years after ECTR.

In vivo implantation and characterisation of a novel 3D-printed multiphasic scaffold in the rabbit knee for scapholunate ligament reconstruction

List of authors:
Hayman Lui*, Cedryck Vaquette², Sanjeev Kakar³, Andre van Wijnen³, Randy Bindra⁴
¹ Griffith University (Gold Coast)
² Queensland University of Technology (Brisbane)
³ Mayo Clinic (Rochester)
⁴ Gold Coast University Hospital (Gold Coast)

Objectives / Interrogation: Previous research has shown that it is possible to synthesise a multiphasic bone-ligament-bone (BLB) scaffold similar to the dorsal scapholunate interosseous ligament (SLIL). This scaffold will facilitate regeneration of composite tissue and can be implanted for clinical use. The rabbit medial collateral ligament (MCL) has similar anatomical properties as the dorsal SLIL and thus, can be used as an animal model for testing this novel scaffold in vivo.

Methods: Multiphasic bone-ligament-bone scaffolds modelled from the dorsal component of the SLIL were 3D-printed with medical grade polycaprolactone (PCL). These simulated a BLB construct with two bone compartments bridged by aligned PCL fibres mimicking the architecture of the native ligament studied from cadaveric specimens. For surgical implantation, the native MCL of the rabbit was removed with holes drilled into insertion and origin points of the ligament on the femur and tibia using a 5mm trephine. The bone compartments of the scaffold was press-fitted into the cavities and stapled in place. The rabbit knee joint was fixed in flexion using 1.4mm K-wires for 4 weeks prior to mobilisation for an additional 4 weeks. In total, 18 samples were implanted into 18 rabbits and harvested at four and eight weeks. Mechanical tensile testing (n=5 per group) and in vivo characterisation of the constructs were conducted.

Results and Conclusions: After 4 and 8 weeks in vivo, the scaffold remained intact. Mechanical testing of the BLB scaffolds showed that they were capable of withstanding normal SLIL physiological forces. After 4 weeks of mobilisation of the knee joint, the scaffolds improved in strength. In vivo study in the rabbits demonstrated that the scaffold was biocompatible and displayed good tissue integration and vascularisation. Upon implantation for 4 and eight weeks, bone formation and ligament remodeling was observed in the corresponding compartments.

Various tenodesis procedures for reconstruction of scapholunate instability fail to restore normal carpal kinematics. This research has demonstrated that it is feasible to fabricate a multiphasic BLB scaffold using additive manufacturing for dorsal SLIL reconstruction. Bone and ligament tissues were formed in their corresponding compartments with similar structural and mechanical properties to the native ligament. The artificial scaffold may provide an alternative to current techniques for reconstruction of scapholunate instability.

Clinical vs. operative findings in hand trauma using our online eHands system

List of authors:
Martin Van*, Francesca Ghini¹, Ravi Mallina¹, Rajive Jose¹
¹ Plastic Surgery and Hand unit, Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: We use eHands as an assessment tool for all our hand trauma patients who present in our unit. It provides a structured way of assessing and documenting the clinical findings. The aim of this study was to investigate the accuracy of our clinical and operative findings and determine factors which may result in any potential discrepancies.

Methods: We conducted a retrospective study of 100 patients who were assessed and operated on between July and September 2018. Clinical examination findings were compared to the operation notes and categorised as completely correct, partially correct and completely incorrect. Grade of assessing doctor, time of assessment and senior review was also collected. A two-tailed T-test was used to assess statistical significance.

Results and Conclusions: Sixty-two percent of patients had a complete correlation between clinical and operative findings. Partially correct clinical diagnosis was found in 26 patients and 12 patients had a completely incorrect preoperative diagnosis. Digital nerve injury followed by flexor tendon was the most common overdiagnosed condition in both the partially and completely incorrect group. Digital nerve and flexor tendon injury was the most frequently missed of the patients who had a partially correct clinical diagnosis. No difference in clinical accuracy was found correlating with the grade of assessor.

Conclusion
The accuracy of clinical examination and operative findings is high using our eHands assessment tool. There is no significant difference in accuracy between grades of assessing doctors.

Hand injuries in sports - A retrospective analysis of 286 cases

List of authors:
Viola Stögner*, Nicco Krezdorn1, Peter Vogt1
1 Department of Plastic, Hand and Reconstructive Surgery, MHH (Hannover)

Objectives / Interrogation: Injuries of the hand account for 3 - 35% of all sport injuries. Hence, the hand is at high risk for injury during sportive activities. The current literature lacks systematic analyses of hand injuries in athletes in German speaking countries.

Methods: We performed a retrospective analysis (2013 -2018) of patients with sport-related injuries of the hand presenting in our department. Our hospital information system was analyzed using both specific search terms as well as ICD-10 codes. Data was further refined by manual screening of full-text clinical reports.

Results and Conclusions: Results: We identified a total of 286 eligible patients. Grouping for type of sport, soccer turned out to be the most common cause for hand injury (n=63; 22.02% of total), followed by equestrian sports (n=48, 16.78%) and handball (n=23; 8.04%). Most injuries occurred within the age group of 25 - 39 years (n=74; 26%), followed by 40 - 59 years (n=62; 22%). Overall male athletes (n=192; 67%) were affected more often than female athletes (n=94; 33%). Overall sport-related hand injuries was more frequently treated in an ambulant setting (n=203; 71%) than inpatient treatment (n=83; 29%). Equestrian sports accounted for the highest absolute hospitalization time (153 days, 34.3% of total, median of 4 days). We further identified differences in treatment strategy (surgical vs. conservative treatment). Types of injuries included fractures (34.3%), soft tissue injuries (25.5%), luxations, sprains and strains of joints and ligaments (17.7%), muscle and tendon injuries (8.1%), and amputation injuries (3.5%).

Conclusion: Hand injuries represent a high burden for the affected individual as well as to the health care system. Young males in prime working age seem to be at the highest risk for these kinds of injuries. Proper diagnosis and individualized treatment by trained hand surgeons are crucial to minimize long term impairments and disabilities. Knowledge of sport-specific injury patterns and their evidence-based treatment are mandatory in that regard.

Does operative timing of pediatric supracondylar humerus fractures affect postoperative early complications?

List of authors:
Seigo Suganuma*1, Kaoru Tada2, Hidetoshi Yasutake3, Takeshi Horii1, Munetomo Takata1, Keito Shimanuki1, Daiyu Tsuji3, Kanu Shimokawa5, Hiroyuki Tsuchiya2
1 Department of Orthopaedic Surgery, Ishikawa Prefectural Central Hospital (Kanazawa)
2 Department of Orthopaedic Surgery, Kanazawa University Hospital (Kanazawa)

Objectives / Interrogation: The purpose of this study is to evaluate whether the time to surgery of Gartland type II and III pediatric supracondylar humerus fractures affects the incidence of postoperative early complications.

Methods: We retrospectively reviewed 172 pediatric patients aged 1 to 15 years who sustained Gartland type II and III supracondylar humerus fractures and who had been operated in our associated institutions between April 2007 and March 2017. Patients with polytrauma, open fractures and neurovascular injury at an initial examination were excluded from this study. As a result, 142 patients were included in this study. The 91 boys and 51 girls with a mean age of 6.5 years included 66 type II and 76 type III Gartland type fractures. The time from fracture to surgery was calculated from the medical records for each patient. The outcome measures evaluated were the incidence of postoperative early complications and the conversion rate to open reduction in type III cases. We defined patients treated within 12 hours as the Early group (EII for type II and EIII for type III) and those treated more than 12 hours after the injury as the Delayed group (DII for type II and DIII for type III). The analysis of group differences was performed using a Fisher’s exact test.

Results and Conclusions: Results
There were 10 complications in 66 type II patients (15.2%) and 14 in 76 type III patients (18.4%). All complications in type II cases were surgical site infections. There was no significant difference between EII and DII. Complications in type III cases consisted of surgical site infections (n = 8, 10.5%) and postoperative neurological deficits (n = 6, 7.9%). There was no significant difference between EIII and DIII. No iatrogenic ulnar nerve injury or compartment syndrome was observed in either type II or III cases. No patients needed to return to the operating room. Conversion to open reduction was needed in 3 patients in EIII (4.8%) and 0 in DIII (0%).

Conclusions
Delayed surgery was not associated with an increased rate of postoperative early complications or the conversion rate to open reduction. We suggest that it is not necessary to perform emergency surgery for type II cases. On the other hand, type III cases are usually treated on an emergency basis. It is still controversial whether the delay of surgery is permissive for type III fractures. Our findings suggest it is possible to treat closed type III fractures without neurovascular injuries in a less urgent manner.

Application of reverse homodigital flap from the dorsolateral aspect of proximal finger based on a digital artery perforator in the middle phalanx

List of authors:
Jing Chen*, Hong Jiu Qin2, Qing Zhong Chen1, Jun Tan1
1 Affiliated Hospital of Nantong University (Nantong)
2 Yijishan Hospital of Wuhu (Wuhu)

Objectives / Interrogation: Local or free digital artery perforator flaps based on a constant distal perforator in the middle phalanx for resurfacing the fingertip defect were frequently reported in previous articles. The donor sites of these flaps all were located on the dorsum or lateral of the middle phalanx, and the flap are not suitable for covering the large area of fingertip defect. Therefore, we reported our experience using a reverse, homodigital flap based on a constant distal perforator in the middle phalanx harvested from the dorsolateral proximal phalangeal area for reconstructing fingertip defects with large area.

Methods: From November of 2017 to April of 2018, 11 fingers with fingertip and pulp defect were treated with this technique. The mean area of flaps was 6 (range 4-8) cm². The flap is designed on the dorsolateral of the proximal phalanx of the injured finger in a teardrop shape. The flap was dissected and elevated superficial to the extensor tenosynovium and the dorsal branch of the digital nerve was identified and divided proximally and included in the flap. 8 mm width of fascial pedicle was dissected and preserved at the distal point of flap. Then the pedicle was elevated in the distal and palmar direction until to the digital artery proximally the middle phalanx neck. The digital artery perforator in this site was not necessary to dissected clearly. Then the homolateral digital neurovascular bundle was dissected proximally from the proximal point of the defect in order to achieve a more free rotation of flap. The flap is then rotated to resurface the fingertip defect. Fingertip sensation is reestablished through coaptation of the proximal end of the dorsal branch of digital nerve to the stump of proper digital nerve.

Results and Conclusions: The color of the most flaps was reddish with capillary reflux slowly in 1 day after operation, and then was gradually reddening. The venous congestion was occurred in 4 flaps, but no treatment was taken. Marginal part necrosis was found and continuous dressing was treated in one of the 4 flaps. There were no other complications. The other flaps survived completely. The average follow-up period was 5 months (range, 4-7 mo). No further flap debulking was required. The mean range of active motion of the proximal and distal interphalangeal joints of the donor fingers were 93 and 76 degrees, respectively. We conclude that this technique is a reliable, simple, and reproducible method for reconstruction of soft tissue defects of the fingertip with large area.

Reconstruction of Severely Hypoplastic Thumb by Non-vascularized Metatarsal Graft with Abductor Digiti Minimi Opponensplasty

List of authors:
Takehiko Takagi*, Ruriko Iigaya, Atsuhito Seki, Shinichiro Takayama
1 Department of Orthopaedic Surgery, National Center for Child Health and Dv (Tokyo)
2 Department of Orthopaedic Surgery, Keio University School of Medicine (Tokyo)

Objectives / Interrogation: Pollicization of index finger has been usually recommended for Blauth IIIb and IV hypoplastic thumb. Although functional result of the pollicization is satisfied, majority of the family desires to keep the number of the digits. We developed two-stage reconstruction procedure, distal two-thirds of the fourth metatarsal bone graft (non-vascularized) with widening of the first web followed by abductor digiti minimi (ADM) opponensplasty.

Methods: From 1980-2018, 76 patients (41 boys and 35 girls) were reconstructed. In the first stage, the distal two-thirds of the fourth metatarsal is transplanted in the reverse manner to form the first carpometacarpal joint without microvascular anastomosis. Widening of the first web is performed using a dorsal sliding flap. More than six months later, ADM opponensplasty is carried out. Extensor index proprius (EIP) and flexor superficialis of ring finger (FDS-R) transfer was respectively added in the second stage. 41 patients were classified to IIIb and 35 were IV. Average ages at the surgery was 3.2 years old. In type IV, metatarsal bone graft was indicated under the condition that the thumb is larger than small finger. Fourth metatarsal head was used in 64 cases and fourth metatarsalphalangeal joint including proximal phalanx was used in 12 cases. Follow-up periods were from 5.2 months to 277 months, average 77.2 months.

Results and Conclusions: Except one case, bony union between grafted metatarsal and distal part of first metacarpal was acquired without significant bony absorption. Fracture of the grafted bone was seen in two cases and additional bone grafts were performed. In the majority of the cases, epiphysis of the grafted bone was remained open more than five years and the functional results are acceptable with high degree of family's satisfaction. Carpometacarpal joint mobility and metacarpophalangeal joint stability were important for good functional results. Metatarsal bone graft with epiphysial plate could be an alternative procedure to pollicization of index finger.

Keywords: hypoplastic thumb; carpometacarpal joint; bone graft
Modified arterialized venous flap for the reconstruction of 12 digits

List of authors:
Jing Chen*, Jun Tan, Qing Zhong Chen, Jin Bo Tang
1 Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: The key to improving the survival rate of the arterialized venous flap is to ensure a good venous return to reduce venous congestion. To mitigate the problem, we designed modified flaps to restrict shunting and aimed to report our clinical experience and outcomes.

Methods: We performed 12 arterialized free venous flaps in 12 patients for digital reconstruction using our modified method between February 2017 and March 2018. The mean age was 41 (range 24-74) years old. The mean area of flaps was 14 (range 5-30) cm². The number of venous pattern of flaps was 5 (II-pattern) and 7 (H-pattern), respectively. All flaps were harvested from the palmar aspect of the ipsilateral forearm. The distal ports of the two veins were ligation. The length of proximal vein pedicles was depended on the recipient site. Partial fat was eliminated and the all connecting minute branches between the two veins were ligation under microscope in order to achieve the thorough shunt restriction. Then the flaps were positioned over the recipient site without inversion. We usually select the thinner vein as the arterialized vein, which was anastomosed in a retrograde manner, with the inflow running against the valves. The other vein was anastomosed with the superficial vein of digit. Close postoperative monitoring is performed. Routine postoperative anticoagulant therapy is used. The patients were followed.

Results and Conclusions: The average operation time was 101 (range 75-150) minutes. The average follow-up time was 10 (range 6-16) months. All flaps survived entirely. The wounds of donor sites were sutured directly except one case. The color, turgor, temperature of 5 flaps resemble the conventional arterial flaps after operation and during follow-up. Seven flaps demonstrated mild-to-moderate venous congestion without any treatment and the swelling of flaps gradually subsided in 7-10 days after operation. At the final follow-up, the appearance of the flap had no difference with those usually observed in arterial flaps.

Arterialized free venous flaps with thoroughly restriction of arteriovenous shunting can offer decreased congestion of venous flaps and improved survival rate. The flap constitutes an ideal donor to repair a small or medium-sized defect of the hand.

Vancomycin is superior to Plectasin against Staphylococcus aureus periprosthetic osteomyelitis in rats.

List of authors:
1 Handsection, Department of Ortopaedic (Hellerup)
2 Institut for Veterinær-og Husdyrvidenskab (Frederiksberg)
3 Department of Orthopaedic, Hillerød University Hospital (Hillerød)
4 Endocrinology and Metabolism, Panum Instituttet (Copenhagen)
5 Leo Pharma (Ballerup)
6 Mikrobiologisk afd. (copenhagen)

Objectives / Interrogation: Commonly used antibiotics cannot always control S. aureus associated infections in orthopaedic and hand implants.
We investigated the ability of vancomycin and plectasin to eradicate S. aureus in a knee prosthesis model of osteomyelitis in rats.
We compared Plectasin in a 20 and 40 mg concentration to vancomycin 20 mg, all antibiotics were given i.p. daily. Plectasin is a peptide antibiotic with therapeutic potential from a saprophytic fungus.

Methods: Thirty Sprague-Dawley rats had prosthesis inserted and divided into three groups (N=10). Vancomycin group including 2 controls and two Plectasin groups (N= 10) 20 mg and (N= 10) 40 mg including 2 controls in each groups. All groups were infected with S. aureus MN8, ica+103 in the tibia and the femur marrow before insertion of the prosthesis. Control rats were given NaCl i.p. After two weeks, the rats were sacrificed and all specimens were analysed.

Results and Conclusions: Results: One rat in the 20 mg Plectasin group and four in the 40 mg Plectasin group died of anaphylactic shock (histamine release). The 20 and 40 mg Plectasin groups both showed a decrease of bacteria but it was not as efficiently eradicated as in the vancomycin group.

Conclusions: Plectasin treatment against S. aureus osteomyelitis reduced the infection. However, Plectasin released histaminestrongly after one day and some of the rats died especially in the 40 mg group. In contrast, Vancomycin reduced the infection significantly in almost of the parameters.

Prognostic factors of radial head arthroplasty outcomes

List of authors: Luis Aguilella*, Jorge Sevil1, Manuel Soler1
1 Hospital Universitario de La Ribera (Valencia)

Objectives / Interrogation: Overlengthening of a radial head implant has been associated with less than optimal clinical outcomes and capitellar erosions. The purpose of this study was to identify which factors, both clinical and radiological, have influenced the clinical results in our series.

Methods: We analysed the relation of the initial injury, the repairs associated to implant insertion and the implant length with clinical outcomes. Two postop radiological measurements were made by two independent investigators: the distance between the proximal edge of the lesser sigmoid notch and the proximal implant edge, and the lateral ulnohumeral joint opening angle. Mean values of both measurements were taken as reference. Clinical outcomes were assessed with range of movement measurements, the Mayo Elbow Performance Score (MEPS) and the DASH. In addition to univariable descriptive analysis, comparisons of means and correlations were made using nonparametric tests.

Results and Conclusions: During the 2005-2017 period, we performed 49 radio head arthroplasties (MoPyC, Bioprofile, Tornier). 31 patients (21 women and 10 men, average 53 years) agreed to be evaluated. Mean follow-up was 5 years. The initial lesion was a Masson type III fracture in 5 cases, type IV in 6, a triad in 12, and an association with other proximal ulnar fractures in the remaining 8. The treatment in 9 cases was just radial head arthroplasty, while in 10 it was associated with coronoid fixation and ligamentous repair. The rest of the cases received different combinations of treatment. Implant length was aligned with the proximal margin of the lesser sigmoid notch in 16 cases, was higher in 12 (mean 3 mm, SD 1.5) and inferior in 3 (mean 3.4 mm, SD 1.7). The lateral ulnohumeral joint opening angle was 10.7º (SD 2.6º). Although the best clinical results in mobility, MEPS and DASH have been obtained in Masson fractures type III and IV, the differences have not been significant, nor have there been differences according to the treatment used. Significant correlations (p <0.05) were observed between the increase in the ulnohumeral angle and the decrease in flexion and supination mobility. Variations in implant length in our series have shown no relation to the clinical outcome.

Conclusions: An overlengthening or shortening up to 3 mm has not shown to alter the clinical results in our series, while an excessive lateral ulnohumeral joint opening has a negative effect on mobility

Keywords: radial head arthroplasty, overlengthening, prognostic factors
Surgical outcome of mallet fracture using bone suture anchor

List of authors:
Takahiro Asano¹, Haruhiko Satonaka¹, Masaya Tsujii², Tadashi Tsukamoto³, Yoshiaki Suzuki¹, Kakunoshin Yoshida³, Takahisa Haraz, Akihiro Sudou²
¹ Ise Municipal General Hospital (Ise, Mie)
² Department of Orthopaedic Surgery, Mie University (Tsu, Mie)

Objectives / Interrogation: Extension block pinning for acute mallet fractures have been reported with good results. However, for chronic cases, various methods have been proposed. We evaluate the clinical outcome of mallet fractures treated with bone suture anchor for mallet fracture.

Methods: We evaluated 11 cases of mallet fracture patients treated with bone suture anchor (JuggerKnot® Soft Anchor Mini 1.0 mm, ZIMMER BIOMET) that were observable for more than 3 months after surgery (8 men and 3 women; mean age, 42 years). The affected fingers were 6 middle fingers, 1 ring finger and 4 little fingers. Two cases were chronic nonunion of mallet fracture after extension block pinning surgery failed. The surgical approach was follow; the dorsal side of the DIP joint was incised and the bone fragment was released with the extensor tendon and JuggerKnot® was inserted to the distal phalanx after making the fracture site sufficiently fresh. The terminal tendon was sutured with the bone fragment reduced. Arthrodesis of distal interphalangeal joint was added with a Kirschner wire inserted from finger apex. The Kirschner wire buried subcutaneously and was removed on 6 weeks after surgery. We examined the degree of flexion, extension lag, and bone union at the final follow-up. Moreover, we compared the results between the cases that undergone surgery within a month from injury and more than a month.

Results and Conclusions: The mean degree of flexion was 53 ° (30-75 °), and the extension lag was 7.3 ° (0-20 °). Two patients showed excellent, 3 showed good and 6 showed fair results on the Crawford's score scale. Radiographic bone unions were not achieved in two cases but no loss of reduction. In the comparative study between the two groups, 5 cases into group A (the average period from injury to surgery was 6.4(0-17) days), and 6 cases into Group C (the average was 51(31-88) days). The average flexion of the group A was 57 ° (40-75 °), and extension lag was 7.4 ° (2-20 °). The group C was 50 ° (30-70 °) and 7.1(0-15 °), respectively. There is no significant difference between the two groups.

The necessity of joint fixation has been suggested from fixation strength of anchor and it was useful to primary arthrodesis with Kirschner wire because it can be washed hands immediately after the removal of stitches. In this study, this method using bone suture anchor was able to obtained good results in both acute and chronic cases. This procedure was considered to be one of widely applicable methods for mallet fracture.

3 University of Oxford, Nuffield Department of Population Health (Oxford)
4 University of California, San Francisco, Department of Plastic and Reconstructive Surgery (San Francisco)

Objectives / Interrogation: The aim of this study was to use routinely collected real world data to identify the incidence of carpal tunnel release surgery (CTR) in the US and England, and to compare the demographics of patients undergoing surgery in each country.

Methods: For English data, OPCS codes prospectively collected as part of routine care were used to identify CTRs from April 1998-2017. For US data, CPT codes were used to identify CTRs in the Humana claims database (PearlDiver Inc, Colorado Springs) from January 2007-December 2016. Patients were followed up until death or the end of the study period. Disease status was defined by ICD codes. Charlson comorbidity index (CCI) was used as an overall marker of comorbidity.

Results and Conclusions: Results
855,832 procedures were found in English data; 68% of patients were female. A significantly higher incidence was seen in women, especially those aged 45-60. A second peak in incidence was seen in the over 65’s irrespective of gender. Mean CCI was 1.6 (SD 2.41); a past medical history of diabetes mellitus was present in 5.8%; obesity in 2.56%, hypothyroidism in 2.43%; rheumatoid arthritis in 0.13%.

80,037 procedures were included from US data; 60% patients were female. 2 peaks in incidence were found; a peak in women aged 45-60, and a peak in both genders from 60-80 years of age. Mean CCI was 2.0 (SD 2.51); a past medical history of diabetes mellitus was present in 1.6% of patients; obesity in 0.7%; hypothyroidism in 0.9% and rheumatoid arthritis in 4.8%.

Conclusions
This large study of real world data suggests that there are two differing aetiologies for CTS: hormonal changes associated with menopause in women, and idiopathic CTS, mainly manifesting in older age groups. These trends were seen irrespective of a public or private healthcare system.

The Ulnar Plus Variance Does Not Adversely Affect the Outcomes of Arthroscopic Repair for Triangular Fibrocartilage 1b Tear

List of authors:
Bong Cheol Kwon¹, Jae-Yeon Hwang¹
¹ Department of Orthopedic Surgery, Hallym University Sacred Heart Hospital (Anyang)

Objectives / Interrogation: There has been a debate regarding the effect of ulnar plus variance (UPV) in the outcomes of arthroscopic repair for TFCC 1b tear. The purpose of this study was to compare the outcomes of arthroscopic repair for TFCC 1b tear between patients with UPV and those without UPV, and to identify risk factors for revision surgery with ulnar shortening osteotomy (UPV).

Methods: We retrospectively analyzed 38 consecutive patients (21 patients with UPV) and 17 patients without UPV) receiving arthroscopic repair for TFCC 1b tear from June 2014 to February 2017. We evaluated the patients with pain visual analogue scale (VAS) at three domains (overall, at hard work, and at rest), Patient-Rated Wrist Evaluation (PRWE), range of motion, and grip strength. Clinical outcomes and arthroscopic findings were compared between the patients with UPV (UPV group) and those without UPV (non-UPV group). A multivariate logistic regression model was used to determine the risk factors for revision surgery with USO.

Results and Conclusions: Demographic data were comparable between the groups (P > 0.05). The subtypes of TFCC 1b tear, signs of ulnocarpal abutment, and the incidence of concomitant intercarpal ligament injuries were not significantly different between the groups (P>0.05). Post-operative outcomes were also similar between the groups regarding the scores for pain VAS and PRWE, and the rates of the patients of the excellent or improved outcomes (P>0.05). The co-existing degenerative central TFCC tear was the only significant risk factor for revision surgery (OR, 30.2; 95% confidence interval, 1.83-500.28; P=0.017) after being adjusted for age and sex.

In conclusion, the ulnar plus variance did not significantly affect the outcomes of arthroscopic repair for TFCC 1b tear, suggesting that simultaneous ulnar shortening osteotomy is not necessary for the patients with UPV. However, the co-existing signs of degenerative central TFCC tear significantly increased the risk of revision surgery with USO.

Clinical Results of Interposition Arthroplasty with or without Intermetacarpal Ligament Reconstruction for Thumb Carpometacarpal Osteoarthritis: a retrospective comparison study

List of authors:
Haruhiko Satonaka*, Masaya Tsujii¹, Takahiro Asano¹, Tadashi Tsukamoto³, Yoshiaki Suzuki¹, Kakunoshin Yoshida¹, Takahisa Hara¹, Akihiro Sudo²
¹ Ise Municipal General Hospital, Department of Orthopedic Surgery (Ise)
² Mie University Graduate School of Medicine, Department of Orthopedic Surgery (Tsu)

Objectives / Interrogation: Objective: Kaarela’s procedure is the simple method for osteoarthritis of thumb carpometacarpal joints (CMC-OA), while is not able to prevent longitudinal instability. Furthermore, there were few studies that compared with the clinical outcomes of the homogenous interposition arthroplasty between without and with suspension. The aim of our study is to describe and to compare the clinical results between the original Karrela’s procedure and a new technique with reconstruction of the dorsal intermetacarpal ligament (IML) in addition to the arthroplasty.

Methods: Methods: 21 patients (3 man and 18 women; mean age, 63y) with CMC-OA were treated by trapeziectomy and Karrela’s procedure without (group K) or with IML reconstruction (group S). Clinical assessments were completed preoperatively and at 12 months postoperatively. These included subjective assessments of pain VAS (0-100), range of palmar and radial abduction, and strength of pulp pinch compared with unaffected side. Moreover, trapezial space ratio was determined by the trapezial space divided by the bone length of the proximal phalanx on the lateral X-ray immediately and at 12 months after surgery.

Results and Conclusions: Results: Pain VAS significantly improved from preoperative 71.0 and 71.0 to postoperative 8.0 and 8.6 in group K and S, respectively. Both volar abduction and radial abduction did not change to a statistically significant degree in both groups. Strength of pulp pinch in group K did not significantly change, while the strength in S group had significantly improved from 73% of unaffected side to 92% after surgery. Trapezial space ratio in group K decreased by 41% from 0.18 immediately to 0.11 at 12 months after surgery. By contrast, there was a decrease of 15% of trapezial space ratio in group S, with 0.27 immediately and 0.22 at 12 months following surgery. Statistical analysis showed a significant difference for the decreased rate of trapezial space ratio between group K and S.

Conclusions: In the Karrela’s procedure, APL, interposed in trapezial space and passed through 1st metacarpal, is considered to play a part in the deep anterior oblique ligament. Moreover, the results in this study indicated that reconstruction of IML in addition to tendon interposition effectively worked against the subsidence of the 1st metacarpal. We believe that addition of IML reconstruction provide better results including pinch strength and long term stability of 1st metacarpal bone.

Reconstruction of the collateral ligament for old dislocation of the DIP joint

List of authors:
Hiroyoshi Hagiwara*, Yukinori Hayashi, Kenji Kiyonaga, Tomoko Horii, Suguru Hagiwara, Takashi Ajiki
1 Tochigi Medical Center Shimotsuga (Tochigi)
2 Jichi Medical University (Shimotsuke)
3 Ishibashi General Hospital (Shimotsuke)

Objectives / Interrogation: We report a case of old dislocation of the little finger. The reconstruction of the collateral ligament was performed with split FDP tendon.

Methods: A 74 year-old-woman was introduced to our institution who was suffering from the DIP joint pain of the right little finger. She fell off her bicycle when she was in junior high school and injured the finger. The injury was thought to be open dislocation of the DIP joint, but only treatment for the wound was conducted. She had felt the restriction of the range of motion and appearance of the deformity of the finger but only slight pain. At 6 years before the presentation, she had begun to feel acute pain at the joint. The pain had deteriorated gradually. Radiographs and computer tomography revealed approximately 70° ulnar deformity of the distal phalanx and dislocation of the DIP joint, which was accompanying osteoarthritic change. Active ROM of the little finger was MPJ 0°/90°, PIPJ 0°/60°, DIP-55°/90°. Q-DASH score was Disability 31.6/ Work 62.5/ Sport 0.

At 3 weeks from the present day, surgical procedure was performed. The collateral ligament of the radial side at the DIP joint was not recognized. 1/3 FDP of the ulnar side was cut at the A3 pulley level and split to the distal phalangeal base, then it was turned over and A5 pulley was incised. A 2.3mm transverse burr hole was made at the condyle of the middle phalanx and passed the split FDP through the hole from ulnar side to the radial side. With applying tension, it was sutured to the soft tissue on the distal phalangeal base at the radial side after reduction of the DIP joint. ROM exercise of the DIP joint was begun from 4 weeks.

Results and Conclusions: At 1 year from surgery, slight ulnar deformity of the distal phalanx was recognized. Active ROM of the finger was MPJ30°/90°, PIPJ0°/90°, DIP-0°/30°. Q-DASH score was Disability 4.5/ Work 0/ Sport 0. Favorable clinical outcome was obtained.

Does Degeneration of Triangular Fibrocartilage Complex Improve after Ulnar Shortening Osteotomy?

List of authors:
Che Ho Lee¹, Jihyeung Kim¹, Hyun Sik Seok³, Kee Jeong Bae¹, Hyun Sik Gong¹, Young Ho Lee¹, Goo Hyun Baek¹
¹ Seoul National University, College of Medicine (Seoul)

Objectives / Interrogation: The degeneration of the triangular fibrocartilage complex (TFCC) is usually combined in patients with ulnar impaction syndrome. Because ulnar shortening osteotomy can decrease the load-sharing through the ulnar carpus, there may be a possibility of indirect healing of TFCC degeneration after ulnar shortening. In this study, we focused on the changes of the TFCC degeneration after ulnar shortening osteotomy using 3D CT wrist arthrography.

Methods: We retrospectively reviewed all patients who were diagnosed as ulnar impaction syndrome and underwent ulnar shortening osteotomy from January 2014 to December 2016. Of them, we enrolled 18 wrists of 15 patients who had checked 3D CT wrist arthrography preoperatively and checked postoperative CT wrist arthrography repeatedly one year after surgery. The average age at the time of surgery was 37 years.

Results and Conclusions: In all patients, the degeneration of TFCC was observed in preoperative CT wrist arthrography. Six wrists were IIA, three were IIB, seven were IIC, and one was IID according to Palmer classification. One year after surgery, the degeneration of TFCC improved in three wrists, and worsened in two wrists. In the other twelve wrists, there were no changes in the degeneration of the TFCC. The average visual analog scale (VAS) for pain was improved from 7 (range, 5–9) preoperatively to 3 (range, 0–6) one year after surgery. Although ulnar side wrist pain was much improved after ulnar shortening osteotomy, indirect healing of the TFCC degeneration was not observed in most of our cases one year after surgery. Therefore, we can conclude that indirect healing of the TFCC degeneration may need more time or may not occur after ulnar shortening osteotomy. The degeneration of the TFCC may not seem to be the main cause of the ulnar side wrist pain in patients with ulnar impaction syndrome.

CHRONIC POST TRAUMATIC TRIANGULAR FIBROCARTILAGE COMPLEX (TFCC) LESIONS IN CHILDREN AND ADOLESCENTS

List of authors:
Sandra Pfanner*, Andrea Poggetti2, Maura Zucchini Maura¹, Massimo Ceruso¹
¹ Hand and Reconstructive Microsurgery Unit, AOU Careggi (Florence)
² Hand and Reconstructive Microsurgery Unit, AOU-Careggi (Florence)

Objectives / Interrogation: Post traumatic triangular fibrocartilage complex (TFCC) lesions in children and adolescents are uncommon and pose complex diagnostic and therapeutic challenges for the surgeon.

Methods: Authors report on a series of 14 pediatric and adolescent patients, means 14.4 y (9-17), 4 males and 10 females affected by TFCC tears (n=4 2A, n= 8 2B, n=2 2C with previously styloid fractures). All cases were sport related trauma (9 tennis, 1 boxer, 1 judo, 1 soccer, 1 musician, 1 equitation) Four Patients were managed with arthroscopy techniques, in the other 10 cases were open repaired. Pre and post-operative Range of Motion (ROM), strength, joint stability and functional score (PRWE score) were performed. The average follow-up was 37 months (8-60 m).

Results and Conclusions: The mean post-operative arch of motion in flexion-extension improves from 90% to 95% of the contralateral side, the radio-ulnar deviation improves from 82% to 91% of the lateral side, the prono-supination arch improves from 71% to 94% of health side. No differences in grip strength recovery compared with contralateral side (32,6 vs 35,7 Kg). The PRWE decrease from 84.4 to 9.85.
The study emphasizes the importance of surgical treatment post traumatic TFCC lesion in persistent ulnar wrist pain and/or instability in children and adolescents.

Outcomes of FPL tendon primary repair in zone 1 and zone 2 by using M-Tang core suture followed with early active mobilization

List of authors:
Zhangjun Pan*
1 yixing people hospital, Jiangsu University Affiliated Yixing Hospital (WUXI YIXING)

Objectives / Interrogation: We reviewed our outcomes of thumb tendon primary repair in zone 1 and zone 2 by using M-Tang core suture followed with early active mobilization in 25 patients, and evaluated the recovery of flexor pollicis longus tendon repairs by robust suture with venting pulley and early active mobilization.

Methods: From January 2014 to December 2017, we performed primary repair for completely divisions of flexor pollicis longus (FPL) tendon in zones 1 and 2 in 25 thumbs using M-Tang core suture repair followed by early active mobilization. These included 17 males and 8 females with a mean age of 39.6 (range 21 to 57) years. Three injuries were in zone 1 and twenty two in zone 2. Eighteen patients sustained injury to the right thumb and seven to the left. Twenty one thumbs had associated digital nerves and arteries injuries. We repaired FPL tendon by using M-Tang core suture with a 4-0 looped suture, followed by running peripheral suture using a 6-0 nylon suture. When the injury site was in zone 1 or the distal part of zone 2, the A2 pulley was vented entirely together with partial venting of the oblique pulley. When the injury site was at the middle or proximal parts of the zone 2, the A1 pulley was vented entirely together with partial venting of the oblique pulley. Extension-flexion test was always performed after tendon repair. Functional outcomes were evaluated with Strickland and Glogovac criteria and Tang criteria.

Results and Conclusions: A total of 25 patients were followed for a mean of 11 months (range 6 to 22) post-surgery. Among three thumbs with zone 1 injuries, two had excellent and one had a good result according to the Strickland and Glogovac criteria, and one had an excellent and two had good results according to the Tang criteria. For the 22 thumbs with zone 2 injuries, 13 had excellent, eight had good and one had fair results according to the Strickland and Glogovac criteria. Nine had excellent, 11 had good and two had fair results according to the Tang criteria. There were no FPL repair ruptures in 25 patients.

We conclude that the A1 pulley can be vented in the FPL tendon repairs in the proximal or middle parts of zone 2 and the A2 pulley and distal oblique pulley can be vented for zone 1 FPL repairs. The oblique pulley can be vented entirely or partially when necessary. Strong repair methods increase repair safety and M-Tang technique allows for safe and efficient early active rehabilitation.

Distal interphalangeal joint osteoarthritis: Silicone arthroplasty versus screw arthrodesis

List of authors:
Lea Estermann¹, Lisa Neukom², Miriam Marks³, Silvia Kündig³, Daniel B. Herren³, Stephan Schindele³
¹ Schulthess Klinik (Zürich)
² Spital Bülach (Zürich)

Objectives / Interrogation: The objective of this study was to compare the outcomes of distal interphalangeal joint (DIP) silicone arthroplasty with DIP screw arthrodesis.

Methods: Patients with a DIP silicone arthroplasty and matched patients with an arthrodesis were examined on average 4.4 years after surgery. Active range of motion (ROM) of the DIP joint and sensibility of the fingertip (Semmes-Weinstein monofilament test) were measured. Patients rated joint pain on a 0-10 numeric rating scale as well as their subjective perception of sensibility, stability and appearance of the affected joint. Patients also completed the Michigan Hand Outcomes Questionnaire (MHQ, score 0-100) to measure hand function. Pre- and final postoperative radiographs were analysed for joint axis deviations and implant situation.

Results and Conclusions: In total, 48 patients were included with 39 arthroplasties and 42 arthrodesis. At follow-up, mean ROM of the DIP silicone arthroplasties was 27° (±15). Arthroplasty patients also had significantly better objective and subjective fingertip sensibility (p<0.01), but were less satisfied with their finger appearance (p<0.05). Overall, patients in both groups were equally satisfied with the treatment result and hand function was similar (MHQ scores were 73 and 77 for arthroplasty and arthrodesis patients, respectively; p=0.22). Pain was only minimal for all patients with an average score below 1. Five arthroplasties (13%) required conversion to an arthrodesis 1-5 years after the primary surgery due to instability and axis deviation in 3 joints and joint irritation in 2 joints. Five arthrodesis screws (12%) were removed between 6 and 12 months after surgery.

Conclusion: DIP silicone arthroplasty is a motion preserving alternative to DIP arthrodesis with high patient satisfaction, although finger aesthetics is superior in fusions. Based on the results, arthroplasty is best indicated in patients with little preoperative joint axis deviation, whereas arthrodesis might be the better choice for unstable and deviated joints with gross osteophytes. Since DIP arthroplasty enables more functionality in pinching and grasping small objects, we recommend this intervention if more function is required in preoperatively stable joints with sufficient collateral ligaments and no axis deviation. DIP arthrodesis should be favored in unstable and/or deviated joints to overcome the aesthetic inadequacies of arthroplasty.

Total Thumb Trapeziometacarpal Joint Arthroplasty: A Retrospective Study of 12 Prostheses Implanted with WALANT Technique.

List of authors:
Camillo Theo MULLER*1, Olivier DEBOCCARD2, Thierry CHRISTEN2, Sébastien DURAND2, Wassim RAFFOUL2
1 CHUV, centre de la main (Lausanne)
2 CHUV (Lausanne)

Objectives / Interrogation: De la Caffinière first described total trapeziometacarpal joint prosthesis in 1974 for treatment of the first carpometacarpal joint arthritis. Even though this technique is more expensive than trapeziectomy, it has some advantages such as faster convalescence. Since we perform this procedure under WALANT technique, we report the perioperative and early postoperative functional results of patients treated with a thumb carpometacarpal joint prosthesis implantation in WALANT technique to consider the use of local anesthesia for thumb arthritis surgery.

Methods: A retrospective study assessed perioperative pain score and functional results of 12 patients treated for trapeziometacarpal advanced osteoarthritis (Eaton and Littler stage III). Pre-, peri- and postoperative assessments included pain, range of motion, and pinch and grip strength. The average follow-up time was 12 months.

Results and Conclusions: The mean pain score measured by a visual analog scale was 8 preoperatively, 2 perioperative and 1 postoperatively. The mean preoperative Kapandji opposition score was 7 and postoperative score were 10. The grip strength improved from 17 kg before to 23 kg after surgery.

Trapeziometacarpal arthroplasty with a joint prosthesis in WALANT appears to be a feasible. Patients suffered minimal intraoperative pain and comparable early functional outcomes to other type of anesthesia. The low perioperative pain score and the good early functional outcome encourages us to recommend this treatment of severe trapeziometacarpal osteoarthritis.

Haptic assisted and VR-based training for minimally invasive K-wire drilling

List of authors:
Johannes Maier*, Jerome Perret, Martina Simon, Stephanie Schmitt-Rüth, Thomas Wittenberg, Christoph Palm, Michaela Huber

1 Regensburg Medical Image Computing (ReMIC), Ostbayerische Technische Hochschule Regensburg (Regensburg)
2 Haption GmbH (Aachen)
3 Fraunhofer Center for Applied Research on Supply Chain Serv. (Nürnberg)
4 Fraunhofer Institute for Integrated Circuits IIS, Image Processing and Biomedical Engineering (Erlangen)
5 Regensburg Medical Image Computing (ReMIC), Regensburg Center of Biomedical Engineering (RCBE), OTH Regensburg and Regensburg University (Regensburg)
6 Department of Trauma Surgery & Emergency Department, University Hospital Regensburg (Regensburg)

Objectives / Interrogation: Looking for less costly and time-consuming training methods for complex bone drilling procedures, we are developing a haptic and visual assisted VR-based training system for complex minimally-invasive K-wire insertion to the human hand [2]. Surgeons can learn, train and improve their bone drilling skills and anatomical knowledge in a real-time and bimanual haptic environment composition. To provide a good training effect, especially the drilling process has to be as realistic and immersive as possible.

Methods: For the user interaction we are using a force-feedback device (Haption Virtuose 6D Desktop, www.haption.com) with a drilling tool mounted to the tip in order to render realistic forces during a simulated drilling process. To guarantee a stable simulation without jerking we separated the drilling process into independent logical phases by using a virtual fixture approach. With virtual fixtures we are able to simulate the K-wire behavior by splitting the complex task into elementary sub-tasks. The transitions between these states are well defined, so that every single phase can be handled completely independently. In real-time calculated forces can be perfectly controlled and transmitted to the user over the haptic device.

Results and Conclusions: Within a formative subjective evaluation we presented our bone drilling prototype simulator on the FESSH conference 2018. A total of 30 surgeons, who had predominantly expert status, tested the drilling procedure and assessed the drilling simulation as authentic and very realistic.

Based on virtual fixtures, simple and discrete drilling phases can reliably simulate the complex minimally invasive bone drilling behavior in a real-time and VR-based environment. In a formative subjective surgeon evaluation, our approach was considered as very realistic and promising. Thus, complex bone drilling based on virtual fixtures has a great potential for future medical training.

Arthroscopic Resection Arthroplasty for Scapholunate Advanced Collapse Wrists

List of authors:
Jessica Cobb*, Tyson Cobb, Anna Cobb
1 Orthopaedic Specialists, PC (Davenport)

Objectives / Interrogation: We previously published early outcomes of arthroscopic resection arthroplasty of the radial column (ARARC) for scapholunate advanced collapse (SLAC) pattern of degenerative wrist arthritis. The purpose of this study was to report mid-term outcomes following ARARC for SLAC wrists.

Methods: Patients (N=31) who underwent ARARC for arthroscopic stage II-IIIB SLAC wrists were prospectively enrolled; 14 of these patients were included in the previous publication. General, regional, or wide-awake anesthesia was used based on patient preference and medical needs. Standard radiocarpal and midcarpal arthroscopy was performed using standard portals. A radiofrequency ablator was used for denervation. Resection of the styloid, arthritic portion of the scaphoid fossa of the radius, and the proximal 2/3rd of the scaphoid were performed using a 4 mm barrel bur. Data were prospectively collected before surgery, and at postoperative intervals of 1, 3, 6, and 12 months, and annually thereafter. Numeric Rating Scale (NRS) for pain (0=no pain, 10=worst pain) and satisfaction with outcomes (0=extremely dissatisfied, 5=extremely satisfied) were obtained. Functional outcomes of grip (position 2 on 5-stage dynamometer), wrist range of motion, and disabilities of the arm, shoulder and hand (DASH; 0=no disability, 100=severe disability) were evaluated. Total arc of motion was calculated by adding flexion, extension, and radial and ulnar deviation.

Results and Conclusions: Mean follow-up was 47 months (range 12-120). Mean age was 62 years (range 40-78) with an equal distribution of nonmanual and manual laborers. Mean pain score was 7 (range 3-10) before surgery and 0.3 (range 0-3) at final follow-up. Mean grip strength was 18 kg (range 5-36) before surgery and 23 kg (range 7-41) at final follow-up. Mean total arc of motion was 113 ° (range 63-170) before surgery and 127 ° (range 61-186) at final follow-up. Mean DASH was 42 (range 16-91) before surgery and 3 (range 0-38) at final follow up. Mean final satisfaction was 4.8 (range 4-5). There were 2 (7%) failures requiring revision surgery for persistent pain.

Mid-term outcomes with 4-year average follow-up demonstrate ARARC for arthroscopic stage II-IIIB SLAC wrists may give good pain relief and increase function. Mean pain, functional outcomes, and satisfaction have not deteriorated with additional follow-up and have improved since our original publication. Longer follow-up and prospective studies comparing ARARC to traditional surgical options should be considered.

Biomechanical Analysis of the Tendon with Z-lengthening (TWZL) Construct: An Alternative Reconstructive Technique

List of authors:
Jeffrey Greenberg*, William J Weller
1 Indiana Hand to Shoulder Center (Indianapolis)
2 Campbell Clinic (Memphis)

Objectives / Interrogation: An alternative to utilization of free tendon grafting is the Tendon With Z-Lengthening (TWZL) technique. This method utilizes the native tendon, z-lengthened and rotated on a distal juncture to provide length in cases of tendon deficiency. This technique obviates the need for tendon autograft and may allow for early active motion (EAM) protocols. This study evaluated the feasibility of the TWZL technique in cadaveric FDP tendons and biomechanically analyzed various suture constructs to determine the ideal one that could potentially allow an EAM rehabilitation protocol.

Methods: The FDP tendons of the index, middle and ring fingers harvested from 20 fresh frozen cadavers were utilized. 60 tendons were randomized into 5 different TWZL construct designs.

Tendon-suture constructs using 3-0 Maxbraid® were tested on a servohydraulic testing machine until failure was observed on the load-elongation recording. Stress-strain graphs were created. Data points on maximum yield and load at 8% strain were recorded for each construct.

Results and Conclusions: The maximum yield data revealed construct #4 to have the highest overall mean load to failure at 150 N compared to all other constructs (p < 0.0003).

Construct #4, at 59 N, had the highest mean load at 8% strain. Constructs #2, #3, and #4 were found to withstand a significantly higher mean load at 8% strain than constructs #0 and #1 (p < 0.0001). Comparison amongst constructs #2 (56 N), #3 (48 N), and #4 (59 N) did not show a significant difference in mean load at 8% strain. Construct #3, however, had standard deviation and confidence limit intervals that fell below the 45 N EAM threshold, whereas both constructs #2 and #4 had 95% confidence limits that fell no lower than 50 N.
Conclusions: The option of having a less morbid and simplified procedure for tendon reconstruction is attractive, especially if an EAM protocol can be initiated at time zero. This study provides evidence that the TWZL technique utilizing either construct #2 or #4 could provide sufficient strength for tendon reconstruction and subsequent early rehabilitation.

A comparison of hand function in Colles and Scaphoid casts using a technologically updated Jebsen Hand Function test

List of authors:
Anuhy Vusirikala*, Daniel Williams¹, Hui Fen Koo¹, Joseph Godwin¹, Leticia Costalago¹, Georgina Erdos¹, Jonathan Esposito¹, Anthea Davy¹
¹ University College Hospital (London)

Objectives / Interrogation: To investigate the impact of Colles and Scaphoid casts on hand function, assessed using the Jebsen Hand Function test (JHFT) with additional technological subtests.

Methods: The JHFT is an objective measure of hand function, consisting of 7 subtests which reflect activities of daily living. 4 additional subtests were created to assess the impact of the casts on the use of technology. These included (1) texting on a mobile phone, (2) typing on a keyboard, (3) using a computer mouse to point and drag, and (4) using a computer mouse to scroll. 20 healthy volunteers were assessed completing the JHFT and additional subtests without immobilisation, in a Colles cast and in a Scaphoid cast. The data was analysed using a paired t test.

Results and Conclusions: Results
The average age of the participants was 28 years (10 male, 10 female). Immobilisation (Colles or Scaphoid) prolonged task completion times of all subtests of the JHFT. In all the JHFT subtests, volunteers performed worse in a Scaphoid than in a Colles cast. In 5 of the 7 JHFT subtests this reached statistical significance (p< 0.05). Immobilisation (Colles or Scaphoid) also prolonged mean task completion times of the technologically updated subtests. Although mean task completion times were greater for the Scaphoid cast than the Colles cast this was not statistically significant. Volunteers often demonstrated adaptations in technique to accommodate immobilisation of the wrist or thumb.

Conclusions
Scaphoid casts have a greater impact on hand function than Colles casts. This was most evident in tasks involving fine motor movements and forearm rotation. The technologically updated subtests confirmed the negative effect of immobilisation, but immobilisation of the thumb did not produce a statistically significant difference when comparing types of cast.

A rare case of thumb polydactyly with metacarpophalangeal joint symphalangism

List of authors:
Sebastian Guenkel*1, Michael Finsterwald1
1 Hand Surgery (Solothurn)

Objectives / Interrogation: A rare case presentation of an 14-year old healthy boy of Ethiopian descent presented with a duplicated thumb on his right hand consisting of a non-functioning hypoplastic radial and a fully developed functional ulnar component. The presented case report should demonstrate a case of rare congenital deformities; usually hand surgeons in the western hemisphere are not confronted with. In the current geopolitical situation more often refugees from less developed countries seek advice for their congenital deformities in a very late presentation. This case attempts to describe such a rarely seen deformity, discusses the classification and treatment options.

Methods: After thorough discussions with the patient and explaining the options with the help of an interpreter, we decided to undergo a resection/reconstruction procedure. During surgery the hypoplastic radial component was resected and the metacarpal head reduced to match the proximal ulnar phalanx. Tendons were dissected proximally. Followed by radial collateral ligament anatomic transosseus. In order to avoid a painful neuroma the remaining nerves of the removed radial component were dissected, crushed and buried into an intraosseus drillhole.

Results and Conclusions: At three months follow-up the patient showed no metacarpophalangeal joint instability, a satisfying motion of the thumb as well as intact sensation, was pain free and pleased with the result. Postoperative X-Rays revealed a normal joint alignment. To our knowledge this is only the second case of thumb polydactyly with metacarpophalangeal joint symphalangism and a single interphalangeous joint reported in the world literature and certainly the latest presentation. Al-Qattan, 2010 mentioned this rare anomaly in one case in his study of 228 hands without providing further details. One patient with metacarpophalangeal symphalangism and two distal phalanges radially was described by Afshar, 2007 whereas a few patient reports of interphalangeous symphalangism of the thumb as well as cartilaginous symphalangism in children can be found in the literature. According to Zuidam et al our presented case would be named Type IV S (Symphalangism) u (ulnar). Our reported case is unique in that it is the only case of thumb metacarpophalangeal symphalangism with a near-normal single distal phalanx. Previously reported cases showed either two distal phalanges (Afshar, 2007), a slightly deformed interphalangeal joint (Al-Qattan, 2010) or symphalangism in more distal joints of the thumb.

A NEW TECHNIQUE TO VERY CHRONIC UCL INJURY WITHOUT ARTHROSIS - AUGMENTATION WITH FIBER TAPE

List of authors:
Eduardo Pereira*, Laura Filippini Lorimier Fernandes¹, Luciano Pereira¹
¹Hospital Albert Einstein (São Paulo)

Objectives / Interrogation: The stability of the thumb is necessary for hand function. The ulnar collateral ligament (UCL) of the metacarpophalangeal joint is the major stabilizer for grip and pinch activities. The prevalence of this injury is approximately 50 in 100000 per year, with 86% of complete rupture. The most common mechanism of injury is forceful abduction during sports. It's not uncommon for the injury to be overlooked in the first visit to the ER, due to the lack of suspicion and incorrect physical examination and also because it doesn't appear on plain x-rays. In addition, the injury often does not heal by itself due to the frequently interposition of the adductor aponeuroses.

Sometimes the patients just seek for medical assistance with a very chronic injury (over 6 months) without arthrosis, which is challenging to decide the treatment. The decision depends on the degree of ligamentous injury and physical demands.

Many types of reconstruction using tendons grafts are described for the treatment, but there is always the damage in the donor's site. The use of suture tape as an internal brace is well established for other ligaments reconstructions. Shin et al recently published a biomechanical study comparing the strength of repair alone and repair augmented with tape in thumb UCL lesion in cadaveric specimens, demonstrating the superiority of the last procedure.

The goal of this study is to present the use of UCL augmentation in very chronic injury without arthrosis with a new technique.

Methods: The UCL and UCL accessory were identified during surgery and they were not trustable for repair. Krackow's style suture were made with a 2-0 fiber wire. The fiber wire and a 2-0 fiber tape were fixed distally with a 3X8mm bio-tenodesis screw (Arthrex, Naples, FL). The tension was adjusted with the MCP joint in 30° flexion to avoid restricted flexion in the joint, and the proximal side of the fiber tape were fixed with an equal screw. The patient wore a cast for 1 week and then a splint for 3 weeks when rehabilitation started.

Results and Conclusions: The immediate strength and stability of the repair were excellent, the passive range of motion was complete.

Three months after surgery the grip and the pinch were stronger than contralateral thumb. There was full range of motion.

This method looks promising for the treatment of this difficult chronic UCL injury without arthrosis.

Ethnic differences in prevalence of Dupuytren disease can be explained by known genetic risk variants

List of authors:
Sophie Riesmeijer¹, Paul Werker², Ilja Nolte¹
¹ University medical center Groningen (Groningen)

Objectives / Interrogation: Dupuytren disease (DD), a fibroproliferative disorder of the palmar fascia that causes flexion contractures in the fingers, is prevalent in people of North-Western European descent and less so in other ethnicities. DD is a complex disorder, influenced by genetic risk variants. We aimed to study if the marked differences in prevalences in DD between ethnic (sub)groups could be explained by differences in allele frequencies of the 26 known genetic risk variants of DD.

Methods: Genetic risk scores (GRS) composed of the 26 DD risk variants were calculated for the 26 populations from the 1000 Genomes database and correlated to observed DD prevalences from literature. For comparison, GRSs were generated for 100 sets of 26 random SNPs and also correlated to observed DD prevalences to determine the significance of the observed correlation. To determine whether differences in allele frequencies between ethnicities were caused by natural selection, fixation indices (Fst) were calculated from the 26 SNPs and from the sets of 26 random SNPs for comparison.

Results and Conclusions: Observed prevalences could be determined from literature for ten populations. Their correlation with the GRS composed of DD SNPs proved to be 0.51 (p<0.00). The Fsts between British and other populations were low for Europeans, ad mixed American, and South-Asian populations, and moderate for East-Asians and Africans, but none of them was significantly different from expected values determined from the random sets.
Conclusion: The 26 known genetic risk variants associated with DD explain for a substantial part (R²=0.26) the differing DD prevalences observed between ethnicities.

Learning curve and risks in carpal tunnel release ultrasounds guided versus endoscopy procedure, a comparative pilot study between a senior surgeon and a junior surgeon, 30 cases

List of authors:
Emmanuelle Richard¹, PASCAL KOUYOUMDJIAN², REMY COULOMB³, OLIVIER MARES¹
¹ Nîmes (Nîmes)

Objectives / Interrogation: The learning curve and risks of sectioning the transverse carpal ligament (CTL) by ultrasounds have never been evaluated so far.

We have evaluated these parameters, on surgical criteria (quality of section and anatomical injuries), by a comparative cadaveric study between a junior surgeon and an experimented one through two section methods: ultrasound carpal tunnel release (UCTR) and endoscopic carpal tunnel release (ECTR).

Methods: We used 30 normal cadaveric wrists (5 fresh frozen, and 15 conserved).

The Junior surgeon did performed 14 UCTR and 6 ECTR without any external help, against 5 for each method for the senior.

We then extensively dissected each wrist to evaluate the quality of section evaluated by the percentage of section (length of sectioned ligament reported to the total CTL length).

We also researched anatomical injury (tendons, vessels, nerves) caused by the section.

Results and Conclusions: The CTL was fully released in half cases for the junior surgeon in each group. The mean percentage of section was 90% with 2 injuries for ECTR and 80% with 3 injuries for UCTR.

![Graph comparing operators for each technique](image)

The senior surgeon did not cause any damage, the mean section was 100% in ECTR and 88% in UCTR.

There were significant differences between junior and senior surgeons in each method on surgical parameters.

The Junior surgeon showed greater fluency in ECTR around 3 wrists against 10 in UCTR, for the inexperienced surgeon.
There is a longer learning curve and an increase of severe lesions by sectioning the CTL by ultrasounds than the reference method.

This study highlights the importance of cadaveric model for the trainee to acquire the method.

Anatomical knowledge are essentials to manage complications.

Midcarpal Arthrodesis in Patients with Advanced Carpal Collapse

List of authors:
Oleg M. Semenkin1, Sergey N. Izmalkov2
1 Samara Regional Clinical Hospital named after V. Seredavin, Samara State Medical University (Samara)
2 Samara State Medical University (Samara)

Objectives / Interrogation: Midcarpal arthrodesis with excision of scaphoid is a common procedure for the surgical treatment of scaphoid nonunion advanced collapse and scapholunate advanced collapse wrists. However, this method has been associated with the increased risk of complications including nonunion and implant failure. The purpose of this study was to evaluate the results of surgical treatment of patients with SNAC and SLAC wrist in stage II and III.

Methods: Between 2005 and 2017 we performed 11 midcarpal arthrodeses in eleven patients (all men averagely aged 42) with 8 SNAC- and 3 SLAC-wrist. The average interval between the injury and surgery was 5 years. The fusion between lunate and capitate, as well between triquetrum and hamate, was performed together with the excision of the scaphoid bone and radial styloidectomy (5 cases). The Kirschner wire (6) and headless compression screws (5) were used for bone fixation. In eight cases we performed the bone graft transfer from iliac crest or used the excised scaphoid. We examined all patients according to the radiological bone healing, active range of wrist motion (AROM), grip strength, pain score (VAS 1-10), complications, DASH-questionnaire, Cooney-Krimmer score. The mean follow-up was 2.5 years (12 months - 13 years). Statistical Analysis was done using SPSS 21; paired t-test; paired Wilcoxon-test.

Results and Conclusions: Radiographic signs of bone fusion were observed in 3-4 months after the operation in all patients. The preoperative AROM was 71.1±14.3% of the contralateral hand, the postoperative one was 58.8±10.4% (p=0.013). Grip strength improved from 58.6±17.6% to 76.6±10.8% (p=0.008). The average intensity of wrist pain at rest and on exertion was 2.6±2.3 and 6.8±1.5 points (p=0.005) preoperatively, and after the surgery it was 0.6±0.9 and 3.1±1.9 points (p=0.003) respectively. The rates of DASH score prior to the operation were averagely 44.5±13.6 points; after the surgery they made 20.6±8.2 points (p=0.003). The function scores measured by the Cooney-Krimmer wrist score improved significantly from 42.7±12.5 to 71.0±9.4 points (p=0.005). The errors and complications included the damage of lunate and radius cartilage (2), DISI deformity (1), K-wire break (1) and drill break (1). There were no changes in the professional activity of the patients.

Conclusion: The midcarpal arthrodesis is a reliable procedure for SNAC and SLAC to achieve a stable and pain-free wrist with the increase of wrist strength due to the decrease of the overall range of motion.

Complications and Reoperations After Triangular Fibrocartilage Complex (TFCC) Debridement

List of authors:
Svenna Verhiel*, Marco Ritt, Neal Chen
1 Massachusetts General Hospital (Boston)
2 VU Medisch Centrum (Amsterdam)

Objectives / Interrogation: Few studies analyze factors associated with reoperation after triangular fibrocartilage complex (TFCC) debridement. Of these studies, positive ulnar variance and incidence of associated lunotriquetral ligament tears are factors implicated in worse clinical outcomes and complications. The aim of this retrospective database study is to identify factors associated with unplanned reoperation after TFCC debridement. Furthermore, we aim to determine the rate and type of reoperation after TFCC debridement, and to report on complications and persistence of ulnar-sided wrist pain after TFCC surgery.

Methods: In this retrospective study, we included all patients older than 18 years of age who underwent TFCC debridement between January 2003 and December 2017. Medical records of patients were assessed for our explanatory variables, unplanned reoperations, complications and reporting of symptoms. We used bivariate (Mann-Whitney U test and Fisher’s exact test) and multivariable analyses to identify factors associated with unplanned reoperation after TFCC debridement.

Results and Conclusions: Among 163 TFCC debridement procedures, there were 31 unplanned reoperations (19%). Seventeen patients underwent ulna shortening osteotomy (10%), 7 patients underwent a revision TFCC debridement (4.3%) and 7 patients underwent surgery of a different type (4.3%). In multivariable analysis, a positive ulnar variance appeared to be the only factor independently associated with unplanned reoperation (odds ratio 4.5; 95% CI 1.5-14). Twenty-three patients experienced a complication (14%), the most common being extensor carpi ulnaris (ECU) tendinitis/tenosynovitis (n=9; 5.5%) and symptoms of the dorsal sensory branch of the ulnar nerve (n=5; 3.1%). At final follow-up, 15 out of 163 patients (9.2%) reported persistent ulnar-sided wrist pain.

TFCC debridement yields satisfactory pain-relief with acceptable reoperation and complication rates. This study can help inform decision making as patients with ulna positive variance have about a 4-fold increased odds of revision surgery involving ulna shortening after arthroscopic debridement.

The Role of Positive Psychology in Understanding Pain Intensity and Disability Among Hand and Upper Extremity Patients

List of authors:
Svenna Verhie1, Jonathan Greenberg1, Emily Zale1, Neal Chen1, David Ring2, Ana-Maria Vranceanu1
1 Massachusetts General Hospital (Boston)
2 University of Texas at Austin (Austin)

Objectives / Interrogation: Psychological distress and ineffective coping have shown to significantly contribute to higher pain and decreased physical function among patients with orthopedic illness. However, little is known about the relationship among positive psychology factors - constructs that enable individuals to thrive and adapt to challenges - and pain and physical function in this population. Purpose of this study was to assess which positive psychology factors are associated with upper extremity physical function and pain intensity.

Methods: In a cross-sectional study, we recruited patients presenting to their regularly scheduled appointment with an orthopaedic surgeon at a Hand and Upper Extremity Clinic of a major urban academic medical center. Of 125 approached patients, 119 (44% men; mean age = 50 ± 17) met screening criteria and agreed to participate. Patients completed a clinical and demographic questionnaire, the Numerical Rating Scale to assess pain, the PROMIS Upper Extremity Physical Function CAT to assess physical function, and 7 measures assessing positive psychology constructs.

Results and Conclusions: In bivariate correlations satisfaction with life (r = .272, p = .003), greater gratitude (r = .248, p = .007), humor (r = .197, p = .033), mindfulness (r = .394, p < .001), and optimism (r = .224, p = .017) were associated with higher physical function. Similarly, satisfaction with life (r = -.411, p < .001), greater gratitude (r = -.411, p < .001), resilience (r = -.262, p = .004), mindfulness (r = .330, p < .001) and optimism (r = -.364, p < .001) were associated with lower pain. In multivariable linear regressions that controlled for relevant clinical and demographic variables, we found that mindfulness remained as sole significant positive psychology correlate of physical function (b = .360, t = 2.293, p = .024, sr2 = .188) and satisfaction with life as the sole significant positive psychology correlate of pain intensity (b = -.11, t = -2.16, p = .033, sr2 = -.184).

While causal inferences cannot be drawn, clinical interventions for this population may benefit from focusing on positive psychology principles aimed at human strengths and flourishing, rather than restricting to the standard medical model of physical therapy and pharmacology/opiates. Targeting mindfulness and satisfaction with life may be of particular benefit for this population. Such interventions focused on developing strengths may bypass stigma associated with traditional psychosocial interventions in orthopedic patients.

Free flap transfers to repair the defects of fingers using the proper digital artery and volar digital veins

List of authors:
Chao Chen*, Liwen Hao1, Zengtao Wang1
1 Shandong Provincial Hospital (Jinan)

Objectives / Interrogation: We report our method of flap transfer to repair the defect of fingers using the proper digital artery and volar digital veins.

Methods: From December 2014 to April 2018, we used free flaps to 12 fingers (11 patients) with soft tissue defect in fingers using the proper digital artery and volar digital veins as the recipient vessels. 11 fingers were operated immediately after injury, one finger was repaired several days after injury. We transferred a total of 5 thenar perforator flaps, 1 groin flap, 5 great toe fibular flaps, and 1 medial plantar artery perforator flap to repair volar soft tissue defects with bony or tendon exposure of fingers. The artery of these flaps was connected to the proper digital artery. One or two veins of the flap were anastomosed to the volar digital veins in the recipient site. In searching for the volar veins of the finger, we first debrided the recipient site and explored the proper digital artery and volar veins at the proximal edge of wound. Then the flap can be designed with a short pedicle of 1-1.5 cm. The anastomosed volar veins were less than 0.5 mm in diameter. We used 12-0 sutures to vascular anastomosis.

Results and Conclusions: All the transferred flaps survived, no vessel crisis happened. The flap covered the defect site sufficiently and scar of operation is minimal and no circulation problems after surgery. Using volar digital veins as recipient veins is a novel attempt. The merits of this approach is that scar of operation is very limited. We transferred the flap based on a short pedicle, which decrease surgical time. The important findings from our series of 12 fingers indicate that volar vein can be used as recipient veins of the flap transfer in the finger, though traditionally dorsal veins are used because they are large and can be easily dissected. We suggest that volar veins can be considered as the recipient veins for free flap transfers in the fingers, provided that the surgeons are prepared to do finer vascular anastomosis of veins with diameter less than 0.5 mm.

Pollicization: new ideas of the biomechanics of the new thumb

List of authors:
Vladimir Zavarukhin*
1 St Petersburg University Clinic (Saint-Petersburg)

Objectives / Interrogation: Pollicisation is one of the most anatomical options for repairing the bilateral hand grip. The main idea of this operation is to create the skeletal anatomy and biomechanics of a normal thumb. However, the surgeon is always limited in the number of motor units which he can use to reproduce the entire volume of motions of the normal thumb and classical technique of pollicization does not imply the creation of an active rotation of the new thumb.

Methods: The new technics was used in operative treatment in 34 patients with hypoplasia of the thumb (type IIIB-IV Blauth) aged 0.5-2 years. Cross-transposition of the interosseus muscles of the index was made with fixation to the lateral bands of the extensor tendon. EDC tendon was fixed to the radial surface of the proximal phalanx throw the tunnel. The maximal follow-up period was 3.5 years.

Results and Conclusions: Results: all patients demonstrated active rotation of the new thumb in combination with abduction. In 64.7% of patients rotation consisted 140-165 degrees; in 23.5% - 120-140 degrees and in 11.8% of patients - less the 120 degrees. All patients had full active extension of the thumb in all joints.
Conclusion: Transposition of the interosseous muscles in pollicization helps to improve the possibilities of active and passive rotation of the new thumb without reducing the amplitude of active extension.

Validity and responsiveness of strength measurements in the assessment of Distal radioulnar joint arthroplasty

List of authors:
Peter Axelsson*1, Johan Kärrholm2
1 Dept. of Hand Surgery, Institute of clinical sciences, Sahlgrenska Academy, University of Gothenburg (Göteborg)
2 Dept. of Orthopaedics, Institute of clinical sciences, Sahlgrenska Academy, University of Gothenburg (Göteborg)

Objectives / Interrogation: To assess responsiveness of lifting strength, forearm torque and grip strength in the evaluation of distal radioulnar joint (DRUJ) implant arthroplasty

Methods: We performed a retrospective review of 18 patients treated with Herbert (n = 12) and Scheker (n = 6) DRUJ implants. Patients, whose arm and grip strength had been assessed both preoperatively and after a minimum follow-up of one year, were included. Observed changes of strength measurements were correlated to changes of patient reported outcome measures such as Disabilities of the arm, shoulder and hand (DASH), Patient reported wrist evaluation (PRWE) and Visual Analogue Scales (VAS) for pain and satisfaction. Measurements for grip strength, forearm torque and lifting strength were performed with the Jamar dynamometer and our recently presented test methods including the Kern- and Baseline instruments. Preoperative values were compared with one-year values. Statistical analyses included Spearman's correlation to explore relationships between variables. Standardized response mean and effect size were used to analyze responsiveness.

Results and Conclusions: Forearm torque was more sensitive to change of clinical outcomes after DRUJ arthroplasty than grip strength, which did not significantly correlate to other strength recordings or any outcome measures. Change in forearm torque and lifting strength had a moderate to strong correlation to change in PRWE and Pain experienced during activity. There were no significant correlations between change in any strength test and change in DASH.

Our findings suggest that the most relevant measures for the assessment of DRUJ arthroplasty are Forearm torque, PRWE and VAS for pain with activity.

Classification of Electrical burns injuries of the Upper Limb

List of authors:
Barbara Jemec¹, Tanveer Ahmed², Sazzad Khondoker², Abul Kalam²
¹ The Royal Free Hospital (London)
² Sheikh Hasina National Institute of Burn and Plastic Surgery (Dhaka)

Objectives / Interrogation: Electrical burns of the upper limb are devastating injuries. To date there are no specific classifications of electrical burns in the upper limb. Due to the high number of electrical burn injuries treated in our institute we offer a classification and treatment algorithm for the immediate reanimation with tendon transfers after soft tissue cover in electrical burns of the upper limb.

Methods: Patient data was collected over one year and analysed with regards to sex distribution, high and low voltage burns, the areas of the upper limb affected, nerves, tendons and bones involved, amputation levels and soft tissue reconstructions including tendon transfers.

Results and Conclusions: Over 6000 burns are admitted to our institute each year. 27% are due to electrical injuries and 29% include the upper limb. Electrical burns cause 42% of the deaths in our burns patient population. The vast majority of electrical burns are due to High Voltage electricity in males. 60% are admitted in the first 2 days post injury, but admissions continue up to 4 weeks post burn. The most common place of injury was the workplace, followed by the home, roadside educational institutes and the playground.

The average Total Body Surface Area involved was 15% (range 1-50%): mostly 2nd and 4th degrees. Nearly half necessitate amputations with nearly a third below elbow amputations. 20% include nerve injuries and include loss of tendons.

Roadside electrical cables
Surgical debridement was usually performed piecemeal and defects covered successfully with local flap. Tendons were buddied, transferred depending on availability and need. On the basis of our data we offer an upper limb electrical burns classification, which facilitates surgical treatment and reconstruction.

burns, electrical burns, tendon transfers, demographics, rehabilitation
Effective Period of Conservative Treatments in Patients with Acute Calcific Periarthritis of the Hand

List of authors:
Kee Jeong Bae¹, Ji Hyeung Kim², Do Weon Lee², Yo-Han Lee², Yeun soo Kim², Young Ju Chae², Che Ho Lee², Qingyuan Li², Hyun Sik Gong³, Goo Hyun Baek²
¹ Seoul National University Boramae Medical Center (Seoul)
² Seoul National University Hospital (Seoul)
³ Seoul National University Bundang Hospital (Seongnam)

Objectives / Interrogation: Acute calcific periarthritis of the hand is a relatively uncommon painful condition with juxta-articular deposits of amorphous calcium hydroxyapatite. Although conservative treatments has been generally regarded effective, there is not much evidence about how long they could be effective.

Methods: We retrospectively reviewed 11 patients who were diagnosed as acute calcific periarthritis of the hand from January 2015 to June 2018. We recommended the use of warm baths, nonsteroidal anti-inflammatory drugs (NSAIDs) and limitation of the activity as an initial treatment. If the pain persisted in spite of the at least 3-months conservative treatments, we explained surgical treatment options. If the pain improved, we recommended gradual range of motion exercises with continuation of daily NSAIDs. Each visual analog scale (VAS) for pain at every 3 months visit (3 months, 6 months, 9 months) were compared with that of previous visit to investigate whether the pain had decreased or not during each time interval. Simple radiographs taken at every 3 months visit were compared with those of previous visit to determine any significant change in calcification amounts during each time interval.

Results and Conclusions: Except one patient with immediate surgical reconstruction of collateral ligaments, 10 patients having 17 affected joints continued the conservative treatments for average 11.1 months. Average pain VAS score at initial visit was 7, while that of 3 months, 6 months and 9 months were 4.3, 3.3 and 2.9 respectively. There was significant reduction in pain VAS scores at 3 months and at 6 months, but not at 9 months (P-value = 0.004, 0.008 and 0.598 respectively). Simple radiographs also showed significant reduction of calcification amounts at 3 months and at 6 months, but not at 9 months (P-value = 0.020, 0.034 and 0.083 respectively).

Patients with acute calcific periarthritis of the hand revealed residual pain and calcifications for relatively prolonged period. Those who continued the conservative treatments including NSAIDs medication showed relieved pain and reduced calcification up to 6 months. This results suggested that the conservative treatments could be tried for at least 6 months before deciding surgical treatments for calcific periarthritis of the hand.

Distal interphalangeal joint arthrodesis using the ADS memory staple - The London Experience

List of authors:
Arvind Mohan*, Anna Allan2, Andreas Fox1, Barbara Jemec2
1 St Thomas Hospital (London)
2 Royal Free Hospital (London)

Objectives / Interrogation: Aims
The ADS memory staple is the first intramedullary shape device in use for distal interphalangeal joint arthrodesis. We describe our experience of the device used in two hand units.

Methods: Methods
An analysis of 17 consecutive patients undergoing single digit DIPJ arthrodesis using the device between October 2013 and February 2018 by two Consultant Plastic Surgeons at two London Teaching Hospitals was performed. Functional and patient reported outcomes as well as complications were measured.

Results and Conclusions: Results
13 female (76%) and 4 male (24%) patients with a median age of 59 years (29-82yrs) were operated on. Indications included osteoarthritis (n=4), traumatic arthritis (n=8), rheumatoid arthritis (n=4) and psoriatic arthritis (1). 13 DIPJs and 4 thumb IPJs were fused. Average follow up time was 32.6 months (7.2-60 months). 4 patients were retired, 2 unemployed and 11 actively working. 16 patients (94%) achieved bony union within 6 weeks of surgery and had a painless, functional hand. Device displacement occurred in 1 patient requiring removal and arthrodesis with K-wires. 2 patients developed a wound infection requiring antibiotics, 1 developed a hypertrophic scar and 1 healed with a mildly rotated DIPJ. There we no instances of skin necrosis, cold intolerance, paraesthesia or osteomyelitis. All patients were satisfied with their final outcome despite the one displacement.

Conclusions
Our study demonstrates high union rates without many of the complications associated with other arthrodesis techniques. We present a rapid, reliable and cost-effective method of DIPJ arthrodesis using a novel new technique with high rates of patient satisfaction.

Treatment of mutilated hands with multiple finger amputation by means of a free flap transfer with digital replantation or revascularization

List of authors:
Chao Chen*, Liwen Hao¹, Zengtao Wang¹
¹ Shandong Provincial Hospital (Jinan)

Objectives / Interrogation: We report our method of free vascularized tissue transfers to repair mutilated hands with multiple finger destructions.

Methods: From August 2016 to April 2018, we treated 6 patients with multiple finger destructions and severe tissue trauma of the hand using free flap transfers. Three hands had amputation through their MP joints of index to little fingers with soft tissue defects of the dorsal hands. These hands were repaired with free groin flap or a venous flap. The flaps were used as flow-through flaps, which connected distally to the digital arteries or dorsal veins for replanting amputated fingers. Two patients had incomplete amputation of two fingers and multiple fractures and dislocations of other fingers. After reduction and fixation of the fractures and joints, lobed anterolateral thigh flaps were transferred to cover soft tissue defects palmarly and dorsally, with revascularization of the incompletely amputated fingers. The more recent case with skin avulsion of palm and dorsal hand, and destruction of vascular circulation in 5 fingers. The hand was repaired with an anterolateral thigh flap with multiple vein grafting for revascularization of 5 fingers. All the cases were treated by heparin over the first 7 days after surgery.

Results and Conclusions: Results: All the fingers survived except postoperative artery crisis happened in one patient and was rescued by surgical exploration and re-anastomosis. The soft tissue coverage is sufficient and all fingers survived after replantation or revascularization. The hand with a venous flap transfer had obvious scar contracture. That patient required scar excision and finger joint release and a groin flap transfer 6 months after initial surgery. Conclusions: Reconstruction of multiple finger destructions accompanied with soft tissue defects in the hand is challenging. We show here that vascularized flap transfer to repair tissue loss in the dorsal or palm of the hand together with distal anastomosis of the vessels to digital artery and veins of amputated fingers can salvage both amputated fingers and severely traumatized hand with extensive tissue losses. We have used end-to-end or end-to-side anastomosis for the flap transfer or finger revascularization distally. The design of the combined transfer or ideal connection of vessels is a key to success of surgical salvage, which should be decided according to intraoperative findings and availability of vessels in these severely traumatized hands.

Multi-lobed groin flaps for coverage of extensive soft tissue defects involving multiple digits and palm or dorsal hands

List of authors:
Chao Chen*, Liwen Hao¹, Zengtao Wang¹
¹ Shandong Provincial Hospital (Jinan)

Objectives / Interrogation: The purpose of this study was to report the feasibility of free vascularized multi-lobed groin flap transfers for hand coverage or for donor sites coverage after finger reconstruction.

Methods: From January 2018 to July 2018, 5 cases suffered multiple soft tissue defects on hand were reconstructed using multi-lobed groin flaps. One patient had skin defects on dorsal hand and proximal area of dorsal skin on index to little fingers, and was reconstructed using a free groin flap with randomized separating distal part of flap into 4 lobes to cover dorsal fingers. The second patient had dorsal hand defect from dorsal wrist extended to middle phalange of index to little finger, which was reconstructed using two lobed groin flaps, so that the four lobes could cover 4 injured fingers individually. The arteries of two groin flap were anastomosed to two ends of a Y-shape vein graft, which was end-to-side anastomosed to radial artery. The third patient had dorsal skin defect on index to little fingers, and was reconstructed using a 4-lobed groin flap based on the superficial circumflex iliac artery and superficial inferior epigastric artery. The arteries were anastomosed to radial arteries through a Y-shape vein graft. These three patients had a large size of dorsal hand soft tissue defects in the hand and in several fingers. Multi-lobed groin flaps based on superficial branch and deep branch were used to cover the donor site defects after finger reconstruction in another two cases.

Results and Conclusions: All the flaps survived except a small size of marginal area necrosis in the case with dorsal skin reconstruction of four fingers. The small wound healed without surgical intention. The repaired fingers generally had acceptable cosmetics and pinch function of these fingers are also acceptable. The sensation of these fingers generally were less than ideal. Free vascularized multi-lobed groin flaps are a useful method for multiple soft tissue defects on hand and fingers. The flap is reliable and cosmetics and pinch function after transfer to the hand is acceptable. However, the sensory recovery of the reconstructed fingers is still a concern after extensive trauma and flap coverage.

Non-Contrast Magnetic Resonance Imaging of Perforators in Preoperative Evaluation of Anterolateral Thigh Flaps

List of authors:
Frank Chen*, Alissa Burge, Aaron Chen, Aoife MacMahon, Daniel Osei, Duretti Fufa
1 Weill Cornell Medical College (New York)
2 Hospital for Special Surgery (New York)

Objectives / Interrogation: The anterolateral thigh (ALT) flap is a commonly utilized perforator-based flap used in upper extremity reconstructive surgery. Previous studies have used MRA and CTA to image the ALT. However, these techniques require contrast or radiation. No prior studies have investigated the efficacy of using non-contrast magnetic resonance imaging (MRI) to assess ALT perforators. Our study investigates the efficacy of using non-contrast MRI to characterize the number, location, and course of dominant skin perforators of the ALT.

Methods: We queried our institutional database for 100 non-contrast thigh MRI exams from July 2013-July 2018 that included an axial fat suppression sequence from the lesser trochanter (LT) to the distal musculotendinous junction of the rectus femoris. We excluded studies with artifact that precluded reliable evaluation. All images were analyzed with OsiriX (Pixmeo SARL, Geneva). Perforator course, size, and location relative to bony landmarks were determined.

Results and Conclusions: Of 100 exams, 277 perforators in 170 legs were identified. Of these, 101 were septocutaneous (36.46%) and 176 were musculocutaneous (63.54%). An average of 1.63 perforators were visualized in each leg (min 1; max 4). The average perforator diameter was 2.53mm (SD 0.5). For n=22 perforators where the ASIS and patella were captured on imaging, the average site of perforator exit along the ASIS-patella line was 0.5 (SD 0.08; min 0.372, max 0.64). Perforators are shown in Figures 1 and 2.
Figure 1. Non-contrast axial T2 Fat suppressed slabbed maximum intensity projection image of the thigh in a 21 year-old woman for evaluation of anterolateral thigh perforator anatomy prior to surgery demonstrates the course of a prominent septocutaneous perforator (red arrowheads) arising from the descending branch of the lateral circumflex femoral artery.
Perforator course, size, and location can be measured using non-contrast MRI. Non-contrast MRI is a low-morbidity imaging modality that may serve as an effective tool to aid in preoperative planning for use of the ALT flap.

Distally based sural neuro-fasciocutaneous perforator flap for foot and ankle reconstruction: surgical modifications for flap pedicle and donor site closure without skin graft

List of authors:
Yiheng Chen*, Zhenglin Chi, Weiyang Gao, Zhijie Li, Tinggang Chu
1 the Second Affiliated Hospital of Wenzhou Medical University (Wenzhou)
2 Yunnan Sino-German Orthopaedic Hospital (Kunming)

Objectives / Interrogation: The conventional procedure of distally based sural neuro-fasciocutaneous flap enables the blood supply and venous drainage by increasing the width of the adipofascial tissue and preserving tiny venous return routes. Moreover, skin graft is a common method for donor site closure, which may influence the aesthetic appearance. The purpose of the study is to modify the pedicle of the flap and to design a relaying flap for the donor site closure without skin graft.

Methods: 12 patients undergoing the modified distally based sural neuro-fasciocutaneous perforator flap for foot and ankle reconstruction were included in this study. The surgical modification for flap pedicle is described. A peroneal-based perforator, a superficial vein, and the vascular axis of the sural nerve should be included in the pedicle. A Z-shape skin incision was used to explore the perforator vessels and a relaying island perforator flap was used to close the donor site without skin graft. Flap survival, complications, flap swelling degree and aesthetic satisfaction were evaluated. The links between the perforator vessels and the accompanying vascular axis around sural nerve were verified in 8 fresh cadavers.

Results and Conclusions: The linking vessels were constant occurrence in 8 cadavers and 12 cases during operation. All flaps survived completely without necrosis. Neither arterial ischemia nor venous congestion was noted. The diameter width and the length of the pedicle ranged from 1.0 to 2.0 cm and 4 to 10 cm, respectively. A relaying perforator island flap was used in 8 cases for donor site closure and no skin graft was performed. No serious donor site complications happened and all patients were satisfied with the aesthetic outcomes at the final follow-up.

The modification for the pedicle of the distally based sural neuro-fasciocutaneous perforator flap is considered as a reliable method for foot and ankle reconstruction. A relaying flap for the donor site closure without skin graft should be recommended.

Defining displacement thresholds for surgical intervention for distal radius fractures - a Delphi study

List of authors:
nick johnson¹, paul leighton², charles pailthorpe³, joseph dias¹
¹ University hospitals of leicester (leicester)
² nottingham university (nottingham)
³ royal berkshire hospital (reading)

Objectives / Interrogation: Distal radius fractures are very common yet controversy exists regarding which require treatment and is reflected by significant variation in surgical intervention rate. Evidence regarding which fractures would benefit from intervention is varied and largely poor quality.

This study had three aims; identify which radiographic parameters are clinically important; quantify the threshold of displacement at which intervention should occur and investigate which patient factors influence the decision to intervene.

Methods: A modified three round Delphi study was carried out and responses were qualitatively analysed.
The Delphi panel was composed of three groups of national and international expert surgeons:
Hand and wrist surgeons,
Trauma surgeons,
International researchers.
46 participants initially agreed to take part. 43 completed the first round and all then completed three rounds.
Participants were asked questions based around case vignettes in patients of three ages (38, 58, 75 years).

Results and Conclusions: For all age groups ulnar variance was ranked as the most important extra-articular parameter, step was ranked as the most important intra-articular parameter.
Agreed thresholds were the same for all parameters for patients aged 38 and 58. Surgeons would intervene with +2 mm ulnar variance, 10 degrees dorsal tilt, 2mm step and 3mm gap. In patients aged 75 the agreed thresholds were 20 degrees dorsal tilt, 3mm step and 4mm gap, consensus was not achieved for ulnar variance.
Mental capacity, pre-injury functional level and medical co-morbidities were ranked as the most important factors influencing the decision to intervene. Qualitative analysis suggested that pre-injury function was the main theme within these factors.
Our findings provide useful advice about which parameters should be measured and radiographic thresholds for intervention. These thresholds may then be modified depending on important patient factors. This information can help guide clinicians with management decisions and reduce variation.

The effect of social deprivation on fragility fracture of the distal radius

List of authors:
nick johnson*, joseph dias
1 University hospitals of leicester (leicester)

Objectives / Interrogation: Social deprivation has been shown to be associated with many adult fractures including distal radius fractures but the mechanisms for this are unclear. The aim of this study was to identify if deprivation was associated with falls risk, mechanism of injury or osteoporosis in patients with a fragility fracture of the distal radius.

Methods: Details of all patients aged 50 years and over presenting with a radiographically confirmed fracture of the distal radius over a one year period, were prospectively recorded. Patients were sent a questionnaire pack including questions regarding place and mechanism of injury, comorbidity assessment, falls risk assessment tool and FRAX assessment of bone health and fracture risk.

Results and Conclusions: 333 out of 521 eligible patients completed the questionnaire (279 female; 54 male, response rate=64%). There was no difference between characteristics of responders and non-responders (p=0.58). DRF rate was higher in deprived quintiles (p=0.040). Less falls occurred in the home in deprived patients (Q1/2: 35%; Q3-5: 48%, p=0.037) with more falls outdoors (Q1/2: 39%; Q3-5: 24%, p=0.001). There was no difference in height at which falls took place with most from standing height (Q1/2: 81%; Q3-5: 86%, p=0.336). Linear regression analysis found no relationship between deprivation rank and FRAX scores (major fracture risk: p=0.274, hip fracture risk: p=0.283) but demonstrated a significant relationship between deprivation and increased number of falls risk factors (p=0.002). Mean number of falls risk factors was higher in the two most deprived quintiles (Q1/2: 3.62: Q3-5: 2.79, p=0.028).

We have identified increased falls risk as an important reason for DRF in deprived patients. Knowing which patients are at highest risk allows interventions to be efficiently targeted. We would recommend resources should be targeted towards patients from deprived areas and focused on specific falls prevention strategies.

Development of three dimensional digital preoperative planning software for the distal humerus fractures

List of authors:
Shin Teramura*, Yuichi Yoshii1, Tomoo Ishii1, Kenichi Akita2
1 Tokyo Medical University Ibaraki Medical Center (Inashiki, Ibaraki)
2 LEXI Co., Ltd. (Toshima-ku, Tokyo)

Objectives / Interrogation: To reproduce anatomical reduction and appropriate implant placement during the osteosynthesis, we developed a 3D preoperative planning software for the elbow fractures. The objective of this study was to assess the usability and reproducibility of the 3D preoperative planning software for the osteosynthesis of distal humerus fractures.

Methods: 1. Trial application phase
From our database of previous elbow fracture patients, we investigated how much slice width of CT scan is appropriate for a 3D preoperative planning. We created 3D images of the fracture site from the different slice widths of CT data. Fracture reduction, implant choice and placement were simulated with those images. After the simulation, we compared 3D images created from postoperative CT images with those from the simulation.

2. Clinical application phase
3D preoperative planning were applied for four distal humerus fracture cases (mean age: 65.8, one male and three females). The preoperative planning were performed in order to determine the reduction, placement and choices of implants. Surgeons performed the reduction and the placement of implants while comparing images between the preoperative plan and fluoroscopy during surgery. After the operation, we carried out CT scans and verified accuracy of the reduction and implants choices and placements. The reductions were evaluated with an angle between the diaphysis axis and a line connecting the medial epicondyle with the lateral epicondyle (ΔC) and an angle between the diaphysis axis and the articular surface (ΔJ) in the coronal plane and distance between the anterior diaphysis and the anterior articular surface in the sagittal plane (ΔD) for the 3D images of distal humerus. The reproducibility was evaluated by the differences of the parameters between pre- and post-operative images.

Results and Conclusions: In the trial phase, it was found imaging slices less than 2mm was favorable to simulate reduction for the fragments. In the clinical application phase, the fracture types of the patients were A1, A3, C1 and C2 according to the AO classification. We applied double plates in three cases and a single plate in one case. The planned sizes of plates were used for all cases. In the results of reproducibility, differences of the measurements ΔC, ΔJ and ΔD were 2.0°±1.7°, 0.7°±2.4° and 1.9mm±3.7mm, respectively. 3D preoperative planning allows visualization of the reduction process and implant placement. It may be helpful for acquiring practical images of osteosynthesis.

Role of an Adjustable Hinged Elbow Orthosis in the Rehabilitation of a Lateral Collateral Ligament Deficient Elbow: An In Vitro Biomechanical Study

List of authors:
Armin Badre*1, Sara Banayan1, David Axford1, Jim Johnson1, Graham King1
1 Roth-McFarlane Hand & Upper Limb Centre, St. Joseph's Health Care (London)

Objectives / Interrogation: Hinged elbow orthoses (HEO) are often used to allow protected motion of the unstable elbow. However, previous biomechanical studies have not shown HEO to improve the stability of an LCL deficient elbow. This lack of effectiveness may be due to the straight hinge of current HEO designs which do not account for the native carrying angle of the elbow.

The aim of this study was to determine the effectiveness of a custom-designed HEO with an adjustable carrying angle on stabilizing the LCL deficient elbow.

Methods: Eight cadaveric arms were mounted in an elbow motion simulator with the arm in the varus position. An LCL injured (LCLI) model was created by sectioning of the common extensor origin, and the LCL. The adjustable HEO was secured to the arm and its effect with 0°, 10°, and 20° (BR00, BR10, BR20) of valgus carrying angle was investigated. Varus-valgus angles and ulnohumeral rotations were recorded using an electromagnetic tracking system during simulated active elbow flexion with the forearm pronated and supinated.

Results and Conclusions: There were significant differences in varus and ER angulation between different elbow states with the forearm both pronated and supinated (P=.000 for all). The LCLI state with or without the brace resulted in significant increases in varus and ER of the ulnohumeral articulation compared to the intact (P< 0.05). The difference between each of the LCLI, BR00, BR10, BR20 states and the intact ranged from 3.8-6.2° for varus and 3.6-5.2° for ER. However, there were no significant differences in varus or ER of the ulnohumeral articulation between any of the brace angles and the LCLI state (P >0.05). The difference between each of the brace angles and the LCLI state ranged from 1.1-2.4° for varus and 0.5-1.6° for ER.

Conclusion
Although there was a trend toward decreasing varus and ER of the ulnohumeral articulation with the application of this adjustable HEO, none of the brace angles examined was able to restore the stability of the LCL deficient elbow. This lack of stabilizing effect may be due to the weight of the brace exerting unintentional varus and torsional forces on the unstable elbow. Previous investigations have shown that the varus arm position is highly unstable in the LCL deficient elbow. Our results demonstrate that the application of an HEO with an adjustable carrying angle does not stabilize the LCL deficient elbow in this unstable position. Varus arm positioning should be avoided in the rehabilitation programs of an LCL deficient elbow.

Paediatric Carpal Injuries: Injury Pattern, Radiological Findings and Patient Care Pathway

List of authors: Cynthia de Courcey*, Sarbjit Kaur, Sami Al-Ani, Andrea Jester, Kerstin Oestreich
1 Birmingham Women's and Children's NHS Foundation Trust (Birmingham)

Objectives / Interrogation: The aim of this study is to characterize the injury pattern, review correlation between plain radiological and MRI findings, and the patient care pathway experienced by under 16's presenting with closed trauma of the wrist.

Methods: A prospective audit of consecutive cases of blunt wrist trauma referred to our tertiary hand and upper limb service was conducted between August 2017 and August 2018.

Results and Conclusions: 72 cases were included. The mean age is 12 years (range 7-16). 72% of patients presented within 48 hours of injury to the emergency department (ED), and 68% were referred to our hand service on the same day. 44% of cases were secondary to fall on an outstretched hand. Management from ED consisted of casting (43%), splinting (35%), volar slab (10%), sling elevation (1%) and none (11%).

The mean period between referral from ED to patients' initial review at the hand service was 4.5 days. 78% of patients described pain, 33% swelling and 22% reduced range of motion of the affected wrist. Plain film radiology revealed fractures in 17% of cases, no fracture in 54% and suspected fractures in 29%.

At the second review, 40% of patients described pain, 4% swelling and 7% reduced range of motion. On MRI, 18% of cases showed no injury, 6% other pathologies and 18% were awaiting scans. All fractures identified on plain film was confirmed on MRI, with an additional 31 carpal fractures seen (10 with suspicious features & 21 with no features of fracture on X-ray). The most common carpal fracture was scaphoid fractures. Other injuries identified on MRI included other non-scaphoid carpal fractures (5 trapezium, 4 each of capitate and lunate, 3 hamate, 2 triquetrum, 1 each of pisiform and trapezoid), metacarpal bases and distal radius fractures, TFCC injury and ganglion.

Patients under the age of 10 were the minority, consisting of 5 cases (7%). All were female, aged 7-9, and underwent MRI. Imaging revealed 2 scaphoid fractures, 1 triquetral fracture and no injury in 2 cases.

47 patients completed treatment, with a mean of 3.4 clinical visits (range 1-7), and mean 5.8 weeks of follow-up (range 1-14). 1 case required arthroscopy.

Paediatric carpal injuries are a relatively uncommon entity, and early detailed imaging in symptomatic wrists that fail to respond to immobilisation may allow earlier diagnosis and timely instigation of treatment. Refinement of the local carpal injury management algorithm based on the results of the prospective audit will be discussed.

Treating women with De Quervain tenosynovitis in puerperium: is the corticoid infiltration effective?

List of authors:
LUIZ VILELA*, Henrique Chamon¹, Bruno Vasconcelos¹, Rafael Lopes¹
¹ HOSPITAL MARCIO CUNHA (IPATINGA)

Objectives / Interrogation: To evaluate if in women in puerperium the infiltration for De Quervain tenosynovitis is effective after another conservative treatments failed.

Methods: This is a prospective study performed in the period of march of 2018 and june of 2018, when 11 women and 13 wrists all of them in puerperium attended a hand surgery office.

10 were submitted a infiltration (1 refused) with betametasone and lidocaine for tenosynovitis De Quervain, 8 were in lactation period.

The average time of symptoms was 7 months (2 months to 2 years)
The average of follow up was 4.8 months (3 to 6 months)

7 women and 9 wrists were evaluated for this study, 3 women were not able to attend the proposal.

In 2 women (3 wrists) two infiltrations were performed, in 5, (6 wrists) one was done
6 right wrists, 3 left
5 patients, 6 wrists were not in lactation period anymore.

All the patients were treated previously with physiotherapy, anti inflammatory drugs and splints without success.

We collected data based on Quick Dash score before and after treatment, which was used for the results

Results and Conclusions: The Quick Dash score pre treatment was 59.5 in average (47.7 to 72.7)
After infiltration the score was reduced to 17.38 (0 to 86.3)

In only 1 patient (1 wrist) the Dash score had increased (the paciente was with symptoms for 2 years and was submitted to two infiltrations)

About the 5 patients (6 wrists) that were not in lactation period a, the Quick Dash score reduced considerably in 4 of them (4 wrists) - 0 to 4.5 points.

We conclude that infiltration with betametasone in patients in puerpery period leads a good result, and this consideration is special for the ones out of lactation period, when the literature shows a resolution of symptoms

The weaknesses of this study was the little time of follow up and few number of patients

We think that for the improvement obtained, and the simple and low cost procedure, this should be considered in a puerperal women refractory to other treatments, specially in non lactation period.

Asymmetric 6-Strand Flexor Tendon Repair - Biomechanical Analysis using Barbed Suture

List of authors:
Jasmin Lee*, Yoke Rung Wong
1 Singapore General Hospital (Singapore)

Objectives / Interrogation: This study investigates the biomechanical performance of the Asymmetric flexor tendon repair technique using barbed suture. The Asymmetric repair technique using monofilament nylon suture was previously reported to have a higher tensile strength than the modified Lim-Tsai repair technique, but its repair stiffness and load to gap force were significantly lower. There is hence an unmet need to improve this technique and the substitution of nylon suture with barbed sutures may be the solution.

Methods: Two groups consisting of 10 porcine tendons each were repaired with the six-strand Asymmetric repair technique using V-Loc® 3-0 and Supramid® 4-0 respectively. The repairs were subjected to a mechanical tester for static testing. The ultimate tensile strength, load to 2mm gap force, repair stiffness, time taken to complete a repair and failure mechanism of the repairs were recorded and analyzed.

Results and Conclusions: All the repairs using V-Loc® 3-0 sutures had significantly higher median values of ultimate tensile strength (64.1N; 56.9N), load to 2mm gap force (39.2N; 19.7N), repair stiffness (6.4 N/mm; 4.7 N/mm) and time taken to complete a repair (9.4mins; 7.7mins). All the repairs using V-Loc® sutures failed by suture breakage while 80% of repairs using Supramid® sutures failed by suture pullout. The use of the barbed sutures in the Asymmetric repair technique, whilst more time consuming, has shown promising improvement to its biomechanical performance (i.e. better ultimate tensile strength, stiffness and resistance to gap formation).

Trapezio-trapezoid (TT) hypermobility may increase range of thumb movement after trapezio-metacarpal (TMC) arthrodesis

List of authors:
Shohei Omokawa*, Junya Højyo
1 Nara Medical University, Department of Hand Surgery (Kashihara)
2 Nara Medical University, Department of Orthopedic Surgery (Kashihara)

Objectives / Interrogation: We conducted kinematic analysis of the thumb using fresh cadaveric extremities to investigate the range of thumb circumduction after TMC arthrodesis with/without associated peri-trapezial resection procedure.

Methods: Eight upper arms were separated at the distal forearm and MCP joint. The hand and forearm other than the thumb ray were fixed to the laboratory table. We attached 3-D electromagnetic tracking sensors to the base and head of the 1st metacarpus. A 50-g load was applied at a point 20 cm distal from the TMC joint to generate the thumb circumduction. We then measured the magnitude of angular and rotational displacement of the 1st metacarpus during the movement. Data were collected in normal thumb (stage0), thumb with simulated TMC fusion (stage1), that with subsequent resection of the TT joint (resection width in 2mm, stage2), and with further resection between the 2nd metacarpal base and trapezium (stage3). The 1-2 intermetacarpal and scapho-trapezial ligaments were left intact during the experiment.

Results and Conclusions: The average range of angular movement of the normal thumb (stage0) demonstrated 58° and 66°, respectively, in radial and palmer abduction-adduction directions. After TMC arthrodesis (stage1), these angular movements showed significant reduction to 17° and 13°, respectively. Rotational movement of the normal thumb (42° and 34°) reduced significantly after the arthrodesis (8° and 5°). Following sequential T-T resection (stage2), the angular and rotational displacement increased significantly (37° and 25°, 22° and 13°, respectively) compared to the thumb with TMC fusion (stage1). These movements further increased in stage3 (49° and 39°, 34° and 25°, respectively), and demonstrated 71% and 78% of normal thumb motion.

TMC arthrodesis decreased the range of thumb circumduction; 24% (angulation) and 17% (rotation) of normal thumb motion. Hypermobility of TT and trapezio-2nd metacarpal joint contributed to remarkable increase of thumb movement without significant instability.

Objectives / Interrogation: The purpose of this investigation was to compare the inter-rater reliability of the Wassel-Flatt (WF), Rotterdam, and Chung classification systems in patients enrolled in a prospective, multicenter cohort study. Our hypothesis is that the WF, Rotterdam and Chung classifications would have similar inter-observer reliability for classification of 150 radial polydactyly cases.

Methods: Five pediatric hand orthopedic surgeons, one orthopedic resident, and one medical student independently reviewed clinical photographs and radiographs of 150 radial polydactyly cases from the CoULD (Congenital Upper Limb Database) registry. After completion of a training set, each rater classified each case according to WF, Rotterdam, and Chung classifications. The intraclass correlation coefficient (ICC) was calculated using two-way random measures with perfect agreement.

Results and Conclusions: To demonstrate that a full spectrum of cases was available, Table 1 exhibits the range of classifications as graded by the 7 raters:

Distribution of Radial Polydactyly According to the Devised Classification System by Rater

The ICC for inter-rater reliability was 0.93 for the WF classification, 0.98 for Rotterdam types I-VIII, and 0.88 for the Chung classification. On average, the raters felt that 59% of the thumbs were accurately captured in the WF, 90% of thumbs in the Rotterdam, and 48% of thumbs in the Chung classification systems.

While the Chung classification system provides the simplest description of thumb polydactyly (4 types) and was designed to better inform surgical treatment, it had the lowest inter-observer reliability and was considered to capture the clinical presentation in the smallest percentage of cases. The Wassel-Flatt classification provides more detail (8 types), and was intermediate in its inter-observer reliability and accuracy in capturing the clinical presentation. Although the Rotterdam classification is most complex, providing the most level of detail (8 types, with 5 subtypes for each, and 3 location descriptors for each), it had the highest inter-observer reliability when considering only type (not sub-types) and was considered to accurately describe the greatest proportion of cases.

The medial femoral condyle free flap: An excellent option for difficult cases

List of authors:
Jorge Quintero*, Rodrigo Moreno
Kleinert Kutz Institute (Louisville)

Objectives / Interrogation: The use of the medial femoral condyle free flap (MFCF) is a versatile option for the treatment of upper extremity nonunions and reconstructive procedures associated with bone loss or osteonecrosis. The benefit of this type of flap is the viability of the bone which favors primary ossification and increases bone density. Vascularized free bone flaps are especially useful for the treatment of recalcitrant nonunions, or non-unions that have failed three or more treatments to obtain consolidation.

Methods: Six patients were included in this report, 3 scaphoid fractures, two non-union and one avascular necrosis of the proximal pole, a recalcitrant non-union of the distal humerus, non-union of a wrist fusion secondary to distal radius excision resulting from Giant Cell Tumor and a thumb distal phalange reconstruction. Age range 37 years old (22-59), 2 females, 4 males, 3 right upper limbs and 3 left upper limbs, 3 right knee donor side and 3 left knee donor side, all patients underwent prior surgery before the MFCF, none of the patients were smokers, Diabetes was present in the patient with distal humerus fracture and the Giant Cell Tumor.

Results and Conclusions: In conclusion, the utility of the MFCF is immeasurably varied, achieving a 100% consolidation in all our cases. The MFCF graft can also be used to manage large bone defects, recalcitrant non-union, bone reconstructions, and management of scaphoid fractures. Achieving complete consolidation with good vascularity gives the patient the best chance of avoiding the development of debilitating osteoarthritis of the wrist joint. The consistent anatomy in the knee makes the MFCF graft easily identifiable, resulting in lower morbidity in the donor area. For these reasons, the authors consider the MFCF flap an excellent treatment option in the arsenal of methods treat non unions with low vascularity.

Factors of distal ulnar morphology to affect symptomatic ECU subluxation and clinical results of anatomic ECU tendon sheath reconstruction

List of authors:
Tae-Min Kim¹, Seoung-Joon Lee¹
¹Konkuk University School of Medicine (Seoul)

Objectives / Interrogation: To evaluate the association between distal ulnar morphology and symptomatic extensor carpi ulnaris (ECU) subluxation and assess the results of anatomic ECU tendon sheath reconstruction.

Methods: Twelve patients with symptomatic ECU subluxation were included. They all treated with anatomic reconstruction of ECU subsheath. Preoperative and final range of motion of wrist joint, grip strength, disabilities of the arm, shoulder, and Hand (DASH) score, and patient related wrist evaluation score (PRWE) were checked to assess the clinical results. At final follow-up, we used ultrasound sonography to check the ECU stability. Ulnar variance, ulnar styloid process length, and ECU groove depth were measured to evaluate the association between distal ulnar morphology and symptomatic ECU subluxation. 24 wrists without ECU subluxation and 24 wrists with asymptomatic ECU subluxation were used as controls.

Results and Conclusions: Results: There were statistically significant difference in ECU groove depth between control and asymptomatic ECU subluxation groups. However, ECU groove depth, ulnar styloid length and ulnar variance showed no significant correlation with symptomatic ECU subluxation. After anatomic reconstruction of ECU subsheath, there was a statistically significant improvement in DASH score, PRWE score, grip strength and there was no ECU subluxation at the final ultrasound sonography.

Conclusion: We think that anatomic reconstruction of ECU subsheath is an effective operative method to stabilize ECU and there is no association distal ulnar morphology and symptomatic ECU subluxation, although asymptomatic ECU subluxation has a trend toward shallower ECU groove.

Precision in the design and division of the thenar flap: Achieving a good result without donor complications or PIPJ contracture

List of authors:
Fang Li¹, Jacqueline Siau Woon Tan²
¹ SGH Hand Surgery Department (Singapore)
² Singapore General Hospital (Singapore)

Objectives / Interrogation: Background:
The thenar flap, first described by Gateman in 1926, has been extensively used in our unit and we have not observed the many criticisms. The thenar flap is usually indicated in volar oblique defects of the index and middle fingers. The main criticisms are donor site morbidity and joint stiffness. We have analyzed in detail the design and techniques required to achieve a good outcome.

Objectives:
By presenting our results and technique, we will dispel the following misconceptions:
The thenar flap results in unacceptable PIPJ stiffness
The donor site needs to be grafted
The thenar flap can only be used in the index and middle finger

Methods: 10 consecutive thenar flap cases were collected over a 6 month period. The demographics, medical history, outcomes, and complications were analyzed. Serial photographs were taken to document intra-operative technique, as well as the final outcome.

Results and Conclusions: Results:
All 10 flaps survived completely. All 10 cases regained full range of motion, and none developed a joint contracture. All donor sites were closed primarily without skin graft. All patients were satisfied with the functional outcome and aesthetic appearance.

The following technical refinements are key to achieving a good result:
The thenar flap must be precisely orientated with both the donor site and the final fingertip in mind.
The thenar flap is divided at 3 weeks, but after 2 weeks the flap and finger are exposed and mobilization is encouraged. This softens the flap, makes division easier and prevents joint contracture.
Secondary design depending on arborization during division is necessary to optimize coverage of residual defect.

Conclusions:
The thenar flap is a versatile flap that can be used to resurface a variety of fingertip amputations. The refinements above can prevent the complications commonly associated with the thenar flap.

thenar flap, aesthetic, precise design
New Arthroscopic Classification of TFCC injuries

List of authors:
Toshiyasu Nakamura¹, Koji Abe²
¹ International University of Health and Welfare, School of Medicine (Tokyo)
² International University of Health and Welfare, Clinical Research Center (Tokyo)

Objectives / Interrogation: Due to several reports of other types of TFCC injury that was not in Palmer's classification, such as the dorsal or coronal tear or due to recent development of DRUJ arthroscopy, we need new thorough classification of TFCC injury both includes RCJ and DRUJ sides. We tried to classify our case series of consecutive 213 TFCC lesions in a year period.

Methods: From July 2014 to September 2015 (1 year 2 months period), 213 wrists of 211 TFCC injury patients who underwent first-look arthroscopy both in the RCJ and DRUJ were included in this study. There were 123 males and 88 females, right wrist of 116, left of 93 and 2 bilateral. Average age of arthroscopy was 39.1 year (range: 13-72). All data were recorded on cards and DVDs.

Results and Conclusions: Results. On radiocarpal arthroscopy, 191 TFCC injuries were categorized as traumatic and 48 as degenerative. The central TFC lesion (Class 1) was noted in 21 wrists: among them, 13 slit tears, 2 flap, 1 double transverse slit, 2 oblique, 1 coronal, and 2 bucket handle tears were found. The radial tear (Class 2) was in 5 wrists including 4 intra-disc tear and 1 rim tear. Peripheral tear (Class 3) was found in 165 including 150 ulnar tears, 10 dorsal, 1 distal, 2 palmar and 2 horizontal tears. 48 wrists indicated degenerative tear (Class 4). On DRUJ arthroscopy, traumatic TFCC injuries were found in 19 wrists, subclassified into proximal slit and proximal fibrillation (Stage 1) in 4, partial RUL avulsion (Stage 2) in 1, relaxed RUL (Stage 3) in 3 and complete RUL avulsion (Stage 4) in 17. Isolated injury was found in 144 wrists (67%), double lesions were found in 65 wrists (30%), and triple injuries were found in 4 wrists. Conclusions. We classified TFCC lesion based upon RCJ (Class 1-4 as the site of injury) and DRUJ (Stage 1-4 as the degree of RUL tears) arthroscopic findings. This system works very well. One third of our series indicated combined double or triple lesion that included lesions onto the RCJ and DRUJ. To diagnose TFCC lesion thoroughly, both RCJ and DRUJ arthroscopy are necessary.

Keywords: triangular fibrocartilage complex injury, arthroscopy, classification
Partial excision of volar plate and dorsal capsulotomy in patients with post-traumatic ankylosis of finger joint in the hand

List of authors:
Min Ho Lee*, 1, Che Ho Lee1, Young Ju Chae2, Jiheung Kim1, Kee Jeong Bae3, Hyun Sik Gong2, Young Ho Lee1, Goo Hyun Baek1
1 Seoul National University Hospital (Seoul)
2 Seoul National University Bundang Hospital (Gyeonggi-do)
3 Seoul National University Boramae Medical Center (Seoul)

Objectives / Interrogation: Post-traumatic ankylosis of the finger joint is one of the complications after traumatic hand injury. If there is no improvement through conservative treatments, surgical treatments can be considered. Although several surgical techniques such as dorsal capsulotomy and release of the accessory collateral ligament have been suggested, the result was not satisfactory. The purposes of this study are to suggest new surgical technique to restore finger joint motion and to present the surgical outcome of this technique.

Methods: We retrospectively reviewed 14 patients, 7 males and 7 females, who were diagnosed as post-traumatic ankylosis of finger joint, underwent partial excision of volar plate and dorsal capsulotomy between January 2014 to June 2016 and followed up for more than one year. There were ten metacarpophalangeal (MCP) joints and four proximal interphalangeal (PIP) joints. The average interval between the initial injury and the surgery were 60 (range, 10 to 120) months.

Results and Conclusions: Of the ten MCP joints, the average range of motion was improved from 31 degrees to 92 degrees one year after surgery. Of the four PIP joints, the average range of motion was improved from 20 degrees to 77 degrees one year after surgery. There were no acute complications such as instability, infection, and wound dehiscence. All the patients were satisfied with the surgical outcomes.
Because this technique does not release both collateral ligaments, the joint stability can be maintained. We can also safely release volar plate and dorsal capsule through anterior and posterior dual approaches. Partial excision of volar plate and dorsal capsulotomy can be one of the good options in patients with post-traumatic ankylosis of finger joint.

ankylosis, volar plate excision, dorsal capsulotomy
Does enzymatic debridement allow us to perform conservative treatment on clinically deep hand burns? A retrospective review.

List of authors:
Danilo Antonio Rivas Nicolls*¹, Irene Gallardo Calero¹, Jordi Aguilera Saez¹, Jordi Serracanta Domenech¹, Pablo Gomez Morell¹, Ricard Palao Domenech¹, Joan Pere Barret Nerin¹
¹ Vall d'Hebron University Hospital (Barcelona)

Objectives / Interrogation: The hands are one of the main locations of burns. In deep second- and third-degree burns, the gold standard of treatment is surgical debridement and subsequent coverage, which can result in suboptimal esthetic and functional results. The aim of our study is to assess whether treatment by initial enzymatic debridement (NexoBrid®) of deep second-degree burns and third-degree burns prevents the need for surgery.

Methods: We carried out a retrospective study of 53 hands with deep burns treated in our center from May 2015 to December 2016. Two experts evaluated the initial photographs of the burns and classified them as surgical or nonsurgical (interobserver kappa statistic 0.83). These assessments were compared with the actual need for surgery for each hand.

Results and Conclusions: Sixteen of the 32 (50%) hands that the experts considered surgical spontaneously epithelialized. Four of the 17 hands (23.5%) that were not considered surgical required a split-thickness skin graft for healing. Enzymatic debridement helps to preserve viable tissue, which reduces the number and extension of surgical interventions, thus favoring better results.

deep burns, hand, enzymatic debridement
New simple technique for syndactyly separation

List of authors:
Yrjana Nietosvaara*¹, Petra Grahn¹, Antti Sommarhem¹
¹ New Children’s Hospital, Helsinki Finland (Helsinki)

Objectives / Interrogation: Web reconstruction in finger syndactyly using a hexagonal dorsal skin flap and a straight midline incision gives a good cosmetic and functional result with little need for skin grafts.

Methods: We developed an easy technique to be used in simple complete (SC), simple incomplete (SI) and complex (C) syndactyly separation without the need of skin graft.

In C and SC nailfold and fingertip reconstruction is done using a technique described by Buck-Gramcko¹¹. Tourniquet is used. Rigorous defatting is done, preserving the digital neurovascular bundles. Wounds are closed with absorbable sutures. Soft dressing is applied for 2 weeks. Patients are discharged the same day.

Skin incision and site for skin graft

Follow-up (FU) was scheduled at 2 weeks, 6 months and 1 year. Scar treatment with silicone sheets/gloves was started at 3 weeks by our occupational therapist.

Parents’ satisfaction of functional and cosmetic outcome was assessed at last FU using a VAS scale (0-100).

Results and Conclusions: 20 patients (16 male, 9 left, 5 bilateral) underwent 30 web reconstructions (16 SI, 8SC, 6C) using our technique at median 16 (11-43) months of age. The level of the web was at PIP in 11 and at DIP in 5 of the 16 children with SI. Skin graft taken from outside the incision site was required in 1 patient (C). None of the patients were lost to follow-up, mean 11 (4-43) months. Complications (excessive scar formation, infection, circulatory or sensory problem) occurred in 1 SC patient who developed a post-operative infection, and web creep at 6 months. Mean functional and cosmetic VAS scores were 95 (63-100) and 90 (45-100).
Simple complete and simple incomplete syndactyly. Pre- and post-operative images 12 months from second surgery.

This new technique for simple and complex syndactyly yields a good cosmetic and functional result with little need for skin graft.

Dorsal bone-ligament-bone reconstruction of chronic, isolated lunotriquetral instability Technique and clinical results

List of authors: Tom Adler*, Janina Riederer, Esther Vögelin
1 Orthoklinik Dornach AG (Dornach)
2 Universitätsklinik für Plastische- und Handchirurgie, INSELSPITAL, Universitätsspital Bern (Bern)

Objectives / Interrogation: Isolated lunotriquetral (LT) ligament injuries are not common wrist injuries and, hence, surgical procedures range from conservative treatment over arthroscopic debridement to soft tissue reconstructions and even arthrodesis. The purpose of our case series is to present one surgical option with a bone-ligament-bone graft treating isolated chronic LT ligament instabilities.

Methods: Despite of knowledge of the more stable palmar ligament we stabilized the arthroscopically proven instability with a dorsally implanted bone-ligament-bone (BLB) graft harvested from the capitohamatal joint. The graft was fixed with one screw in each bone block and the LT joint was transfixed using a headless compression screw (HBS). 5 patients were treated at our institution between September 2009 and January 2017. All patients were assessed with range of motion (ROM), grip strength, radiographic stress views, the Michigan Hand Questionnaire (MHQ) and DASH score pre- and postoperatively.

Results and Conclusions: All patients (4 men, 29.3 (19-40) years; 1 woman, 35 years) suffered from an isolated chronic LT instability and were followed up between 6 months and 6 years after surgery. The ROM remained minimally decreased to preoperative. The grip strength improved (34kp to 46kp). The MHQ at final follow up ranged between 66 and 100%. On average the DASH score improved from 70.3 to 33.3. Subjective pain varied between 0 and 6 using NRS depending on stress load.

3 of 5 HBS screws were removed. One patient showed a breakage of the HBS screw at last follow up with a dynamic instability of 1mm opening with radial abduction compared to the other side. The stress views of the other patients did not indicate an instability. No osteoarthritis could be seen in the final radiographs in all patients.

All patients returned to and since have kept their previous activity levels and occupation until last follow up.

All patients showed a significant improvement in DASH score and grip strength. Previous activity levels were achieved without exception, even though one breakage of the HBS screw was observed.

The dorsal BLB reconstruction can be a reasonable surgical option in patients with isolated chronic LT instabilities, preserving wrist kinematics better than an arthrodesis. However, it can be discussed whether the more complicated procedure is superior to a conventional fusion.

Keywords: wrist, lunotriquetral, instability, reconstruction
Chronic, isolated lunotriquetral instability Biomechanical testing of the Bernese surgical treatment and review of the literature

List of authors:
Janina Riederer*, Esther Vögelin¹, Luzian Haug¹, Tom Adler²
¹Universitätsklinik für Plastische- und Handchirurgie, INSELSPITAL, Universitätsspital Bern (Bern)
²Orthoklinik Dornach AG (Dornach)

Objectives / Interrogation: Chronic lunotriquetral (LT) instability is rare and, hence, a variety of different treatment options exist. Up to date best results for chronic LT instability have been shown with soft tissue reconstruction techniques, which are technically demanding or are non-anatomic. Less demanding options include the arthrodesis with a reported high complication rate.

A technique combining the advantages of both existing techniques would be preferable. Using the dorsal bone-ligament-bone (BLB) reconstruction, we tested a less demanding technique that provides stability but also is thought to save the kinematics of the carpal bones.

We present the current literature and the biomechanical test results of our technique with a dorsally implanted bone-ligament-bone (BLB) graft.

Methods: A literature review using pubmed was performed. The anatomy, epidemiology, biomechanics and published treatment options of LT instability are summarized.

For biomechanical testing, 10 cadaveric forearms were evaluated with computertomography (CT) in different loaded positions. LT ligaments were sequentially sectioned. BLB reconstruction were performed harvesting the graft from the capitohamatal joint. Initially, the LT was also transfixed using a compression screw (CCS) simulating arthrodesis. At last the CCS screw was removed and the reconstruction alone was tested. CT’s were performed at the beginning and after each single step. A 3-dimensional software calculated the motion between the carpal bones in comparison to the normal wrist after each of the steps.

Results and Conclusions:
Sectioning of the dorsal part of LT had little effect on kinematics, however sectioning of the palmar part in addition, resulted in an increased mobility in the LT joint.

Arthrodesis showed to increase significantly the motion in the adjacent joints up to fourfold difference.

Restoration of the physiological kinematics could partially be achieved after removing the CCS screw testing the reconstruction alone. Compared to totally cut LT ligament the reconstruction showed less motion without significance, but was not as stable as the uncut ligament.

We present and compare the used BLB graft reconstruction to other techniques. Biomechanical testing with BLB grafts is satisfactory. Compared to arthrodesis, more physiologic carpal kinematics resulting in less straining of the adjacent joints was measured.

2 Department of Clinical and Experimental Medicine, Department of Hand Surgery, Plastic Surgery and Burns (Linköping)
3 HAKIR, Department of Hand Surgery, South General Hospital, Department of Clinical Science and Education, Södersjukhuset (Stockholm)
4 National Diabetes Register, Centre of Registers (Gothenburg)

Objectives / Interrogation: To evaluate if diabetes affects outcome after surgical treatment for cubital tunnel syndrome.

Methods: Data from the National Quality Register for hand surgery procedures (HAKIR) were combined with data from the Swedish National Diabetes Register (NDR) to evaluate patients who had surgery for cubital tunnel syndrome 2010 - 2016. Outcome was assessed by QuickDASH (Disabilities of Arm, Shoulder and Hand) preoperatively, and at three and 12 months postoperatively. A simple linear regression was used to predict QuickDASH scores at 12 months based on the following variables: diabetes, gender, type of surgery (simple decompression or transposition) and age at time of surgery. Mann-Whitney U-test with post hoc Bonferroni correction and Chi2 were used to compare groups. Each treated hand was analysed as a separate statistical entity.

Results and Conclusions: During the study period, 1394 cases were surgically treated for cubital tunnel syndrome. We found no significant differences in QuickDASH scores between cases with or without diabetes (Table 1), neither pre-operatively nor postoperatively, irrespective of type of diabetes. No differences in QuickDASH scores were observed between those with and without diabetic retinopathy.

Patients' QuickDASH scores at 12 months increased by 9 (95% CI 3-14; p=0.002) points if the patient was a female and by 11 points (95% CI 2-19; p=0.019) if the surgical method was a transposition. Patients with diabetes had a smaller improvement in QuickDASH scores than patients without diabetes (Table 1).

Patients with diabetes benefit from surgical treatment for cubital tunnel syndrome almost to the same extent as patients without diabetes, regardless of type 1 or type 2 diabetes. Presence of retinopathy did not influence outcome among cases with diabetes. A higher risk for residual problems, as defined by higher postoperative QuickDASH scores, was observed in females and after ulnar nerve transpositions.

How trapeziometacarpal arthritis and scaphotrapeziotrapezoidal arthritis affect the postoperative recovery of carpal tunnel syndrome.

List of authors:
Kaori Sugiura*1, Takao Omura1, Michihito Miyagi2, Tomokazu Sawada3, Ryo Okabayashi1, Takashi Ogawa1, Hiroaki Ogihara4, Yukihiro Matsuyama1

1Hamamatsu University School of Medicine (Hamamatsu)
2Shizuoka Cancer Center (Nagaiizumi)
3Shizuoka City, Shizuoka Hospital (Shizuoka)
4Hamamatsu Red Cross Hospital (Hamamatsu)

Objectives / Interrogation: Carpal Tunnel Syndrome (CTS) is the most common peripheral compression neuropathy primarily affecting postmenopausal women. Trapeziometacarpal (TMC) and scaphotrapeziotrapezoidal (STT) arthritis is also commonly encountered in postmenopausal women. The purpose of this study is to examine the prevalence of TMC and STT arthritis in patients with CTS, and to analyze how the arthritis affect the postoperative recovery of CTS.

Methods: 123 hands who underwent carpal tunnel release between 2002 and 2017 were studied. The patients consisted of 34 men and 89 women, with a mean age of 65.8 (33–92) years old. The mean follow up period was 11.7 (3–24) months. The severity of the TMC arthritis was determined using Eaton's classification. The patients were divided into four groups; joints with TMC stage 1 or less without STT arthritis were classified as group N (63 hands), joints with TMC stage 2 and 3 were classified as group TMC (39 hands), joints with TMC stage 4 were classified as group TMCSTT (12 hands) and joints with just STT arthritis were classified as group STT (9 hands). For the evaluation of CTS, pre and postoperative manual muscle testing (MMT) of abductor pollicis brevis (APB) and distal motor latency (DML) detected on the APB muscle was examined. These results were cross compared between group N and the rest of the groups.

Results and Conclusions: The electrophysiological study showed that the mean preoperative DML had no statistical difference among the groups. The mean postoperative DML was 4.53ms for group N, 4.97ms for group TMC, 4.51ms for group TMCSTT and 4.83ms for group STT, showing statistical significance between group TMC and group N. However, when we performed one-way covariance analysis to exclude the influence of age, age adjusted mean DML was 4.66ms for N group and 4.85ms for group TMC, which showed no statistical difference.

The muscle strength recovery of APB revealed that, the number of the cases with MMT 3 or less showed no statistical difference preoperatively. However, postoperative evaluation showed that while only 14 hands (22%) in group N and 1 hand (11%) in group STT showed MMT 3 or less, 16 hands (41%) in group TMC and 5 hands (42%) in group TMCSTT failed to achieve over MMT 3, showing statistical significance between group TMC, TMCSTT and group N.

We conclude that the prevalence of TMC and STT arthritis was 41.5% and 7.3% in patients with CTS. The presence of TMC arthritis in patients with CTS negatively affects the postoperative recovery of the APB muscle after carpal tunnel release.

Keywords:
CTS, TMC arthritis
Severity diagnosis of carpal tunnel syndrome using sagittal view of MRI

List of authors:
Mao Yamada*, Masatoshi Amako1, Ryoji Fujimaki1, Masashi Isaji1, Shinya Kondo3, Hiroshi Arino2, Kazuhiro Chiba1
1 National Difference Medical College (Tokorozawa-city, Saitama)
2 Tokyo Medical Center (meguro-ku, Tokyo)

Objectives / Interrogation: MRI has been gradually spreading for diagnosis of carpal tunnel syndrome. Most reports have been used axial images for the diagnosis, however, we focused on sagittal view of T2 fat suppression because pathology of the entrapment point can be well-described. The purpose of this study is to clarify the usefulness of sagittal view of MRI on diagnosis of carpal tunnel syndrome, and to compare with clinical or electrophysiological severity.

Methods: Sixty-three hands of 55 patients with carpal tunnel syndrome (19 males, 44 females, average age: 62.3 years) were included. All patients' wrist underwent simple MRI, and pseudo-neuroma was high signal on the sagittal image of T2 fat suppression. The maximum anteroposterior diameter (AP-D) and the distance between the proximal end of the high signal area and the wrist joint (LT-D) were measured. We also evaluated clinical severity according to Hamada's classification (Stage I: positive sensory disturbance without thenar muscle atrophy; Stage II: with thenar muscle atrophy; Stage III: impossible for thumb opponents). Motor nerve conduction study was performed and distal latency (DL) was measured, and more than 6.5 msec. was considered as severe group. We compared the AP-D and the LT-D and Hamada's classification and DL.

Results and Conclusions: There was significant positive correlation coefficient between the LT-D and DL (r=0.52, p<0.05), but not significance between the AP-D and DL. There was no significant correlation between the AP-D or LT-D and Hamada's classification. The cut-off value of the AP-D obtained using the ROC curve was 2.9 mm, which was significantly associated with Hamada stage II and III (p = 0.01). Similarly, the LT-D cutoff value was 8.9 mm, which was significantly related to severe group of DL (p = 0.04). Although high reliability of diagnosis for patients with carpal tunnel syndrome has been reported using axial view of MRI, we focused on sagittal view of MRI because constriction and/or pseudo-neuroma can be described. This study revealed that patients with more than 2.9 mm of AP-D and more than 8.9mm of LT-D could be diagnosed as severe group on clinical and electro-physiological studies. We believe carpal tunnel syndrome should be diagnosed using MRI without electro-physiological studies.

Reconstruction of multiple adjacent large finger pulps with the modified sensate free proximal ulnar artery perforator flap

List of authors:
Jiadong Pan*, Xin Wang¹
¹Ningbo 6th hospital (Ningbo)

Objectives / Interrogation: To study the clinical effect of the reconstruction of multiple adjacent large finger pulps with the modified sensate free proximal ulnar artery perforator flap (PUAP).

Methods: From February 2013 to May 2016, 29 fingers in 13 patients with adjacent large finger pulp defects crossing the DIP joint were reconstructed by the modified sensate free PUAP. In order to reconstruct the sensation of two pulps in each patient (26 pulps), both of the proximal and distal ends of the cutaneous nerve in PUAP were dissected and anastomosed. There were 8 fingers in 4 patients with the index and middle finger pulp defects, 12 fingers in 6 patients with the middle and ring finger defects, and 9 fingers in 3 patients with the index, middle and ring finger defects. The flap size was from 5 cm × 3.5 cm to 7.5 cm × 4 cm, and the perforator artery was anastomosed with the digital artery in 7 cases and with the joint branch of digital artery in 6 cases. The artificial syndactyly of two or three digits were divided in 7 and 12 weeks accordingly after the flap transfer.

Results and Conclusions: 12 flaps survived uneventfully except the venous congestion was found in one flap which was salvaged successfully by acupuncture bleeding. Also, no congestion or ischemia occurred right after releasing the artificial syndactyly. The time of follow up was from 11 - 32 months with the average of 18 months after the last surgery. The static two point discrimination of the two groups was (7.08 ± 1.14) mm and (8.23 ± 2.12) mm, in which the pulp sensation was reconstructed respectively by the anastomosis between the digital nerve and the proximal or distal end of the cutaneous nerve in PUAP. These 26 sensate pulp flaps were also assessed by the Semmes-Weinstein monofilament test with the result of diminished light touch in 18 pulps and diminished protective touch in 8 pulps. The total active motion in all 29 fingers was (249±5.8) °. No patients but 2 suffered slight cold intolerance in the 2 insensate pulps. Conclusion The modified sensate free proximal ulnar artery perforator flap is a practical alternative for the reconstruction of multiple large adjacent pulps with satisfactory functional and aesthetic outcomes. Through anastomosing the proximal and distal end of the cutaneous nerve through PUAP with the unilateral digital nerve of two adjacent fingers, reliable sensation of the both pulps could be reconstructed.

Frozen thumb replantation: cases report

List of authors:
Liwen Hao*1, Chao Chen1, Zengtao Wang1
1 Hand and Foot Surgical Center, Shandong Provincial Hospital, Shandong University (jinan)

Objectives / Interrogation: There is few report on replantation of a finger which has already been frozen. We report a case of successful replantation and functional recovery of a finger which was frozen before it was brought to us for replantation surgery.

Methods: A 59-year-old woman sustained a traumatic amputation of the right thumb. Her family members mistakenly put the thumb directly in ice (about -20° C), causing the thumb to freeze entirely. When she came to our hospital 5 hours after her injury, we saw that the severed thumb was frozen and was as hard as a stone. We put the thumb in the 5 ° C refrigerator freezer and the ice melt slowly. We replanted the thumb 2 hours later, after the frozen thumb was completely thawed and softened. We anastomosed two superficial dorsal digital veins, the proper radial digital artery of the thumb and the proper digital nerve of both sides.

Results and Conclusions: The thumb survived when the patient was followed up 6 weeks post operation, and the replanted thumb start to function.
Before this case, we replanted a 9-year-old girl's severed thumb. Her parent also mistakenly put the thumb directly in ice, which was also replanted successfully. We conclude based on the present case and our previous case that the frozen severed thumbs can survive after replantation.

Repair of a long finger defect with transfer of a great toe flap combined with second toe joint and iliac bone graft

List of authors:
Liwen Hao*, Chao Chen, Zengtao Wang
1 Hand and Foot Surgical Center, Shandong Provincial Hospital, Shandong University (jinan)

Objectives / Interrogation: We present the method of repairing 32 fingers with a great toe flap combined with the proximal interphalangeal (PIP) joint of the second toe and the iliac bone graft.

Methods: Between January 2010 and January 2018, 32 fingers with traumatic loss distal to the metacarpophalangeal (MP) joint were reconstructed with transfer of a great toe flap was combined with the proximal interphalangeal (PIP) joint of the second toe and the iliac bone was grafted. The second toe was grafted with the iliac bone. The free groin flap was used to repair the skin defect of the great toe.

Results and Conclusions: 32 cases of reconstructed finger and free groin flap survived completely. 1 finger was re-explored 8 days post operation owing to arterial embolism. We found the reconstructed fingers has sufficient length, but not good enough sensation and finger joint motion. However, because of the normal MP joint, these reconstructed fingers still can have basic function.
Transfer of a great toe flap combined with PIP joint of second toe and iliac bone graft can be used for reconstruction of finger loss with acceptable outcomes. However, the range of active motion of the reconstructed finger and lack of good recovery of sensation remain problems of this method.

reconstruction, second toe joint, iliac bone graft
Mechanics of a smith's fracture. -Caused by falling on the palm of the hand with wrist dorsal flexion-

List of authors:
Yusuke Matsuura*, Tomoyuki Rokkaku, Kazuki Kuniyoshi
1 Chiba university (Chiba)
2 Chiba municipal hospital (Chiba)
3 Nagareyama central hospital (Nagareyama)

Objectives / Interrogation: Smith’s fractures generally occur when falling on a flexed wrist; however, orthopedic trauma surgeons often encounter distal radius fractures with volar displacement in patients who have allegedly fallen on the palm of their hands. In our survey, 62% of patients were injured on the palm of the hand. However, it is not known the mechanism of Smith’s fractures. The aim of this study was to reveal the pathogenesis of Smith’s fracture

Methods: The research plans are performed through a step-by-step investigation. First, to predict the type of distal radius fracture with finite element model (FEM), we created a 3D FEM from CT data of the wrist and analysis fracture pattern. Second, to obtain experimental proof of Smith’s fracture occurring upon the application of an impact on the palmar side using fresh frozen cadaver. Finally, to predict stress distribution on the distal radius when Smith’s fracture occurs.

Results and Conclusions: As the angle between the long axis of the forearm and the ground decreases, the fracture line shifts to the volar side and Smith’s fracture was predicted by FME when its angle was small. In cadaver study, Smith-type fractures were occurred in seven of 10 wrists. In FEA study to predict stress distribution, compression force was applied on the lunate fossa and transmitted to the volar side of wrist. Tensile stress was generated at the dorsal side of the wrist. Therefore, the dorsal cortical bone broke by traction force, and a proximal fragment was dorsally displaced by rotation moment.

In conclusion, Smith’s fractures occur not only as a result of falling on the dorsum of the hand during volar flexion, but also as a result of falling on the palm of the hand during dorsal flexion.

Smith fracture, finite element model, cadaver
EPINEPHRINE-LOCAL ANESTHESIA - NO TOURNIQUET FOR CARPAL TUNNEL RELEASE - 66 CASES

List of authors:
Luciano Poitevin*, Solange Ferraguti
1 Buenos Aires University Hospital (Buenos Aires)

Objectives / Interrogation: A recent development in Hand Surgery is the use of epinephrine-local anesthesia without tourniquet. This method is allegedly safe and allows checking digital mobility. The goal of this study is to assess the intra and postoperative efficacy and comfort of this innovative anesthesia in 2 groups of patients with carpal tunnel release (CTR). Interrogations were: Incidence of arm pain, complications, amount of bleeding, patient satisfaction, length of hospital stay.

Methods: 66 CTR were performed through a mini-open approach, divided in 2 groups: a) n=27: 2% lidocaine + 0.5% bupivacaine + epinephrine 1:200.000 + light sedation by anesthesiologist; b) n=39: 2% lidocaine + epinephrine 1:200.000. Descriptive, comparative, retrospective, observational study through a phone inquiry on: 1) Pain at needle prick, injection or during surgery; 2) Additional anesthetic requirement; 3) Length of analgesia; 4) Dyspnea; 5) Brachialgia; 6) Nausea - Vomiting; 7) Hospitalization ; 8) Care by a family member; 9) Time to eating; 10) Post-op medication; 11) Sleep quality; 12) Dressing staining; 13) Future choice of a different anesthesia.

Results and Conclusions: There were 66 patients: 17 males and 49 females, with a mean age of 66.9 ys. (21-90), operated on between 2008 and 2018. All the cases were performed on an outpatient basis. Post-op hospital stay was 1-3 hours. Bleeding was minimal and did not hinder the surgery. All the patients were satisfied and would choose this procedure instead of general or regional anesthesia. They did not report intra or post-op side-effects, regardless of the group which they belonged to. They also did not show statistic difference regarding comfort. Anesthesia length was mostly more than 6 hours, especially with the addition of bupivacaine. CTR under local lidocaine + epinephrine, without tourniquet, has been safe and with no complications. Bleeding was minimal and visualization clear. Bupivacaine addition lengthens the analgesia time. Benefits for patients were: No intra nor immediate postoperative pain, neither local nor at the usual placement of the tourniquet; and less hospital stay. The inherent simplicity of the operating room should reduce costs. Though the participation of an anesthesiologist is adviceable, it is not mandatory, depending on local regulations. We do not recommend performing the surgery outside an operating room, nor to omit a pre-surgical evaluation.

Keywords: no tourniquet carpal tunnel release local epinephrine anesthesia

Long-term follow-up of scapho-lunate reconstruction with the DRAW technique

List of authors:
Norman Della Rosa*, Nicolo' Bertozzi1, Giulia Colzani1, Roberto Adani1
1 OU of Hand Surgery (Modena)

Objectives / Interrogation: Aim of this study was to evaluate the long-term effectiveness of the DRAW technique, which is a personal arthroscopic-assisted minimally invasive technique to reconstruct the scapholunate (SL) ligament using the trapezoid-to-second metacarpal joint bone-ligament-bone graft.

Methods: Between January 2009 and June 2014, thirty-one patients underwent the arthroscopic-assisted minimally invasive technique to reconstruct the SL ligament. All patients presented with chronic (>6 weeks) SL dissociation (19 Geissler type III, 12 Geissler type IV lesions) and no signs of arthrosic degeneration. Briefly, the surgical technique consisted in: SL rotatory subluxation reduction and stabilization with percutaneous K-wires, trapezoid-to-second metacarpal graft harvesting that was eventually advanced and secured within a tunnel created through the SL bones. A volar cast in neutral position of the wrist was applied and maintained in place for about 2 months when K-wires were removed and active range of motion exercises began. Follow-up visits were performed at 3, 6, 12 months, and every year afterwards. Radiographic, functional, and subjective outcome measurements were collected during the outpatient visits. Statistical analysis was performed with a significance threshold of P < 0.05.

Results and Conclusions: Mean follow-up was 71.55 months (range 50 to 115). All the grafts were in place with no SL synostosis or any carpal bone necrosis reported. No progression toward SLAC was observed in any patient. Only four patients had SL gap > 3 mm at the final follow-up however they returned to a pain-free wrist that allowed returning to their daily life activities. Patients were returned to work by the end of the 4th month and to contact sports and heavy jobs by the end of the 6th month. All the radiographic, functional and subjective outcomes analyzed not only significantly improved between the preoperative period and the 24-month follow-up but they also were maintained at the last follow-up or further improved (wrist mobility, grip strength). The DRAW technique ensures anatomical SL ligament reconstruction through a minimally invasive arthroscopic-assisted technique that does not require extensive capsulotomy, hence dramatically lowering the risk for reduced postoperative wrist mobility. The restored normal kinematics was also demonstrated by the long-term follow-up, where functional outcomes were even improved, while wrist degenerative changes were prevented.

Comparison between dorsal capsuloplasty techniques for chronic injuries of the scapho-lunate ligament: Viegas vs Berger.

List of authors:
Ettore Di Giovine*, Enrico Lancellotti1, Norman Della Rosa2, Roberto Adani3
1 Orthopaedic Institute (Modena)
2 Orthopaedic Institute (Reggio Emilia)
3 OU of Hand Surgery (Modena)

Objectives / Interrogation: All the many surgical techniques reported in medical literature for the reconstruction of the scapho-lunate ligament show benefits as well as complications, especially regarding stiffness. This study compares two dorsal capsuloplasty techniques widely used and validated for the treatment of chronic partial scapho-lunate ligament injuries: Berger vs Viegas techniques.

Methods: This is a retrospective study of 39 patients (25 females and 14 males) aged between 14 and 59 years (mean value 31.6yrs. ± 13.22) suffering from chronic partial scapho-lunate (SL) ligament injury corresponding to type III in Geissler's classification. They were divided into two groups of 20 subjects each; group A received Viegas' technique while group B received Berger's technique. All patients reported a history of direct blunt trauma to the wrist. Inclusion criteria were as follows: chronic partial tear of the ligament (Geissler type III); absence of joint chondropathy; follow-up up to 6 months. These were assessed both pre- and post-operatively by measuring function (PRWHE), grip strength (JAMAR), radio-lunate and scapho-lunate angles and by evaluating flexion-extension range of motion.

Results and Conclusions: The outcome revealed clinically and statistically significant differences in favor of Viegas' technique in terms of recovery of autonomy, recovery of grip strength, reduction in the SL angle and, finally, recovery of wrist flexion. The study showed that Viegas' capsuloplasty is more effective than Berger's in terms of grip strength recovery, recovery of disability, range of motion, especially flexion, and correction of the carpal angles, especially the SL. The Authors believe that this is due to the biomechanical properties of Viegas technique. We also believe that this study also provides interesting information regarding the indication of one technique over the other to treat Geissler' type III lesions in relation to type of patient, work and sport activity performed.

Can we make tendon transfers shorter? Biomechanical comparison of different suture techniques

List of authors:
Katalin Muraközy*
1 Kenézy University Hospital Debrecen (Debrecen)

Objectives / Interrogation: In tendon surgery early mobilisation is the key to have superior outcomes. It reduces adhesion formation, improves tensile strength, vascularity and cellularity of the repair site. The side-to-side (STS) technique was developed to provide the adequate strength to allow early mobilisation. The original description suggests 50mm overlap region. The idea of this study was to measure the strength and stiffness of STS sutures with smaller overlap region, to find the minimal length needed. We tested the Pulvertaft (PT) repair and three types of the STS repair with 50mm, 40mm, 30mm overlap region.

Methods: Flexor digitorum profundus tendons were freshly harvested from mangalica pig front legs. We used standard 7mm wide tendons. For the PT technique we used the 3 weave modification with cross-stitch sutures at the insertions, and 2 stitches at both ends. For the STS repair we measured the wanted overlap region, secured it with two end stitches, and made the running cross sutures on both sides of the repair. All mechanical tests were carried out using a fatigue testing machine (Instron8874). The free ends of the repairs were wrapped in wet gauze and secured with clamps. All tendons were pre-conditioned, were allowed to stress-relax for 30secs, and then were elongated to failure. The tendons were kept wet with physiological saline solution. We measured load of first failure, ultimate load and repair stiffness.

Results and Conclusions: All but one failure occurred in the repair region, one occurred at the clamp. PT repairs failed with the graft tendon pulling out of the recipient. STS repairs failed with longitudinal shearing of the tendon fibers. The ultimate load (highest force till failure) was significantly higher at all of the STS repairs than the PTs. There was no significant difference between the various STS repairs at ultimate load. The stiffness (slope of the linear region of the load deformation curve) of all the STS repairs were higher than the PT repairs.

The main result of this study was that the STS suture method tested here produced stronger and stiffer repairs compared to the tested variation of the PT repair. The 30mm overlap STS suture strength is not significantly lower than the STS repair with the 50mm overlap. All tested repairs provide more than enough strength to allow early mobilisation. STS repairs offer more strength, more stiffness, thinner reconstruction site than the PT repair. The 30mm overlap region also can be used on shorter tendons which otherwise would need grafting.

Scaphoid fractures with scapho-lunate ligament involvement: instability or ligamentous laxity? Role of arthroscopy and pinning

List of authors:
Federico Pilla*, Vito Duca, Norman Della Rosa, Giulia Colzani, Roberto Adani
1 Rizzoli Orthopaedic Institute (Bologna)
2 Orthopaedic Institute (Sassuolo)
3 OU of Hand Surgery (Modena)

Objectives / Interrogation: The aim of this study is to evaluate the role of arthroscopy in the treatment of scaphoid fractures; and in particular we investigated if ligament alterations found arthroscopically corresponded to actual lesions or just laxity. Furthermore, we evaluated if treatment through the pinning of the scapholunate joint can alter the results.

Methods: We performed a retrospective study on 39 patients that underdrew surgery from 2010 to 2016 for scaphoid fractures. Patients were divided in 4 groups (A, B, C, D) based on the surgical technique adopted and the finding of a lesion of the scapholunate ligament: A - fixation with a percutaneous screw without the use of arthroscopy, B - arthroscopy assisted fixation with a percutaneous screw without signs of scapholunate ligament lesions, C - arthroscopy assisted fixation with a percutaneous screw with signs of partial scapholunate ligament lesions, treated through pinning, D - arthroscopy assisted fixation with a percutaneous screw with signs of partial scapholunate ligament lesions, not treated.

The inclusion criteria were B-type scaphoid body fractures (B1 and B2). Exclusion criteria were proximal fractures, pseudarthrosis or severe arthritic degeneration.

Results and Conclusions: Of 29 cases treated with arthroscopy assistance only in 9 cases there were no scapholunate ligament lesions. In the other 20 cases, according to the Geissler classification, there were 2 type I lesions, 5 type II lesions and 13 type III lesions, no type IV lesion was detected. Our results show the pain to be modest (VAS scale). The ROM results show a small difference (the average ROM 6° in group A, 3.89° in group B, 10° in group C, and 7.3° in group D).

The results were on average good to excellent in all groups. In our study groups we observed no statistically significant differences of the outcomes analyzed.

From our experience and results the treatment of acute partial scapholunate lesions through pinning is not necessary. The differences between our 4 study groups are not statistically significant and so the 4 treatment options should be considered equal.

Ulnar head offset to restore DRUJ stability

List of authors:
Jorge Orbay*, Edward Tremols¹, Raul Galindo¹, Lauren Vernon¹, Victor Morales¹, Sophia Poirier¹
¹The Miami Hand & Upper Extremity Institute (Miami)

Objectives / Interrogation: The distal radioulnar joint (DRUJ) is essential for forearm rotation. Stability is provided by the articulation of the ulnar head with the sigmoid notch and the supporting soft tissue stabilizers (TFCC and distal oblique band of the interosseous ligament or DIOL). In some cases of DRUJ dysfunction, an ulnar head replacement is necessary to address pathology in the bony structures. In lieu of using a constrained DRUJ prosthesis, surgeons often rely on reconstructing soft tissues to provide DRUJ stability. However, this is difficult and stability is frequently poorly restored. We hypothesize that by incorporating an offset on the ulnar head implant that can be dialed into the rotational position to where it is most beneficial, tension will be reintroduced to the DIOL and additional stability will be provided.

Methods: Cadaveric forearms were used to measure the relative displacement of the ulna during simulated push pull (piano key sign) testing of the wrist. The ulna was fixed to a rigid beam and the hand was pinned through the 2nd-5th metacarpals allowing the radius to be rotated and fixed in supination, neutral, and pronation. The initial location of the radius was measured under a 5lbF preload. Gradual loads were applied up to 20lbF and the resultant displacement was measured. The TFCC was then excised to create DRUJ instability. The magnitude and direction of instability was measured by comparing radial displacement under load to that of the intact specimen. The ulnar head was then replaced with an ulnar head arthroplasty of the same size as the native head. Measurements were then repeated using a standard ulnar head (no offset) and repeated with a 2mm offset ulnar head. Specimens were tested in pronation, neutral, and supination and with the direction of the offset dialed into full pronation, neutral and full supination.

Results and Conclusions: The addition of a 2mm offset decreased displacement of radius relative to the ulna in all positions but most effectively in the direction in which the offset was dialed. Conclusion: A directed 2mm ulnar head offset may improve stability of the DRUJ joint after ulnar head replacement.

Biomechanics of External Fixator of Distal Radius Fracture, a new approach: Mutifix Wrist

List of authors:
Norman Della Rosa*, Giulia Colzani1, Giovanna Petrella1, Nicolo' Bertozzi1, Roberto Adani1
1 OU of Hand Surgery (Modena)

Objectives / Interrogation: The management of distal radius fractures includes several techniques, starting from cast immobilization till surgery through different treatments: plates and screws, external fixators.
Aim of this presentation is to assess and evaluate which are the key factors that may affect the stability and stiffness of the Mutifix wrist and to present the clinical experience related to the implant for this new external fixator device

Methods: The new external fixator device named Mutifix Wrist ® is based on the use percutaneous pins or K wires linked to ax external support that ensures rigidity to the whole construct.
Mutifix Wrist is an external fixator whose main body is made of a shapeable aluminum alloy that can allocate multiple k-wires having random orientations.
The holes on the aluminum bar can house K wires whose diameter varies between 1,5 mm and 2 mm and whose orientation depends on the fracture characteristics and on the reduction strategy adopted.
Thanks to this, the device is versatile and can adapt to different patient's and fracture's characteristics. The k wires are clamped to the bar with the use of a dedicated tool by plastic deformation of the bar around the holes. In addition to this a 5 mm carbon bar can be connected to the main frame body to stiffen the construct. The carbon bar is linked to the aluminium bar through the steel clamps at the end of the main fixator body and allows (as an option) to place additional out of the plane clamps to fix additional pins in multiple planes. These k wires are fixed to the carbon bar through an optional clamp.
K wires or pins allows to cross the fracture and to fix small bone fragments in case of comminuted fractures.
This external fixator, non-brindging, is a very versatile device because it allows to place pins or wires in multiple directions, angulations and planes achieving an optimal reduction in different kind of fractures.

Results and Conclusions: Compared to ORIF with plate the use of an external fixator is an easy method, reduces the risk of damage for surrounding soft tissues, permits to maintain the obtained reduction. Moreover, is a really versatile technique that allows to manage both intra and extra articular fractures.

Interposition arthroplasty with the Amandys pyrocarbon implant in rheumatoid wrist

List of authors:
Victor Lestienne*, Philippe Bellemère², Thierry Loubersac², Yves Kerjean², Etienne Gaisne²
1 Institut de la main Nantes atlantique (Saint-Herblain)
2 institut de la main Nantes Atlantique (Saint-Herblain)

Objectives / Interrogation: Management of the pancarpal arthritis in rheumatoid wrist is controversial. The most common treatment is total wrist fusion, but total wrist replacement offers a motion-preserving alternative. The purpose of this study is to present the results of the interposition arthroplasty with the Amandys pyrocarbon implant in rheumatoid wrist.

Methods: We performed a retrospective review of 28 interposition arthroplasties for rheumatoid wrist arthritis. Eighteen females and 5 males were included, with a mean age of 55.7 years. The mean follow-up was 45 months. We measured range of motion, grip strength, pain (VAS). Function was evaluated preoperatively and at the last follow-up with the DASH and PRWE scores.

Results and Conclusions: Results Mean range of motion in flexion-extension was maintained while mean inclination and rotation range of motion, mean grip strength, pain and function scores who showed significant improvement. The mean range of motion increase postoperatively from 65° to 70° in flexion-extension, from 25° to 35° in inclination and from 130° to 147° in rotation. The mean grip strength increase from 10kg (54% of the contralateral side) to 17 kg (78%). The mean pain score decreased from 6,3/10 to 2,5/10. The mean PRWE score decreased from 62/100 to 27/100. The mean QuickDash score decreased from 63/100 to 33/100. All patients were satisfied or very satisfied. Three patients had an early reoperation for repositioning their dislocated implant. No implant had to be removed.

Conclusions Amandys arthroplasty is a reliable alternative to total arthrodesis or total wrist prosthesis in rheumatoid wrist. The implantation technique must be rigorous in order to avoid technical errors that can lead to potential implant instability. Indications must be limited to a well-aligned wrist with competent capsular structures.

Biomechanical Comparison of Trapeziectomy and Suture button suspension-plasty versus Trapeziectomy and FCR ligamentous reconstruction for Thumb Carpometacarpal Arthritis

List of authors:
Monica Ramirez*, Ben Zellner2, Samita Goyal3, Mei Wang4, Cameron Best4, Hani Matloub3
1 Universidad Industrial de Santander, Hospital Universitario de Santander, Department of Plastic Surgery (Bucaramanga, Santander)
2 Medical College of Wisconsin, Department of Hand Surgery (Wauwatosa, WI)
3 Medical College of Wisconsin, Department of Plastic Surgery (Wauwatosa, WI)
4 Medical College of Wisconsin, Department of Orthopedic Surgery (Wauwatosa, WI)

Objectives / Interrogation: Osteoarthritis of the trapezio metacarpal joint is common and disabling. Several procedures have documented success in treating pain and instability. Central to the majority of the treatment is trapeziectomy. Our objective was to compare the results of suture button (SB) suspension-plasty and FCR tendon ligamentous reconstruction after trapeziectomy under cyclical loading of a mechanical model designed to simulate lateral pinch of the thumb and index finger.

Methods: 18 fresh-frozen below elbow cadaver specimens were used, they were randomly assigned in two groups: 9 underwent trapeziectomy and suture button and 9 trapeziectomy and FCR suspension procedure. Scapho-metacarpal distance was measured using fluoroscopy before and after trapeziectomy, and either type of reconstruction and biomechanical testing which was conducted on a servo hydraulic load frame (Bionix Landmark, MTS, Eden Prairies, MN) to simulate lateral pinch. Fixed amount of weights were tied to the sutures connecting the tendons of flexor pollicis longus (FPL, 300g), adductor pollicis (AdP, 150g), and abductor pollicis longus (APL, 200g).

Results and Conclusions: The mean scapho-metacarpal distance pre-trapeziectomy for the FCR reconstruction group (n=9) was 11.13 mm with a standard deviation of 2.18 mm. The average post-trapeziectomy space for the FCR specimens (n=9) was 8.38 mm with a standard deviation of 1.63mm. This difference was statistically significant (p=0.0006).
The mean scapho-metacarpal distance pre-trapeziectomy for the Suture button group (n=9) was 9.3 mm with a standard deviation of 2.87 mm. The average post-trapeziectomy space for the SB specimens (n=9) was 6.63 mm with a standard deviation of 3.07 mm. This difference was statistically significant (p=0.0022).

For the matched pairs, the post testing subsidence was 2.66 mm (SD 2.04) for the SB specimens (n=9) and 2.74 mm (SD 1.68) for the FCR specimens. This was statistically insignificant (p=.53).

Biomechanical testing indicates there is statistically significant subsidence after trapeziectomy and either FCR reconstruction or Suture Button reconstruction. However, when both procedures are compared, there is no statistically significant difference in the subsidence (p=0.53) between Trapeziectomy and FCR and Trapeziectomy and SB suspension.

Suture button suspension shows biomechanical results that are comparable to FCR interposition.

Return to employment after carpal tunnel release (REACTS): a prospective cohort study

List of authors:
Lisa Newington¹, David Warwick², Theodosia Salika¹, Jo Adams³, Karen Walker-Bone¹
¹ University of Southampton, Lifecourse Epidemiology Unit, Southampton General Hospital (Southampton)
² University Hospital Southampton NHS Foundation Trust (Southampton)
³ University of Southampton, Health Sciences (Southampton)

Objectives / Interrogation: To explore when and how patients return to different types of work after carpal tunnel release (CTR) and to identify the key factors predicting the duration of post-operative sick leave.

Methods: Participants with CTS (carpal tunnel syndrome) were recruited pre-operatively from 16 UK sites. Eligibility criteria included: working in paid employment for more than 20 hours per week and no history of CTR. Demographic, clinical, functional and occupational details were collected at baseline. After CTR, participants were followed-up weekly until return to work with a symptom diary, and by self-reported questionnaire at 4 and 12 weeks. Operative details were extracted from the medical records.

Results and Conclusions: Results:
A total of 222 individuals were recruited (61% female). Mean age was 51 years (SD 9.9) and mean body mass index was 29.6 (SD 6.1). Most participants had experienced CTS symptoms for more than a year and 40% were expecting bilateral CTR via staged procedures. Fewer than half of participants were diagnosed with classic CTS according to Katz hand diagrams. Mean Atroshi CTS-6 scores were 3.3 (SD 0.9) for the right and 3.4 (SD 1.0) for the left.

Nineteen percent of participants were self-employed, 77% were employed with a permanent contract and seven individuals had a temporary or zero hours contract. Forty-four percent of participants worked in manual occupations using the National Statistics Socio-Economic Classification. Median expected work absence after CTR was 14 days (IQR 14-28 days); 17.5 days for manual workers (IQR 14-28 days) and 14 days for non-manual workers (IQR 10-28 days).

Study follow-up will be completed in January 2019. The return to work processes and timescales will be summarised descriptively and a Cox Proportional-Hazards analysis will be used to determine the key factors influencing return to work time among this cohort.

Conclusions:
There is a lack of evidence-based information advising when patients might expect to be able to return to different occupational duties after CTR and these findings will help shape future guidance. We have recruited a cohort of patients undergoing CTR and will describe the reported time taken to return to different types of work. Analysis of the determinants of return to work time may identify potential targets for the development of interventions to improve return to work outcomes after CTR.

¹ University of Oxford, NDORMS, Botnar Research Centre (Oxford)
² University of Oxford, Nuffield Department of Population Health (Oxford)

Objectives / Interrogation: The aim of this study was to use a routinely collected data generated in the NHS in England to identify the incidence of revision CTD surgery, and the patient factors associated with revision. The secondary aim was to identify the rate of other complications following CTD surgery.

Methods: Validated procedure codes (OPCS codes) were prospectively collected as part of routine care were used to identify primary and revision CTDs in adults from April 1998- 2017. Disease status was defined by ICD-10 code. Patients were followed up until death or April 2017. Where possible, episodes were linked for those who had undergone both primary and revision CTD to calculate time to revision. Cox regression analyses were used to identify factors influencing revision.

Secondary complications studied included trigger finger, tenosynovitis, wound dehiscence, wound infection, tendon injury and median nerve/ vascular injury.

Results and Conclusions: 855, 832 primary CTDs were undertaken, 68% in women, with a significant peak in surgeries undertaken in women between 45-60 years of age. 29,288 (3.4%) of patients underwent revision CTD in the 19 year period; 18,737 primary CTDs were linked with a revision on the same hand. The median time to revision was 351 days (IQR 144 to 966). Time to revision was significantly influenced by male gender, increasing age and a past medical history of diabetes. The overall rate of complications in the first 30 days after surgery was 0.05% and 0.34% for complications occurring at any time following surgery.

Using real world data over 19 years, the incidence of revision CTD in England was 3.18 per 1000 person years. A history of diabetes, increasing age and male gender were significant factors in revision. Over 50% of patients that undergo revision do so within one year of primary surgery and the overall complication rate is very low.

Darrach's procedure in total wrist arthroplasty

List of authors:
Trygve Holm-Glad¹, Magne Røkkum¹, Ole Reigstad¹
¹ Oslo University Hospital, University of Oslo (Oslo)

Objectives / Interrogation: Concomitant painful arthrosis in the radiocarpal and DRUJ joint may be treated by combining total wrist arthroplasty (TWA) with resection of the distal ulna (Darrach's procedure). Results following Darrach's procedure combined with TWA and Darrach's procedure performed on wrists with previously implanted TWA are presented.

Methods: From 2001 to 2017 Darrach's procedure was performed on 30 (25 Motec®, 5 ReMotion®) of 164 prosthetic wrists, either in combination with (17/30 wrists) or median 14 (2 to 55) months following TWA implantation (13/30 wrists). The patients completed the QDASH and PRWHE scores and graded radial and ulnar sided wrist pain preoperatively and at follow-up. AROM (flexion, extension, radial and ulnar deviation), forearm rotation, and grip strength were measured.

Results and Conclusions: In one patient a dorsally prominating ulna end caused rupture of the extensor tendons to the 3.-5. fingers two months after the procedure. He was reoperated with tendon transfer and further shortening of the ulna. Additional ulna shortening (re-Darrach) was done in two patients after 15 and 31 months due to continuing pain and radiological impingement between the radius and the shortened ulna. In 6/30 patients the arthroplasty was revised to a new arthroplasty (5) or arthrodesis (1) due to muscular imbalance (1) or loosening of the distal (3), proximal (1) or both components (1) after median 3.2 (0.5-9) years.

Two years after combined TWA and Darrach's procedure (n=17) there was a significant improvement in PRWHE (65 vs 27), Q-DASH (50 vs 26), radial sided wrist pain at rest (31 vs 16) and activity (64 vs 31), ulnar sided wrist pain at rest (38 vs 10) and activity (65 vs 21), supination (59 vs 73°), AROM (74 vs 110°) and grip strength (JAMAR 13 vs 19 kg) (p<0.05). Pronation (80 vs 77°) was unchanged.

Darrach's procedure performed on wrists with TWA in situ (n=13) resulted in significant improvement of ulnar sided wrist pain at rest (39 vs 15) and activity (72 vs 36) two years later (p<0.05), without affecting pain on the radial side of the wrist at rest (18 vs 17) or activity (34 vs 35). Pronation improved significantly (76° vs 82°, p<0.05). Supination (72 vs 79°), AROM (104 vs 103°) and grip strength (JAMAR 19 vs 20 kg) remained unchanged.

Conclusions: Darrach's procedure results in ulnar sided pain relief and improves function in patients with TWA and painful DRUJ arthrosis.

3D finite elements study of stresses in the wrist and effect of different osteotomies used in Kienböck's disease.

List of authors:
Emmanuel Camus*, Anna Aimar, Luc van overstraeten, Frédéric Schuind, Bernardo Innocenti
1 SELARL Chirurgie de la main, ULB Free Brussels University (maubeuge)
2 ULB Free Brussels University, BEAMS Dpt (Brussels)
3 HFSU Tournai, ULB Free Brussels University (Tournai)
4 ULB Free Brussels University (Brussels)

Objectives / Interrogation: In Kienböck's disease, conservative surgical techniques aim to decompress the lunate. Many osteotomies are proposed. most involve the radius, the ulna or the capitate. Seven procedures were compared in terms of unloading by the authors.

Methods: To validate the comparison, a 3D finite elements model was built. The model was obtained from the segmentation of CT scans of an healthy wrist and imported into a finite element calculation software (Abaqus-Dassault systems). Authors add the ligaments, the cartilage shell and the TFCC with physical properties according to the litterature.
The radius axial shortening (AS), lateral closing (LC), medial closing (MC), the Camembert osteotomy without (C) and with Sennwald osteotomy (CS), the capitate shortening without (Ca) and with the hamate (CaH) shortening were compared.

Results and Conclusions: The different osteotomies were simulated, and the contact forces and stresses were recorded. In the anatomical model, the loads towards the forearm are brought by the scaphoid at 56%, the lunate at 30%, the triquetrum at 14%.
In AS they are respectively 41%, 29%, 28%;
in LC 50%, 45% and 5%;
in the MC 20%, 61%, 18%;
in the Ca 79%, 11%, 10%;
in the CaH 70%, 5%, 25%;
in C 53%, 29%, 18%;
in the CS 80%, 0%, 20%.
In this model, The osteotomies that best discharge the lunate are the CaH osteotomy and the CS osteotomy. Compared to initial model, the CaH osteotomy overloads ulna, whose contact force increases from 14% to 25%. In the CS, most of the stresses are supported by the scaphoid, the ulna overload is minimal and the lunate discharge is complete. The Camembert-Sennwald osteotomy seems, in this model, to best unload the lunate, without overloading the ulna.

Istvan Zoltan Rigo¹, Asgeir Amundsen¹, Preben Olsson Dowland¹, Balazs Simon¹, Jens Holthusen³, Jan-Ragnar Haugstvedt¹
¹Ostfold Hospital Trust, Dep. of Orthopaedics (Gralum)

Objectives / Interrogation: Painful distal radioulnar joint (DRUJ) can be a consequence of distal radial fracture, ulnar impaction syndrome or general inflammation disease. Intact DRUJ is a prerequisite for normal load transfer from the hand to the forearm under heavy lift. After resection of distal ulna (Darrach procedure), which is the standard treatment in many centres for painful DRUJ, the biomechanics will be negatively changed, patients experience often painful impingement between the ulnar stump and the radius and instability of the forearm. Ulnar head replacement can reconstruct the normal load transfer and publications show good results up to 11 years follow up. Our intention is to show our short term results with uHead ulnar head prosthesis.

Methods: This implant consists of an uncemented stem and a head, both made of cobalt-chrome. The head includes two holes for placement of stitches against the TFCC and the ECU subsheath.
Nine patients were operated with uHead implant at our hospital between 2014 and 2017, all women, mean age of 66 years (range 48-82), 6 in the right hand. The diagnosis was osteoarthritis of the DRUJ without instability; 8 distal radius sequel and one psoriatic arthritis. Two patients received partial and one total wrist fusion at the same time, one operated with total wrist fusion earlier. The follow up was 9 (5-14) months.

Results and Conclusions: The mean pro-supinasjon ROM increased from 149 (80% of the other hand) to 163 degrees (92%). Grip strength increased from 10.1 (46%) to 12.4 kg (62%). VAS pain score decreased from 6.4 to 2.7, the Quick DASH score from 66.1 to 37.1 and the PRWHE from 73.4 to 37.6. All of the patients were satisfied with the results. We observed two complications, one irritation of the dorsal branch of the ulnar nerve and one loosening of the head from the stem. The latest was reoperated 3 days later; with removal of the stabilising stitches between the head and the soft tissues the problem became resolved. Since then we have dropped placement of these stitches.

Our results are promising, comparable with other published series. UHead implant seems to be a good solution to DRUJ arthritis without instability, however this well-documented implant is retrieved from the marked after fusion of the producer to a bigger company.

Keywords: DRUJ, osteoarthritis, hemiarthroplasty
A Rare Case of Seymour Fracture in an Adult with Non-Fused Growth Plates

List of authors:
Mohammed Farid*, Mohamed Shibu
1 The Royal London Hospital (London)

Objectives / Interrogation: Introduction

Longitudinal bone growth is influenced by a number of nutritional, hormonal and genetic factors. The mechanism for growth plate fusion is not fully understood yet. One hypothesis indicates that delayed fusion may be related to deficiency or resistance to oestrogen in adolescence. We present the first reported Seymour fracture (Salter Harris I) in an adult with failed growth plate fusion.

Methods: Case Report

A 19.5 year old man presented with a left (non-dominant) little finger open juxta - epiphyseal fracture of distal phalanx. This was consisted with a Seymour type fracture (Salter Harris I) with involvement of nail bed, germinal matrix and unugal subluxation. The injury was secondary to a fall from a bicycle 2 days prior to our clinic review. Five days post injury, the injury was managed with open reduction, nail bed repair (6/0 vicryl rapide) and one axial K-wire (0.9 mm) fixation. Further clinical assessment based on Greulich and Pyle (GP) and Tanner-Whitehouse (TW) revealed bone age of 14.5 and 14.3 years respectively. The K-wire was removed 4 weeks post-operatively and DIPJ was splinted for further 2 weeks. The patient regained normal extension of DIPJ post rehabilitation and was followed-up for 6 months without any functional deficit. A referral to endocrinology team was made to rule out any growth hormone, thyroid or pituitary related diagnoses.

Results and Conclusions: Conclusion

The correlation of radiological bone age was a key to guide our management of the first reported Seymour fracture in an adult. Actual age should not be the sole indicator to rule out juxta-epiphyseal fractures in adolescent patients. The management of Seymour fractures should be according to bone age rather than actual age.

Interest of endoscopic release in recurrent carpal tunnel syndrome

List of authors:
Amirouche DAHMAM*, Gero MEYER ZU RECKENDORF1, Jean-Luc ROUX1
1 Institut Montpelliérain de la Main (Montpellier)

Objectives / Interrogation: A direct approach is the standard procedure for the treatment of recurrent carpal tunnel syndrome. However, this may be technically challenging due to adhesions and an increased risk of iatrogenic injuries. Endoscopic release of the median nerve within the carpal tunnel has become a well-controlled procedure, providing better anatomical vision than the conventional technique, thanks to the advances in technology. The aim of this work is to study the interest and feasibility of endoscopic release in the event of carpal tunnel recurrence.

Methods: Seven patients, with a mean age of 61 years old, presented a clinical symptomatology of carpal tunnel syndrome after an average of 6 years following initial surgery for median nerve release, by mini-open surgery in 6 patients and endoscopic surgery in one patient. Electromyography was positive in all patients and confirmed the recurrence. All patients were treated with endoscopic carpal tunnel revision surgery. They were informed of the risk of conversion to open surgery and all were reviewed and clinically evaluated.

Results and Conclusions: Endoscopic release was successfully performed except in one case in which the anterior carpal retinaculum did not deviate sufficiently in its distal part due to its thickness. We undertook an open conversion to complete the release. In all cases, the anatomical elements were visualized in order to protect them before section of the anterior carpal retinaculum. All patients were satisfied and reported an improvement in symptomatology.

Recurrence after carpal tunnel surgery is rare and should trigger a search for incomplete release in the majority of cases. Open surgery is the most commonly used technique and some authors advocate neurolysis of the median nerve associated with a protection flap as required. The interest of endoscopy is to visualize all the anatomical parts such as the median nerve, flexor tendons and the superficial palmar arch, in order to protect them before safely cutting the anterior retinaculum on its ulnar side, unlike with the open approach. Neurolysis exposes the patient to a risk of iatrogenic nerve damage. We believe that, for a first recurrence, it is sufficient to perform a simple release without any associated procedures. This study shows that endoscopic release of recurrent carpal tunnel can be safely performed with good results. Mastering the endoscopic technique is essential and reverting to open surgery must be the rule for cases with difficult visibility.

Infection rates following carpal tunnel decompression in the community. Experience from the U.K.

List of authors:
Vishal Palial*, Shabih Siddiqui
1 University Hospitals of Leicester, Leicester General Hospital (Leicester)
2 Kettering General Hospital (Northamptonshire)

Objectives / Interrogation: The demand for elective hand surgery in England is predicted to double by 2030 as compared to 2011. With such increase in demand, the U.K. must seek strategies to reduce costs of treatment whilst still maintaining standards of care. Carpal tunnel decompression (CTD) performed in a treatment room rather than in theatre may provide an alternative setting whilst achieving cost savings. As yet, there are no U.K. based studies that identify the risk of infection following surgery performed in a treatment room and there are no studies whatsoever assessing the qualitative outcomes from patients undergoing hand surgery outside a theatre environment.

Our aim in this study was to identify the incidence of infection following CTD when performed in a primary care setting and to assess the qualitative outcomes following the procedure via patient reported outcome measures (PROMs).

Methods: A prospective review was performed in all patients undergoing open CTD in one single primary care centre by a single surgeon between January 2012 and August 2017. All identified patients within the study period were asked to complete the Boston Carpal Tunnel Syndrome questionnaire (BCTQ). This was completed before surgery and again at 6 months following surgery via postal questionnaire. A superficial infection was defined as an infection treated by antibiotics, either enteral or intravenous. A deep infection was defined as a collection requiring surgical debridement in theatre. Independent and paired t-test statistical analysis using SPSS V.23 (IBM Corp.) was performed to test significance of qualitative outcomes.

Results and Conclusions: Completed outcomes were available for 335 patients. The average age at time of surgery was 59 (range 26 - 94). Seventy per cent of cases were female. Sixty-two per cent of patients had surgery on their dominant hand. Two superficial infections requiring treatment with antibiotics were identified resulting in a superficial infection rate of 0.6%. There were no deep infections identified. There was a statistically significant improvement in both symptom and functional outcomes following surgery with results comparable to other studies where surgery was performed in theatre.

We believe that carpal tunnel decompressions performed in a treatment room is both safe and effective and surgeons should consider this as an alternative setting to the main operating room.

JOINT SPACER - A NOVEL THERAPEUTIC OPTION FOR RHIZARTHROSIS

List of authors:
Robert MULH*1, Uros KOVACIC2, Tea Jedlovcnik1, Bostjan LAH1
1 GH NOVO MESTO, Departement of hand and plastic surgery (NOVO MESTO)
2 FACULTY OF MEDICINE, Institute of Pathophysiology (LJUBLJANA)

Objectives / Interrogation: Thumb basal joint arthritis that affects up to 11% and 33% of men and women in 50s and 60s, respectively, is treated by several surgical techniques (Menon's interposition or LRTI arthroplasty, Mini TightRope CMC Technique). By using RegJoint spacer and avoiding resection of FCR or APL tendon, we simplify and shorten the surgery. We hypothesize that this new technique is a better alternative for rhizarthrosis operation, because it reduces post-OP pain and shortens the time until complete recovery.

Methods: In 92 pts (aged 43 - 81 years) with rhizarthrosis, dorsoradial longitudinal incision at the base of the thumb was performed. We created a capsular flap with a distal base over the TMC joint, following partial or complete resection of the trapezium. Thereafter, we inserted the RegJoint disk spacer and firmly sutured the capsule. In 23 pts we performed additional beak (volar) ligament reconstruction with APL or FCR tendon. Patients began with physiotherapy after 3 weeks of immobilization. Thereafter, we monitored their recovery for 1 year post-OP by performing QuickDASH score, VAS, Kapandji's 10-point functional score, Mayo wrist score and X-ray. The statistical significance of improvements were tested with 1W RM ANOVA (p < 0.05).

Results and Conclusions: All monitored parameters statistically significantly improved until the first month post-OP. Average measures of QuickDASH score reduced from 43.5 pre-OP to 34.5, 26.4 and 21.3 1m, 3m and 1y post-OP, respectively. Average VAS score, which was 7.1 pre-OP, also improved to 5.7, 3.1 and 1.9 1m, 3m and 1y post-OP, respectively. Kapandji's functional score improved from 4.7 point pre-OP to 5.9, 8.1 and 9.2 point 1m, 3m and 1 year post-OP, respectively. Mayo wrist score that was 45 preOP improved to 54, 69 and 76 1m, 3m and 1 year post-OP, respectively. Pre- and post-operatively X-ray controls were made to evaluate the distance between the base of first metacarpal bone and the remaining trapezium/distal pole of scaphoid. The average distance statistically significantly increased from 0.3 mm to 3.1 and 3 mm after 1 and 3 months, respectively. Until the 1st y post-OP the distance narrowed to 2.1 mm.

Using this novel and feasible technique of rhizarthrosis therapy, the final recovery outcomes are at least comparable to the other surgical techniques. Most importantly, we can perform earlier mobilization with significantly lower pain and stable (well-positioned) base of first metacarpal, which enables earlier return of patient to the workplace.

Treatment of congenital upper limb muscular hypertrophy in hand

List of authors:
Wen Tian*, Junhui Zhao1, Guanglei Tian1
1 Dept. of Hand Surgery, Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To introduce the hand deformity of congenital upper limb muscular hypertrophy and the treatment strategy.

Methods: From May 1992 to October 2012, 13 cases of congenital upper limb muscular hypertrophy were diagnosed by clinical characteristics, operative exploration and pathology result. The primary or other secondary macromelia were excluded. There were 8 males and 5 females with an average age of 6 (2 to 20 years). The presentation of the hand deformity, intraoperative exploration, the surgical treatment and outcomes were reviewed.

Results and Conclusions: Results The deformity of hand mainly includes excessive spreading in metacarpophalangeal (MP) joint, hyper-abduction of the thumb to radial and palmar side and hypertrophic web spaces, ulnar deviation and flexion deformity at the MP joints and cross finger deformity. Intraoperative findings include multiple aberrant intrinsic and extrinsic muscles with abnormal origin, insertion and orientation, and increased volume. The main surgical choice was proper resection of the aberrant muscles, abnormal musculature and skin to reduce volume of the thenar and hypothenar eminence, correction of hyper-abduction on thumb and little finger and correction ulnar deviation and flexion of the MP joint. Other treatment strategies included metacarpal osteotomy to correct cross-finger deformity, surgical release skin and soft-tissue to correct MP joint flexion, relocation and stabilization the central band to help correcting ulnar deviation and flexion of the MP joint. All the patients got different degrees of cosmetic and functional improvement with an average follow-up of 2.5 years.

Conclusions The hand deformity of congenital upper limb muscular hypertrophy was mainly attributed to congenital aberrant intrinsic and extrinsic muscles with abnormal insertions and orientation, and increased volume. Surgical corrections can improve the appearance and function of the hand to different degrees.

Bilobed Flap in Hand Clinodactyly Reconstruction: Technique Description and Result Appraisal

List of authors:
Ricardo Kaempf*1, Pedro J Delgado2, Márcio Aita3, Samuel Ribak4, Enrique Vergara Amador5
1 Hospital Santa Casa de Porto Alegre (Porto Alegre)
2 Hospital Universitário Montepríncipe (Madrid)
3 Faculdade de Medicina do ABC (São Paulo)
4 Pontifícia Universidade Católica de Campinas (Campinas)
5 Fundación Hospital de la Misericordia, (Bogota)

Objectives / Interrogation: Clinodactyly is a congenital hand deformity that is characterized by coronal angular deviation and may occur in thumbs or fingers . Surgical treatment is indicated for severe angulations. Among described techniques, one of the options consists of bone alignment by wedge-shaped addition osteotomy of the anomalous phalanx. Such alignment maneuver creates a problem in skin cover, along with soft tissue tension at the concave aspect of the deformity. Hence, some sort of skin flap is required for the adequate operative wound closure. We aim to demonstrate the aforementioned technique, and to assess the results of bilobed flap in the treatment of hand clinodactyly.

Methods: Retrospective study of patients that were submitted to this surgical procedure between January 2008 and January 2017. Five patients were included in the study, including nine operated digits. Surgical indication consisted of angular deviations above 30 degrees. Patients with thumb deformities, as well as those deformities associated to syndromes, were not excluded from the study. Functional and cosmetic outcomes with the technique were assessed, as well as complications and the satisfaction rates of the family.

Results and Conclusions: All patients had satisfactory functional and cosmetic results, with a mean skin healing of 18.6 days. Among nine operated digits, only one of the patients presented vascular compromise at the distal portion of the first flap lobe, albeit without necrosis or the need for any additional procedure. Patients were followed up on a minimum of 12-month interval. No deformity recurred during the observation period.

The use of bilobed flap for the treatment of hand clinodactyly is a good option for skin cover after the osteotomy.

ELECTROSPUN PLGA NANOFIBERS ON COLLAGEN AS A NERVE CONDUIT

List of authors:
Shalimar Abdullah*, Sharina Khalid1, Min Hwei Ng1, Hazla Mohd Haflah1, Izzat Al-Fattah Yahaya1
1 Universiti Kebangsaan Malaysia (Kuala Lumpur)

Objectives / Interrogation: Defects in peripheral nerve poses can pose as a difficult problem for surgeons to address. Many different techniques have been utilized to address this gaps including inserting a nerve conduit. We aim to develop an aligned biocompatible cell-seeded PLGA on collagen mat as a nerve conduit for use in peripheral nerve regeneration. Our previous work utilised skin fibroblasts but this current work utilised human mesenchymal stem cells differentiated into nerve cells. We will describe the method of constructing a tubular conduit from electrospun PLGA and the addition of collagen layer and human mesenchymal stem cells (hMSC) into this conduit.

Methods: The solvents used were poly lactic-co-glycolic acid (PLGA) PL85GA15 was used with Dichloromethane (DCM) and Dimethylformamide (DMF). We utilised the electrospinning technique. We analysed fiber morphology, average diameter and interfiber junction and tested for mechanical strength. The neural-differentiated human mesenchymal stem cell (hMSC) was seeded into the collagen-layered nanofibers and a biocompatibility assessment was done to assess cell viability. Aligned electrospun PLGA on a collagen sheet was rolled into a tubular conduit. The designed conduits were seeded with hMSC and investigated with physical, mechanical and microscopic analyses and the degradation rate was measured.

Results and Conclusions:
The electrospun fibres were elongated, relatively aligned and with a smooth surface. The fibres had a diameter of average length of 0.96 microns. The constructed aligned fibres were successfully seeded with mesenchymal stem cells which had further differentiated into neural cells.
The nerve conduits measured 40.0mm long, an internal diameter of 2.0mm and thickness of 1.03mm. The degradation study of nerve conduit showed the PLGA fibres did not degrade further after 12 weeks.

Using electrospun PLGA for nerve conduit construction is inexpensive and can be replicated. Fibres which are aligned improves growth of neurite and enhances maturation. Nerve conduit tensile strength is improved by adding collagen. This nerve conduit composed of collagen-layered PLGA and seeded with hMSCs is biocompatible and suited for nerve cell proliferation. Thus it has the potential to be inserted into a nerve gap in peripheral nerve surgery.

Lunate preserving pronator quadratus pedicled bone graft in the treatment of Kienböck's Disease

List of authors:
Young Ho Shin*, Jun O Yoon¹, Jae Jung Ryu¹, Tae Kyoong Lee¹, Shin Woo Choi¹, Jae Kwang Kim¹, Gwan Bum Lee²
¹ Asan Medical Center (Songpa-gu)
² Asan Medical Center, Department of Orthopedic Surgery (Songpa-gu)

Objectives / Interrogation: Pronator quadratus (PQ) pedicled bone graft (BG) was one of the vascularized BG option for the treatment of Kienböck's Disease. We inserted a pronator quadratus pedicled bone graft to the avascular lunate with preserving the cortico-cartilaginous portion of the lunate.

Methods: Twenty seven patients with Kienböck's disease (three patients of Lichtman stage II, 13 patients of IIIA and 11 patients of IIIB) were treated by lunate preserving PQ pedicled BG between September 2005 and July 2014 and followed more than two years. There were 14 men and 13 women; the mean age at the time of surgery was 42.4 ± 13.4 years (range, 17-66 years). Radiological changes including lunate morphology, Lichtman stage and radiological parameters were compared between preoperative and final follow up. The wrist flexion/extension angle, grip strength, and Disabilities of the Arm, Shoulder and Hand (DASH) scores, pain VAS were also evaluated.

Results and Conclusions: Eighteen patients (66.7%) showed radiological improvement in lunate at least one of sclerosis, cystic changes or fragmentations after operation: sclerosis in 14, cystic changes in three, and fragmentation in five patients. The preoperative Lichtman stage was not changed in 23 patients, but aggravated in 4 patients. In radiological evaluations, Stahl index was significantly decreased after operation (p=0.012), but no significant differences were observed in the radioscaphoid angle and carpal height ratio. The grip strength was significantly improved after operation (p<0.001), but was not in wrist ROM. The mean DASH score was 16.7 ± 14.0 (range, 1.7-50.8) and 18 patients (66.7%) did not have any pain at the wrist during daily activity. Lunate preserving PQ pedicled BG could improve lunate morphology in some extent, but did not restore the already changed carpal malalignment. However, this technique was effective in pain control and grip strength improvement. This technique could be a useful alternative to previous vascularized BG techniques in the treatment of Kienböck's Disease.

Outcomes after Long Gap Allograft Reconstruction in the Upper and Lower Extremities: A Retrospective Review

List of authors:
Brendan Mackay*, Matthew Blue, Joash Suryavanshi, Bradley Osemwengie, Nancy Swinford, Desirae Mckee
1 Texas Tech University Health and Science Center (Lubbock)

Objectives / Interrogation: The use of processed nerve allograft (PNA) in peripheral nerve surgery is rapidly evolving. Favorable outcomes have been reported for PNA as compared to autograft in the upper and lower extremities, and cranial nerves, for gaps up to 70mm. Yet, there is limited data on reconstruction of gaps greater than 70mm. Autograft data is also limited in longer gaps, and shows mixed results. To evaluate the effects of PNA, we selected patients with insufficient donor nerves, to evaluate the use of allograft to reconstruct injuries with gaps greater than 70mm. The objective was to evaluate early outcomes for PNA repair of injuries greater than 70mm at an academic Level-1 trauma center.

Methods: Retrospective review of patients who underwent reconstruction with PNA greater than 70 mm was performed. All procedures were performed by fellowship trained hand surgeons. Functional recovery, Tinel's sign, and sensory tests were recorded for all postoperative follow-up visits. When possible, electromyogram testing (EMG), nerve conduction study (NCS) were obtained to quantify re-innervation. Acute and sub-acute nerve transfers were cataloged. Complications and revision procedures were also recorded.

Results and Conclusions: Ten patients were included in our study. Average age was 31 (range 21-41 years). Eight patients (80%) were male. Ninety percent of reconstruction were in the upper extremity with an average gap length after resection of 17cm (7.5-36cm). All patients had multiple connected allografts used during their reconstruction. Mean follow-up was 4 months. All patients showed signs of nerve regeneration through the PNA, and advancing Tinel's. Five patients had EMG/NCS studies, one of which had serial studies performed. Two patients showed return of activity in a motor unit of the reconstructed nerve. Seven patients underwent Semmes Weinstein testing, and demonstrated some return of sensibility in the nerve distribution. The two longer term follow up patients showed signs of motor return and increasing range-of-motion. No complications directly related to nerve reconstruction or revisions were observed.

All patients in our cohort have shown short-term improvement in strength, sensation, and functional outcomes after allograft reconstruction of nerve injuries with gaps greater than 70 mm. Quantitative assessment of recovery is ongoing but encouraging. Early data suggests that long-term follow-up may show the use of allograft in nerve gaps greater than 70 mm to be a promising reconstructive option.

TFCC foveal tear with distal radius fracture

List of authors:
Hiroshi Ono*, Daisuke Suzuki¹, Ryotaro Fujitani²
¹ Hand Surgery Center, Nishinara Central Hospital (Nara)

Objectives / Interrogation: Purpose: This study aims to evaluate the hypothesis that TFCC foveal tear is accompanied by distal radius fracture (DRF) with severely dislocated distal fragment of the radius. We also determined which specific radiological parameters were associated with TFCC foveal tear.

Methods: Methods: We retrospectively reviewed consecutive 137 patients with unstable DRFs treated by arthroscopic ORIF during a 3-year periods from July 2015. There were 111 female and 26 male, 64 right and 73 left hands, mean age 70y.o. According to AO classification, type A were 24, B were 5, and C were 108 cases. Radiographic parameters such as radial inclination (RI), ulnar variance (UV), volar tilt (VT) of preoperative standard PA and lateral radiographs were measured in all cases. At operation, TFCC foveal insertion was observed arthroscopically by DRUJ approach or radiocarpal approach through teared TFCC disc proper if possible. The TFCC foveal insertion was divided into two groups (normal and tear). Tear group included both complete and partial tear of TFCC foveal insertion. We compared the radiographic parameters between two groups by T test. We conducted the logistic regression analysis to investigate parameters associated with TFCC foveal tear by odds ratios (ORs) and 95% confidence intervals (CIs) for RI, UV, and VT and the ROC analysis to investigate the cutoff value.

Results and Conclusions: Results: There were 40 cases in tear group and 97 in normal group. The mean RI, UV, VT of two groups (tear/normal) was 13.8/17.1, 4.1/2.4, -21.4/-8.9, respectively. All these parameters were statistically significant different between two groups (p= 0.015(RI), 0.024(UV), and 0.0009(VT)). Logistic regression analysis demonstrated only the VT was significantly different (OR: 0.971, 95%CI: 0.9510 to 0.992, p=0.0058). The ROC analysis showed the VT had the area under the curve at 69.1%. Using a cutoff of -13.2 degree, VT had 58% specificity and 75% sensitivity for TFCC foveal tear. Conclusion: Our data demonstrated the distal radial fragment of DRF with TFCC foveal tear dislocated more severe than that with normal TFCC fovea. If the VT of preoperative radiograph is smaller than -13.2 degree, the TFCC foveal insertion should be observed directly or arthroscopically.

Suture Technique with strain relief for repair of flexor tendons of the zone II of the hand

List of authors:
Luis Antonio Buendia\textsuperscript{1}, Heitor José Rizardo Ulson\textsuperscript{2}
\textsuperscript{1}Hospital Samaritano São Paulo, Hospital Municipal Tatuapé São Paulo (Sao Paulo)
\textsuperscript{2}Hospital Samaritano São Paulo (Sao Paulo)

Objectives / Interrogation: To assess the joint mobility of patients submitted to primary repair surgery of the flexor tendon injuries of the hand with the modified Kessler- Kleinert technique associated with a dynamic anchorage pull out suture, for relieving the tension at the Kessler- Kleinert suture.

Methods: Eight patients from eleven fingers with injuries occurred within maximum 5 days with short-incised or short-blunt cuts referred from the Emergency Room of the institution. All patients received were informed consent and clarified prior to surgical procedure, and performed under WALANT anesthesia. The surgical technique was based on the Kessler- Kleinert type tenorrhaphy with 4-0 mononylon core plus epitendon running suture with 6-0 mononylon. At the end a double-loop was added with 3-0 nylon monofilament running parallel to this tendon inside the tendon sheath, anchoring proximally and distally to the initial terminal-terminal repair. With this technique we obtained a reinforcement of the tendon ends: thus protecting the suture site. The dressing and placement of an orthosis or plaster splint were applied, the immobilization was removed and the patient was referred to the occupation therapy service, where they were encouraged to use both: actively and passively operated finger

Results and Conclusions: The results of the passive and active measurement of the range of motion (TAM) at the MTF, IFP and IFD joints of the affected fingers during the period of postoperative follow-up at the different occasion showed a considerable gain with statistical significance $p<1$. The Multiple Comparisons analysis of Bonferroni and the ANOVA method were used. The Disabilities of the Arm, Shoulder and Hand (DASH) Score showed a Satisfaction Level of 8.75. According to Strickland’s criteria we had 8- fingers (72.27%) excellent results, 18.18 %. 2- fingers(18.18 %) good results and 1- finger (0.9%) regular results. All patients were evaluated in the first week after the surgical procedure, after the third week, at 3 months and 6 months of post operative follow up. This considerable gain in amplitude in the early phases of the postoperative recovery may be related to the immobilization release, achieved early due to the anchorage suture technique which allowed early active motion. No infection, pull out suture failure occurred

2 Hospital Mãe de Deus (Porto Alegre)
3 SP hand center (São Paulo)
4 Hospital do Cajuru (Curitiba)
5 Hospital Universitario HM Monteprincipe (Madrid)

**Objectives / Interrogation:** Background: Despite the high prevalence of unstable neck metacarpals fractures (boxer's fractures) there is still no consensus concerning the preferred method and ideal moment of treatment, especially in active patients where the time or type of management can have a strong psychological impact on the outcomes.

Purpose: To compare ROM (range of motion), working return time, VAS (visual analogue score), quick DASH (disability arm, shoulder and hand) and radiographic outcomes of two methods of definitive internal fixation in active patients in boxer's fractures, operated in the first week.

**Methods:** prospective, randomized trial, included fifty patients, mean age years (range, 18 - 40 years) were randomized and treated to definitive intramedullary fixation using 2 headless screws (n=20) or bouquet (2 or 3 k-wires) (n=20). The patients were assessed on working time return, ROM (range of motion), patient reported outcome QuickDASH (disability arm and shoulder and hand), VAS (visual analog scale) and radiographic evaluation at 6 months.

Type of study/level of evidence Therapeutic II

**Results and Conclusions:** Results At 6 months, there were no differences between the two groups in terms of ranges of motion, postoperative pain (VAS), or Quick DASH score. The overall complication rate was 4.76% in the screw group, compared with 5% in the bouquet group.

Conclusions In treatment of the active patients with unstable boxer fractures, headless screws and bouquet fixation prove to be safe and reliable treatment. The outcomes were similar into groups.

Histological Evaluation of Processed Nerve Allograft Following Nerve Banking in Revision Limb Salvage Procedure.

List of authors:
Brendan Mackay*, Matthew Blue¹, Joash Suryavanshi¹, Bradley Osemwengie¹, Nancy Swinford¹, Desirae Mckee¹
¹Texas Tech University Health and Science Center (Lubbock)

Objectives / Interrogation:
Nerve reconstruction is an essential part of limb salvage. Processed nerve allograft (PNA) utilization is a growing component of limb salvage. Revisions to limb salvage can unfortunately be a necessary multi-step process. Nerve banking has been proposed as a means of preserving sacrificed nerve autografts in the past, however no study has evaluated the banking of nerve allografts. We present the histological assessment of banking nerve allograft by burying it within a patient's muscle during revision limb salvage.

Methods:
We performed a retrospective review of patients that underwent PNA reconstruction of peripheral nerve injuries who had complications necessitating take down of previously placed graft. PNA was salvaged by burying their graft within the patient's own muscle. The histopathology of the in situ banked nerve graft after storage in the patients muscle was qualitatively compared to the histopathology of the nerve graft before original implantation.

Results and Conclusions:
Two patients were included in our case series. Patient 1 had a right ulnar nerve injury from a gunshot wound. He underwent ulnar nerve reconstruction using PNA. Five days post-operatively, the patient had wound necrosis in the region of the reconstructed nerve. The graft removed from the original reconstruction was implanted in the intact triceps muscle. Two weeks after banking, the patient underwent revision ulnar nerve reconstruction and the banked allografts were removed for evaluation. Patient 2 had a brachial plexus injury secondary to a motor vehicle collision. The patient underwent significant brachial plexus reconstruction with PNA. Twelve days post-operatively, the patient sustained an unsalvageable vascular complication and underwent amputation. The Graft was salvaged and implanted into the pectoralis major muscle. Two days post-amputation, patient underwent TMR and banked grafts were removed for evaluation. Histologic analysis of the in situ banked graft as compared to nerve graft pre-implantation reveals good structural preservation, presence of Schwann cells, and no signs of cellular infiltration from rejection or reaction.

We present a novel technique of nerve allograft banking within intact muscle tissue. Histopathologic slides showed no qualitative difference between pre-implantation and salvaged allograft. This study suggests that acellular nerve allografts are safe and retain adequate integrity after in situ muscle banking.

Comparative study of the use of antibiotic therapy and antibiotic prophylaxis in the treatment of Swanson Type I open fractures of the hand.

List of authors:
Paulo Randal Pires Júnior*, paulo randal pires¹, Leandro A. de Figueiredo¹, Marcella Rodrigues Costa¹
¹Hospital Madre Teresa (BELO HORIZONTE)

Objectives / Interrogation: Prophylactic antibiotic treatment after orthopedic surgery is a controversial issue. The present study aimed to compare the efficacy of antibiotic therapy with that of antibiotic prophylaxis in the treatment of Swanson type I open fractures of the hand.

Methods: The prospective study involved 179 patients presenting Swanson type I open fractures of the hand, all of whom were submitted to conventional surgical treatment in a trauma reference hospital during 16 months. Group 1 patients (n = 92) were hospitalized for 3 days and received intravenous antibiotic therapy (four doses of cefalotin per day; 140 mg/kg/day). After release, patients received four oral doses of cefalexin per day (30 mg/kg/day) for 7 days. Group 2 (n = 87) patients remained in hospital for only a short period (less than 24 hours) during which they received intravenous antibiotic prophylaxis (three doses of cefalotin) every 4 h. No oral medication was prescribed after release. Both groups were followed-up each week for 1 month after the injury. Standard statistical methods were applied to evaluate frequency distributions, the Fisher exact test was employed to establish the statistical significance of frequency association and differences were considered statistically significant for p inferior to 0.05.

Results and Conclusions: The study population comprised more males (90.5%) than females. Crushing was the most frequent cause of injury (29.6%). Seventy-five patients (41.9%) presented lesions (180 in total) of soft tissues associated with the fractures, with a significant predominance (p < 0.001) of lesions of the extensor tendons. The infection rate among the overall population was 2.2% (two cases in each group) with no significant differences between the groups. Antibiotic prophylaxis is as effective as antibiotic therapy for complementing surgical treatment of Swanson type I open fractures of the hand to avoid early infections, which may contribute to shorter hospitalization periods.

Mid-term results of K-now total elbow arthroplasty

List of authors:
Takaya Mizuseki*, Tetsuo Masuda¹, Osami Suzuki¹
¹Hiroshima Prefectural Rehabilitation Center (Higashi-Hiroshima)

Objectives / Interrogation: K-now total elbow is a non-constrained elbow prosthesis designed and manufactured in Japan. K-now total elbow arthroplasty (TEA) is mainly indicated in the elbow with rheumatoid arthritis. The most significant feature of this prosthesis is that humeral component is modular and condylar size can be adjusted with different size of humeral stem. Since we started using this prosthesis, ten years has passed. We reviewed the mid-term results of this total elbow and tried to elucidate inherent complications.

Methods: Since 2007, we started using K-now TEA in patients with rheumatoid arthritis with severe elbow joint destruction. Between 2007 and 2013 we performed 20 K-now TEAs on 19 cases with RA. At a follow-up of seven years two months on average, one had died of unrelated cause. There were 17 women and two men with a mean age of 63 years (34 to 72). All of them except the deceased were reviewed radiologically and clinically assessed using Japanese Orthopaedic Association elbow performance score (JOA elbow score). The joint destruction was rated as Larsen grade 4 in 11 elbows, grade 5 in seven elbows and one ankylosed elbow.

Campbell approach was used to expose the joint. Sizes of the ulnar component, condylar component and the humeral stem are predetermined. At surgery, trial component is inserted to see the snug fit. Then, condylar component and the humeral stem is assembled and firmly fixed by tightening the posterior screw. Ulnar component is fixed using bone cement. Soft tissues are sutured primarily, and the elbow is kept in the splint for 10 days.

Results and Conclusions: One patient developed metallosis in the affected elbow joint and condylar prosthesis was revised after three years four months. At revision, diffuse metallosis was noted and the screw fixing the condylar prosthesis to the humeral stem was found to be loose. In no other patients, metallosis, breakage or loosening of the either stem was found radiologically. The averaged JOA elbow score improved from preoperative 51 points to postoperative 83 points, including the revised patient. The mean arc of flexion/extension improved from preoperative 116/29 degrees to postoperative 131/26 degrees on average. Pronation/supination improved from preoperative 52/68 degrees to postoperative 72/78 degrees.

In conclusion, K-now total elbow arthroplasty has proved to be a durable elbow prosthesis. However, there is a risk of development of metallosis when the screw that connects condyle and the stem becomes loose.

The Effect of Carpal Alignment on Post-Operative Range of Motion After Four Corner Fusion in Wrists with Type 1 Lunates

List of authors:
Logan McGinn*, Ruby Grewal1, Nina Suh2
1 Division of Plastic & Reconstructive Surgery, Roth I McFarlane Hand & Upper Limb Centre, St. Joseph's Health Care (London)
2 Division of Orthopaedic Surgery, Roth I McFarlane Hand & Upper Limb Centre, St. Joseph's Health Care (London)

Objectives / Interrogation: Restoring carpal alignment during four-corner fusion (4CF) to neutral position has been discussed in the literature as an important factor in range of motion preservation. To date, there have been limited studies focusing on whether the amount of capitate radial overhang relative to the lunate has an impact on functional outcomes. In this study, we explored the effect of specific parameters of carpal alignment on range of motion and grip strength of patients with lunate type 1 wrists treated with 4CF.

Methods: A retrospective chart review of a single-surgeon’s practice over a six-year period was conducted to identify 15 patients with 15 lunate type I wrists who underwent 4CF for SLAC or SNAC. All wrists were treated with headless compression screw fixation. Primary functional outcomes included percentages of maintained pre-operative flexion-extension arc (FEA) and grip strength. Pre- and post-operative radiographs were analyzed to obtain lunocapitate and radiolunate angles and the amount of capitate radial overhang relative to the lunate. Scatterplots of primary functional outcomes were created to visualize data distribution against carpal alignment parameters and Pearson correlation coefficients were compared.

Results and Conclusions: Pre-operative lunocapitate angle (LCA) was the strongest predictor of percentage FEA maintained post-operatively, with many patients having actually improved their range. The greater the LCA pre-operatively, the greater maintained range post-operatively ($r = 0.77$). Furthermore, LCA correction was positively correlated with percentage maintained FEA ($r = 0.52$). Reduction of capitate radial overhang relative to lunate was negatively correlated with percentage maintained FEA ($r = -0.54$); meaning that greater the overhang and the less this articulation was reduced, the better post-operative range of motion outcomes patients were able to achieve. The relationship between radiolunate angle and functional outcomes was negligible. Grip strength was not strongly correlated with any alignment parameters.

four-corner fusion, carpal alignment
Non-vascularized ulnar nerve graft reconstruction as an efficient treatment for brachial plexus paralysis

List of authors:
Paulo Randal Pires Júnior*, paulo randal pires¹, Gustavo Pacheco Martins Ferreira², Marcella Rodrigues Costa¹, Sumner William Niquini², Tiago Dórea Rosário Falcão²
¹Hospital Madre Teresa (BELO HORIZONTE)
²Hospital Maria Amélia Lins (BELO HORIZONTE)

Objectives / Interrogation: Brachial plexus paralysis is a serious injury for which different forms of treatment are available. The aim of this study was to evaluate the functional outcome of non-vascularized long ulnar nerve graft reconstructions for the restoration of elbow flexion in patients presenting complete brachial plexus injury.

Methods: The retrospective cross-sectional study involved 14 patients who had undergone 25 non-vascularized reconstructive graft procedures during 1999-2009 at two hand surgery reference hospitals. Elbow flexion force was evaluated throughout the follow-up period (average 40 months) using the Medical Research Council muscle strength scale.

Results and Conclusions: The average age was 25 years among the predominantly male gender (92.8%), and motorcycle accidents constituted the principal (71.4%) cause of injury. The left side of the body was affected in 57.1% of cases, and denervation time varied between 4 and 14 months. Most patients presented the C5 stump intact, and this was the donor root in 14 cases. The priority outcome was elbow flexion, with ulnar nerve grafting being performed in the musculocutaneous (n=9), median (n=6), radial (n=4), axillary (n=1), posterior fascicle (radial and axillary) (n=3), and lateral fascicle (median and musculocutaneous) (n=2) nerves. Outcomes of reconstructive surgeries were considered very good (M4; n=6), good (M3; n=8), substandard (M2; n=5) and poor (M0/M1; n=6).

Non-vascularized nerve grafts can be indicated for the treatment of complete brachial paralysis. The procedure is technically easier than vascularized graft reconstructions, and does not require vascular microsurgery thus reducing the time of anesthesia and the need of microscope or magnifying glass.

THE USE OF RADIAL SENSITIVE NERVE GRAFT IN NEUROTIZATION OF MUSCULOCUTANEOUS NERVE FOR TREATMENT OF BRAQUIAL PLEXUS AVULSIONS

List of authors:
Paulo Randal Pires Júnior*, paulo randal pires¹, Marcella Rodrigues Costa¹, Gustavo Pacheco Martins Ferreira², Rodrigo José de Resende Santos²
¹Hospital Madre Teresa (BELO HORIZONTE)
²Hospital Maria Amélia Lins (BELO HORIZONTE)

Objectives / Interrogation: Brachial plexus trauma is increasingly prevalent, and restoring active elbow flexion is a treatment priority. The most effective techniques, in relation to the avulsion lesions, involve the neurotization for the biceps-brachial muscle, either with graft or nerve transfer.
This study presents a surgical technique that uses the radial sensitive nerve as a graft for the neurotizations of musculocutaneous nerve from accessory nerve in the treatment of avulsions of the brachial plexus to restore elbow flexion, and evaluates the results obtained with the technique.

Methods: A cohort study of patients with traumatic brachial plexus lesion submitted to this surgical technique and followed at a reference hospital from June / 2009 to August / 2017. Twenty-two patients were included, reassessed regularly for a period of 2 years after surgery. The elbow flexion strength was classified according to the Medical Research Council scale which ranks from 0 (no contraction) to 5 (normal motor force).

Results and Conclusions: The majority were male (94.4%) and the age ranged from 16 to 45 years. The most prevalent age group was 20 to 29 years. The majority of lesions (18 cases, 81.8%) were with total impairment. The mean time between the trauma and the surgical procedure was 195 days. The results were evaluated after 3, 6, 12 and 24 months. At the end of this study, it was observed that 54.5% of patients had M4 strength and 77.2% of good results with effective force M3 or higher.
Radial sensory nerve grafting allows the grafting of up to 25cm grafts, presents a convenient surgical approach and close to the donor site facilitating per operative technique. In addition, it does not generate sequelae and there is no postoperative functional loss, since the patient already presents the deficit previously in the total lesions of the plexus. The present study presents similar results to the literature: the review found success rates of 51.3% to 100% in neurotizations for the musculocutaneous nerve (force equal to or greater than M3).
The radial nerve graft technique showed several advantages in the surgical procedure, in addition to success rates similar to other grafts already reported in the literature, which favors this procedure.

Length changes of distal accessory band of Interosseous membrane during forearm rotation - a 3D CT study in vivo

List of authors:
Jun Tan*, Yucheng Sun¹, Jing Chen¹
¹ Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Interosseous membrane of the forearm plays very important role in forearm stability. The early studies described five ligamentous components in the interosseous membrane of the forearm (central band, accessory band, distal oblique bundle, proximal oblique cord, and dorsal oblique accessory cord) and classified them into 3 portions (distal, middle and proximal) according to their location. In the present study, we investigated in vivo length changes of ligaments from distal and middle portions (central band, distal accessory band and distal oblique bundle) during forearm rotation to understand the function of the ligaments.

Methods: Computed tomography of six adult forearms from six healthy volunteers was obtained at 5 forearm positions: maximum pronation, 45 degrees pronation, neutral position, 45 degrees supination and maximum supination. According to previous anatomic study we marked out the attachments of each ligaments on 3-dimensional models of the radius and ulna. The 3-dimensional ligament lengths' path between attachments during forearm rotation were measured and calculated based on computer modeling and simulation.

Results and Conclusions: The three portions of central band presented same fashion during the forearm rotation: the length increased significantly from maximum pronation to neutral position, but it stayed almost static from neutral position to supination. However, the distal accessory band and distal oblique bundle showed the same fashion, which was different from that of central band: the length increased significantly from maximum pronation to neutral position, but it decreased significantly from neutral position to supination. The distal accessory band has the length changes similar to those of the distal oblique bundle, which is very different from those of the central band. The findings suggest that distal accessory band functions in conjunction with the distal membranous portion of the interosseous membrane of the forearm.

Outcome of Stretching for Treatment of Trigger Finger in Patients on Hemodialysis

List of authors:
Nahoko Iwakura*, Yoshinori Nagata¹, Rita Sasaki¹, Yoshihito Takatsuki¹, Yasushi Terayama², Ken Okazaki¹
¹ Department of Orthopaedic Surgery, Tokyo Women's Medical University (Tokyo)
² Department of Orthopaedic Surgery, Hasuda Hospital (Saitama)

Objectives / Interrogation: Trigger finger is common in hemodialysis patients. The main treatments for trigger finger are steroid injections and surgery. This retrospective study aimed to evaluate the therapeutic effects of passive finger extension and active finger flexion exercise as conservative treatment in hemodialysis patients.

Methods: Between April 2011 and March 2017, 58 trigger fingers of 29 hemodialysis patients (10 men and 19 women) (HD group) were enrolled in this study. The mean age was 61.2 years and the mean follow-up duration was 10.9 months. All patients were instructed in the stretching method at the first visit, and the flexor tendon sheath was concurrently injected in some of the patients at their request. The modified Wolfe classification score was recorded, and compared between first and last visits. The number of injections, recurrence rate, and surgical rate were evaluated using medical records, and compared with those in non-hemodialysis patients with trigger finger (non-HD group) who were evaluated during the same period.

Results and Conclusions: There was significant improvement in the Wolfe classification score between the first and last visits. In the HD and non-HD groups, 22.4% and 43.2% did not receive injections, recurrence rates were 48.3% and 23.3%, and surgical rates were 24.1% and 4.8%, respectively. The non-injection rate was lower in the HD group. The recurrence and surgical rates were significantly higher in the HD group.

The number of hemodialysis patients has increased, and long-term dialysis patients are also increasing in Japan. Trigger finger in hemodialysis patients is reportedly prone to occur in multiple fingers, and is likely to recur. Our findings showed that the recurrence and surgical rates were significantly higher in the HD group than in the non-HD group. However, stretching is an easy and noninvasive treatment, and is worth trying before surgery.

RED BLOOD CELL TRANSFUSION AND ITS ASSOCIATION WITH FREE FLAP THROMBOSIS

List of authors:
Carlos Torres*, Lina Franco
1 Hospital de San José, Clínica la Carolina (Bogotá)
2 Hospital de San José, Clínica Santa Bárbara (Bogotá)

Objectives / Interrogation: to establish the relationship between the use of perioperative transfusions and the development of vascular pedicle thrombosis in free flap procedures

Methods: Retrospective cohort comparing the incidence of vascular pedicle thrombosis over the first 7 postoperative days (168 hours) considering the exposed group as patients who received blood transfusions in the 24 hours prior, during or 24 hours after surgery; versus the Unexposed group, patients who did not receive transfusions during that period of time. Kaplan Meier survival curves were developed and compared; the incidence rates were estimated and a proportional risk regression was done to adjust for confounding variables.

Results and Conclusions: Results: 157 free flaps in 135 patients were included. The incidence of vascular pedicle thrombosis was higher among patients transfused (30.2%) versus the non-transfused (15.8%). When adjusting for clinical confounding variables, the hazard ratio was calculated at 2.68 (95% CI: 1.09 to 6.59).

Conclusion: Perioperative red blood cells transfusion is associated with a higher risk of vascular pedicle thrombosis. Because no association was established between pre-surgical anemia and free flap survival, the decision to transfuse shall be based on the individual clinical condition of each particular patient, rather than on a range of hemoglobin or hematocrit.

Tendon Healing Strengths after Repair with Three Different Configurations in a Chicken Model

List of authors:
Youlang Zhou*, shuguo xing1, Qianqian Yang1
1 Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Objectives: To evaluate tendon healing strengths after different suture constructs in a chicken tendon repair model.

Methods: Materials and Methods: Sixty chicken flexor tendons were repaired with the following three repair configurations: a two-strand Kessler suture (group 1); a two-strand core suture with an additional circle loop repair (group 2) and a four-strand core suture repair with three separate stitches of peripheral suture (group 3). Biomechanical of flexor tendons was measured by a material testing machine. Twenty-six repaired tendons were tested to record healing strengths at week 4 and twenty-eight tendons were tested to record baseline repair strengths on day 0. The others were used to take photos for observation of suture constructs. We conducted power analysis and obtained a sufficient power of above 70% that proved the sample size to be adequate. Analysis of variance with Tukey post hoc test was used for comparison of the means of the data among the different repair methods groups.

Results and Conclusions: Results: At weeks 4, the ultimate strength of tendon in group 3 was 57.3 ±19.5 N, which was 10 times higher than that of the tendons in group 1 (5.7±1.1 N) (p<0.001). The strength of the tendons in group 2 (34.9±15.8 N) was only 60% that of the tendons in group 3 (p=0.024), which was nearly 6 times higher than that of group 1 (p=0.003). Baseline repair strengths of tendons was significantly different among three groups on day 0. Tendons in group 1 showed the lowest repair strength (5.5±0.9 N) and the tendons in group 2 were 8.4±1.4 N. Tendons in group 3 showed the highest repair strength (14.4±2.6 N) than two other groups (p<0.001). We found that the multi-strand repair techniques significantly increase the healing over the first four weeks after surgery with about 400% increase in the strengths (for both groups 2 and 3), but the strengths of the tendon with a two-strand repair (group 1) does not significantly change over the 4 weeks of tendon healing.

Conclusions: Multi-strand repair techniques enhance tendon healing strengths and significantly increase the healing after surgery, but a two-strand core repair does not significantly change the healing strength of the healing tendon. The increase of the strength by the multi-strand repair is more evident when a more stable repair configuration is used.

Comparison of healing strengths of flexor tendons repaired with two multi-strand configurations in a chicken model

List of authors: Qianqian Yang*, shuguo xing¹, Youlang Zhou¹
¹ Affiliated Hospital of Nantong University (Nantong)

Objectives / Interrogation: Objectives: To investigate the tendon healing strengths between two multi-strand configurations in a chicken model.

Methods: Materials and Methods: Fifty-six chicken flexor tendons were repaired with two four-strand configurations: a four-strand repair consisting of a two-strand core Kessler suture with an additional circle loop repair (group 1) and a four-strand core Kessler suture repair with three separate stitches of peripheral suture (group 2). The healing strengths of the repaired tendons were measured at weeks 2, 3 and 4 after repair and were analyzed statistically. The data was analyzed with two-way analysis of variance. Tukey test was used for comparison of the means of the data between the different repair methods groups at the same time-points and between different two points. We set the level of significance at p<0.05.

Results and Conclusions: Results: At weeks 2, tendons in two groups showed the similar mean ultimate strengths (6.5±1.6 N in group 1 and 7.0±2.3 N in group 2). At weeks 3, the ultimate strength of tendons in group 2 (17.1±4.9 N) was statistically different from that in group 1 (12.2±3.1 N) (p=0.033). At weeks 4, the healing strengths of tendons in group 2 (64.3±19.6 N) was significantly higher than that in group 1 (40.7±24.7 N) (p=0.039). In group 1, the means healing strengths of the tendons increased from 6.5 N at weeks 2 to 12.2 N at weeks 3 and to 40.7 N at weeks 4; the percent increase was 86% from weeks 2 to 3 and 234% from weeks 3 to 4, respectively. In group 2, the percent increases in the strengths were much greater (144% increase from weeks 2 to 3, and 276% from weeks 3 to 4).

Conclusions: The four strength repairs with three separate stitches of peripheral suture produce greater healing strengths of the repaired tendon than that of a repair of two-strand repair with one circle loop suture.

Medium to long term outcomes of pyrocarbon total PIP joint arthroplasty

List of authors:
Mark Ross*, Mathias Häfeli1, Ruby Strauss1, Greg Couzens1, David Gilpin1, J Alexa Potter1
1 Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: Pyrocarbon total arthroplasty is an established treatment option for arthritis of the proximal interphalangeal joint (PIPJ). We hypothesized that despite the varied results published in literature, pyrocarbon for total PIPJ arthroplasty can produce reliable and effective outcomes.

Methods: 101 total PIPJ arthroplasties have been performed in 75 patients since 2002. Prior to surgery, 14 patients completed baseline questionnaires and 52 had their range of motion measured. These were compared to 44 joints assessed at 5 years or later after surgery. 31 joints were assessed between 5 - 9 years and 19 joints at equal or greater than 10 years (6 joints were seen at both time points). Assessments included QuickDASH and PRWHE questionnaires and measures of range of motion, grip and pinch strength. Non-parametric Wilcoxon rank sum test for independent samples was used for analysis.

Results and Conclusions: Visual Analogue Scale pain decreased from a median of 68 at pre-operative assessment to 1 at equal or greater than 10 years (p=0.0001), while satisfaction increased from 7 to 98 at the same intervals (p=0.03). QuickDASH and PRWHE scores improved from 46.6 and 71 respectively at pre-op assessment to 29.5 and 18.5 at equal or greater than 10 years after the surgery (QuickDASH not significant, PRWHE p=0.002). Global Rating of Change showed a median of +6 for symptoms and +5 for function. Range of motion increased from baseline to 5 - 9 years (flexion 70° compared to 50° before surgery, p=0.004). There is a slight reduction in flexion and an improvement in extension (decrease in fixed flexion) at 10 years (flexion 60° compared to 50° before surgery, not significant). Grip strength was maintained after arthroplasty (not significant). Eight joints are known to have undergone revision surgery: 5 revisions to other arthroplasty (4 silicone, 1 pyrocarbon total due to secondary trauma), 2 revised to joint fusion (one a result of secondary trauma at 7 years post index surgery), and one with details unknown. An additional six have undergone secondary surgery without revision for tenolysis/release.

This is a large case series with 19 patients followed up for 10 years or longer. Results compare favourably with published series in clinical and functional outcome measures. Joint revision rate is low and reoperation rates comparable to other studies. Pyrocarbon for total PIP joint arthroplasty can produce reliable and effective outcomes.

Results of dorsal and volar reconstruction of scapholunate ligament with FCR tendon

List of authors:
Christian Kindler*, Bernhard Lukas
1 Schoen Klinik München-Harlaching (München)

Objectives / Interrogation: The technique for scapholunate ligament (SLL) reconstruction described by Corella yields reliable and satisfactory results in patients with static or dynamic scapholunate dissociation.

Methods: Seven patients underwent dorsal and palmar reconstruction of the SLL with part of the FCR tendon using the Corella technique. We modified the original technique by reducing the arthroscopic to a mini-arthrotomy technique in order to minimize surgery time. The main goal was to avoid injury to the carpal extrinsic ligaments and the posterior interosseus nerve. So far we report on our first 7 patients with a minimum follow up of 8 months, at least 3 more patients will follow until time of presentation. Clinical and radiological outcomes were measured pre- and postoperative in a prospective manner.

Results and Conclusions: Patients were between 24 and 68 years of age at surgery; all were male. The operative hand was dominant in 57%. There was an average 5,5 months from the time of injury to surgery (range, 2 - 30 mo). A total of 86% had a static deformity.

Results of the Quick DASH showed an average of 7,7 (SD 4,7) postoperative. Grip strength (Jamar dynamometer) showed postoperative 42,0 kp (SD 9,9 kp) at the operated side versus 53,6 kp (SD 10,9) at non-operated side. Pain in rest (0-100, visual analog scale) improved from 0,8 (SD 1,2) preoperative to 0,7 (SD 1,5) postoperative, Pain in activity improved from 6,8 (SD 1,8) to 2,8 (SD 2,5).

Flexion-extension total arc of movement reduced from 109 degrees to 107 degrees (SD 12,0).

On x-ray, the SL interval improved from 5,6 mm (SD 1,5 mm) to 5,0 mm (SD 2,0 mm). The SL angle improved from 74 degrees (SD 5,7) to 70 (SD 8,6).

6 out of 7 patients would do the surgery again, 5 resulted in pain reduction, 6 were satisfied with the result, all 7 got back in their original occupation.

In our cohort this technique results in a satisfactory pain relief. The other clinical parameters were not statistically significant. On x-ray only in 3 of 7 patients we could improve the SL intervall (reduction of > 1mm) or the SL angle (reduction > 5 °) although all had obvious reduced SL intervall and angle intraoperative. In more than 50% the tendon reconstrucction seems to fail over time. Possibly and we think most likely the FCR tendon does not heal within the carpal trabecular bone but at the cortical bone which is exposed only limited by this technique.

UPPER LIMB SURGERY FOR NON-COMMUNICATIVE PATIENTS WITH SEVERE SPASTICITY: THE ROLE OF THE CARER BURDEN SCORE

List of authors:
Claudia Gschwind*, Jayne Yeomans
1 Royal North Shore Hospital, Department of Hand Surgery & Peripheral Nerve Surgery (St Leonards)
2 Royal North Shore Hospital, Department of Physiotherapy (St Leonards)

Objectives / Interrogation: Severe upper limb spasticity (ULS) can lead to difficulties with personal care and hygiene. Washing, dressing, trimming nails can be painful, poorly tolerated and in cases of severe contracture nearly impossible.

Despite the high incidence of acquired brain injuries and subsequent ULS in developed countries, there are only a few papers demonstrating the benefits of upper limb surgery with regards to improved ease of care postoperatively in patients who are unable to communicate. The Carer Burden Score (CBS) has been used to document improved ease of care in patients with ULS after Botulinum Toxin injections into target muscles. We applied the CBS to our patients preoperatively and again once treatment was finalized to document improvement in ease of care.

Methods: The patient's main carer was asked to fill in the CBS preoperatively and once treatment was finalized. The CBS grades for activities - cleaning the axilla, dressing the patient, cleaning the palm and cutting the fingernails - according to the degree of difficulty encountered from 0 to 4.

The most common procedures performed were wrist fusion, superficialis to profundus transfer, and neurotomies of the deep branch of the ulnar nerve and motor branch of the median nerve. In many cases the intrinsic muscles had to be released.

We assessed 49 limbs with the CBS pre-operatively and after 3 months.

Results and Conclusions: In all cases we found a significant drop in the CBS, supporting our statements of improved ease of case post spasticity surgery.

Ease of care for patients with ULS can be improved by Botulinum Toxin injections, as shown by several studies. However, the effect of Botulinum Toxin lasts for about 3 months only. Surgery brings a more lasting effect in ease of care which should translate into long term reduction of health costs.

Peripheral nerve torsion

List of authors:
Jong woo Kang¹, Hyun jae Sung², Jung heum Baek¹, Jong woong Park²
¹ Korea university, Ansan hospital (Ansan)
² Korea university, Anam hospital (Seoul)

Objectives / Interrogation: Nerve torsion is a rare cause of peripheral nerve palsy and their etiologies are not well known. They are sometimes misdiagnosed as compressive neuropathies and the treatment and clinical results are different with compressive neuropathies. The purposes of this study are to describe the clinical differences between peripheral nerve torsion and common compressive neuropathy and to present the stages and possible pathomechanism for peripheral nerve torsion with three cases of peripheral nerve torsion which had the different degree and symptoms severity of nerve torsion each other.

Methods: We described the history, neurological symptom and physical examinations, findings of ultrasonographic images and electrodiagnostic studies, and the surgical appearances and degree of the torsion with three cases of peripheral nerve torsion. Also, the possible pathomechanism of nerve torsion was presented and the final clinical results were evaluated with the neurological physical examination, ultrasonographic images, and electrodiagnostic studies.

Results and Conclusions: One patient had radial nerve torsion and the others had median nerve torsion in the upper arm. At first, two of them were misdiagnosed as posterior interosseous nerve syndrome or anterior interosseous nerve syndrome though the lesions existed in the upper arm. All patients needed surgical treatment. The three patients had the different degree of nerve torsion each other. Also, all the nerve had the restriction of nerve gilding due to nerve adhesion and had its branch around nerve torsion site, which pulls the main nerve. It suggested important clues about the pathomechanism of peripheral nerve torsion. The symptoms were gotten better in two patients though it was not changed in one patient after surgery. Accurate localization and diagnosis with electrodiagnosis and ultrasonography are very important for the treatment of peripheral nerve torsion.

Objectives / Interrogation: To measure and analyze the tactile sensation of human hand, several devices have been introduced. Von Frey filament test is a mainstay in clinical setting, however, the results can be affected by variable factors such as touch speed. Moreover, the differences between two adjacent grades of filaments are too large to detect fine change. We developed a new tools for evaluation of tactile sense (active Von Frey filament test; AvF), and hypothesized that AvF show different pattern of measured values.

Methods: The AvF was developed to provide an accurate force for human skin sensation. The touching force of the AvF started at 1mgf much lower than 1st grade (8mgf) vF. D’Arsonval movement is chosen as an actuator. After acquiring IRB approval, 32 normal subjects were examined. In the autonomous zone of the median and the ulnar nerve, i.e., index and 5th finger volar tip were examined using AvF and vF without vision. Each measured value was collected and the correlation between AvF and vF was evaluated.

Results and Conclusions: Mean value of AvF was significantly higher than that of vF (111.3±46.9 vs 24.1±9.8) (p<0.01) with larger variance. Spearman correlation coefficient between AvF and vF was 0.341.

AvF can provide more precise values with continuous units for tactile sensation. Values of AvF and that of vF might be not that correlated.

Ideal cup position in trapeziometacarpal joint arthroplasty: a biomechanical cadaver study

List of authors:
Annelien Brauns*, Pieter Caekebeke¹, Joris Duerinckx¹
¹ZOL Genk (Genk)

Objectives / Interrogation: It has been suggested that in trapeziometacarpal total joint arthroplasty, the trapezial cup should be positioned parallel to the proximal articular surface of the trapezium (PAST). This suggestion was based on radiographic measurement of the range of motion of healthy joints. The goal of this study was to biomechanically test this statement.

Methods: 7 fresh frozen cadaver hands were mounted in a test jig and the different thumb musculotendinous units were loaded. An Arpe metacarpal stem was implanted and combined with 3D-printed trapezium cups. These cups were available in 17 different inclinations relative to the PAST (neutral and 10°, 20°, 30° or 40° of palmar, dorsal, lateral or medial inclination). For every cup inclination, stability of the prosthesis was assessed through its entire passive range of motion (flexion, extension, abduction, adduction, retropulsion and opposition). Outcome was dislocation or not. All these measurements were performed with both 15° offset and straight necks. Logistic regression was used to determine the odds ratio for dislocation and its significance for the different oblique cup inclinations compared with neutral cup placement.

Results and Conclusions: With the cup in neutral position relative to the PAST, no dislocations were observed in any direction of thumb motion. In flexion, a significantly higher dislocation rate was observed when an offset neck was combined with the cup in 30° or more of dorsal inclination. Using a straight neck increased the risk of dislocation, starting at 10° of dorsal cup inclination. In opposition, the number of dislocations was significantly higher when a straight neck was combined with the cup in 10° or more of dorsal inclination, an offset neck with the cup in 20° or more of dorsal inclination, or both stem types with the cup in 30° or more of medial inclination. In adduction and retropulsion the prosthetic joint dislocated with the cup in 30° or more of lateral inclination. Cup inclination is an important factor in prosthetic joint stability. Ideally the cup should be placed parallel to the PAST. Flexion and opposition are the motions that are most prone for dislocation. We recommend the use of an offset neck and to avoid placement of the cup in dorsal inclination relative to the PAST.

Intraosseous tension-band wiring for displaced Bennett's fracture

List of authors:
Daniele De Spirito
1 Ospedale Regionale di Lugano (Lugano)

Objectives / Interrogation: Bennett's fractures still represent a challenge in hand surgery because of the articular involvement, the difficult management of the small fragment and the stability of fixation. Several fixation techniques have been described, such as percutaneous pinning, k-wires, screws, external fixation and arthroscopically assisted fixation. Tension-band wiring has also been described as a reliable technique and it's employable even in presence of a very small fragment. We propose a refinement of the already described tension-band wiring technique in order to preserve all its advantages but with less invasiveness and allowing an easier removal of the device.

Methods: By means of a standard Wagner J-shaped incision at the base of the first metacarpal, the fracture is exposed and reduction is obtained with direct visualization of the articular surface. A k-wire 1.2mm is inserted from the dorsal aspect of the metacarpal base through the fragment until the exposure of 2-3mm of its tip at the volar side. A second k-wire is then used to perforate the metacarpal, parallel but just 5mm distal to the first k-wire. A 0.4mm metal cerclage loop is then passed through the second hole and anchored to the tip of the first k-wire. Dorsally the two tails of the cerclage are then twisted and secured around the tail of the k-wire, previously bent and cut, applying the desired compression. A removable splint is applied in the immediate post-op time and assisted rehabilitation starts within a week. We have treated three cases with this technique so far and in just one case the device has been removed ten months after fixation. The removal took just five minutes under local anesthesia by means of a small dorsal incision, removing the k-wire first and then extracting the metal cerclage with no need to cut it.

Results and Conclusions: All the fractures achieved the radiological consolidation within 6 weeks and the full range of motion was recovered within 3 months in all cases. The satisfaction of the patients was high and there were no complications even at the time of second surgery.
In conclusion, tension-band wiring for treatment of Bennett's fractures gives several advantages comparing to other devices such as a stable fixation even with very small fragments, a strong compression at the site of fracture and a low cost. Furthermore, our intraosseous refinement of the technique allows the removal of metal devices very easily in a safe and minimally invasive way.

Morphologic characteristic of the first web space in congenital thumb duplication in infants

List of authors:
Liying Sun*, Wen Tian¹, Yang Guo¹, Yong Yang¹, Shanlin Chen¹, Wenyao Zhong¹
¹ Beijing Jishuitan Hospital (Beijing)

Objectives / Interrogation: To analyze the morphologic characteristic of the first web space in thumb duplication in infants (1.5-3 years old) and to assess reliability of three palmar thumb abduction measurement methods about the first web space.

Methods: 130 patients (110 duplication thumbs and 20 tenosynovitis with one side) were involved in between February in 2016 to June in 2018. 18 months to 3 years old, average age was 23.1 ± 6.1 months. According to Wassel classification, we classified the 110 thumbs in type I (2), type II (18), type III (7), type IV (48), type V (6), type VI (12), type VII (17). One observer used the special vernier caliper and goniometer to measure the first web space distance in Cambridge-Keeling method, the intermetacarpal distance (IMD) and intermetacarpal angle (DIMA) between the first and second metacarpal in 130 patients to acquire the both sides data. The other one observer measured 50 normal sides (including 20 patients in tenosynovitis and 30 cases in duplication thumbs) independently to determine the intraobserver reliability. Compared the difference between thumb duplication and the normal side using paired t test.

Results and Conclusions: There were 38 thumbs in total in Wassel type I, II, III and type IV without the first metacarpal upright ulnar deviation. The first web space distance, IMD and DIMA were 2.59 ± 0.46 cm and 2.47 ± 0.39 cm, 3.47 ± 0.45 cm and 3.39 ± 0.37 cm, 41.84 ± 3.22° and 41.81 ± 3.39° between normal and unnormal sides, without statistically significant difference (the distance: t=3.372, p=0.451, IMD: t=1.529, p=0.144, DIMA: t=0.224, p=0.826). There were 72 thumbs in Wassel type IV with the first metacarpal head ulnar deviated and Wassel type V, VI, VII totally. The first web space distance, IMD and DIMA were 2.68 ± 0.33 cm and 2.19 ± 0.47 cm, 3.47 ± 0.36 cm and 3.02 ± 0.53 cm, 42.32 ± 3.87° and 35.35 ± 6.73° between normal and impaired side, with statistically significant difference (the distance: t=5.257, p=0.000, IMD: t=4.585, p=0.000, DIMA: t=7.730, p=0.000). The mean values of the first web space distance in 130 normal thumbs was 2.62 ± 0.33 cm. The IMD and DIMA were 3.48 ± 0.31 cm and 43.43 ± 3.43°. The intraclass correlation coefficient (ICC) values for intraobserver reliability about the first web space distance, IMD and DIMA were 0.74, 0.80 and 0.71, respectively. The first web space narrowing in thumb duplication was mainly in Wassel type IV with the first metacarpal ulnar deviation and Wassel type V, VI, VII. ICC of the first web space distance, IMD and DIMA indicated substantial reliability to assess the first web space in little children.

Outcome of 32 pollicisations for thumb hypoplasia or aplasia during the period 1987-2016

List of authors:
Ida Neergård Sletten¹, Magne Røkkum¹, Inger Helen Bolstad¹, Anne Birgit Stavenes³, Mona Irene Winge¹
¹ Division of Orthopaedic Surgery, Oslo University Hospital (Oslo)

Objectives / Interrogation: Pollicisation of the index for thumb hypoplasia or aplasia is performed to create pinch and cylinder grip. The objective was to investigate the clinical outcome in our institution.

Methods: Twenty-five consecutive patients (32 thumbs) had their anomaly classified using OMT, modified Bayne and modified Blauth criteria. Associated anomalies, operative technique, complications, and additional surgeries were recorded. Reach Out©, QuickDASH©, EQ-5D©, and visual analogue scales (VAS) on thumb function and appearance quantified upper extremity function and life quality. Thumb ROM, Kapandji score, sensibility, grip and pinch strength, and results of four functional tests were recorded.

Results and Conclusions: Age at time of operation was median 26(12-101) months. 3/25 patients had unilateral CULA as their only malformation. 16/25 had bilateral CULA, and 13/25 had a syndrome. 14/25 underwent additional upper limb surgery. For 11/32 thumbs, there was abnormal axis formation of the entire ipsilateral upper limb. Modified Buck-Gramcko technique was used in 31/32 pollicisations. There was one iatrogenic vein laceration repaired micro-surgically, and one postoperative thumb malrotation, which required a later osteotomy. Further 5/31 cases had additional thumb surgeries. Twenty-three patients/30 thumbs came for follow-up (94%), aged median 12(2-33) years. Patients >8 years reported median VAS 78(5-100) on thumb function, and median VAS 72(14-100) on thumb appearance. Adult patients reported inclusion of their thumb in pinch grip median 92(10-100)% of the time, and in cylinder grip median 97(3-100)% of the time. Reach Out was median 17(1-37), QuickDASH was median 7(5-39), EQ-5D-3L index was median 1.00(0.62-1.00), and EQ VAS was median 90(50-100). Active arc motion was median 38(0-70)° in the IPJ, and median 50(0-105)° in the MCPJ. 24/30 thumbs could palmarly be abducted to the tip of the 3rd finger. 15/30 thumbs had a Kapandji score of 6 or higher. Grip strength was median 25(3-65)% of reference values, and pinch strength was median 30(0-79)% of reference values. All thumb pulps had intact 2-3 mm two-point discrimination. For 26/30 thumbs, picking up a pearl, a dice and a table tennis ball was easy. The sticker test was easy in 18/30 cases.

Conclusion: Most patients were satisfied with their result. Abnormal anatomy was found in the pollicised indices of the four patients who failed all four functional tests (immobile joints due to severe RLD modified Bayne type 4, or absent flexor tendons).

Case report of a complex fracture (C3-3 distal radius - Gustilo Type II - Type 3 DRUJ) associated with a B2 scaphoid fracture at the dominant arm and resorption bone edema with scaphoid fracture at the contralateral wrist.

List of authors:
Emanuele Gerace*, Pier Luigi Bonucci, Marcello Marcialis, Emmanuelle Richard, Guido Cristiani
1 Università di Ferrara, Orthopaedic Clinic (ferrara)
2 Hesperia Hospital, Hand Surgery unit (Modena)
3 Department of Orthopedics and Traumatology center of Nimes (Nimes)

Objectives / Interrogation: High energy impact injuries of the wrist entail complex fracture patterns of the wrist and ligaments injuries, depending on the dynamic and the position of the hand at the time of the trauma. The lesions are often bilateral and occur in male patients with high functional demand.

We report a case of a 51 years old male with bilateral wrist lesions that occurred in a car accident. Right dominant wrist: plurifragmentary dislocated radius fracture with lesion of the sigmoid cavity (AO C3-3; Gustilo type 2; Fernandez type 3), multifragmentary distal ulna fracture with DRUJ lesion associated with bone and soft tissue loss (DRUJ Fernandez type 3), and scaphoid fracture (Herbert and Fisher B2).

Left wrist: it was investigated with x rays with no sign of fracture. After 10 weeks he underwent a magnetic resonance that showed a dislocated scaphoid fracture with bone edema and bone resorption.

Methods: At first the patient was treated in another hospital. He underwent a damage control stabilization of the fractures with external fixator and dermal substitute in the area of the exposition. 3 weeks after the trauma he came at our attention showing no sign of infection. We removed the external fixator and we fixated the fracture with volar plate and screws, filled the bone defect with a graft, we removed the dermal substitute and we covered it with autologous dermal grafting. The scaphoid fracture was stabilized with a staple and percutaneous k-wire.

The left wrist was stabilized with a staple and bone grafting (omolateral olecranon).

He executed biophysical stimulation for two months after surgery in both wrists.

Wounds were medicated periodically. Clinical and radiological follow up was completed every month.

Results and Conclusions: At 2 months follow up the fractures showed signs of consolidation and wounds healed. At 3 months the patient returned to work. 1 year after, right wrist AROM was 50° of flexion, 55° of extension, 10° of radial deviation and 5° of ulnar deviation. Left wrist AROM was 80° of flexion, 70° of extension, 10° of radial deviation, 30° of ulnar deviation. We did not notice any complication.

The fixation method we choiced for this case provided high compression in the area of the bone graft. Early mobilization avoided stiffness and the onset of algodistrophy. Biophysical stimulation aided bone graft integration and fracture healing.

This is a rare bilateral complex lesion. Early treatment and absolute stability of the fracture assured a good clinical and functional outcome.

Plate fixation for unstable displaced distal radius fractures in children

List of authors:
Caroline Selles*, Jeroen Egmond\(^1\), Berry Cleffken\(^3\), Gert Roukema\(^3\), Cornelis van der Vlies\(^1\), Niels Schep\(^3\)
\(^{1}\) Maasstad Hospital (Rotterdam)

Objectives / Interrogation: Fractures of the wrist account for 25-36% of all pediatric fractures. Although pediatric fractures have remodeling potential, unstable fractures and fractures with a rotational deformity require reduction and fixation. More invasive volar plate fixation is less popular in pediatric patients. However, volar plate fixation enhances anatomic reduction and allows for functional postoperative treatment. This may lead to less redislocations, malunions, and improved functional outcome. To the best of our knowledge, only one case study is available which describes volar plate fixation for a displaced distal radius fracture in a 13-year-old child.
The purpose of this study was to present the functional outcomes of pediatric patients treated with volar plate fixation for unstable displaced distal radius fractures.

Methods: In this retrospective observational cohort all pediatric patients surgically treated for unstable distal radius fractures between September 2010 and July 201 were reviewed. Patients aged between 4 and 17 years treated with volar plate fixation were included. The primary outcome was the Patient Rated Wrist Evaluation (PRWE) after at least 12 months follow-up. Secondary outcomes were range of motion and grip strength compared to the uninjured wrist, postoperative radiological parameters, complication and incidence of plate removal.

Results and Conclusions: A total of 26 patients with a median age of 12.5 years were included. Median PRWE was 3 after a median follow-up of 29 months. range of motion and grip strength did not differ significantly between the injured and uninjured wrist. In two patients stiffness was reported as a complication, which was successfully treated with physical therapy. No wound infections were found. Plate removal was performed in 15 patients.
Volar plate fixation for unstable displaced distal radius fractures in children provides excellent functional outcomes.

distal radius fracture, pediatrics, volar plate fixation, functional outcome
The Mangled Hand and Forearm - Algorithm for Treatment

List of authors:
Lyudmil Simeonov*
1 University Hospital for Emergency Medicine (Sofia)

Objectives / Interrogation: Mangling injuries of the upper extremity usually provoke significant disability of hand function and have a lasting psychological impact on the patient. In the absence of a structured approach to the treatment of these injuries, the surgeon can easily get lost in the chaos of mangled tissues. In this presentation an algorithm for the diagnosis and treatment of the mangled hand and forearm will be presented.

Methods: Eighteen patients with 19 mangled hands and forearms were operated and followed for an average period of 8 years. Demographic information including; age, sex, etiology and mechanism of injury, diagnostic and surgical procedures was recorded. The hand cases were classified and evaluated using Del Pinal’s classification. The diagnostic algorithm contains two main points; assessment of the vitality and functional capacity of the available tissues and the judgment of which structures should be saved and which should be sacrificed in order to maximize final hand function. The therapeutic strategy contains two stages: Acute and Reconstruction. The main therapeutic principles are: 1) saving the life, and 2) saving the most important functions of the hand. The treatment is characterized by multiple operations until an acceptable level of hand function is achieved.

Results and Conclusions: Eight out of 11 operated hands were restored to an acceptable function. Acceptable function, according to Del Pinal’s definition is a hand with an opposition-capable thumb and two or 3 movable digits. Five cases were originally classified as “crippled hand” and after reconstruction were evaluated as “acceptable”. Three of the injured hands were originally classified as “mutilated hand”. After treatment they were defined as “acceptable”. In 3 cases there was no change in the functional level. Sixteen patients did not achieve full range of motion in the hand. Eight of hands did not recover full sensation, and 3 of them had incomplete motor recovery. Two out of 6 replanted fingers necrotized and were removed.

Conclusion: Management of the mangled hand and forearm requires a completely different treatment approach than that of simple hand injuries. In order to achieve the best possible results, the lead surgeon must be capable to evaluating and prioritizing treatment options. The proposed algorithm gives a systematic approach on how to create a realistic plan for restoring integrity and function after these devastating injuries.

Fingertip reconstruction with V-Y advance flaps combined with bone and nail bed grafts after amputation

List of authors:
Yongjun Rui*
1 Wuxi Ninth People's Hospital (Wuxi City)

Objectives / Interrogation: Fingertip amputation is a common hand injury, especially in industrial areas. The ideal treatment is fingertip replantation. However, if the fingertip blood vessels are slender or the damages are severe, replantation makes no sense. This study aimed to provide an objective method of treating fingertip amputations with no indication for replantation is to reestablish functional and esthetic properties.

Methods: During March 2010 and October 2014, 15 patients underwent the treatment of V-Y advanced flaps combined with bone and nail bed grafts to fingertip reconstruction. Patients' age ranged from 18 to 69 years (mean 35.3 years). All patients underwent emergency surgery, with a time delay after injury of 4-12h (mean 7.1 h). In each case, the amputation was a crush or avulsion injury, making microsurgical replantation not feasible. The defects were located in the nail root in 11 cases and in the middle of nail in 4 cases, the area ranging 1.4 cm × 0.5 cm-1.4cm × 1.1cm in size.

Results and Conclusions: All the flaps and nails survived, and the incisions healed at I stage. The average follow-up time was 12mouths (6-28 mouths). The patients all satisfied with the appearance and the function of the reconstructed fingertip, average subjective satisfaction score was 8.87. The bone graft healed at 6-8 weeks. The mean two-point discrimination was 5-6 mm. The nails graft growth were all flat, no nails, but some slightly smaller than normal. All patients returned to their jobs. This study shows that V-Y advanced flap combined with bone and nail bed grafts to reconstruct fingertip with no replanted conditions could make the length of the finger and the shape of the nail preserved, and operation simple, which is a valuable new surgical method.

fingertip reconstruction,V-Y advance flaps,amputation
Mini-operative treatment of tennis elbow using bipolar radio-frequency

List of authors:
Dawid Mrozik*, Agnieszka Jackiewicz¹
¹HANDPROJECT Clinic, SWISSMED Private Hospital (Gdansk)

Objectives / Interrogation: Lateral epicondylitis or tennis elbow is a noninflammatory, degenerative condition of the origin of the ECRB or EDC, associated with overuse and characterized by: absence of inflammatory cells, profusion of disorganized collagen and fibroblastic hypertrophy, nutritional flow is compromised, making it difficult for tenocytes to synthesize the extracellular matrix necessary for repair and remodelling. A principal aim in treatment of tendinosis is to establish a biologic healing response. The purpose of this study was to evaluate the long-term results, safety and effectiveness of using RF-based microtenotomy to treat tennis elbow.

Methods: It was prospective, nonrandomized, two-center clinical study. Into the study were involved 49 patients (28 men and 21 women) with symptomatic epicondylitis lateralis (tennis elbow) for at least 6 months and had failed conservative treatment. The average age of patients was 44,9 years (range: 26-57). Dominant limb was involved in 89% of the patients. As operative method we used bipolar microtenotomy of extensor carpi radialis brevis and/or common extensor tendon using TOPAZ Microdebrider device (ArthroCare, EU). Before operation was done VAS, DASH and clinical examination. Postoperative clinical assessment: 2 and 14 day. Follow-up: 12 and 24 months after operation: VAS, DASH, USG, clinical examination. USG: LOGIQ e GE Healthcare device with a 7,7-15Mhz linear transducer.

Results and Conclusions: The dominant arm was involved in 89% with unilateral involvement. There were no perioperative or postoperative complications related to the procedure. The mean VAS decreased from 8,8 before operation to 2,6 (p=0,001). Postoperative DASH value was 21,6. There were found ultrasonography abnormalities 24 months after operation:
- focal hypoechoic area: 36 patients (74%)
- focal anechoic area: 16 patients (33%)
- cortical irregularity of the lateral epicondyle: 34 patients (70%)
- tendon thickening: 13 patients (27%)
- intratendinous calcifications: 11 patients (22%)
- increased vascularity: 9 patients (18%)

1. RF-based microtenotomy appears to be a safe and effective method for treating patients with chronic tendinosis.
2. Microtenotomy is a technically simple procedure to perform and is associated with a rapid and uncomplicated recovery. Pain relief was achieved rapidly in all patients and diminished even further with time.
3. Ultrasonography is a widely and inexpensive imaging study for assessing tendons providing useful information on the severity and stage of tendon pathology.

Modified Brunelli technique for flexor tendons repair in zone II

List of authors:
Alexandru Valentin Georgescu*, ileana ileana matei¹, irina irina capota², Octavian Olariu²
¹ University of Medicine Iuliu Hatieganu Cluj Napoca, Clinical Hospital of Recovery (Cluj Napoca)
² Clinical Hospital of Recovery (Cluj Napoca)

Objectives / Interrogation: The repair of flexor tendon lesions in Zone II remains one of the most challenging problems in hand surgery. The functional outcome depends to both a very accurate surgery and a very intensive hand therapy. We will present our experience by using a modified Brunelli technique, which moves the tension from the suture site distally, what allows the very early beginning of hand therapy and improve the quality of functional results.

Methods: Our method consists in using a two-strand suture repair by passing a 2/0 stitch through the tendon from its insertion to the proximal stump, and then back to the fingertip were is knotted in a tie-over fashion. A running 4/0 suture at the disruption level completes the procedure. This procedure allows the beginning of passive movements in the first postoperative day, the active movements in the second day, and movements against resistance after 3-4 days. We used this procedure in 156 patients, 115 men and 67 female aged between 6 and 75 years. One flexor tendon was disrupted in 139 patients, two in 11, three in 3, and four in three. Both the profundus and sublimis tendons were interested in 101 patients. Digital nerves disruption was found in 113 patients, and a skin defect in 23 patients.

Results and Conclusions: The average follow-up was 14 months. All patients continued to have the same social life and were able to work in the same place. No problem on the finger pulp related to the tie-over suture was recorded. We had only one rupture. According with the scoring system proposed by Strickland, our results can be judged as excellent in all the cases (regain of 75-100% of normal active movement). According with the scoring system proposed by Lister, the results can be judged as good (regain of flexion to within less than 3cm of the distal palmar crease) in 30% of cases, and as very good (regain of flexion to within 1cm of the distal palmar crease and an extension deficit less than 15 degrees) in 70% of cases. Moving the tension from the repair site to the finger pulp allows the very early beginning of the active mobilization against resistance. This contributes to a very good modeling of the tendon, minimal adhesion formation, and avoids the joints stiffness and the extension deficit of the interphalangeal joints.

Wide-awake local anesthesia no tourniquet (WALANT) proximal row carpectomy

List of authors:
Camillo Theo MULLER¹, Olivier DEBOCCARD², Wassim Raffoul²
¹ CHUV, centre de la main (Lausanne)
² CHUV (Lausanne)

Objectives / Interrogation: Wide-awake local anesthesia using no tourniquet (WALANT) hand surgery is a still gaining popularity. WALANT has been used by hand surgeons when operating on skin, nerve entrapments, tendons and bones. The limits of hand surgery under local anesthesia are permanently being pushed further.

We report a proximal row resection performed under local anesthesia in WALANT: The 57 years old patient underwent multiple surgery for "trapeziometacarpal arthrosis". Due to the persistent, pain her general practitioner organized a consultation in our tertiary center. During clinical evaluation, she indicated the center of the wrist as "source of pain". Flexion and extension of the wrist was very painful. The power grip was 11 kg at the examined hand versus 28 kg on the contralateral hand. The radiographs show a lunocapitate joint arthritis. The patient is not willing to undergo four-corner fusion or wrist arthrodesis therefore we propose a proximal row carpectomy in WALANT.

Methods: We injected 8 ml Lidocain 2% with ephedrin and 10% natrium bicarbonats around the wrist and 2 ml intra-articulair.

After transvers skinincision and a radial based capsular flap we extirpated bones radial and ulnar to the common digital extensor with help of a burr.

Results and Conclusions: Perioperative painscore was VAS 0.

We offer technical insights on how to perform this procedure as well as the main advantages, which are associated with using WALANT proximal row carpectomy.

Functional outcome of distal interphalangeal joint arthrodesis

List of authors:
Jinchul Oh*, Ho-Jung Kang¹, Yun-rak Choi², Il-hyun Koh³, Won-taek Oh², JungJun Hong¹
¹ Gangnam Severance Hospital (Seoul)
² Severance Hospital (Seoul)
³ Yong-In Severance Hospital (Yong-In)

Objectives / Interrogation: Distal interphalangeal joint (DIPJ) arthrodesis can be used to treat pain, deformity, or instability associated with arthritis of DIPJ. It is not common procedure, but effective for creating a painless stable joint. The purpose of this study was to analyze DIPJ pathologies, clinical and functional outcomes of DIPJ arthrodesis with K-wires.

Methods: From April 2010 to December 2017, we retrospectively analyzed 10 patients who underwent DIPJ arthrodesis. Among them, 5 cases were treated for degenerative arthritis, 2 cases for traumatic arthritis, 2 cases for infection and 1 case for congenital synostosis. The mean follow-up period was 14.5 months, with an average age of 57.4 years. Four of the cases were in the fifth finger, 4 cases in the third and 3 cases in the second finger. Arthrodesis was done with K-wires except 1 case with cannulated headless screw. Plain radiographs were used to assess radiological results. Clinical and functional results were assessed by VAS score, DASH score, fusion angle, pulp and side pinch power, and grip strength.

Results and Conclusions: Radiologically, joint congruency was maintained in all cases. Mean DASH score was 8.5, and VAS score was 1.2. For complications, 1 patient had pin site infection, which was cured after conservative treatment. In an infection case, we did revision surgery for nonunion, and achieved fibrous union. The other cases fused successfully, including 1 fibrous union. Mean pulp and side pinch power were 78.5% and 75.2% of normal side, respectively. Mean grip strength was 82.2% of normal side. When compared fibrous union to bony union cases, mild decrease in pulp and side pinch power of fibrous union group was seen (71.2% and 70.2% VS 78.5% and 75.2%), but grip strength (90.4% VS 92.2%) and DASH score (7.2 VS 8.5) were similar.

In the treatment of DIPJ pain with variable causes such as degenerative, traumatic, infection or congenital deformity, arthrodesis results in satisfactory functional outcome even with fibrous union.

² Clinical Hospital of Recovery (Cluj Napoca)

Objectives / Interrogation: Coverage of complex tissue loss in the hand after severe traumas by crushing or avulsion is very challenging. These defects involve generally all the anatomical structures. The difficulties in repairing such a compromise hand are primarily related to the necessity to obtain an as good as possible functionality. The key of obtaining a good functional rehabilitation is to perform, whenever is possible, both the reconstruction and coverage as an all-in-one procedure.

Methods: We take into account the cases with very complex injuries involving all the structures of the hand. In 70% of our cases we used local or regional perforator flaps, and in 30% of cases free flaps.
In case of need to cover soft tissue defects over repaired fractures, vessels, nerves and tendon lesions, we prefer to use-whenever is possible-local or regional perforator flaps; if the skin defect is to big, a free flap is preferred.
For composite skin and bone defects we use generally composite flaps including bone.
For amputations or devascularized segments with skin defects, a free flow-through flap is used.
For amputations of different segments, and especially of the thumb accompanied by skin defects, we cover the defect with a free flow-through-flap which is used in mean time to revascularize one or more toe transfers.

Results and Conclusions: All the hands treated by this protocol survived. The failure rate of the flaps was comparable with the one in the literature. By using local/regional perforator flaps we experienced no complete necrosis, but only a transitory venous congestion (20%) followed by a superficial necrosis in 5% of cases. We lost 2 free flaps out of 45 (4.4%). We obtained a satisfactory functional rehabilitation of the reconstructed hand in 10% of cases, a good one in 40% of cases, and a very good one in the remaining 50%.

Conclusions
In complex injuries of the hand the modality of reconstruction is up to the team experience. The use of local/regional perforator flaps has a very good indication in small and medium skin defects, and only in the purpose of coverage. The use of free flaps remain the gold standard in solving big composite defects. The emergency all-in-one reconstruction and the beginning of kinetotherapy as soon as possible after surgery are the key stone of a good functional recovery.

Fate Mapping the Developing Limb Bud to Decipher the Origin of Congenital Hand Differences

List of authors:
Wee Lam*, Saunders Dillan1, Julia Oh1, Lucy Freem2, Helen Sang2, Megan Davey2
1 Royal Hospital for Sick Children, Edinburgh, St Johns hospital, Livingston, University of Edinburgh (Edinburgh)
2 Division of Developmental Biology, The Roslin Institute (Edinburgh)

Objectives / Interrogation: The processes of developmental patterning occurs in the embryo long before anatomical structures are visible. When these unseen developmental processes such as cell signalling and fate specification go wrong, however, congenital hand differences can occur. To understand where specific tissues are derived from and how they are patterned, developmental biologists undertake ‘fate mapping’ in model organisms, such as the chicken and mouse in order to establish the origins of the tissues that comprise the limb. We present the next generation of limb bud fate mapping using novel transgenic chicken embryos (Roslin Chameleon) that have a Cre-inducible, multi-fluorescent Cytbow construct. This method was used to determine the origins of the radius and ulna, structures that have been neglected in previous fate maps due to technical constraints.

Methods: Embryos were generated from a cross between heterozygous Chameleon males and stock hens generating eggs. These embryos allow implanted Cre protein within cells in the limb bud mesenchyme to exhibit fluorescence, even through cell multiplication, and therefore structures could be traced through their subsequent development. After 7 days, limb buds were fixed and processed for histology and immunohistochemistry, Optical Projection Tomography or Light Sheet Microscopy. In order to create accurate fate maps, the location of the bead for each fluorescent limb was plotted onto a stage specific outline of the wing bud, split into six segments - the stylopod, anterior and posterior zeugopod, anterior, medial and posterior autopod. These sections were imposed on the early limb bud, depending on the eventual location of the fluorescence induced by each bead.

Results and Conclusions: Application of an agarose bead soaked in TAT-Cre protein acted immediately and transiently to induce recombination in the transgene in a limited number of limb bud cells. Expression of fluorescent proteins was equal, stable and exclusive, occurring within 5 hours of TAT-Cre application and within a 380um distance from the bead. A total of 18 stage 20HH limbs buds were successfully implanted and had resulting fluorescence. After anatomical examination, 2 were found to have labelled cells in the radius and 2 in the ulna. Extrapolation from the placement of the bead at stage 20HH allowed us to hypothesise the origin of the cells which give rise to the forearm. Such a fate map allows us to potentially decipher the origins of congenital hand differences such as radial or ulnar aplasia.

The usefulness of Disability of the Arm, Shoulder and Hand (DASH) in patients with shoulder disorders.

List of authors:
Masatoshi Amako¹, Masashi Isaji², Mao Yamada¹, Ryoji Fujimaki¹, Shinya Kondo², Kazuhiko Chiba¹
¹ Department of Orthopaedic Surgery, National Defense Medical College (Tokorozawa, Saitama)
² Department of Orthopaedic Surgery, Japan Self Defense Forces Central Hospital (Setagaya, Tokyo)

Objectives / Interrogation: Disability of the Arm, Shoulder and Hand (DASH) is one of the most popular patients' oriented functional measures in the upper extremity and is widely used for patients with hand, finger, and elbow disorders, however, has rarely been used in patients with shoulder disorders. The purpose of this study was to assess the usefulness of DASH for patients with shoulder disorders.

Methods: Shoulder function of patients who underwent arthroscopic surgery for rotator cuff tear (RCT, n=58) and Bankart lesion (BL, n=112) were evaluated using DASH preoperatively and 3, 6, 9, 12, 18, 24 month postoperatively. Simultaneously, we evaluated Japan Orthopaedic Association Shoulder Functional Score (JOA score: Surgeons' oriented outcome measure), and isokinetic shoulder rotatory muscle strength. Isokinetic muscle strength was measured using Biodex System 3 (Biodex, NY) at 60 deg/sec condition, and contralateral peak torque ratio (injured side peak torque was divided by contra-lateral side peak torque). We assessed correlations between DASH, JOA score, and muscle strength.

Results and Conclusions: Preoperative DASH was 39.8 (SD:23.2) in patients with RCT, and gradually decreased to 4.1(SD:1.6) at 24 months after surgery. On the other hand, DASH was 13.2 (SD:13.0) in patients with BL, and significantly decreased to 6.9 (SD:6.6) by 6 months after surgery, and kept in low score later than 6 months. JOA was recovered to the same transitional change in patients with RCT and BL. There was significant correlation and coefficient between DASH and JOA score (r=-0.77, p<0.01). External peak torque ratio was also recovered to the same translation, and there was significant negative correlation between DASH and external peak torque ratio (r=-0.46, p<0.01).

In conclusions, the strong correlation between DASH and JOA score supported its validity and reliability in assessing shoulder function. DASH also reflected the isokinetic shoulder rotational muscle strength, and should be widely used in evaluating QOL in shoulder disorders. DASH was a very effective measure in patients with shoulder disorders.

Reversed Vascularized Second Metatarsal Flap for Reconstruction of Type IIIb and IV Thumb Hypoplasia with Reduced Donor Site Morbidity

List of authors:
shanlin chen*, Bo Liu1, shanlin shanlin chen2, dedi tong1
1 beijing jishuitan hospital (beijing)
2 beijing jishuitan hospital , beijing university (beijing)

Objectives / Interrogation: To investigate the validity, efficacy and safety of utilizing a reversed vascularized second metatarsal composite flap for Manske type IIIb and IV hypoplastic thumb reconstruction, without impairing the functions of the donor site.

Methods: An osteocutaneous flap containing a section of second metatarsus and its distal head was transferred in reversed position to reconstruct metacarpophalangeal joint with trapezium remnant or the base of second metacarpus, dorsalis pedis artery anastomosed to residual radial artery or the common digital artery; great saphenous vein to cephalic or opisthenar vein. Donor site was reconstructed by a split half of the third metatarsus. Various staged reconstructions were commenced months later. The thumbs were evaluated with grip, key-pinoc and the skills in performing daily activities through a detailed VAS questionnaire.

Results and Conclusions: From May 2014 to Jan 2017, 15 patients, with 7 type IIIB, and 8 type IV thumbs were reconstructed. 13 metatarsal flaps had complete survival (86.7%). With average of 19.3-months follow-up, the reconstructed thumbs had pleasant appearance; The donor foot presented in good appearance without any sign of impaired function. X ray further evidenced good bone fusion in second and third metatarsal. Patients and parents have high recognitions and acceptance on the new thumb. Reconstruction of an unstable hypoplastic (Manske type-IIIB and IV) thumb with use of a vascularized metatarsus is an effective alternative to pollicization of the index finger, especially when parents insist on saving the thumb at all costs.

An alternative direction of the borehole for ligament reconstruction after resection of the trapezium in basal joint osteoarthrosis: a comparative study in 32 cadaver hands

List of authors:
Leon van Bömmel¹, Sören Könneker¹, Peter M. Vogt¹
¹Medizische Hochschule Hannover, PÅHW-Chirurgie (Hannover)

Objectives / Interrogation: Ligament reconstruction of the basal joint of the thumb after trapeziectomy is a common technique in patients with osteoarthrosis. For this procedure different donor tendons and techniques are described. However, there is no exact report about the best borehole direction in the basis of the first metacarpal bone to avoid proximalization and beware mobility. In this study we investigated an optimized borehole direction for ligament reconstruction.

Methods: In 32 cadaver hands trapeziectomy and ligament reconstruction described by Epping with splitted tendon of the flexor carpi radialis muscle was performed. In each first metacarpal bone we used two different borehole directions through the basis: "standard" and "Vogt". Radiological measurements were performed after trapeziectomy with and without ligament reconstruction through the two drill channels.

Results and Conclusions: The distance between the first metacarpal bone and the scaphoid after trapeziectomy and ligament reconstruction was 9.3 ± 2.7 mm when using the standard drill hole and 10.4 ± 2.7 mm when using the Vogt drill hole (p<0.01), respectively. The relative proximalization compared to preoperatively was 4 mm with the standard drill hole and 3 mm with the Vogt drill hole (p<0.01). The distance between the first and second metacarpal bone in anterior-posterior radiographs was 7.9 ± 2.9 mm when using standard drill hole and was 6.2 ± 2.1 mm when using the Vogt drill hole (p=0.001), respectively.

In ligament reconstruction after trapeziectomy using the splitted tendon of the flexor carpi radialis muscle described by Epping proximalization can be reduced using a special drill hole in the basis of the first metacarpal bone.

Objectives / Interrogation: Comparison of SCAphoid fracture osteosynthesis by MAGnesium-based headless Herbert screws with titanium Herbert screws: protocol for the randomized controlled SCAMAG clinical trial

Methods: The trial is designed as a multicenter, blinded observer, randomized controlled parallel two-group post market trial. Approximately 190 patients will be randomized (1:1) with stratification by center either to titanium or magnesium-based compression screws. Follow-up is 1 year per patient. Surgical procedures and aftercare will be performed according to the German treatment guideline for scaphoid fractures. The first primary endpoint is the patient-rated wrist evaluation (PRWE) score after 6 months. The second primary endpoint is a composite safety endpoint including bone union until 6 months, no adverse device effect (ADE) during surgery or wound healing and no serious ADE or reoperation within 1 year. The third primary endpoint is the difference in change MRI artifacts over time. Non-inferiority will be investigated for primary endpoints 1 (t-test confidence interval) and 2 (Wilson's score interval) using both the full analysis set (FAS) and the per protocol population at the one-sided 2.5% test-level. Superiority of magnesium over titanium screws will be established using the FAS at the two-sided 5% test-level (Welch test) only if non-inferiority has been established for both primary endpoints. Secondary endpoints include quality of life.

Results and Conclusions: This study will inform care providers whether biodegradable magnesium-based implants are non-inferior to classical titanium Herbert screws for the treatment of scaphoid fractures in terms of wrist function and safety. Furthermore, superiority of magnesium-based implants may be demonstrated using MRI, which is used as surrogate endpoint for screw degradation.

Arthroscopic distal hemitrapeziectomy versus open distal hemitrapeziectomy without interposition in osteoarthritis of the first CMC joint; Two year follow up results of a randomized controlled trial

List of authors:
Cecile van Laarhoven, Martijn Baas, Henk Coert, Michiel Zuidam, Richard Koch
1 Erasmus Medical Center (Rotterdam)
2 University Medical Center Utrecht (Utrecht)
3 Haga Hospital (Den Haag)

Objectives / Interrogation: For osteoarthritis of the CMC thumb joint, trapeziectomy is described as the treatment with least complications. Removal of the total trapezium, gives a higher chance to shortening and collapse of the thumb, with less postoperative strength. Distal hemitrapeziectomy doesn't have these drawbacks. The last years there is more experience in arthroscopic surgeries for the CMC thumb joint.
The objective of this study is to compare arthroscopic with open hemitrapeziectomy without tendon interposition in a randomized controlled trial.

Methods: All patients with Eaton and Littler grade 2 or 3, seen on the outpatient clinic, with failed conservative therapy, were asked to participate in the study. After obtaining informed consent, patients were randomized to either open or arthroscopic distal hemitrapeziectomy. Patients filled in the Patient Reported Wrist and Hand Evaluation (PRWHE) and hand measurements were done preoperatively and at 3, 6, 12 and 24 months postoperatively.

Results and Conclusions: We included 87 patients; 42 in the open group and 45 in the arthroscopic group. The mean operation time for the open technique was 25min and 35min for the arthroscopic technique (significant p=0.00).
The preliminary results are shown in Image 1.

The PRWHE showed significant improvement at 26 weeks, 1 year and at 2 years for both groups, compared to preoperative (no significance between groups). Satisfaction was good to excellent for the open group in nearly 80% and nearly 70% for the arthroscopic group. The grip power also improved significantly at 1 and 2 year follow up for both groups, compared to preoperatively. The range of motion with Kapandji was 9 preoperative and improved to 10 for both groups at follow up. These are the preliminary results of our RCT arthroscopic versus open distal hemitrapeziectomy. The results show a significant improvement for both techniques after 1 and 2 year follow up, but not between groups, except for operation time. At the time of the congress, we will present the results of 87 patients with a minimum of 1-year follow up and 50 patients with a minimum of 2 year follow up.

Intraoperative NCS During Open Carpal Tunnel Release: A Pilot Study

List of authors:
Dominick Congiusta*, Michael Yeranosian1, Dena Abdelshahed1, Socrates Brito2, Peter Yonclas1, Michael Vosbikian1, Irfan Ahmed1
1 Rutgers New Jersey Medical School (Newark, New Jersey)
2 Chicago Hand and Orthopedic Surgery Centers (Oak Brook Terrace, Illinois)

Objectives / Interrogation: Operative management of carpal tunnel syndrome (CTS) involves release of the transverse carpal ligament (TCL) and often the volar antebrachial fascia (VAF). Evidence of a difference between TCL and TCL+VAF release is lacking. We aimed to conduct a pilot study to measure changes of intraoperative nerve conduction velocity (NCV) after CTS surgery and compare outcomes of variable degrees of decompression.

Methods: Patients aged 18-65 years diagnosed with idiopathic CTS and who failed conservative management were included in this study. Cases were excluded if they had prior surgical release, had diabetes, acute CTS, trauma, or cervical spine radiculopathy. Outcomes included motor and sensory amplitude and latency. Electrodes were placed on the skin intraoperatively, along the abductor pollicis brevis, index finger, and forearm. TCL and VAF release were performed in the usual manner. Outcome data were recorded at baseline, after TCL release, and after TCL+VAF release. A single-tail t-test was then performed for analysis.

10 patients were included in this study. From baseline to TCL+VAF release, mean motor amplitude, mean motor latency, mean sensory amplitude and mean sensory latency decreased (p>0.05). There were no statistically significant differences in mean sensory or motor function between TCL and TCL+VAF release.

The lack of significant findings suggests that NCV may not be useful for assessing intraoperative improvement. As a pilot study, we highlight the need for future research in the form of case-control studies to determine the utility of intraoperative NCV. These studies should be conducted with larger numbers of patients and multiple hand specialists.

Simultaneous bilateral distal biceps tendon avulsions: Simultaneous versus staged repairs. A report of two cases and literature review.

List of authors:
Lucas Braga Jacques Gonçalves¹, Marcella Rodrigues Costa¹
¹Hospital Madre Teresa (BELO HORIZONTE)

Objectives / Interrogation: Distal biceps tendon avulsions are uncommon and can be treated non-operatively or surgically. Surgical treatment is often requested by people that desire strong supination on their activities. Only a few cases of simultaneous bilateral distal biceps tendon avulsions are published and no consensus exists on the management strategy: staged or simultaneous repair.

Methods: This paper presents two patients with simultaneous bilateral distal biceps avulsions, and brings reviewed literature with only eight cases published. All patients were men, with a mean age of 44 years old. The first case report is a 32 year-old male who heard a pop in both arms associated with acute pain. He was trying to roll a car back over on the road and presented bruise in both forearms and loss of supination power. The hook test was abnormal bilaterally and the patient had a history of anabolic steroid use. Magnetic resonance imaging (MRI) showed bilateral complete distal biceps tendon avulsion and staged surgical procedures were performed. The second case is a 46 years old male subject that presented to the hospital, one week after a painful pop in both elbows during a preacher biceps curl. He had no history of anabolic steroid use and there was marked bilateral proximal biceps migration and a mild bruise in both forearms. The hook test was abnormal bilaterally. MRI showed bilateral complete distal biceps tendon avulsion, and he was submitted to simultaneous repair.

Results and Conclusions: After reviewing the collected published experiences it was found that some articles were based on chronic tears and others had acute lesions, among which half were treated surgically simultaneously and others staged. All of them had satisfactory outcomes, assuming that chronicity of the lesion and the management strategy selected may not interfere in the final result.

One downside of the simultaneous approach is the functional limitation due to initial immobilization. However, some authors demonstrated that immediate elbow mobilization after repair of the distal biceps was not associated with failure. A drawback of the staged approach is the possibility of initiating a heterotopic ossification (HO) cascade as happened with the first case of this paper; therefore a HO prophylaxis might preclude that outcome.

Although a high heterogeneity was found regarding the lesions and its treatment, a simultaneous or a staged approach might be used when operating on these lesions. Both yield satisfactory outcomes.

In-vivo 3D motion analysis of the wrist during dart-throwing motion after 3-corner fusion and RSL fusion

List of authors:
Lisa Reissner*, Gabriella Fischer², Maurizio Calcagni³
¹ University Hospital Zurich, Balgrist University Hospital (Zurich)
² Institute for Biomechanics, ETH Zurich (Zurich)
³ University Hospital Zurich (Zurich)

Objectives / Interrogation: Cadaver studies showed a better dart-throwing motion (DTM) after radioscapholunate (RSL) fusion compared to 3-corner fusion (3CF). The aim of the study was to measure the range of motion (ROM) of the wrist during DTM in patients after RSL fusion and 3CF with a 3D motion capture system and to compare it with healthy volunteers.

Methods: The kinematics of the wrist of twenty healthy volunteers as well as five patients after 3CF and five patients after RSL fusion were recorded during the performance of the DTM as well as three basic motion tasks (BMT). A marker set consisting of 13 skin markers was used to collect the kinematic data of the wrist with a 3D motion capture system. The maximum ROM was calculated from the BMT.

Results and Conclusions: During the DTM, 20 healthy volunteers showed a mean flexion-extension (FE) ROM of 99° and mean radial-ulnar deviation (RU) ROM of 44°. As expected after 3CF and RSL fusion, patients had a significantly reduced maximal ROM during BMT and DTM for the FE and RU ROM compared to the healthy controls (p<0.003). Comparing the two patients groups, the RSL patients had a significantly smaller RU ROM during the BMT than the 3CF patients (p<0.001), but the ROM during DTM did not differ significantly between the two patients groups. Regarding the ROM exploitation during the DTM, all three groups used between 61-66% of their maximal FE ROM, but for the RU ROM, the RSL patients used 131% of their maximal RU ROM, which is significantly more than the 3CF (85%) and healthy group (89%) (p<0.03).

These findings suggest that the ROM during DTM after 3CF and RSL fusion are similar, contradicting the traditional cadaver studies. After RSL fusion, patients had a better RU ROM during DTM, than during the BMT in the true RU plane.

The introduction of human Mesenchymal Stem Cells to clinically available nerve substitutes

List of authors:
Femke Mathot*, Nadia Rbia, Allen Bishop, Andre van Wijnen, Alexander Shin
1 Mayo Clinic (ROCHESTER)

Objectives / Interrogation: We hypothesized that seeding human adipose derived Mesenchymal Stem Cells (MSCs) on the surface of clinically available nerve replacement treatments (Avance Nerve graft and NeuraGen Nerve guide) could provide extra biological support and potentially enhances the outcomes of these nerve substitutes.

Methods: An MTS assay examined the viability of human MSCs at different time intervals when a 2mm segment of Avance Nerve Graft (group I) or NeuraGen Nerve Guide (group II) was added to their environment (n=3 per group per time point). MSCs were seeded by using a non-traumatic dynamic seeding strategy, preserving the inner ultrastructure of the nerve substitutes. 1 million MSCs per nerve substitute were transferred to conical tubes containing either a 10mm Avance nerve graft or a 10mm NeuraGen nerve guide. The conical tubes were rotated in a bioreactor for 6, 12 and 24 hours after which cell counts were performed to obtain seeding efficiencies. The distribution of the MSCs was mapped with live/dead and Hoechst stains. Fixed cross-sectional sections of the seeded nerve substitutes were Hoechst stained to observe the migration of cells inside the graft.

Results and Conclusions: The viability of MSCs was not influenced by the presence of both nerve substitutes. For group I, a seeding efficiency of 18.23% was obtained after 6 hours, increasing to 66.46% after 12 hours (p<0.001) after which the efficiency decreased to 59.90% after 24 hours (p=1.00). For group II, the seeding efficiency increased from 52.08% after 6 hours to 94.17% after 12 hours (p=0.009) and decreased to 52.50% after 24 hours (p=0.009). Seeding efficiencies were significantly higher for group II after 6 and 12 hours of seeding (p=0.007 and p=0.025) (figure 1). Live/dead stains, Hoechst stains and SEM on all time points showed a uniform distribution of viable MSCs over the entire surface of both nerve substitutes (figure 2). Cross-sectional sections revealed that the MSCs were absent on the inside of group I, but were present on the inside of group II.

Conclusion: Viable human MSCs can be seeded on both nerve substitutes without harming the inner ultrastructure; 12 hours is the optimal seeding duration. Human MSCs were seeded on the surface of both nerve substitutes in a uniform matter. MSCs only migrated into the NeuraGen nerve guide during dynamic seeding. Our method showed to have great clinical potential to improve and individualize peripheral nerve repair.

The effect of the coronoid nonunion on the terrible triad of the elbow.

List of authors:
Lucas Braga Jacques Gonçalves¹, Marcella Rodrigues Costa¹
¹ Hospital Madre Teresa (BELO HORIZONTE)

Objectives / Interrogation: Lesions involving an elbow dislocation associated to a radial head and a coronoid process fractures are called the terrible triad of the elbow. Historically, this lesion often presents difficulties in its approach and unsatisfactory results such as instability, osteoarthritis and elbow stiffness. This study aims to evaluate the clinical and radiographic results of the surgical treatment of the terrible triad of the elbow and the impact of coronoid nonunion on outcomes.

Methods: There were collected 48 cases of terrible triad of the elbow treated operatively by the same hand surgeon. Seventeen patients were excluded and the final sample had 31 patients that were evaluated for an average of 25 months after surgery (range 13 to 51 months). There were 19 male and 12 female with an mean age of 43 years (± 14.5). In 17 patients the coronoid was fixed using the lasso technique, eight were fixed using screws or k-wires and six were not fixed. The radial head fractures was treated with osteosynthesis (14 patients), arthroplasty of the radial head (12 patients), or resection of a small fracture (5 patients). The lateral ligament complex (LLC) was repaired in all patients and the medial collateral ligament (MCL) was repaired in 5 patients. The patients were then divided in two groups: coronoid healing (C) and coronoid nonunion (CN).

Results and Conclusions: The coronoid healed in 18 patients (group C) and did not in 13 patients (CN group). The final average arc of flexion and extension was 111°. The average pronation was 69° and supination was 63°. The mean DASH was 13 and the average MEPI was 85. According to the MEPI, 24 patients (77%) had good or excellent results. There were 30% of failure of coronoid fixation non related to the fixation method. Despite this high rate, the results were not affected by the loss of coronoid fixation. There was no statistically significant difference between the results of patients in whom the coronoid healed and those with nonunion. The coronoid nonunion doesn't affect the final results in patients submitted to surgical treatment of terrible triad of the elbow.

Keywords:

Scaphoid Hemi-Resection and Arthrodesis of the Radio-Carpal Joint (the SHARC Procedure) for Isolated Radio-Carpal Arthritis Provides Biomechanically and Clinically Functional Outcomes

List of authors:
William Seitz*
1 Cleveland Clinic (Cleveland)

Objectives / Interrogation: Recessed arthrodesis of the radiocarpal joint with distal scaphoid hemi resection can reduce pain and provide functional motion through the mid carpal joint.

Methods: 27 patients with advanced radiocarpal arthritis (11 patients following failed treatment of complex distal radius fractures, 8 patients with scapholunate advanced collapse, 4 patients with scaphoid nonunion with advanced collapse and 4 patients following failure of treatment for transcaphoid perilunate fracture dislocation) were treated with a procedure to recess the lunate and proximal pole of scaphoid into the metaphyseal bone of the distal radius, resection of the distal one half of the scaphoid was also performed to allow enhanced motion of the capitate head within the midcarpal joint as a "universal joint". Fixation of the lunate and proximal scaphoid was achieved through flexible tension plates. Controlled early active motion was begun one week after surgery (patients have been followed for an average of 6.8 years, range 2-14 years).

Results and Conclusions: Results
All 27 patients developed a stable union at the arthrodesis site. None had hardware problems and there were no infections. Range of motion increased from an average preoperative total arc of flexion-extension of 32° to 61°; to a total arc of flexion extension of 68° to 110° (range 42° to 110°). Pain ratings on a visual analog scale decreased from an average of 8.7 to 1.2. Twenty-five of 27 patients demonstrated significant increase ability in their activities of daily living. One patient had persistent stiffness and was not pleased with his limited motion but had significant pain relief. One patient developed mid carpal arthritis and was converted to a total wrist arthroplasty.

Conclusion
Scaphoid hemi resection and limited arthrodesis of the radio-carpal joint is a viable motion sparing procedure for isolated radiocarpal arthritis. Although there are limitations in the total degree of movement, the motion which persists is functional, pain relief has been substantial and the long-term (4-16 yr) follow-up suggests minimal deterioration. This procedure is technically straightforward and appears to be a viable alternative to total wrist arthrodesis when the mid carpal joint is reasonably spared. Revision to total wrist arthroplasty remains a viable salvageable procedure

Keywords:
Preliminary results of vein wrapping for treating hyperaesthesia of the superficial sensory radial nerve.

List of authors:
Nur Azree Ferdaus Kamudin*, Amir Adham Ahmad2, Ahmad Suparno Bahar3, Shalimar Abdullah3
1 Universiti Sultan Zainal Abidin, Faculty of Medicine, Orthopaedic & Traumatology Department (Kuala Terengganu)
2 International Medical University, Faculty of Medicine, Orthopaedic Department (Seremban)
3 Universiti Kebangsaan Malaysia, Faculty of Medicine, Orthopaedic & Traumatology department (Kuala Lumpur)

Objectives / Interrogation: Hyperaesthesia of superficial sensory of radial nerve following decompression of de Quervain tenosynovitis is relatively common. The oversensitive pain is described as a sharp-slicing pain located over the radial aspect of the dorsum of wrist till the base of the thumb. The pain occurs continuously even at rest. Although in most cases, hyperaesthesia is successfully treated with opioids, adjuvant medication (antidepressant, anticonvulsant, baclofen or topical local analgesia) and physiotherapy (transcutaneous-electro-nerve-stimulator and desensitization), some authors propose for surgical procedures (adhesiolysis, neurolysis, vein wrapping). A few authors reported success in treating hyperaesthesia for median nerves. However, to our knowledge, there is no case report of vein wrapping in treating hyperaesthesia of the superficial sensory of the radial nerve.

Methods: We report vein wrapping in treating hyperaesthesia of the superficial sensory of radial nerve following surgery for de Quervain. An 80-year-old male with chronic left wrist pain was diagnosed with de Quervain tenosynovitis and underwent surgical decompression of the first extensor compartment. The pain of this left wrist did not resolve more than a year despite regular physiotherapy and medication. The pain was described as a "sharp" pain even on slight touch at the dorsal radial aspect the wrist with the pain score of 8. There was no weakness of wrist, fingers or thumb in extension.

Results and Conclusions: Using the same incision from previous surgery, the superficial sensory of radial nerve was identified and we noticed the nerve was covered with previous fibrous tissue. It was pale, irregular and swollen. There was no neuroma of the nerve. We harvested the dorsal vein of the wrist, 6 cm in length, and wrapped it cylindrically around the affected nerve. Immediately on day 1 postoperative, the sharp pain of wrist reduced from 9 to 5. We assessed the pain score in the clinic in 2 weeks, 4 weeks and 6 weeks. The pain score was decreasing on each occasion. The patient was satisfied and improved in his wrist motion.

Dynamic wrist radiographs in wrists with and without ganglion cysts

List of authors:
Nadine Hollevoet*, Ellen Beuckelaers
1 Ghent University Hospital (Ghent)
2 Ghent University Hospital (Ghent)

Objectives / Interrogation: The exact pathophysiological mechanism of ganglion cysts of the wrist is still not completely understood. The aim of the study was to investigate if carpal instability plays a role.

Methods: Thirty-three patients with a dorsal or palmar ganglion of the wrist and 33 patients without cysts were included in the study. Standard anteroposterior and lateral radiographs of the wrist, clenched fist and anteroposterior views with the wrist in ulnar deviation were taken. Radiological parameters that may indicate carpal instability were measured and compared between the two groups, including: the width of the scapholunate joint space on anteroposterior views and the scapholunate, capitulunate and radiolunate angle on the lateral views.

Results and Conclusions: No statistical significant difference in scapholunate gap and scapholunate and radiolunate angle could be found between the two groups. Mean capitulunate angle measured 13.5° in wrists with a ganglion and 8.1° in wrists without. Although this difference was significant, the values were within the normal range.

Conclusion:
Carpal instability may not play a role in the etiology of ganglion cysts.

Keywords:
ganglion wrist carpal instability
A Trial for effective subchondral support during volar locking plate fixation for distal radial fractures with cannulated screws

List of authors:
Kazuaki Mito*
1 Fujita Health University (Nagoya)

Objectives / Interrogation: In volar locking plate (VLP) fixation for distal radius fracture, it is significant to put the distal screws next to subchondral bone, which minimizes the postoperative correction loss, which is related to the clinical outcome. We developed a method for effective subchondral support operation with using cannulated screws at distal screw holes of VLP and assessed the utility.

Methods: 39 cases of distal radial fracture in 39 patients were included in the study. Global Form (Nexmed, Chiba, Japan) was employed for internal fixation to treat distal radial fractures. The mean patient age was 62.1 years, and the mean follow-up period was 460.1 days. According to the AO classification, there were 13 patients with type A and 26 with type C. At all the distal screw holes, 0.8 mm guide wire was inserted along the subchondral bone with feeling the touch of bone and a 2.4 mm cannulated locking screw was set in the position. We evaluated postoperative clinical outcomes on postoperative corrective loss in radiographs, minimum distance between distal screws and the radial subchondral bone (MD [mm]) in CT images, the Modified Mayo Wrist Score (MWS), and DASH score. Statistical analysis was done with the unpaired two-tailed Student's t-test.

Results and Conclusions: The mean amounts of correction loss were VT-2.2°, RI-2.29°, and UV+0.85 mm, and the mean MD was 1.59 ± 1.60. Regarding MWS, the results were "excellent" in 24 patients, "good" in 10, "fair" in 5 and "poor" in 1. The mean DASH score was 7.7. The Pearson's coefficients of correlations between the mean MD and the amounts of correction loss with respect to VT, RI, and UV were 0.11, 0.08, and -0.35, respectively, and a weak correlation was observed with the UV. No statistically significant difference was found between MD and the clinical outcome (p = 0.45).

Our trial can be useful for effective subchondral support with screws to treat distal radius fractures.

Keywords:
subchondral support, distal radius fracture, cannulated screw
Macrodactyly: literature review and author's experience.

List of authors:
SAMIR HAikal JUNior¹, Guilherme Ferreira simões², Eduardo Barbosa Coelho Neto³, Rafael Lima Lopes⁴, Marcella Rodrigues Costa⁵
¹ Hospital Maria Amélia Lins (BELo HORIZONTE)
² HOSPITAL DAS CLÍNICAS (BELO HORIZONTE)
³ Santa Casa de Misericórdia de Belo Horizonte (BELO HORIZONTE)
⁴ Hospital Márcio Cunha (Ipatinga)
⁵ Hospital Madre Teresa (BELO HORIZONTE)

Objectives / Interrogation: Macrodactyly is an unusual congenital deformity, characterized by the exaggerated growth of a finger or segment, leading to a poor function limb and unacceptable aesthetic. There is no specific cause and different surgeries should be chosen depending on patient's conditions and clinical presentation. This study objective to collect data from the literature including epidemiology, pathophysiology, clinical presentation and classification; understand the different surgical techniques already described, their indications and results; and report the author's experience.

Methods: It has been done literature review about macrodactyly in databases and medical records. The author's patients were follow since the first medical appointment until 2017. Some patients were lost in contact. It was obtained pictures of patients hands, before and after surgical treatment.

Results and Conclusions: Literature shows an incidence of macrodactyly of 0.9%, manifesting at birth or at the first three years of life, predominantly unilateral. Soft tissues and bones are enlarged, with the palmar face and extremities being more involved. Most are not genetically inherited, but may be associated with syndromes as Ollier, Maffucci, Klippel-Trenaunay-Weber, and Proteus. Theories about the etiology include pathological alteration of the peripheral nerve, increased blood supply or hormonal disturbance. The pathology is divided in four types, being type 1 the more common, related to lipofibromatosis. Indications of surgical treatment are exaggerated and progressive growth, angular deformity, carpal tunnel syndrome and causalgia. Among the surgical techniques are found from soft tissue procedures, such as slimming of the fingers, resection of nerve segments, towards processes such as epiphysiodesis, shortening, filming or amputation of the distal phalanx, osteotomies for correction of deformities, falangectomy and amputation of the whole finger or segment. The main surgical indications among author's patient were exaggerated and progressive growth.

The multiplicity of presentations of macrodactyly and the variety of surgical techniques described makes the treatment challenging. The author concludes that it was not possible to select a single surgical technique for all patients and the treatment is always individualized. It is important to instruct parents about prognosis and results, once it will not be possible to obtain a normal segment despite correct treatment.

Preliminary results after ulnar shortening osteotomy using a "low-profile" locking plate with an ulnopalmar approach

List of authors:
Athanasios Terzis\(^{1}\), Florian Neubrech\(^{1}\), Julia Sebald\(^{1}\), Michael Sauerbier\(^{1}\)
\(^{1}\) BG Trauma Center Frankfurt am Main (Frankfurt am Main)

Objectives / Interrogation: The most common cause for symptomatic ulnar impaction syndrome is either a malunion after distal radius fracture or the congenital ulnar plus variance. Decompression of the ulnocarpal joint with ulnar shortening osteotomy is the commonly used treatment. The purpose of the study was to investigate the effectiveness of ulnar shortening osteotomy using a new, "low-profile" locking plate. With this device the closure of the osteotomy gap is performed with a compression spindle.

Methods: Between June 2016 and March 2018 ulnar shortening osteotomy was performed in 20 patients using the new locking plate. 12 patients were male and 8 patients female at a mean age of 46 years. The indication for ulnar shortening was in 8 patients a malunion after distal radius fracture, in 12 patients a congenital positive ulnar-plus variance. 14 of the 20 patients underwent a previous arthroscopic debridement of the TFCC area. The osteotomy of the ulna was done in all patients in an ulnopalmar approach and the osteotomy in 45° degrees. Arc of motion, grip strength (Jamar Dynamometer), pain (using the Visual Analogue Scale) and activities of daily living (DASH Score) as well as radiological outcome were assessed.

Results and Conclusions: Mean follow-up time was 11.3 months. There was a significant pain reduction (VAS; 7.2 to 2.2, \(p<0.05\)) and improvement of function (DASH; 50.44 to 27.4, \(p<0.05\)). Range of motion and grip strength improved as well compared to the contralateral side. The average ulnar shortening was 3.5 (1.5-7) mm. Bony union was achieved in all patients after a mean time of 4 months. Overall patient satisfaction was rated by 18/20 patients as very good, 1/20 as good and 1/20 as not good. There was no implant associated complication. The mean time required to return to work was 4.7 months. Ulnar shortening osteotomy using a low profile locking plate allows for an exactly defined oblique osteotomy as well as a safe closure of the osteotomy gap using a compression spindle. There was no nonunion or other implant associated complication in our series. Overall patient satisfaction was high.

Trigger finger in ocean rowing - a hindrance to performance

List of authors:
Ted Welman*, Maxim Horwitz
1 Chelsea and Westminster NHS Foundation Trust (London)

Objectives / Interrogation: Trigger finger is a mechanical condition that can result following repetitive finger movements. Ocean rowing is an expanding extreme sport that typically involves periods of weeks to months doing little other than repetitive rowing strokes. In our experience, a high proportion of ocean rowers suffer from trigger finger(s). We aimed to identify the prevalence, severity and longevity of the condition in this cohort following an ocean crossing.

Methods: Prospective observational study. Ocean rowers who planned to start a crossing in 2018 were identified using the Ocean Rowing Society (ORS) online portal. All rowers were consented to take part prior to departure and asked to fill out a survey containing a trigger finger self-scoring system on arrival.

Results and Conclusions: 98 people were registered to attempt an ocean rowing crossing in 2018, of which 88 were a part of the Talisker Whisky Atlantic Challenge (TWAC) race. A high proportion of responses documented suffering from painful clicking and locking of the affected digit. Symptoms were often present in more than one finger and were commonly bilateral.

Trigger finger is a common complaint amongst ocean rowers and can have an effect on performance. Triggering can prevent sufficient grip strength on the oar, resulting in ineffective strokes and the danger of damaging or losing an oar in bad weather. Interestingly, those that did suffer from the condition reported complete resolution of symptoms without treatment.

Hypertrophic nonunion after ulnar shortening osteotomy with low profile ulnar shortening plate

List of authors:
Jong woo Kang*, Jung heum Baek¹, Hyun jae Sung¹, Young woo Kwon², Jong woong Park²
¹ Korea university, Ansan hospital (Ansan)
² Korea university, Anam hospital (Seoul)

Objectives / Interrogation: The most common and critical complication after diaphyseal ulnar shortening osteotomy is delayed union or nonunion. The authors describe 2 cases of hypertrophic nonunion after diaphyseal ulnar shortening osteotomy with low profile ulnar shortening plate and recommend the reasonable treatment with additional mini-plate fixation.

Methods: Additional mini-plate fixations were performed for all hypertrophic nonunion without bone grafting. Serial four planes simple radiography were taken after the additional mini-plate fixation until osteotomy union.

Results and Conclusions: One nonunion was united at 1 month and another was united at 2 months after the additional mini-plate fixation. Hypertrophic nonunion after diaphyseal ulnar shortening osteotomy with low profile ulnar shortening plate can be reasonably treated with additional mini-plate fixation without bone grafting.

Tetanus Quick Stik - is the NHS missing a trick?

**List of authors:**
Ted Welman¹, Natalie Carroll¹, Andrew McKean¹, Shakeel Rahman¹, Luke Moore¹, Maxim Horwitz¹
¹ Chelsea and Westminster NHS Foundation Trust (London)

**Objectives / Interrogation:** Lacerations and open hand fractures make up a significant proportion of admissions under hand surgeons. These patients require determination of tetanus immunity to allow prophylaxis if deemed at risk of contamination. Studies show that 57% of patients are unable to recall seroprotection status. The "Tetanos Quick Stik®" (TQS) is a 10-minute bedside test for tetanus immunity that boasts 100% specificity and 80% sensitivity. We aimed to identify the potential cost saving of the TQS at a tertiary plastic surgery centre.

**Methods:** Retrospective literature searches of EMBASE, Medline, Pubmed and Google Scholar were conducted. Search terms included "tetanos quick stik", "tetanus prophylaxis" and "cost analysis". Financial data on tetanus prophylaxis was collected from the clinical coding and pharmacy departments. Published statistics were then applied to our hospital data.

**Results and Conclusions:** Studies have demonstrated that TQS can avoid treatment with vaccine or tetanus immunoglobulin (TIG) in 77% of patients. Our hospital spent £21,376 over the financial year 2017/18 on vaccine doses and TIG. Using published data, we have identified a potential cost saving of £7162.18 (34%) in our centre alone and £8,929.86 across the whole trust.

The TQS is a cost effective bedside tool, available on NHS Supply Chain, that has potential to make significant cost savings in the NHS. We have developed a protocol that is being implemented in our trust for tetanus prophylaxis in the ED.

Gene interaction profiles of differentiated and undifferentiated adipose derived mesenchymal stem cells dynamically seeded onto a processed nerve allograft

List of authors:
Femke Mathot*, Nadia Rbia¹, Andre van Wijnen¹, Allen Bishop¹, Alexander Shin¹
¹Mayo Clinic (ROCHESTER)

Objectives / Interrogation: The gene expression profile of adipose derived mesenchymal stem cells (MSCs) seeded onto a substrate varies depending on the cells interaction with the remaining extracellular matrix. The effect of undifferentiated cells or cells differentiated into Schwann-like cells seeded onto a processed nerve allograft is unknown. The purpose of this study was to determine the gene expression profiles of differentiated and undifferentiated MSCs before and after seeding onto a processed nerve allograft in order to determine the mechanism of action of both stem cell types when used in peripheral nerve repair.

Methods: 65 sciatic nerve segments from Sprague-Dawley rats were harvested and decellularized. MSCs were harvested from Lewis rats and cultured. Half of the MSCs were differentiated into Schwann-like cells. Undifferentiated MSCs and differentiated MSCs were dynamically seeded on the surface of the decellularized allografts. The interaction between cells and the nerve graft was evaluated by qPCR-analysis of neurotrophic (GDNF, PTN, GAP43, PMP22), angiogenic (CD31, VEGF1), extracellular matrix (ECM) (COL1A1, COL3A1, FBLN1, LAMB2) and regulatory cell cycle genes (CAPS3, CCBN2).

Results and Conclusions: Seeding of undifferentiated MSCs led to enhanced expressions of neurotrophic (NGF, GDNF, PMP22), ECM (FBLN1, LAMB2) and regulatory cell cycle genes (CCNB2), mostly after 7 days, while the interaction with differentiated MSCs led to enhanced expressions of neurotrophic (NGF, GDNF, GAP43), angiogenic (VEGF1), ECM (FBLN1) and regulatory cell cycle genes (CASP3, CCNB2) within the first week.

Conclusion: Undifferentiated and differentiated MSCs have a different baseline gene expression, which changes after seeding onto a processed nerve allograft. Differentiated MSCs were observed to express high regenerative gene levels in the first 72 hours after seeding, while undifferentiated MSCs expressed high regenerative gene levels a week after seeding. These findings imply that both cell-types effect nerve regeneration in different stages and that a combination of undifferentiated AMSCs and differentiated AMSCs might lead to superior nerve regeneration.

Keywords: Differentiated MSCs, undifferentiated MSCs, gene expression, nerve regeneration, stem cells, nerve allografts
Acute Compression of the Median Nerve at the Elbow by the Lacertus Fibrosus: Biomechanical Translation from Partial Rupture of the Biceps at the Myotendinous Junction.

List of authors:
William Seitz*^1
^1 Cleveland Clinic (Cleveland)

Objectives / Interrogation: Objectives
Patients with acute partial distal biceps rupture develop acute median nerve compression due to a shift of the Lacertus Fibrosis.

Methods: Methods
A series of 18 consecutive cases of acute median nerve compression in the antecubital fossa is presented resulting from an extremely forceful injury to the elbow. In all cases, a sudden severe attempt at elbow flexion was performed against a severe counterforce resulting in immediate severe pain radiating from the elbow down to the forearm. The pain was severe, persistent and unremitting and worsened with passive elbow extension and forearm pronation. Duration of symptoms was 3-16 months until definitive diagnosis was made. Multiple diagnosis including "elbow strain", medial and/or lateral epicondylitis were erroneously entertained and patients were treated with a variety of modalities unsuccessfully prior to definitive treatment. Surgical decompression was performed in all cases.

Results and Conclusions: Results
Evidence was found at the time of surgery of partial rupture of the distal myotendinous junction of the biceps brachii creating increased tension across the median nerve by a tethered lacertus fibrosis. Common characteristics found in all cases included: identifiable forced flexion injury against resistance; severe unremitting pain from the time of injury especially with resisted elbow flexion, passive extension and pronation, or direct compression over the antecubital fossa; evidence of partial rupture of the distal myotendinous junction of the biceps at surgery; and prompt complete persistent relief of symptoms following surgical decompression.

Conclusion
Awareness of the potential for acute compression of the median nerve by the lacertus fibrosis following a severe flexion injury can prevent erroneous diagnosis and improper treatment. It can help the treating surgeon differentiate this entity from the more chronic forms of compressive neuropathy. Surgical decompression provides definitive management with a predictably effective outcome.

A sustainable model for teaching the management of upper limb conditions in Low and Middle Income Countries - experience from the British Foundation of International Reconstructive Surgery and Training (BFIRST)

List of authors: Barbara Jemec¹, Wee Lam², Matt Fell³, Bran Sivakumar⁴, Andrew Yam⁵, Andrew Flemming⁶, Simon Kay⁷, Vaikunthan Rajaratnam⁸
¹ The Royal Free Hospital (London)
² Royal Hospital for Sick Children, Edinburgh (Edinburgh)
³ Royal Devon and Exeter Hospital (Bristol)
⁴ Great Ormond Street Hospital for Sick Children (London)
⁵ Gleneagles Medical Centre (Singapore)
⁶ St George's Hospital (London)
⁷ Leeds General Infirmary (Leeds)
⁸ Khoo Teck Phuat Hospital (Singapore)

Objectives / Interrogation: Hand surgery training remains a vital part of surgical education in Low and Middle Income Countries (LMIC). Often neglected in respect to more ‘life-threatening’ conditions, the neglected injured or congenitally malformed hand has a profound impact on the quality of life of the affected individual. Traditional volunteering has focused on solving crises by performing surgeries in quantity, in short trips by surgeons with their trainees, with the educational component neglected. The British Foundation of International Reconstructive Surgery and Training (BFIRST) was set up as the charity arm of BAPRAS to teach plastic and hand surgery in LMICs. In close collaboration with other organisations, BFIRST aims to equip the local surgeon ‘so that one day they can teach their own’ through feedback, community-oriented curriculum and clear entrustible professional activities.

Methods: Hand surgery-specific projects were chosen for reflection for the purpose of this presentation. A total of five projects were included: Bangladesh, Cambodia, Sri Lanka, Vietnam and Zimbabwe. For each of this project, the specific needs of the country were analysed and experiences gathered from the volunteers, in conjunction with the local hosts. A strategy of Defining the curriculum, Designing the curriculum and Delivering the curriculum was used.

Results and Conclusions: Each of these five countries present with different needs. For example, there was a high proportion of electrical hand burns in Bangladesh and efforts were made to design a specific classification to guide the treatment. For Cambodia, valuable experiences were shared with expert collaborators that crystallised the theories of education including Pareto’s analysis, targeted workshops and robust feedback systems. In Sri Lanka and Zimbabwe, the focus was on congenital
hand anomalies; local surgeons asked for this and the specific curriculum was delivered. Finally, in Vietnam (and Cambodia), brachial plexus was the main focus and allowed competencies to be developed over a few years.

Augmented Mini External Fixation Provides Biomechanically Stable Support of Ulnar Sided CMC Fracture Dislocation

List of authors:
William Seitz*, Lauren Wright1, Reiji Nishimura2
1 Cleveland Clinic (Cleveland)
2 The Jikei University School of Medicine (Tokyo)

Objectives / Interrogation: Objectives
Management of ulnar sided CMC fracture dislocations by means of ligamentotaxis provided through miniature spanning external fixation stabilization with precise but limited intra-articular fragment realignment and fixation with K wires can provide restoration of articular architecture and digital alignment while allowing early return to function followed by durable, positive patient reported outcomes.

Methods: Methods
10 patients (eight men, two women) received acute surgical repair of ulnar-sided CMC fracture dislocations with intra-articular comminution using K-wires & spanning miniature external fixators. Follow-up was ranged 1-8 years, average 3.4 years. All radiographs were reviewed and evaluated by two independent reviewers. Patients were asked to rate their level of pain, answer a series of patient perceived outcomes questions using the Quick DASH subjective outcome instrument for functional assessment.

Results and Conclusions:
Results
There were no major complications. There were 2 transient pin tract infections which resolved with oral antibiotics; no nerve or tendon injuries. All implants were removed in the clinic without need for additional surgery. All hands healed primarily with maintenance of a congruent joint space without radiographic evidence of displacement or subsequent arthrosis. Patient satisfaction was high and function was near normal with minimal if any pain (average 1.2 on VAS scale). All patient's felt they had returned to pre-injury hand function status.

Conclusion
Ulnar-sided CMC fracture dislocation tends to be an injury sustained by young males most frequently during an argument or moment of rage. Despite a potential for noncompliance in this group. Biomechanically advantageous augmented external fixation has promoted early return to function, minimal disability with maintenance of early motion and functional activities of daily living. Patients have been compliant in careful pin site care, returning for follow-up and especially fixator removal. As such we have found this surgical technique preferable to K wire fixation alone with casting. Our surgical technique with rehabilitation protocol will be presented.

ulnar sided CMC fracture dislocations, ligamentotaxis, Biomechanically advantageous augmented external fixation
Complications of semi constrained total elbow arthroplasty in non-rheumatoid patients: lessons learned with application in an active population with biomechanically restrictive implants

List of authors:
William Seitz*1
1 Cleveland Clinic (Cleveland)

Objectives / Interrogation: Objectives
Expanded application of TEA has been reported in patients with osteoarthritis, posttraumatic arthritis and in cases of severe trauma precluding fracture reconstruction, with reports of successful outcomes. Such patients, however, tend to be younger, more active, and therefore potentially place higher demands and stresses on current less than physiologic implants. We reviewed our institute’s experience in non-rheumatoid patients with the hypothesis of finding poor compliance with activity limitations and a high rate of complications

Methods: Methods
Over a ten-year period, the authors have implanted 64 linked total elbow arthroplasties in 64 patients (age 38-84, mean 58 years; 39 men, 29 women) with osteo or post-traumatic arthritis, or unreconstructable fractures. Initial results at two years demonstrated satisfactory results with a high satisfaction rate and a low complication rate with four early reoperations (6.4%), comparable to other published reports. But longer term follow-up at 4-10 years has demonstrated a higher implant related complication rate. Reoperation was required in an additional 21 patients (32.8%). Compliance with physical restrictions was minimal.

Results and Conclusions: Results
Total elbow arthroplasty has added immensely to our armamentarium of tools for the treatment of rheumatoid arthritis, especially in low demand patients who lead a sedentary lifestyle. Clearly, as indications for application of this technique have expanded to include a more active patient population, implant stresses and resultant failure rates have been found to increase with longer-term follow-up. These findings suggest a need to rethink implant design to become more responsive to physiologic loads demanded in more active patients and to counsel future patients as well as existing patients with current implants regarding the limits and potential failure of existing implant designs.

Conclusion
Future implant designs should incorporate more anatomic load sharing characteristics to accommodate the demands of this more active population of patients.

total elbow arthroplasties, non-rheumatoid patients
Computer Guided Templating for Osteotomy and Fixation of Complex Distal Radius Deformity Provides Cost-Effective and Anatomic and Biomechanically Superior Results to "Free-Hand" Surgery

List of authors:
William Seitz*
1 Cleveland Clinic (Cleveland)

Objectives / Interrogation: Objectives
Three-dimensional computer modeling and generation of drilling and cutting guides can enhance precision by adding the ability to precisely correct deformity following malunion of the distal radius. The cost of this added technology ($2,500) may be offset by decreasing the operative time required for "free hand" surgical correction.

Methods: Methods
A cohort of 35 patients undergoing distal radius osteotomy were managed by "free hand" tri-planer osteotomy to correct rotation, angular, and length deformity. Healing rates, restoration of alignment, and tourniquet times were recorded for all cases. A prospective series of 14 patients with complex deformity of the distal radius were managed using three-dimensional CT guided computer generated modeling and templating utilizing the contralateral wrist in mirror image as a reference to correct deformity, using preoperatively fabricated drilling, osteotomy and bone removal guides. Postoperative imaging was used to compare outcomes with the contralateral wrist. Operative time was recorded.

Results and Conclusions: Results
Of the 35 patients in the 1st group, 5 had delayed or nonunion requiring re-operation; radial osteotomy surgical time averaged 173 minutes, average, radial & ulnar osteotomies, 271 minutes. There was a mean inability to correct length of 2.5 mm. Angle of inclination was restored to 7 degrees and volar tilt corrected to neutral. In group utilizing 3D templating length was restored to within 1 mm of the contralateral wrist. Angle of inclination was restored to 10 degrees. Volar tilt to 8 degrees. All but one patient healed primarily. Average time for radial osteotomy was 109 minutes, and for radial and ulnar osteotomy was 150 minutes. With "free hand" osteotomies, three patients developed infection. In the templating group there were no infections.

Conclusion
Cost effectiveness of precision templating is evidenced by an average decrease of 64 minutes OR time for radial osteotomy and 81 minutes for radius and ulnar osteotomy showed a significant reduction in OR costs ($4,153 and $5,256 and respectively in our institution). The potential for limiting infection by reduced operating time also adds to patient safety, while precision restoration of anatomy offers a greater potential for long-term successful outcomes.

"free hand", Cost effectiveness , reduction in OR costs, Three-dimensional computer modeling
INTRINSIC TENDINOPATHIES IN THE HAND

List of authors:
ROBERTO MELENDEZ*†
† CLINICA REINA SOFIA (BOGOTA)

Objectives / Interrogation: Objective:
The expression "Intrinsic tendinopathies in the hand" refers to mostly unknown entities that are rarely described in the bibliography but whose occurrence is increasingly frequent. For over 20 years the author has assembled many clinical observations to build a complex and original conception of the problem, describing 20 pathological entities classified in the following five groups:
1. Interossei muscles: first dorsal interossei, second dorsal interossei.
2. Extensor apparatus of the fingers: tendinitis of the extensor hood, tendinitis of the extensor apparatus central band.
3. Thenar muscles: proximal thenar zone, distal thenar zone, first metacarpal base zone.
4. Hypothenar muscles: distal tendinitis of the abductor digiti minimi, tendinitis of the opponens digiti minimi.
5. Related extrinsic extensor tendons: tendinitis of the extensor indicis proprius, tendinitis of the extensor digiti quinti proprius, tendinitis of the extensor digitorum communis vincula from the 3rd to the 2nd fingers, tendinitis of the extensor digitorum communis vincula from the 5th to the 4th fingers and/or of the 5th finger extensor digitorum communis tendon.

The clinical characteristics, the etiopathogenesis and the physical examination manoeuvres leading to confirm the diagnosis are described for every subgroup, and the resources for their treatment and prevention are also explained. We believe that these remarks, made upon the way of doing the clinical history, the use of means of diagnostic and therapeutic aspects, have allowed us to develop concepts that are useful for the management of this pathology.

Methods: Materials and Methods:
Over 20 years of files were reviewed. Careful clinical observation had followed to the identification, definition and characterization of 20 pathological entities.

Results and Conclusions: Results:
A useful and practical intrinsic hand tendinopathies classification is presented. It defines 5 groups according to their location in the hand, as well as 20 varieties according to the intrinsic tendon affected.

Conclusions:
A classification of intrinsic tendinopathies is presented according to their location in the hand. The concept of "intrinsic hand tendinopathies" is introduced and relevant issues are defined about their classification, diagnosis and treatment.

Keywords: Tendinopathies, intrinsic, Interossei muscles, Extensor apparatus of the fingers, Thenar muscles, Hypothenar muscles, Related extrinsic extensor tendons.
GANGLIONS IN THE HAND AND WRIST: A NEW CLINICAL AND SURGICAL APPROACH

List of authors:
ROBERTO MELENDEZ
1 CLINICA REINA SOFIA (BOGOTA)

Objectives / Interrogation: Objective:
Surgical resection of the ganglions in the hand tends to be regarded as a simple intervention. However, this is far from real. For over 30 years the author has assembled surgical and clinical observations to build a complex and original conception of the problem. We believe that these remarks, made upon the way of doing the clinical history, the use of means of diagnostic aid and surgical aspects, have allowed us to develop concepts useful for the management of this pathology. The point of origin of the ganglion is not always to be found in a structure in the area of location of the cyst but may be far from it. Consequently, a number of cases are presented as “GANGLIONS OF ECCENTRICAL LOCATION” and a classification is proposed according to the location of the cyst and its point of origin.

Methods: Materials and Methods:
Over 30 years of files were reviewed. Careful dissection had followed the path of the pedicle to its origin.

Results and Conclusions: Results:
Nine groups were classified according to the location of the cyst and 43 varieties according to their points of origin. Conclusions:
A clasification of ganglions of the hand and wrist is presented according to the location of the cyst and its point of origin. The concept of “ganglions of eccentric location” is introduced and relevant issues are defined about their diagnosis and surgical management

Long Term Outcomes of Congenital Hand Reconstruction Using Free Toe Phalanx Transfer Results in Minimal Donor Site Morbidity

List of authors:
William Seitz*, Noah Raizman, Adam Meisel
1 Cleveland Clinic (Cleveland)
2 Orthopaedic Medicine and Surgery (Washington DC)
3 MidAmerica Orthopaedics (Palos Hills)

Objectives / Interrogation: Objectives
A report of pain & dissatisfaction in foot function in children having undergone free toe phalanx transfer as part of the reconstruction process for congenital hand difference has been recently reported. Having performed over 200 such procedures over 28 years, the authors have not appreciated this complication. We hypothesized using our technique of a dorsal approach with extensor tendon splitting, extra periosteal sharp dissection, careful flexor tendon preservation and extensor tendon repair, there is little, if any morbidity or functional impairment following free toe phalanx transfer.

Methods: Methods
44 children with multiple toe phalanx transfers at least two years post-surgery were administered the Oxford Ankle Foot Questionnaire for Children (OXAFQ-C) as appropriate, as well as the Foot and Ankle Ability Measure (FAAM). The patients families were also asked whether they were satisfied with the overall outcome of the surgical treatment, would they undergo the same treatment again, whether the upper extremity outcome justified the lower extremity morbidity (if any), and would they recommend the same surgical treatment to another child/family with a similar condition. All date was collected and analyzed by independent observers who had not participated in the care of the patients.

Results and Conclusions: Results
Almost universally, pain, function, activities, sports, footwear, were rated extremely highly (<1.0) Satisfaction in all areas was high (1.0), the only sense of mild dissatisfaction was in appearance (3.4), and having others at some time being unkind (4.2). Every patient / family (44/44) said they would go through the surgery again and would recommend it to others.

Conclusion
Free toe phalangeal transfer using the 2nd & 3rd toes of one or both feet can provide needed functional bone stock to congenitally hypoplastic digits as part of the reconstruction process. When performed carefully using a dorsal, extra periosteal approach with protection / preservation of the flexor tendon minimal foot complications and a high satisfaction rate can be expected.

Free toe phalangeal transfer,
Exploring the Axillary Nerve through the Deltopectoral and Axillary approaches: Is there a true "Blind Spot"?

List of authors:
Scott Wolfe*1, Alfonso Pérez1, Rishabh Jethanandani3, Bilal Mahmood3, Steve Lee1
1Hospital for Special Surgery (New York)

Objectives / Interrogation: The axillary nerve (AN) is at risk of iatrogenic injury during arthroscopic shoulder procedures that use anchors or sutures in the anteroinferior or inferior margin of the glenoid (6-o'clock position). This injury most frequently occurs in a so-called "blind spot" that is located between the surgical exposure limits of the medial deltopectoral approach and the posterior approach to the AN. The aim of this study was to evaluate the feasibility of exploring the 6-o'clock position using a lateral deltopectoral approach, extended as needed with an anterior axillary approach. We hypothesized that 1) the lateral deltopectoral approach allows neurolysis of the AN at the 6 o'clock position, and 2) that an axillary extension of this approach enables sufficient exposure for AN repair, graft or nerve transfer.

Methods: Four axillary nerves were dissected combining the deltopectoral approach-medial to conjoint tendon (A), the deltopectoral approach lateral to conjoint tendon (B) and the axillary approach (C) in three sequences: A-B-C, B-A-C and C-B-A. After the first approach was completed the proximal and distal margins were marked. Additional exposures with the second and third approach and the 6-o'clock position were also marked. When the three approaches were completed, the AN was excised and the amount of exposed nerve with the three approaches was measured.

Results and Conclusions: The deltopectoral approach using the medial interval to the conjoint tendon did not allow exposure of the AN at the 6 o'clock position. This exposure was accomplished using the lateral interval of the deltopectoral approach and the axillary approach. The deltopectoral approach lateral to the conjoint tendon allowed 28-46% length of AN exposure, including the 6 o'clock position, but not to the level of the terminal branches. The axillary approach was able to expose the terminal branches of the AN (but not the nerve-muscle junction) and the 6 o'clock position of the glenoid. A combination of the 3 approaches exposed 81-94% of the total length of the AN.

The deltopectoral approach allowed visualization of the AN at the 6 o'clock position when explored lateral to the conjoint tendon. The achieved visualization allows the surgeon to assess continuity of the nerve at the 6 o'clock position, perform neurolysis, but not perform nerve repair at this site. If nerve repair with or without graft or a nerve transfer is attempted, a combination of the 3 approaches should be used with an axillary extension of the incision.

Keywords: brachial plexus, axillary nerve, surgical exposures, iatrogenic injuries, shoulder
DISTAL RADIUS FRACTURES: INTERNAL FIXATION USING VOLAR LOCKING PLATES AND CORRELATION OF CLINICAL FINDINGS WITH PATIENTS’ SATISFACTION. EXPERIENCE OF OUR CLINIC

List of authors:
NIKOLAOS PAPOULIDIS*, PANAGIOTIS KANELLOS1, KONSTANTINOS TOLIS1, ANASTASIA KREXI1, APOSTOLIS CHAMPIPIS1, IOANNIS PALAVOS1, SARANTIS SPYRIDONOS1
1 GENERAL HOSPITAL OF ATTICA "KAT" (ATHENS)

Objectives / Interrogation: Distal radius fractures are 18% of all orthopedic fractures in adults. Besides their high frequency, they also have a wide range of age distribution and they can be the result of both high and low energy injuries. The best method of treating these kinds of fractures is still debatable. However, locked volar plating is widely used with good reported results

Methods: During the years 2015 and 2018, 83 patients (54 female and 29 male) were operated in our clinic. Their mean age was 51.3 years old. According to AO classification their fractures varied from type A2 to C3. In the majority of cases, closed reduction had been tried and was deemed unsuccessful, so we moved on to a surgical approach, using various volar locking plating systems. All the patients were operated by the same surgeon and were followed up from 6 to 24 months

Results and Conclusions: Patients were clinically examined (flexion - extension of the wrist, ROM of the wrist, grip strength, key - pinch strength) followed by radiographic check at 1, 3, 6, 12 and 24 months. There were no cases of wound infection. 4 patients were reoperated because they were under 40 years old and in these cases we routinely remove hardware one year after the operation. One patient suffered from FPL injury and was reoperated 2 years after the first operation. In order to discriminate between satisfied and dissatisfied patients, we used the Michigan Hand Outcome Questionnaire, Patient-Rated Wrist Evaluation and also DASH score. We observed that the patients felt more satisfied only when they gained back more than 85% of the ROM of their wrist. It is also worth mentioning the fact that patients, during their rehabilitation, sought to restore more of their grip strength than to improve their key-pinch strength

Distal radius fractures are peculiar type of fractures. Locked volar plating has very good results when assessed by an experienced and skilled surgeon. Patient's satisfaction is a complex idea and incorporates the success of the operation because it reflects the impact of the functional outcomes to the patient’s everyday life. However the relationship between patient's satisfaction and clinical measures of hand outcome has yet to be established

Keywords:
distal radius fractures, volar plating, patient's satisfaction
Smoking is associated with ulnar nerve entrapment: a birth cohort study

List of authors: Sina Hulkkonen*, Juha Auvinen, Jouko Miettunen, Jaro Karppinen, Jorma Ryhänen
1 Helsinki University Hospital (Helsinki)
2 University of Oulu (Oulun yliopisto)

Objectives / Interrogation: Our aim was to study whether smoking is associated with ulnar nerve entrapment.

Methods: The study population consisted of the Northern Finland Birth Cohort with expected date of birth in 1966 (N=8716). History of smoking, pack years, body mass index (BMI) and socio-economic status were recorded at the 31-year follow-up in 1997. Data on hospitalizations due to ulnar nerve entrapment neuropathies was obtained from the Care Register for Health Care. Hazard ratios (HR) with 95% confidence intervals (CI) and population attributable risk percentages (PAR%) were calculated adjusted for gender, BMI and socio-economic status.

Results and Conclusions: A total of 66 patients were diagnosed with ulnar nerve entrapment in the follow-up between 1997 and 2016.

Ulnar nerve entrapment, smoking and background factors.

Smoking ten or fewer pack years before the age of 31 years was associated with more than doubled (HR=2.57, 95% CI=1.29-5.15) and smoking over ten pack years before the age of 31 years more than five times higher risk (HR=5.61, 95% CI=2.80-11.23) for ulnar nerve entrapment later in life compared to non-smokers in the adjusted analyses. PAR% for smoking (reference of no smoking) was 53.6 in the adjusted analysis.

The Stener-like lesion of the radial collateral ligament of the thumb: an anatomic study.

List of authors:
Rafael Jakubietz*, Fabian Gilbert, Sylvia Bernuth, Michael Jakubietz, Rainer Meffert
1 Universitätsklinikum Würzburg (Würzburg)

Objectives / Interrogation: Injury to the radial collateral ligament of the thumb is less common than on the ulnar side and often diagnosed in the chronic state. The counterpart of the Stener lesion on the radial side is very uncommon and only few reports in the literature can be found. The aim of this cadaver study was to evaluate the anatomy of the radial collateral ligament in relation to the surrounding structures.

Methods: 5 cadaver thumbs from participants of the willed body program were dissected. After splitting the EPL tendon the capsule was exposed and the radial collateral ligament was transected distally. After closure of the EPL tendon ulnar displacement of the first MCP joint was performed until the proximal stump penetrated the space between the EPL and APB tendon. This was repeated in full extension, 30 and 45 degrees of flexion.

Results and Conclusions: Results
In the position of 45° of MCP flexion a ulnar stress of 30° caused a Stener-like lesion of the radial collateral ligament of the thumb in full extension the fascial alignment of the EPL and APB remained tight and no Stener-like lesion was seen.

Conclusion:
On the radial side of the thumb increased flexion of the MCP joint in combination with ulnar stress increase the chance of creating a stinger-like lesion. During flexion of the MCP joint the fascial alignment between the EPL and APB tendon seems to widen which may predispose the distally ruptured radial collateral ligament to be loaded upon the extensor hood between the EPL and APB tendon when the radial stress is reversed into the neutral position.

Fascia flaps: local and pedicled alternatives

List of authors:
Rafael Jakubietz*, Michael Jakubietz¹, Karsten Schmidt²
¹ Universitätsklinikum Würzburg (Würzburg)

Objectives / Interrogation: Fascia flaps have an important role in soft tissue reconstruction of the hand when tendons are exposed. Both free flaps and local fascia flaps are available to the hand surgeon. In this retrospective study patients requiring soft tissue reconstruction of the hand with fascial flaps were evaluated.

Methods: 13 patients were identified, which underwent reconstruction of gliding surfaces or capsular structures with a fascial flap. In 6 patients the fascia only version of the posterior interosseous artery flap was used whereas in 3 cases a free temporoparietal fascia flap was applied. In 4 patients an ALT flap was used.

Results and Conclusions: All free flaps healed completely. In the local fascia flap into cases a distant tip necrosis developed which required repeated skin grafting. In one case persistent osteomyelitis required shortening arthrodesis. No amputations were necessary.

Conclusion: Fascia flaps embody a specific entity of flaps which are well applicable to soft tissue reconstruction of the hand were a thin and pliable reconstruction is mandatory. Although local options such as the fascia only intraosseous posterior flap are available, the microvascular tissue transfer has shown fewer complications in this series. Besides the ease of insetting, the available size of the free flap can be considered a major advantage.

Grift Hand Spastic, tetraplegic, and obstetric paralysis

List of authors:
Guillermo Loda

1 Guillermo Loda (Ciudad Autonoma de Buenos Aires)

Objectives / Interrogation: Personal Approach
Brief description of an anatomical analysis of "grift hand"
Different and known surgical procedures, indications, suggestions, difficulties and complications are mentioned in this presentation
A new surgical procedure is presented so as to facilitate and minimize time of the surgery with excellent results when treating such a serious deformity as "grift hand"

Methods: This practice is called "serpent technique", it corrects the intrinsical paralysed muscles. Adding to this procedure the Aponeuro- poli-dermodesis on the palm of the hand

Results and Conclusions: Considering this complex pathology, spasticity, tetraplegic and obstetric paralysis different procedures are performed simultaneously such as tendon lengthening, tendon transplant, and capsuloplasty
All the procedures should be in a one step surgery

Keywords: -
Complex osteotomies with patient specific guides

List of authors:
Christian Kindler*1, Bernhard Lukas1
1 Schoen Klinik Muenchen-Harlaching (München)

Objectives / Interrogation: Sometimes corrective osteotomies may be challenging. Three dimensional osteotomies are difficult, especially if intraarticular cuts are necessary. Advanced computer based analysis and planning offers new possibilities. We planned to use this technique in selected cases and started our collaboration with "CARD - The Balgrist" end of 2016. This institute offers 3D analysis and patient specific guides, produced by "Medacta". The question was, if this technique results in clinical and economic satisfaction for the patient and the hospital.

Methods: In our clinic we collected 17 patients with complex, mostly posttraumatic deformities from wrist to elbow joint. In these cases bilateral 3D analysis were performed. In 11 out of 17 cases we did corrective osteotomies with patient specific 3D guides, planned by "CARD" and produced by "Medacta". The following pathologies were treated: intraarticular distal humerus malunion, radial neck malunion and deformity, proximal radius malunion with radial head subluxation, forearm shaft malunion, distal radius nonunion with severe deformity and DRU-joint dislocation, intrarticular distal radius malunion, congenital ulna minus-deformity, double metacarpal malunion, olecranon malunion.

Results and Conclusions: Bilateral 3D Analysis offers new possibilities, a specific insight in malunion and deformity. In combination with patient specific guides, osteotomies get easier, sometimes render possible and much more accurate as without guides. But it may be difficult to transfer the preop planning into the “in vivo” situation, due to soft tissue, scar tissue, unstable nonunion and the fitting of the guide to the bone. In our patients we received good results in all, the patient satisfaction was high. All osteomies healed.
The technique is very expensive and not covered by the german health system. But it makes sense to use this modern technique in selected complex cases, despite the high costs. In the german system osteotomies at hand level are not cost-effective, double osteotomies at forearm level cover the costs adequate.

Scaphoid non-union - should we treat it arthroscopically?

List of authors:
Fernando cruz², silvia silverio², leonor fernandes³

¹ hospital Lusiadas (Lisboa)
² hospital Lusiadas, hospital santanna (Lisboa)
³ hospital Lusiadas, centro hospitalar torres vedras (Lisboa)

Objectives / Interrogation: In the treatment of scaphoid nonunion, the aim of arthroscopy is to reduce risk and operative duration, shorten recovery and immobilization time and improve bone healing, preserving vascularity as much as possible and makes the procedure safer and more accurate.

The aim of this presentation is to analyze our results with this innovative treatment and to compare it with similar clinical cases that underwent open treatment in our institution.

Methods: Fifty four patients with scaphoid non-union were treated in our hospital from 2009 to 2017.
In the open group (n= 25), patients were treated with open reduction, debridement, cortico-cancellous bone graft from distal radius and fixation with a compression screw.
Arthro group (n= 29), were treated arthroscopically with focus debridement, distal radius cancellous graft when needed, and fixation with compression screw.
Post-operatively patients have the same protocol and were kept in a plaster for 4 weeks followed by splint for another 4 weeks, and they underwent hand therapy beginning at 6-8 weeks.
All the patients were revised at the final follow-up using the Modified Mayo Hand score, Visual analogue scale and radiological assessment in AP and profile

Results and Conclusions: Average age and male/female ratio of the patients in both groups were similar (Open: 35 years (19-69) and M:F ratio 14:2, Arthro: 28 years (20-61) and M:F ratio 14:1).
We lost three patients (12%) in open group and two patients (6%) in arthro group to follow-up.
In open group 20 patients (81%) achieved radiological union at an average follow up of 26 weeks (16-32). All patients but three (81%) achieved good functional outcome at mean follow up of 52 weeks (32-74).
In Arthro group, 27 patients (89%) achieved radiological union, at an average follow up of 17 weeks (16-27). At 52 weeks all patients but two, with proximal pole non-union, achieved good functional outcome.
The average final Mayo score was 78,3 in the Open group and 92,3 in the Arthro group.
There was a better range of movement in group B ( mean F/E 55-0-50) comparatively with group A ( mean F/E 47-0-39)
Arthroscopic treatment of scaphoid nonunions seems to bring a better functional outcome with shorter time to reach consolidation compared with the open treatment.
Both techniques present similar consolidation rates after one year.
Even if arthroscopy is a difficult technique, with a long learning curve, we believe arthroscopic treatment of scaphoid nonunions should be provided to patients if possible.

Keywords: scaphoid non-union, arthroscopy
Objectives / Interrogation: Describe the new technique "POLAR" for its acronym in English "Palmar oblique ligamentodesis for articular rescue" for the treatment of Bennet's fractures with small fragment, less than 1/6 of the articular surface (type 2A in the classification of the author), and its clinical application.

Methods: The technique described by the author is explained, and a series of 10 cases is presented, which present Bennet fractures, with joint involvement less than 1/6, with an age range of 25-42 years, injury time of 2-5 weeks. In these patients, the osseous fragment is removed and a bone anchor inserted to reattach the oblique palmar ligament at the base of the thumb, allowing early rehabilitation and functional recovery, with good articular stability.

Results and Conclusions: 10 patients were treated with this technique, 8 with bone anchors and 2 with intraosseus suture, followed by an early rehabilitation protocol. A minimum follow-up of 6 months and a maximum of 2 years was performed, Grip and index-thumb pinch dynamometry was on average 85% compared to the healthy side, without the presence of instability or pain, with minimal restriction in the Arcs of movement with respect to the non-injured side, all patients returned to work without limitation.
(Another study was conducted to complement this paper, performing finite element tests with computer simulations, presented in another abstract)

Acute scapholunate dissociation, "A" assembly an effective option for its treatment.

List of authors:
Fidel Cayon*, Gabriel Alegria1
1 Centro de Especialidades Ortopedicas (Quito)

Objectives / Interrogation: Objectives: To evaluate the result of the treatment with an "A" Assembly with percutaneous kirschner wires for the treatment of acute injuries of the scapholunate joint.

Methods: Methods: We performed a retrospective study for the evaluation of the results obtained with the "A" assembly for acute scapholunate dissociation. If we achieve an adequate reduction of the joint and we can maintain it during the acute scarring process, we will have a ligament that will be able to adequately fulfill its function. We propose the technique of an assembly in "A" with Kirschner wires for the treatment in acute, this technique consists of the placement of a first guide wire between the scaphoid and the lunate to help us as an axis for the closure of the affected joint in the trauma, once this is achieved we must also fix with a percutaneous wire the scaphoid towards the Capitate bone, this will act as an attachment element when placing the last wire from the lunate to the Capitate. We took all the patients operated by our team with this surgical technique from January 1, 2016 to June 30, 2018 and we evaluated the reduction obtained radiographically as well as the discomfort that the patient currently presents after the removal of the wires evaluating strenght, range of motion and pain.

Results and Conclusions: Results: In 7 cases we have used the "A" assembly for the treatment of Scapholunate lesions, we have achieved reduction of the joint in 100% of the cases, verifying the same radiologically. Radiological studies have been carried out with follow-up Immediately, one and 3 months after the injury, in 1 case a scapholunate dissociation was again identified in the third month, although clinically it remained asymptomatic. We evaluated the pain, range of motion and strength at 3 and 6 months, comparatively with the contralateral wrist. In the VAS scale the pain maintained an average of 2/10 (1-6) at 6 months post-trauma, the mobility arches reached an average of 80% (90-70) on the contralateral side and the strength reached 80% on the contralateral side.

Conclusions: The assembly in "A" in the acute injuries of the scapholunate joint is a valid treatment for its management, allowing an adequate primary healing of the ligaments, achieving pain relief, maintenance of the force and the range of motion in functional ranges.

Iatrogenic nerve injury following steroid injection for thumb basal joint arthritis - A rare complication

List of authors:
Qureish Vanat*, Manish Gupta1, Dominic Power1
1 Queen Elizabeth Hospital NHS Trust (Birmingham)

Objectives / Interrogation: Intra-articular steroid injections are commonly used for symptomatic relief in early degenerative arthritis (Eaton Grade 1 & 2) of the basal joint of thumb. This is considered a relatively safe procedure with few complications such as variable symptom relief, skin depigmentation and the occasional infection reported in literature.

Methods: We report and describe a case that was complicated with an iatrogenic injury to a branch of the superficial radial nerve. This was confirmed on surgical exploration. The neuroma was excised and the proximal nerve end was protected with a synthetic neural cap.

Results and Conclusions:
This is a rare complication of a commonly performed simple procedure and has not been previously reported in published literature. We will discuss the possible aetiology of this iatrogenic injury in our patient and make recommendations for prevention, early diagnosis and management.

Keywords:
iatrogenic, nerve injury, neuroma, superficial radial nerve, basal thumb joint
Trapeziometacarpal arthroplasty, Case report with Ball and socket type prostheses.

List of authors:
Fidel Cayon*, Gabriel Alegria1
1 Centro de Especialidades Ortopedicas (Quito)

Objectives / Interrogation: Objective: To evaluate the pain, strength and mobility arches in the trapeziometacarpal joint in patients undergoing MAIA Prosthesis (Group Lepine, France) placement by the same hand surgeon from January 1, 2015 to June 30, 2018

Methods: A retrospective study of case reports was carried out, taking all the cases operated by the same hand surgeon in which trapeziometacarpal MAIA prostheses (Group Lepine, France) were placed. The patients were evaluated before the surgery with the VAS scale and the grip strength with a pulse dynamometer, after the surgery and with a follow-up of up to 3 years we evaluated the result again and compared it with the same measures of the contralateral hand.

Results and Conclusions: Results: Four patients were operated performing the arthroplasty, all with grade III rhizarthrosis according to the Eaton-Glickel classification, all cases underwent total arthroplasty with ball and socket type prostheses with dorsal joint approach. All cases were a dominant hand. The 4 patients improved their strength achieving 80% of the grip strength in relation to the contralateral side, the mobility arcs compared to the non-operated side reached 90% in all of them, all patients reported pain relief. No complications were reported.

Conclusion: the MAIA prosthesis (Lepin Group, France) is an adequate surgical option for the treatment of Rizarthrosis in patients with grade III classification that achieves adequate pain relief and functional mobility.

List of authors:
Gabriel Alegria*, Fidel Cayón
1 Centro de Especialidades Ortopedicas (Quito)

Objectives / Interrogation: OBJECTIVE: To evaluate the outcomes (range of motion, function, and pain relief) of the semi constrained prosthesis in posttraumatic arthritis.

Methods: METHODS: A single surgeon performed proximal interphalangeal (PIP) total replacement arthroplasty (TRA) in 3 joints using a dorsal approach. Patients with posttraumatic arthritis or osteoarthritis of the PIP joint were included. Range of motion, pain, satisfaction, postoperative key pinch and grip strength, and Disabilities of the Arm, Shoulder, and Hand questionnaire data were collected. Complications, component integration were noted. Average follow-up was 24 months (range, 6-24 mo).

Results and Conclusions: RESULTS: Total arc of motion averaged 40° before surgery and improved significantly in all patients, for an average postoperative arc of motion of 61°. Grip strength averaged 30 kg in the affected hand and 35 kg in the contralateral hand after surgery. VAS score improved from 5 to 1. Postoperative key pinch strength averaged 6 and 7 kg in ipsilateral and contralateral hands, respectively. The average Disabilities of the Arm, Shoulder, and Hand score after surgery was 14. No coronal plane deformity or postural deformity was observed. Good component integration and range of motion were observed in all joints.

CONCLUSIONS: The semi constrained prosthesis to dorsal approach to PIP TRA can result in excellent range of motion, function, pain relief and good satisfaction with minimal complications in patients with osteoarthritis or posttraumatic arthritis. The dorsal approach offers the advantages of wide exposure and allowing early postoperative motion. This case series demonstrates compelling data for a prospective PIP TRA in patients with osteoarthritis and posttraumatic arthritis.

RADIOCARPAL WRIST ARTHRODESIS WITH CANNULATED SCREWS, CASE REPORT

List of authors:
Gabriel Alegria*, Fidel Cayón
1 Centro de Especialidades Ortopedicas (Quito)

Objectives / Interrogation: OBJECTIVE: The aim of this study was to evaluate an alternative for wrist fusion by using cannulated screws.

Methods: MATERIAL AND METHOD: Total wrist arthrodesis is commonly performed using fixation plates, which can produce soft tissue irritation, often require removal, and limit the ability to position the hand in space. Cannulated screws (Acutrak 2 Headless Compression Screw System) for wrist fusion from Acumed, USA were used according to the manufacturers' instructions. The articular surfaces of the radius, scaphoid, lunate, and capitate were debrided, and a cannulated screw inserted from the base of the radial styloid and dorsal radius to the carpal joint. Cancellous allografts were added to the decorticated wrist bones. One wrist was treated with this technique and followed for a minimum of 6 months. Indications for fusion was old arthritis secondary to SLAC. Patient was evaluated before surgery and at final follow-up using the VAS pain score and grip strength measurements using a hand-held dynamometer.

Results and Conclusions: RESULTS: The patient improved his grip strength and decreased his pain score. Was suitable fusion united, and no dorsal soft tissue problems or required implant removal. This device deliver stable fixation, facilitates hand placement, and does not require removal.

CONCLUSIONS: The use of cannulated screws for radiocarpal fusion is a good easy alternative for wrist fusion without the problem of the size of the plate device commonly used.

Development of method for measuring the thumb pronation and palmar abduction angles during opposition movement using a three-axis gyroscope

List of authors:
Koji Fujita*, Tomoyuki Kuroiwa1, Toru Sasaki2, Akimoto Nimura2, Yuta Sugiura3, Atsushi Okawa1
1 Tokyo Medical and Dental University, Graduate School of Medical and Dental Sciences, Dept. of Orthopaedic and Spinal surgery (Tokyo)

3 Keio University (Kanagawa)

Objectives / Interrogation: Thumb opposition is vital for hand function and involves pronation and palmar abduction. The improvement of pronation is often used as one of the evaluation items of the opponensplasty method for severe carpal tunnel syndrome. However, most of the studies used substitution evaluation methods for measurement of the pronation angle. Thus, there is still no appropriate method for measuring thumb pronation angle accurately in carpal tunnel syndrome patients. In recent reports, a wearable gyroscope was used to evaluate upper extremity motions and it can be possibly used for accurate measurement of the thumb pronation angle along the three-dimensionally moving bone axis. Thus, we investigated the reliability of measuring thumb pronation using a gyroscope and evaluated whether this method can be used to detect opposition impairment.

Methods: The participants were volunteers with unaffected upper limbs (32 hands) and patients with carpal tunnel syndrome (27 hands). The pronation and palmar abduction angles during opposition movements were measured using a three-axis gyroscope that included a three-axis accelerometer. The gyroscope was fixed onto the first metacarpal bone and the thumb phalanx.

Results and Conclusions: The pronation and palmar abduction angles of the metacarpal bone and the palmar abduction angles of the phalanx significantly decreased in the carpal tunnel syndrome group.

The range of motion during opposition movement

The pronation angle of the metacarpal bone during opposition movement peaked later than the palmar abduction angle in all hands. We were able to measure the thumb pronation and palmar abduction angles using the three-axis gyroscope, and this tool was able to detect impairments of thumb opposition due to carpal tunnel syndrome. This could be a tool for measuring thumb and finger angles and for detecting impairments caused by various diseases.

Resting Forearm Position and its Relevance to the Dart Thrower's Motion

List of authors:  
Mark Ross*, Libby J Anderson¹, Amaan Sood¹, Greg Couzens¹  
¹ Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: We propose that the net effect of forearm rotational motion is to keep the oblique DTM (Dart Thrower's Motion) axis aligned with the visual axis during wrist motion in order to improve accuracy through visual control. We also propose that the default resting position of the forearm places the hand approximately 35° pronated relative to the vertical axis, which brings the oblique axis parallel to the visual axis.

Methods: For the first aim, we used the optical motion capture system (Optotrak Certus®) with infrared emitting surface markers to perform an integrated 3D upper limb kinematic analysis on 4 subjects. For the second aim, we examined 20 normal volunteers using motion analysis technology to ascertain the comfortable resting position of the dominant and non-dominant limbs.

Results and Conclusions: The targeting phase (coupled, biplanar motion) occurs when the oblique plane axis aligns with the visual axis at approximately 35° of forearm pronation. The targeting phase is the only portion of oblique plane activity which demonstrates true DTM (coupling of flexion/extension and radial deviation/ulnar deviation). When asked to rotate into a comfortable resting position, subjects adopted a mean resting forearm posture of 37° of pronation. The average comfortable resting forearm position of the non-dominant limb was found to be angled approximately 6 degrees greater in pronation when compared to the dominant limb. This difference was statistically significant.

The majority of function in oblique plane activities takes place in the extension/radial deviation quadrant, in pronation. There is little utilisation of the flexion/ulnar deviation quadrant or supination during dart-throwing motion activities. The targeting phase is the only phase demonstrating true DTM (collinear coupling of flexion/extension and radial deviation/ulnar deviation). The comfortable resting position of the forearm is in approximately 37° pronation, which corresponds to the position required to align the oblique plane axis with the visual axis.

THE USE OF AUGMENTED REALITY AND ENHANCED TECHNOLOGIES IN HAND SURGERY: A SYSTEMATIC REVIEW

List of authors:
Yasser Al Omran*¹, Tiffanie-Marie Borg², Catrin Sohrabi², Ali Abdall-Razak³, Hauwau Hayat Nadama⁴, Simon Myers², Ali Ghanem²

¹ University Hospital North Midlands NHS Foundation Trust (Stoke-on-Trent)
² Barts and The London School of Medicine (London)
³ Imperial College School of Medicine (London)
⁴ University of Nottingham Medical School (Nottingham)

Objectives / Interrogation: Augmented reality utilizes a set of technologies that superimposes digital information into the real world and is a rapidly growing field. In Surgery, augmented reality may provide the surgeon access to radiological and sonographic images enabling for better contextual surgical planning and navigation; a feature which may be very fruitful in hand surgery due to the small structures encountered and the dynamic nature of operations. A systematic review exploring the use of augmented reality and enhanced technologies in hand surgery is therefore warranted to explore current augmented reality technologies and to guide future augmented reality-related strategies that can be used in Hand Surgery.

Methods: A systematic literature search of Medline, EMBASE, and Web of Science databases was performed using appropriate search terms in order to identify all applications of Augmented in hand surgery from inception to September 2018. All articles were reviewed by two authors and a qualitative synthesis performed of those articles that met the inclusion criteria. The systematic review and results were conducted and reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta Analysis (PRISMA) guidelines.

Results and Conclusions: A total of 282 articles were identified for title and abstract review. Fourteen studies met the inclusion criteria. Most of the applications of augmented reality and enhanced technologies relate to dynamic infrared thermography with some benefits being highlighted with its use. The feasibility of augmented reality in hand surgery has been demonstrated in specific indications. Augmented reality in Hand Surgery is still in its infancy. As technology develops, it is expected that the use of augmented reality and other enhanced technologies will become more commonplace in the field of hand surgery.

Ligament Reconstruction and Tendon Interposition and Partial Trapeziectomy for Pantrapezial Arthritis

List of authors:
Mark Ross*, David Gilpin1, Christopher James1, Susan E Peters1, Richard Benson1, Bradley Gilpin1
1 Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: The purpose was to evaluate whether removing the scaphotrapezoid joint (STJ) when performing a Ligament Reconstruction and Tendon Interposition (LRTI) for pantrapezial arthritis resulted in any clinical or radiographic compromise compared to LRTI alone.

Methods: In a consecutive cohort of 198 thumbs having surgery for CMCJ +/- pantrapezial arthritis, 78 patients were selected to generate two closely matched cohorts and a cross-sectional review was completed of both clinical and radiological outcomes at an average of 41 months (range: 6 - 203). 43 thumbs with no STTJ arthritis had LRTI alone. 35 with pantrapezial arthritis had LRTI and excision/interposition of STJ.

Results and Conclusions: When comparing LRTI vs LRTI plus partial trapeziectomy the only significant difference, though small, was in favour of the LRTI for satisfaction VAS (median 99 vs 90.5/100). Grip strength, lateral pinch strength, tip pinch strength, Kapandji score, pain on normal activity, Patient Rated Wrist Evaluation or QuickDASH score showed no significant differences. Radiographic analysis did not demonstrate significant differences (mean degrees: LRTI vs LRTI plus partial trapeziectomy) for radio-lunate (RL) angle (11 vs 13), capito-lunate angle (12 vs 11), scapholunate angle unloaded (55 vs 54), scapholunate angle loaded (50 vs 49). In both groups 10 patients had a RL angle > 15 degrees. In the LRTI plus partial trapeziectomy group, 2 had scaphoid and lunate extension; with 3 observed in the LRTI group.

We demonstrated that there was no increased risk of poorer clinical outcome or the development of a DISI deformity following resection of the proximal pole of the trapezoid with tendon interposition in the residual gap. The management of pantrapezial arthritis with LRTI and proximal trapezoid excision and STJ interposition appears satisfactory on short to medium term clinical and radiographic follow-up.

Surgery and Rehabilitation Following Revision Open Carpal Tunnel Release with Hypothenar Fat-pad Flap

List of authors:
Thomas Maxwell*, Wilma Walsh, Mark Ross
1 Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)
2 Extend Rehabilitation (BRISBANE)

Objectives / Interrogation: Scar adhesions of the median nerve in the carpal tunnel (CT) following open carpal tunnel release (OCTR) can result in recurrent CT syndrome with pain, sensory and motor deficits. Revision surgery with pedicled hypothenar fat-pad flap (HFPF) aims to prevent re-adherence of scar tissue and improve perineural vascularity. This study reports the outcomes of patients undergoing revision OCTR with HFPF.

Methods: This is a prospective study of a consecutive sample of 13 patients (14 wrists) who underwent revision OCTR with HFPF and were assessed preoperatively and at 6 weeks, 3, 6 & 12 months or greater post-op. 6 wrists (42.9%) were female and 11 (78.6%) dominant. Median patient's age at surgery was 60 (range 39 - 78) years and median follow-up time was 14 (range 1.5 - 36) months. Nine wrists had had one prior operation, three wrists had had 2, one wrist had had 3, and one wrist had had several prior operations. Median interval from most recent CTR was 36 (range 4 - 240) months.

The following measures were used for assessment: Levine's CT Questionnaire (LCTQ), QuickDASH and Patient Rated Wrist and Hand Evaluation (PRWHE), pain (Visual Analogue Scale), grip and pinch strength, and improvement using the Global Rating of Change (GRC). Comparisons are made between data collected before the surgery and at most recent follow-up equal or greater to 12 months (n=7). Results are reported as median (25% - 75%).

Results and Conclusions: LCTQ scores for symptoms decreased from pre-operative value of 3.6 (1.9 - 2.7) to 2.5 (1.3 - 1.4) at last follow-up. PRWHE scores dropped from 41.5 (15 - 57) at baseline to 16.3 (1.6 - 55.4) at last follow-up, paralleled by QuickDASH scores which dropped from 42.5 (22.7 - 54.6) to 31.8 (13.6 - 43.2). Pain diminished throughout the time course from 41 (15.3 - 60.5) to 7.5 (4 - 39).

Grip and pinch strength were maintained from baseline to most recent follow-up from 20.3 (10.9 - 28.8) to 16.1 (9.3 - 22.9) in grip, 4.0 (2.0 - 5.5) to 5.3 (2.9 - 5.6) in lateral pinch strength and 3.5 (2.3 - 5.0) to 2.9 (2.4 - 3.8) in tip-to-tip pinch strength. Finally, GRC scores for symptoms and function were positive and tended to increase from 5 (3.3 - 6.8) at 6 weeks post-operative to 6 (0 - 7) at final follow-up and from 3 (-2 - 5.5) to 4 (-1 - 5.5) respectively.

These results, combined with those presented in the literature, suggest that OCTR with HFPF shows outcomes better than revision without flap while being much simpler than other pedicled and free flaps.

Stress behavior in CMC thumb in Bennett's fracture: Finite element analysis

List of authors:
Carlos Torres*, Mauricio Toro, Carlos Morales
1 Hospital de San José, Eciplast (Bogotá)
2 Techfit, Sampedro Inc. (Bogotá)

Objectives / Interrogation: Evaluate the effort that occurs in a normal CMC thumb during grip and index-thumb pinch in comparison with a joint with a Bennett's fracture.

Methods: A 3D reconstruction using the Mimics® software was performed on images obtained by CT of a healthy right hand. A solid model was generated using design software to perform the finite element analysis. Subsequently, we proceeded to simulate a Bennett's fracture by performing an axial cut corresponding to 1/6 of the articular surface of the first metacarpal and removing the resulting fragment. The software used for the simulation by finite elements was Ansys®. The solid models were assigned cortical bone and cartilage properties as appropriate: a Young's modulus of 18 GPa and a Poisson's coefficient of 0.2 for bone (Gislon, Stansfield, & Nash, 2010), and a Young's modulus of 10MPa and a Poisson's coefficient of 0.45 for cartilage (Carrigan, Whiteside, Pichora, & Small, 2003). Both between the cartilage with the trapezius, and between the cartilage and the metacarpal, a rigid fixation contact was established.

The next step was to generate the mesh which was refined in the contact surfaces with 0.4mm elements to improve the analysis in those points. Subsequently, an axial compression force was applied on the distal articular surface of the metacarpal as illustrated in Figure 3, with a value of 66.1N simulating the force that is exerted on the metacarpophalangeal joint when grip force is made. To simulate the role of the ligaments that stabilize the joint when making a clamp, the movement of it was limited only on the axial axis of the metacarpal.

Results and Conclusions: The simulated model does not show a significant difference between the efforts that occur in the joint when it is healthy or when it presents a Bennett type fracture, which seems to indicate that in this type of fractures the joint is not subjected to greater stresses than those who would be subjected in a normal situation.

It could support the advantages of the P.O.L.A.R technique (presented in other abstract)

Keywords: finite element analysis, Bennett's fracture, stress behavior
Four-corner fusion in SLAC & SNAC wrist surgery: Does method of fixation really make a difference?

List of authors:
Logan McGinn*, Ruby Grewal
1 Division of Plastic & Reconstructive Surgery, Roth I McFarlane Hand & Upper Limb Centre, St. Joseph’s Health Care (London)
2 Division of Orthopaedic Surgery, Roth I McFarlane Hand & Upper Limb Centre, St. Joseph’s Health Care (London)

Objectives / Interrogation: Four-corner fusion (4CF) has traditionally been reported to have a higher complication rate with similar functional outcomes as the PRC. To date, there have been limited comparisons that specifically focus on whether the fusion method utilized in 4CF affects functional outcomes and complication rates. In this study, we explored the differences in outcomes of two different fixation methods in 4CF and how these compare to traditionally reported 4CF outcomes in the literature.

Methods: A retrospective chart review was conducted to compare headless compression screw (HCSF) versus staple fixation (SF) in four-corner fusion for SLAC or SNAC wrist in a single surgeon’s practice over a ten-year period. Primary functional outcomes included pre- versus post-operative flexion-extension arc and grip strength, complication rate and time to union. Two-tailed T-tests were used to compare the outcomes of HCSF and SF methods. The Chi-squared test was used to evaluate the complication rates associated with each method.

Results and Conclusions: Sixty-two patients with sixty-four wrists were identified; 38 wrists were treated with HCSF and 26 with SF. The majority of patients were male (84%) with an average age of 60.2 years and 52.9 in the HCSF & SF groups, respectively. Patients were followed on average for a 10-month period. HCSF patients had improved flexion arc post-operatively (108% of pre-operative arc), whereas SF patients lost an average of 30.4% or 27.9° of their pre-operative range (p-value:0.00003). Grip-strength was improved in both groups. A statistically significant higher complication rate was associated with SF (50%) versus HCSF (13.2%). Hardware failure (3), hardware associated pain (4), dorsal impingement (2) and infection (3) were the most common complications of SF, whereas neuropraxia (2) and hardware failure (3) were the most common complications associated with HCSF. The higher complication rate and equivocal functional outcomes traditionally reported for 4CF may be associated with specific fixation methods such as the SF.

Patients treated with SF have a statistically significant greater loss of flexion-extension arc post-operatively, are immobilized longer, experience a higher rate of complications and re-operations. Various fixation methods are available for 4CF, however functional outcomes and complication rates are inconsistent among these methods.

Long Term Outcomes of Medial Epicondylectomies

List of authors:
Libby J Anderson*1, Mark Ross1
1 Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: We hypothesized that medial epicondylectomy is a safe and effective method to treat medial epicondylitis and ulnar neuritis, with good medium to long-term patient outcomes.

Methods: This is a study of a consecutive sample of 29 patients who underwent medial epicondylectomy and were assessed preoperatively and at 3 & 6 months and 2, 3, 4 or 5 years after surgery. 2 patients had medial epicondylectomy alone and 27 patients also had ulnar neurolysis, 7 of whom had additional procedures such as removal of osteophytes (2 patients), debridement (2 patients), biopsy (1 patient), medial collateral ligament reconstruction (1 patient) or removal of plate (1 patient). 7 participants (24.1%) were female and 12 (41.4%) had surgery on the dominant side. Median patient's age at surgery was 49 (range 24 - 75) and median follow-up time was 12 months (range 3 - 60 months).

We measured pain and satisfaction (Visual Analogue Scale), Patient-Rated Elbow Evaluation (PREE), function (QuickDASH), Global Rating of Change (GRC), and grip and pinch strength. Results are reported as median (25% - 75%). Comparisons are made between preoperative values (n=28) and one year after surgery (n=14) or last follow-up equal or greater than 2 years (n=8).

Results and Conclusions: Pain decreased from 46.5 (9.8 - 66.5) before surgery to 7.5 (3.8 - 26.5) at last follow-up, whereas satisfaction increased from 15.0 (5.3 - 51.3) to 90.0 (53.3 - 95.3). Function scores improved from baseline values of 43.7 (20.4 - 57.8) for PREE and 54.5 (22.2 - 64.2) for QuickDASH to 17.0 (7.2 - 37.8) and 20.5 (17 - 37.8) respectively at last follow-up. GRC scores for symptoms and function increased throughout the time course from 3 (1 - 5) and 3 (1 - 4) respectively at 3 months after surgery to 5 (3 - 7) and 4 (0 - 6) at last follow-up equal or greater than 2 years.

Range of motion increased slightly with flexion shifting from 135° (130 - 144) to 140 (138 - 149), extension from 0° (-2.5 - 5.5) to 6° (0 - 20.3), supination from 80° (77 - 85) to 85° (77.5 - 97.5), and pronation from 85° (75 - 90) to 82.5° (75.5 - 85). Grip and pinch strength tended also to increase from 31.3 (16.5 - 45.5) to 37.4 (36.8 - 48.3) kg in grip, 5.4 (4.0 - 7.6) to 6.5 (4.4 - 8.9) kg in lateral pinch strength and 4.0 (3.0 - 4.6) to 5.1 (3.5 - 5.8) kg in tip-to-tip pinch strength.

These results, combined with those from the literature, suggest that medial epicondylectomy is a safe and effective procedure to treat medial epicondylitis and ulnar neuritis.

The Role of Neurolysis for Hourglass Constrictions in Chronic Parsonage-Turner Syndrome

List of authors:
Scott Wolfe*, Karthik Krishnan¹, Darryl Sneag¹, Joseph Feinberg¹, Ogonna Nwawka¹, Steve Lee¹
¹ Hospital for Special Surgery (New York)

Objectives / Interrogation: Wide variability in recovery of patients affected by Parsonage-Turner syndrome (PTS) is now recognized, with up to 60% experiencing residual motor deficits or pain. Using high-resolution MRI and ultrasound (US), we routinely identify hourglass constrictions (HGCs) in affected nerves of patients with persistent motor paralysis from PTS. We hypothesized that patients with chronic PTS and HGCs would experience motor recovery and functional improvement following microsurgical epi- and perineurolysis of the constrictions.

Methods: Eight patients (3 F), ages 21-61 years, with chronic motor palsy from PTS and HGCs were treated with microsurgical epi- and peri-neurolysis of HGCs. Average time from symptom onset to surgery was 12.0 ± 4.7 months. Preoperative electrodiagnostic (EDX) testing and manual motor testing confirmed complete muscle denervation in the distribution of affected nerve(s). HGCs were identified in one or more nerves in all patients using 3.0 T MRI and US. Microneurolysis was indicated for the following: failure to improve clinical and EDX function after 6 months with 3 successive exams, each at least 6 weeks apart (n = 3), or 12 months without improvement since symptom onset (n = 5). Muscle strength was assessed pre-and postoperatively using the modified Medical Research Council (MRC) scale and EDX.

Results and Conclusions: Average postoperative clinical and EDX follow-up was 13 months (range, 4-29) and included data on 27 of 29 affected muscles. Thirty HGCs in 11 nerves were identified on imaging and confirmed intra-operatively, involving the pronator teres and anterior interosseous fascicles of the median nerve, suprascapular, axillary and radial nerves proper. One patient presented with bilateral disease. 7/8 patients experienced functional recovery and 6/8 experienced electrical recovery in the majority of affected muscles. Average MRC increased from 0.5 ± 1.1 to 3.3 ± 1.6 among the 7 patients with unilateral disease and from 0.3 ± 1.0 to 2.5 ± 2.0 for the entire cohort (p<0.01). EMG revealed significant motor unit recovery from axonal regeneration in 16/28 muscles (p<0.01). Microsurgical epi- and peri-neurolysis of HGCs in this small cohort was associated with significant electrical and functional muscle recovery at an average follow-up of 9.5 months. We recommend microsurgical epi- and perineurolysis of HGCs for patients with PTS motor palsy who fail to improve with non-operative treatment.

carpectomy the proximal row vs arthrodesis four corner in patient with SNAC and SLAC

List of authors:
Francisca Vazquez Alonso*, José Joaquín Díaz López1, enrique hernandez salcedo1
1 UMAE de traumatologia y ortopedia (naucalpan edo de mexico)

Objectives / Interrogation: evaluate the functional outcome of patients with advanced lesions and collapse scapholunate advanced collapse scaphoid nonunion treated with proximal row carpectomy versus four corners arthrodesis.

Methods: A retrospective, cross-sectional descriptive study, which will be held in the city of Naucalpan, State of Mexico, in the Medical Unit of High Specialty (UMAE), Hospital of Traumatology and Orthopedics Lomas Verdes is made, the study population were rightholders patients Mexican Social Security Institute, 19 rightholders patients, not probabilistic consecutive cases operated on of carpectomy row proximal versus 52 patients after arthrodesis of 4 corners, consecutive cases nonprobability in the period from 2010 to 2015.

Results and Conclusions: 71 patients, 62 male patients (87.3%) and 9 female patients (12.7%) were analyzed. For Carpectomy were 14 male patients (73.7%) and 5 female patients (26.3%), for patients with four corners arthrodesis were 48 male patients (92.3%) and 4 female patients (7.7%) were included. SNAC 48 patients (67.6%) and 23 patients with SLAC (32.4%) were identified. Proximal row carpectomy 19 (26.8%) and 52 four-corner arthrodesis (73.2%) were performed. Of the total patients, 65 of them (91.5%) were enrolled without any complications, 3 patients with delayed consolidation (4.2%), with residual pain two patients (2.8%) and 1 patient with infectious process (1.4%) were identified. Reintegration time was an average of 5.83 months. The Wilcoxon rank test was performed wherein the variable postoperative pain and preoperative pain have significant value of p <.001. The same test was performed for the Quick Dash prior to the surgical procedure and Quick Dash after the surgical procedure with significant value of p <.001. U test of Mann-Whitney rank was performed for the two groups with a p <.411 for preoperative pain, postoperative pain ap of .037. Conclusions: The technique of four corners arthrodesis means more surgery time and costs that proximal row carpectomy, but the reincorporation of the patient is faster and satisfaction with the results is slightly higher, plus practically not observed a frequency of complications. Pain before the procedure and after the same was observed with a similar relief four corners arthrodesis and proximal row carpectomy, so the final decision to opt for some is directly related to the patient's occupation and physical demands over other factors.

carpectomy, arthrodesis four corner, snac, slac
DESCRIPTION AND OUTCOMES OF SURGICAL TECHNIQUE FOR TREATMENT OF SCAPHOID NONUNION WITH OLECRANON BONE GRAFT.

List of authors:
paulo randal pires¹, Paulo Randal Pires Júnior¹, Marcella Rodrigues Costa¹, Gustavo Pacheco Martins Ferreira², Daniel Barbosa Regazzi²
¹ Hospital Madre Teresa (BELO HORIZONTE)
² Hospital Maria Amélia Lins (BELO HORIZONTE)

Objectives / Interrogation: The best treatment for scaphoid nonunion remains controversial and this paper describes a surgical technique for the treatment of nonunion of the scaphoid with the rate of consolidation based on radiographs. The aim of this study is to demonstrate a less morbid procedure with good results when compared to several techniques described in the literature.

Methods: A group of 21 patients with the diagnosis of nonunion of the scaphoid was submitted to surgical treatment at an orthopaedic service from December 2013 to December 2017, however six had to be excluded from the research. It was obtained than, 15 cases who had the complete follow-up and medical records. The surgical technique used a palmar approach to access the scaphoid and clean the nonunion focus. An osteotome or a tweezers was kept in focus to maintain bone height, length and correct alignment. The fixation of the scaphoid with hadless screw was made prior to graft placement, in contradistinction to literate techniques. Subsequently, bone graft obtained from olecranon was positioned in the nonunion space. The wrist was immobilized with short splint postoperatively for 4 weeks, when rehabilitation was instituted. Patient’s radiographs were analyzed at all appointments until radiographic heal of the scaphoid were seen.

Results and Conclusions: All 15 patients were male such as literature data. The site of involvement was the middle third of the scaphoid associated with reabsorption larger than 5mm, subchondral cysts and malalignment. The mean age found was 35.2 years (18-53) and the most affected hand was dominant (60%). The average time to consolidation was 3.4 months (2-5) and all patients demonstrated consolidation on the radiographs in the postoperative follow-up. There was no need to use computed tomography or other image exams to diagnose the consolidation.

Recent techniques show high rates of consolidation, around 88% to 92% despite the type of bone graft (vascularized or non-vascularized). Some authors obtained consolidation with an average time of 6.2 weeks using vascularized graft, and others even 10.2 weeks. This paper shows 100% of heal using a non-vascularized ulna graft, with an average time of 3.4 months.

The treatment for scaphoid nonunion remains a challenge and this study brings a good option for the surgical technique with encouraging results when compared to techniques established in the literature.

Teriparatide can enhance bony union of beta-tricalcium phosphate in cases of corrective osteotomy post distal radius malunion: a case series

List of authors:
Yukiko Morimoto*, Yusuke Sogabe, Akira Kawabata, Kiyohito Takamatsu
1 Yodogawa Christian Hospital, Orthopedic surgery (Osaka)

Objectives / Interrogation: Teriparatide activates osteoblastic bone formation and effectively promotes bony union in distal radial fractures. Here we report two cases of distal radius malunion simultaneously treated using corrective osteotomy and beta-TCP with daily administration of teriparatide for osteoporosis.

Methods: The first case was a 64-year-old woman who underwent osteotomy for distal radius malunion. The surgery, which was performed 6 months after the trauma, comprised the following three steps: 1) an initial opening-wedge osteotomy, 2) implantation of an artificial bone graft (beta-TCP) in the bone defect, and 3) radius fixation using a volar locking plate. The patient was administered teriparatide injections (40 mg/day) for osteoporosis. Bony union was achieved within 3 months of surgery. The second case was a 57-year-old woman who also underwent osteotomy for distal radius malunion. The surgery, which was performed 5 weeks after the trauma, followed the same protocol as stated for the first case. This patient also received daily teriparatide injections for osteoporosis. Bony union was achieved within 7 weeks of surgery.

Results and Conclusions: Discussions:
Aspenberg, in his report, reported that teriparatide enhances bony union following distal radius malunion. In particular, autologous bone grafting is considered the gold standard for the treatment of segmental bone defects in patients with distal radius malunion treated using corrective osteotomy. However, in osteoporotic patients, it is difficult to obtain a good quality graft even from the iliac bone. Yasuda reported that, as an alternative to autologous bone graft, bony union can also be provided using an artificial bone graft. Interestingly, Jacobson, in an animal model, reported that an artificial bone graft supplemented with teriparatide provides good bony union. Teriparatide reportedly promotes bony union; however, no study has yet demonstrated its role in artificial bone graft healing. Conclusion:
The addition of teriparatide to artificial bone grafts allows early bony union. This study indicates that teriparatide could help enhance bony union. Further, this method may serve as an alternative method of autogenous bone grafting.

HAND SURGERY IN A FIELD HOSPITAL IN COX’S BAZAR, BANGLADESH

List of authors: Shalimar Abdullah*1, Levin Kesu Belani1, Amir Adham Ahmad2, Munir Osman3
1 Universiti Kebangsaan Malaysia (Kuala Lumpur)
2 International Medical University (Kuala Lumpur)
3 96 Naval Hospital (Lumut)

Objectives / Interrogation: Cox’s Bazar is a border town in Bangladesh currently supporting approximately 1 million Rohingya refugees from Myanmar. The Malaysian government has sent the Malaysian army field hospital as part of a government to government initiative supporting the influx. The army orthopaedic surgeon had requested a hand surgeon to perform four difficult cases of hand surgery in May 2018.

Methods: The four cases were all children ranging in age between 1 year 3 months, 2.5 years, 3 years and 6 years old. They all involved the right hand. One case was due to the 6-year-old child being allegedly thrown into a fire by the military of a neighbouring country and suffered right ring and little finger severe dorsal contracture with ulnar deviation. The other three cases were domestic injuries of holding a burning charcoal, being involved in a burning house and an electrical burn. Two cases were categorized as severe such as the case above and a severe right wrist contracture with right 2nd -4th MCPJ hyperextension.

Results and Conclusions: The average time for operation was 2 hours. All surgeries required full thickness skin grafts from the groin / antecubital fossa. Instruments needed include a sharp Steven’s tenotomy scissors, Adson’s toothed forceps, K-wires of various sizes from 1.0 - 1.4 and a good K-wire driver. The K-wires are left for 2-3 weeks to allow the skin grafts to adhere. Caution is needed during the healing period as the dressings are changed as the patients' level of hygiene is questionable in a refugee camp.

Conclusion
Hand surgery for wrist and finger contracture release can be comfortably done in a limited orthopaedic setting with minimal levels of sterility.

Early Experience with a Novel Synthetic Scapholunate Ligament Construct

**List of authors:**
Benjamin Hope¹, Mark Ross¹, Ruby Strauss¹, Greg Couzens¹
¹ Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

**Objectives / Interrogation:** It is hypothesised that use of a woven polyurethane "artificial ligament" is suitable for reconstructing the scapholunate ligament. We have previously described the mini Lockdown, a technique for entirely transosseous passage of a tendon graft through the proximal row [%1].

**Methods:** The mini Lockdown "artificial ligament" is anchored in the distal scaphoid, routed through drill holes in the proximal row and passed across the triquetro-hamate joint to be secured into the dorsal capitate. The proximal row tunnels are the same as employed in the "SLT" reconstruction [%1]. The mini Lockdown is used in three SL ligament reconstruction situations: 1. in place of temporary K-wire fixation following acute repair or late reconstruction, 2. in conjunction with a strip of FCR via the same transosseous proximal row tunnels (an augmented SLT), or 3. in isolation via the SLT tunnels (a mini Lockdown RASL). Sixteen study participants (1 female, 7 non-dominant) of median age (range) of 41.5 (15 - 60) years who had the mini Lockdown procedure since July 2016 were assessed prior to surgery and at 3, 6 and 12 months after surgery. Measures included Visual Analogue Scale (VAS), Global Rating of Change (GRC), PRWHE and QuickDASH patient reported questionnaires, range of motion and strength measures. Median time to follow-up (range) was 5 (3 - 12) months. Only the most recent follow-up equal or greater than 6 months is reported below.

**Results and Conclusions:** Patient-reported VAS median pain scores decreased from 46.0 to 10.0 and satisfaction increased from 13.5 to 87.0 from pre-operative assessment (n=16) to most recent follow-up (n=9). PRWHE and QuickDASH scores improved from 61.5 and 40 respectively at pre-operative assessment (n=16) to 21.0 and 15.9 at most recent follow-up (n=9). Active range of motion was assessed pre-operatively (n=13) and compared to most recent follow-up (n=9): median wrist flexion/extension decreased from 60/60° to 50/58°; supination/pronation increased from 85/89° to 88/90°; and median radial/ulnar deviation increased from 12/25° to 15/20°. Between pre-operative assessment (n=12) and most recent follow-up (n=9), grip and two-point pinch increased from 77.5% to 78.9% and 73.5% to 100% of the contralateral side respectively.

The mini Lockdown technique offers promising early results showing that it is capable of correcting and maintaining large and longstanding deformities. The design process is ongoing.

Do post-operative radiographs change the management following internal fixation of distal radius fractures?

List of authors:
Stefanie Wieschollek*, Bradley Gilpin¹, Jamie McKenzie¹, Paul Hak¹, Mark P Robinson¹, Greg Couzens¹, Mark Ross¹
¹Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: The utility of obtaining routine post-operative radiographs following the internal fixation of distal radius fractures is poorly defined. The purpose of this study was to determine whether post-operative radiographs influence the current management of fractures of the distal radius following internal fixation.

Methods: We retrospectively reviewed all patients that underwent internal fixation of distal radius fractures over a five year period. We interrogated patient files to determine whether patients were returned to theatre on the basis of routine post-operative radiographs. A total of 543 procedures were performed with 1340 radiographs obtained on these patients over the ensuing six weeks.

Results and Conclusions: Of these patients only seven returned to theatre. All patients that returned to theatre were either symptomatic or had findings prompting revision that were also identifiable on intra-operative radiographs that had not been addressed intra-operatively.

The evidence did not support routine post-operative imaging following the internal fixation of distal radius fractures.

A case of atypical phenotype of bilateral polysyndactyly in Joubert syndrome

List of authors:
Yoko Kishi*, Hideto Okazaki1, Kenta Kikuchi1, Kenji Ogushi1, Mariko Hasegawa1, Akihiro Igarashi1, Masahiro Hatanaka1, Junko Fujino1, Taizen Urahashi1, Hitoshi Ikeda1

1Dokkyo medical university, saitama medical center (saitama)

Objectives / Interrogation: Joubert syndrome (JS), first described by Marie Joubert in 1968, is a congenital anomaly characterized by episodic hyperpnea, abnormal eye movement, ataxia, and intellectual disability. Congenital deformities of the extremities are mostly postaxial polydactyly of the hands and preaxial polydactyly of the feet. Typically, a y-shaped metacarpal bone between the middle and ring finger is seen on x-ray. Our patient had bilateral polysyndactyly of the ring finger from the middle phalanx to distal phalanx in the right hand and from the metacarpal bone to the distal phalanx on the left and polydactyly from the proximal phalanx to the distal phalanx of the right great toe. Here, we describe this atypical case in comparison with previous reports.

Methods: Case report: The patient was a male infant born in normal vaginal delivery with a weight of 3278g at 38 weeks and 3 days' gestation. He was referred to our hospital due to screening because of tongue tumor and hand malformations. Examination revealed abnormal eye movement, polydactyly of the ring fingers bilaterally, and polysyndactyly of the right great toe with the typical molar tooth sign on magnetic resonance imaging. There were no retinal, renal, hepatic, or orofacial defects. Our comprehensive literature search of PubMed on congenital hand anomalies in JS revealed that from 1968 to 2017.

Results and Conclusions: Only 12 reports have described about polydactyly in detail. The average of morbidity of polydactyly is 30.19% (8-100%). In our case, first, separation was successfully performed for the right hand and right foot, and then 3 months later for the left hand. The incidence of JS is between 1/80,000 and 1/100,000 live births. JS is classified into 6 types, pure JS, JS with ocular defect, JS with renal defect, JS with oculorenal defects, JS with hepatic defect, and JS with orofaciodigital defects. Our case was diagnosed as JS with orofaciodigital defects. Several candidate genes were published such as AHI1, CC2D2A, CEP290, ARL13B, C5orf42, TCTN2 in JS with orofaciodigital defect, but we have not done genetic testing yet. Considering the associated intellectual disability, it is important to make use of the fingers easier by surgery because of the lack of active flexion in the right ring finger. Careful observation and guidance for the patient and the family are also important.

Clinical and Radiological Outcomes of a Trapezometacarpal Interposition Implant

List of authors:
Thomas Maxwell*1, Stefanie Wieschollek1, J Alexa Potter1, Ruby Strauss1, Susan E Peters1, Greg Couzens1, Mark Ross1
1 Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: The Pyrocardan® trapezometacarpal interposition implant is a free intra-articular spacer composed of pyrocarbon. It is a biconcave resurfacing implant that is both ligament and bone-stock sparing. A primary indication for use is early- to moderate-stage trapezometacarpal osteoarthritis. This study examined survivorship, clinical and patient-reported outcomes with the Pyrocardan® implant. It was hypothesized that the postoperative outcome measures of the Pyrocardan implant would be comparable to those seen with LRTI surgeries and Bellemère's original series [1].

Methods: In this prospective case series, 33 patients (21 female) received a total of 39 Pyrocardan® implants from 2012 to 2017. Patients were assessed pre-operatively and at 6 weeks, 3 months, 6 months, 1 year, 2 years and beyond (long term) wherever possible. The post-operative pain and function outcome measures were analysed alongside a matched cohort of LRTI patients from our own institution. These results will be discussed in relation to Bellemère's published results [1].

Results and Conclusions: There have been no complications or revision surgeries for the series. One patient has had a subsequent MCPJ fusion. All 39 joints were followed up post-operatively at an average of 17 months (range 6 weeks - 5yrs). Average age at operation was 57 years (range 46 - 71). Thirty-four of the 39 joints were assessed greater than or equal to 6 months post index surgery. Outcome measure scores improved from pre-operative assessment to the most recent follow up equal or greater than 2 years. Median PRWHE score decreased from 65.7 to 17.5, median QuickDASH from 50.0 to 17.5 and on visual analogue scales median pain decreased from 63.5 to 13.0 and satisfaction increased from 8.5 to 90.0. Average grip strength at a minimum of two years was 28.7kg, as compared to LRTI (19.6kg) and Bellemere's series (25kg). In an age matched cohort assessed at a minimum of 2 years, average grip strength increased from 17kg pre-op to 28.9kg post-op in the Pyrocardan patients and from 17kg to 20kg in patients who underwent an LRTI procedure.

Pyrocardan provides a safe, effective treatment for pain relief and improved functional use of the hand for trapeziometacarpal arthritis. Patient-reported clinical outcomes were at least equivalent to LRTI and are comparable to Bellemère's original series [1]. Grip and pinch strength were better in the Pyrocardan series.

Stainless steel versus titanium volar multi-axial locking plates for fixation of distal radius fractures: a randomised trial

List of authors:
Greg Couzens*, Justin Alexander¹, Paul Hak¹, Samantha Rayner¹, Steve Frederiksen¹, Susan E Peters¹, Louise Lee³, Jeremy Loveridge³, James S Logan¹, Mark Ross²
¹ Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: Titanium and stainless steel volar plating systems for distal radius fractures are both in common use in orthopaedic surgery. Titanium implants have been reported to have benefits including reduced implant stiffness, increased biocompatibility and diminished stress shielding compared to stainless steel implants, however tenosynovitis and extensor tendon ruptures have been reported in the use of titanium plates and may be less common with stainless steel implants.

This study aimed to determine the clinical outcomes and effectiveness of the two devices used to manage distal radius fractures.

Methods: This is a double blinded, randomised controlled trial with outpatient data collection investigating the effectiveness of the two interventions. Pain and satisfaction in a visual analogue scale (VAS), function measured with the PRWHE and QuickDASH, wrist range of motion and grip strength were measured. As expected from a randomised allocation study, no baseline differences were found between groups in demographic or outcome measures. Preliminary data are reported as median (25% - 75%) values.

Results and Conclusions: Data has been collected from 46 stainless steel and 49 titanium-plated forearms, 32 and 27 of which have had at least one assessment equal or greater to 3 months after surgery. Analysis at 3 months showed VAS pain and satisfaction to be 15.0 (7.25 - 45.75) and 78.5 (49.5 - 92.3) respectively for stainless steel participants and 15.2 (2.0 - 28.0) and 80.0 (45.25 - 96.0) respectively for titanium participants. At three months, PRWHE measured 26.0 (10.0 - 40.5) for the stainless steel group and 15.0 (5.50 - 43.5) for the titanium group, whereas QuickDASH scores were 15.9 (9.1 - 34.1) for the stainless steel group and 20.0 (2.3 - 40.9) for the titanium group. Measures of wrist range of motion were similar between the two groups at 3 months. Grip strength was 19.3 kg (14.3 - 22.0) and 17.0 (11.3 - 24.0) respectively. Three revisions per group were recorded at most recent follow-up (stainless steel 7 months (range 4 - 40) and titanium 5 months (range 0 - 33)). No differences were found to be statistically significant.

These results suggest that the plates are comparable in terms of their functional, clinical, and radiological outcomes, and that the revision rates do not differ. The outcomes of this study should allow surgeons to make a more informed choice between stainless steel and titanium volar locking plates when fixing distal radius fractures.

Preoperative Two Point Discrimination Predicts Response to Carpal Tunnel Release

List of authors:
Lauren Wessel*, Charles Ekstein1, Danielle Marshall1, Duretti Fufa1, Daniel Osei1
1Hospital for Special Surgery (New York)

Objectives / Interrogation: Two-point discrimination (2PD) correlates to digital innervation and is used as a measure of carpal tunnel severity. However, there is no study to date that has assessed whether preoperative 2PD scores predict symptom severity or response to surgery. The primary aim of this study was to determine the predictive value of preoperative 2PD scores on postoperative symptom severity following carpal tunnel release.

Methods: All patients who underwent carpal tunnel release by a single fellowship-trained surgeon between 2014 and 2018 were retrospectively reviewed. Diagnosis was based on CTS-6 criteria, and surgery was offered based on failure of conservative management. Evaluation of static 2PD was performed and absent preoperative 2PD was defined as a measurement >10 mm. Pre- and postoperative QuickDASH and Levine-Katz scores were recorded. Pearson correlation coefficients assessed the relationship between preoperative 2PD scores, postoperative 2PD scores, and patient-rated outcome scores.

Results and Conclusions: Eighty-four hands were analyzed in this study. Mean post-operative follow-up was 1.8 years. Mean pre- and postoperative 2PD was 7.6mm (n=67) and 6.5mm (n=52), respectively. A higher initial 2PD was associated with an increased likelihood of improvement in 2PD postoperatively ($r^2 = 0.088$, $p=0.006$) unless 2PD was absent.

![Figure 1](image)

Figure 1. Percent of patients demonstrating improvement in 2PD score from pre- to postoperative based on preoperative most affected digit 2PD score.

Additionally, there was a positive correlation between pre- and postoperative 2PD ($r = 0.61$, $p<0.05$)
Patients with absent preoperative 2PD were the least likely to demonstrate postoperative improvement in 2PD from baseline with only 40.0% (6/20) of patients demonstrating improvement in contrast to 68.8% (44/64) patients otherwise (p = 0.03).

**Keywords:**
Carpal Tunnel Syndrome, Two Point Discrimination, Prognosis

**Figure 2.** Linear regression comparing preoperative 2PD score with (a) postoperative 2PD score (Pearson correlation, 0.780; P < 0.5) and (b) delta 2PD (Pearson correlation, 0.288, P = 0.006).
Investigation of nerve regeneration promoting factor in bioabsorbable nerve conduits coated with induced pluripotent stem cell-derived neurospheres

List of authors:
Takuya Yokoi*, Takuya Uemura, Kiyohito Takamatsu, Kosuke Shintani, Ema Onode, Mitsuhiro Okada, Hiroaki Nakamura

1 The Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine (Osaka)
2 The Department of Orthopaedic Surgery, Osaka General Hospital of West Japan Railway Company (Osaka)
3 The Department of Orthopaedic Surgery, Yodogawa Christian Hospital (Osaka)

Objectives / Interrogation: Introduction: We previously reported the effectiveness of a bioabsorbable nerve conduit coated with iPSc-derived neurospheres in young and aged mice. Transplanted neurospheres in the nerve conduit differentiated into S100 positive - Schwann-like cells and migrated adjacent to nerve stumps. These cells maintained their property and remained, and located in the vicinity of the axons at least 14 days after transplantation. Here, we investigated nerve regeneration promoting factor in bioabsorbable nerve conduits coated with neurospheres.

Methods: Methods: The nerve conduit (external diameter 2 mm, internal diameter 1 mm and length 7 mm) was composed of an outer layer of a poly lactide mesh and an inner layer of a porous sponge composed of 50% L-lactide and 50% caprolactone. Mouse iPSCs were neurally induced in vitro using a published protocol. The secondary neurospheres derived from mouse iPSCs were suspended in each conduit (2,600,000-4,000,000 cells per conduit) and cultured in the conduit for 14 days. We then implanted them in the left sciatic nerve gap (5 mm) as iPSc groups (young mouse; n=6, aged mouse; n=6). Bridging of the nerve gap using the nerve conduit alone was designated as the control groups (young mouse group; n=5, aged mouse group; n=5). We investigated gene expression of nerve regeneration factor in the nerve conduit by using real time PCR on Day4 and Day7 after transplantation and compared iPSc group with control group.

Results and Conclusions: Results: In the iPSc groups, on Day4 and Day7 after transplantation, gene expression of nerve regeneration promoting factors (ATF3, BDNF, and GDNF) was elevated compared with control groups.

Conclusion: According to in vivo imaging results in the same experimental system, the survival rate of transplanted neurospheres in the nerve conduit increases at the early phase (Day4 and Day7) after transplantation. From the results of this study, it is considered that the these neurotrophic factors and transcription factor increased in the nerve conduit at the early phase, which may promoted peripheral nerve regeneration.

Can cross sectional area of median nerve predict the prognosis of local steroid injection for carpal tunnel syndrome?

List of authors:
Hyun Il Lee*
1 Ilsan Paik Hospital (Goyang)

Objectives / Interrogation: The local steroid injection for carpal tunnel syndrome (CTS) is effect treatment modality which usually gives immediate symptomatic relief without invasive procedure. However, the long-term efficacy is frequent concern of injection therapy and it is not well known for prognostic factor to influence the result of local steroid injection. Our purpose of this study was 1) to report the long term success rate of sonography-guided local steroid injection and 2) to determine whether cross sectional area (CSA) of median nerve could be used for prognostic factor of steroid injection.

Methods: In a retrospective study, 37 patents with CTS were treated with corticosteroid injection guided by ultrasonography. CAS of median nerve was measured at lunate level when the median nerve had the largest size of CSA. Sixteen patients were classified as severe group according to CAS larger than 15mm^2. The other 21 patients were classified as mild group. Demographic factor, symptom, initial quick-DASH score, Boston carpal tunnel Questionnaires (BCTQ) and the result of nerve conduction study (NCV) was assessed at baseline. The injection failure was determined when the patients had symptomatic failure with or without re-injection and surgical release.

Results and Conclusions: Symptomatic failure rate was 51% (19 patients) in all patients. Eleven patients (30%) underwent carpal tunnel release after minimum 6 month follow-up (average 15 month).

The two group had similar baseline demographic factors. Thenar atrophy was more pronounced in severe CSA group (P=0.041). There were no significant differences in initial quick-DASH or BCTQ score, whereas amplitude of motor nerve conduction study and grade of NCV for severe CSA group was significantly severer than that of the mild CSA group. At last follow-up 50% of patients in the severe CSA group and 52% in the mild CSA group has symptomatic failure (P=0.886). Twenty five percent of patients in the severe CSA group required carpal tunnel decompression compared to 33% in mild CSA group (P=0.583)

In conclusion, Overall failure rate of steroid injection was 51%. The CSA dose not have prognostic value in prediction of the success of local steroid injection. In other words, the large CSA dose not preclude the possibility of long-term symptomatic relief after local steroid injection.

Robust genetic diagnosis of split-hand/foot malformation by exome sequencing

List of authors:
Gang Han*, Zhengsheng Chen¹, Li Chen¹, Ruiji Guo¹, Wenhai Sun¹, Bin Wang¹
¹Shanghai 9th People's Hospital (Shanghai)

Objectives / Interrogation: This study aimed to evaluate the genetic diagnostic yield and accuracy of exome sequencing for Chinese patients with split-hand/foot malformation (SHFM), a severe heterogeneous congenital anomaly characterized by hypodevelopment of the central ray of the hands and feet.

Methods: A cohort of 8 families and 4 sporadic patients with SHFM was investigated. Genomic DNA were prepared from peripheral blood of affected and unaffected individuals. Whole exome sequencing (WES) was performed to identify pathogenic mutations. Array-based comparative genomic hybridization (aCGH), cytoscan, qPCR, and Sanger sequencing was performed to validate the WES findings. WES data of an additional cohort of 24 patients with non-SHFM congenital hand anomalies were analyzed as a control.

Results and Conclusions: Pathogenic variants of TP63, c.G956A:p.R319H and c.T602A:p.L201H, were identified in two families. In the remaining patients, copy number analysis of the WES data identified pathogenic 10q24 duplication in 5 individuals out of 3 families, which was validated by cytoscan and qPCR. Duplication in 10q24 was not detected by WES in an additional cohort of 24 individuals with non-SHFM congenital hand anomaly. Importantly, qPCR analysis of the copy number of 10q24 region showed a definite consistency with WES in all individuals. Genotype-phenotype analysis showed no unique feature that can differentiate families with TP63 mutation and 10q24 duplication. Thus, our study demonstrated that WES was an accurate and sensitive method in detection of the pathogenic 10q24 duplication. Together with TP63 mutation, a single WES testing could yield a diagnosis rate of about 40% (5/12) for SHFM patients, at least in our cohort. Since there is no clear genotype-phenotype correlation, WES could be a cost-effective method for genetic diagnosis for SHFM.

split-hand/foot malformation, TP63, 10q24 duplication, genotype-phenotype correlation
The use of Integra® Dermal Regeneration Template (IDRT) in the reconstruction of post-traumatic soft-tissue defects of the dorsum aspect of the hand and/or fingers

List of authors:
Hussein CHOUGHRI*, Elias SAWAYA1, Amirouche DAHMAM1, Philippe PELISSIER1
1 University Hospital of Bordeaux-Pellegrin. Michelet Centre (Bordeaux)

Objectives / Interrogation: Traumatic injuries of the dorsum aspect of the hand and/or fingers often leave soft-tissue defects with exposed bone, joint, and/or tendon. Required treatment includes skin grafting, local rotational, pedicle or free flap. The purpose of this study was to report our experience with use of Integra® dermal regeneration template (IDRT) followed by delayed split-thickness skin grafting (STSG) for management of complex dorsum soft tissue defects.

Methods: A prospective study was conducted on all patients sustaining dorsal traumatic soft tissue-defects of the hand and/or fingers with exposed bone, joint, and/or tendon, from September 2008 to October 2013, who were treated with IDRT, followed by STSG. Integra® grafting was performed 12 times in 14 wounds, 9 men and 3 women were included. The mean age was 37± 9 years (6-79). The dominant hand was involved in 5 cases (42%). The IDRT was applied to 6 hands, 4 fingers, 1 thumb and 3 hands and forearm. The mechanism of injury includes Do-it-Yourself accidents (DIY) in 3 cases, public roads in 5 cases, degloving injury in 1 case, necrotizing fasciitis in 2 cases and a work accident in 1 case.

Results and Conclusions: Mean follow-up of 48±6 months (27-85 months). Days from injury to Integra® application were on average of 6 days (0-24), and from Integra® placement to STSG an average of 27 days (21-41). The size of residual soft tissue defect ranged an average of 17cm² (6-150). Integra® and subsequent STSG take rate was 100% and the cosmetic results assessed with the Vancouver Scale was an average of 2 (1-4). In a case, there were defect of the extensor pollicis longus tendon, which required two staged tendon grafting reconstruction, with silastic rod placement during the first stage, followed by autogenous tendon graft 4 months later.

In conclusion, IDRT combined with secondary split-thickness skin grafting is an effective method for the treatment of wounds defects located of the dorsum aspect of the hand and/or fingers, with exposed tendon and/or bone and joint, with good functional and aesthetic results. This can potentially lessen the need for local rotational or free flap coverage. Moreover, in case of failure this technique does not cut the bridges to traditional repair.

Bilateral Symmetrical Congenital Trigger Thumb and Middle Finger in a 2-Year-Old Child: A Case Report

List of authors:
Parunyu Vilai*, Sorasakdi Vechmamontien
1 Department of Orthopaedics. Srinakharinwirot University (Nakorn Nayok)

Objectives / Interrogation: Isolated congenital trigger thumb and trigger finger is well known in literature and has a developed treatment algorithm. Non-operative treatment in congenital trigger thumb has good clinical outcome in comparison to trigger finger. However, bilateral symmetrical congenital trigger thumb and finger is extremely rare and roles in treatment remains elusive.

Methods: We described a 2-year-old child presented with fixed thumb interphalangeal joint and triggering of middle finger both hands symmetrically. The patient was diagnosed with bilateral symmetrical congenital trigger thumb and trigger middle fingers. The symptoms of the left hand resolved non-operatively with physiotherapy but the pathology on the right hand required surgery. The A1 pulley was released in the right thumb and right middle finger. Subsequent release of the A3 pulley and ulnar head flexor digitorum superficialis of the middle finger was resected. The outcomes were good post-operatively and the patient and parents were satisfied with the treatment.

Results and Conclusions: Bilateral trigger finger in addition to trigger thumb is very rare and can be treated both non-operatively and surgically. The left hand of this patient received physiotherapy treatment and surgical treatment on his right. Both the symptoms on his right and left hand resolved with return to full function. There is more to explore on the possibilities of non-operative roles in treating bilateral trigger fingers and trigger thumb.

Use of medial femoral condyle flap for treatment of non-union and avascular necrosis of the upper limb. Cadaveric study and morbidity analysis of 18 cases.

List of authors:
Gonzalo Mallarino*, Camilo Romero¹
¹ Fundación Cardioinfantil (Bogotá)

Objectives / Interrogation: 1. To describe the vascular anatomy of the medial femoral condyle flap in a cadaveric study,
2. To demonstrate a relevant classification for the clinical practice.
3. Review our experience for the treatment of non-union, and avascular necrosis in the upper limb through a case series, making an emphasis on donor-site morbidity and Patient Reported Outcomes (PRO's)

Methods: First phase: twenty legs of 10 cadavers were studied with an intravascular injection of latex; the pedicle length, ramification pattern, and femur length was described.
Second phase: A retrospective study of 18 patients with avascular necrosis or non-unions of the upper limb, that were reconstructed with medial femoral condyle flap, was conducted. Time from injury to reconstruction, consolidation, and pain improvement was recorded. Higgins questionnaire was used in the 6th month follow-up in order to describe patient overall satisfaction, and complaints regarding both the donor and the receptor area in order to assess the outcomes with PRO's; X-rays of the knee used for flap dissection were utilized to further describe donor-related morbidity.

Results and Conclusions: In phase one, the pedicle raised from the genicular descending artery in 20 (100%) of the cases. Vascular anatomy variability was best described with “Y” and “H” patterns. “Y” pattern was more frequent being found on 13 (65%) the specimens. 94% of cases from phase two were secondary cases, that had received previous surgery. The average time from injury to reconstruction was 24 months, and to bone union was 2,5 months. All patients referred improvement in pain, and were satisfied with the results, no alterations were found on the X-rays. Conclusion: The medial femoral condyle is a flap with a rather consistent anatomy, which is better described with the "Y" and "H" classification. All patients reported improvement of pain, with minimal subjective and objective donor-site morbidity, making of the medial femoral condyle flap a very useful option for non-unions, and avascular necrosis of the upper extremity, even when multiple surgeries have been previously attempted and failed.

Postoperative pain management to the patients with distal radial fractures without opioid

List of authors:
JEONGHWAN KIM*, Young Ju Chae1
1 Seoul Medical Center (SEOUL)

Objectives / Interrogation: Postoperative pain control (PPC) to the patients is becoming more important practical issue that affects patient satisfaction, surgical outcome and safety. Many drugs were prescribed for PPC. However, the term 'Opioid Epidemic' is being used as the prescription of opioid has rapidly increased and raised the issue of opioid abuse. And the higher rate of opioid side effects in elders is a new problem that may require a longer hospitalization period. Therefore, PPC without opioid is becoming more important issue. The surgery to distal radius fracture (DRF) is one of the most common hand surgeries. Therefore, if PPC without opioid was possible in DRF patients, the opioid use in hand surgery might be considerably decreased. We hypothesized that PPC with non-opioid drugs could be sufficient for the patients with distal radial fractures.

Methods: Patients who scheduled for DRF surgery were the subjects of this study. Patients chose their anesthesia method between GA or BPB according to their own preferences. They were prescribed 2g of IV propacetamol every 6 hours after surgery. Additional 1g of IV propacetamol was prescribed for patients who complained of pain beyond VAS 3. And 50mg of tramadol was prescribed for the patients with uncontrolled pain by propacetamol.

We evaluated the pain experience of each patient 8 times from preoperative period (P0) to postoperative (P) 48 hours with VAS scale and the request for additional analgesics.

Results and Conclusions: To date, 55 patients have been enrolled in this study. And 43 patients chose BPB, and twelve patients chose GA. In BPB group, additional prescription of propacetamol except every 6-hour use was 49 times in 42 patients (97%), and the time of request of additional propacetamol were 5 at P3H, 31 at P6H, and 13 at P12H. In GA group, additional additional prescription of propacetamol except routine 6-hour use was 20g in all 12 patients, the time of request of additional propacetamol were 1 at P1H, 4 at P2H, 6 at P3H, 5 at P2 6H, and 4 at P12H. Tramadol was used in 8 patients (18%) in BPB group, and in 1 patient (10%) in GA group. There was no further request for additional analgesics after P24H. And there was no patient who needed tramadol prescription more than once.

In this study, pain of 82% of the patients in BPB group and 90% of the patients in GA group were successfully controlled without any opioid use. We believe that the use of non-opioids could be sufficient not to all, but to most of the DRF patients for their postoperative pain management.

Comparison of radiation exposure of major organs between mobile CBCT and MDCT in hand and foot

List of authors: Hyunkyu Yu*, Byung Taek Kwon¹, Hongje Kang¹
¹ Wonkwang University hospital (Iksan)

Objectives / Interrogation: Computed tomography (CT) imaging is often required for accurate diagnosis and treatment because of the complicated joint structure when trauma or disease occurs. There is a risk of exposing the main organs (brain, eye, thyroid, thymus, testis or ovary) to radiation exposure at the time of shooting. In the extremities, the use of recently developed mobile CBCT may reduce the risk of radiation exposure. The purpose of this study was to compare the radiation dose of major organs between mobile CBCT and MDCT and to evaluate the safety and usefulness of CBCT.

Methods: This is a prospective voluntary randomized study. This study was designed for adults who require CT scans for hand and foot disease or trauma from August 2017 to March 2018. The patients were divided into two groups of 20 patients each. Mobile CBCT was performed in group A and MDCT was performed in group B. Reference point corresponding to the major organs (brain, eye, thyroid, thymus, or testis or ovary) was set and attached a thermoluminescent dosimeter chip (TLD chip). After CT scan, the radiation dose irradiated on the TLD chip was measured.

Results and Conclusions: The surface dose at the center was not significantly different between group A and B. In hand CT scan, the surface dose of brain, eye, thyroid, and thymus was found to be 0.0022 mGy, 0.0025 mGy, 0.0038 mGy, 0.0049 mGy and 0.0023 mGy respectively, in group A, while average dose of 0.5046 mGy, 0.5255 mGy, 0.1482 mGy, 0.0909 mGy and 0.0062 mGy in group B. And there was a statistically significant difference between the two groups. In foot CT scan, Surface dose in gonads was 0.0032 mGy in group A and 0.0443 mGy in group B, which was lower in group A, which was statistically significant. The use of mobile CBCT in the CT of the hand and foot may reduce unnecessary radiation exposure to nearby organs other than the site. New studies are needed to reduce the radiation exposure of adjacent organs during the CT scan of the central part of the body adjacent to the critical organs such as the clavicle, spine, and pelvis. In the orthopedic area, it is considered that the conventional MDCT for extremity can minimize the damage caused by radiation exposure by performing radiation shielding on the part other than the center of scan.

Keywords: CBCT, MDCT, radiation dose, TLD chip
Replantations in Norway 2010-2017

List of authors:
Johanne Korslund¹, Ole Reigstad¹, Rasmus Thorkildsen³, Magne Røkkum²
¹ Oslo University Hospital (Oslo)
² Oslo University Hospital, University of Oslo (Oslo)

Objectives / Interrogation: The first replantation in Norway was performed in 1983. Since 1994 all replantations in Norway have been performed at one hospital. The number of replantations per year steadily increased, stabilizing between 50 and 70 per year for the last two decades, except for a 3 year period. We assessed the replantations performed in Norway between 2010 and 2017.

Methods: From 01.01.2010-31.12.2017 380 patients, 48 (2-92) years of age underwent replantation surgery. Of these there were 45 (12%) women and 32 (8%) children <18 years. 34 patients (9%) had proximal upper extremity amputations (13 wrists, 21 lower arms). 3 patients had toes/feet replanted, and one patient had his penis replanted. The remaining 342 patients had 512 fingers replanted, including 135 thumbs. The dominant side was amputated in 42% of the injuries. 82% of the injuries were classified as crushing injuries, 15% avulsion, and only 3% guillotine.

Results and Conclusions: 32/34 (94%) of the proximal upper extremity replantations survived. 338/512 fingers (66%), and 88/135 thumbs (65%) survived. Due to secondary circulatory failure 146/512 (28%) fingers underwent repeated microvascular surgery to restore circulation. This secondary surgery saved 58/146 (40%) fingers. During the follow up period, 56% of the replanted fingers needed further surgery after primary replantation, including secondary recirculation surgery, smaller wound revisions, coverage procedures, scar correction, tenolysis or pseuarthrosis surgery. 3/338 (1%) were amputated at a later stage because of pain, stiffness and bad function. The patients came from all over Norway, proportionately to population distribution in the different regions of the country.

Replantation is a demanding procedure for the patient with a long period of hospitalization and rehabilitation. Approximately half of the patients need more than one surgery. The surgery is technically demanding, time consuming and requires considerable resources both during the initial hospitalization and during follow up. Centralization to one centre has allowed us to gain, and maintain surgical experience despite a small population (5 million). The results are not quite as good as those cited from other centres, but the high percentage of crushing injuries may in part explain this.

Echogenicity of palmar Dupuytren nodules is not a predictor of disease progression in terms of increase in nodule size

List of authors: Sanne Molenkamp*, Dieuwke C. Broekstra¹, Paul M.N. Werker¹
¹ University Medical Center Groningen, Department of plastic surgery, HPC: BB81 (Groningen)

Objectives / Interrogation: Activity of Dupuytren nodules may be measured with ultrasound. It has been suggested that early nodules appear hypo-echogenic, whereas older nodules appear iso- to hyper-echogenic. The aim of this study was to analyse whether echogenicity of Dupuytren nodules can be used to predict disease progression in terms of increase in nodule size and to calculate the reliability of measurement of echogenicity.

Methods: Sonographic assessment of a single Dupuytren nodule was performed in 91 patients participating in an existing longitudinal cohort at our hospital. Echogenicity of nodules was matched to growth, measured with physical examination, one year later, using linear regression analysis. A sensitivity analysis was performed, using data of a year prior to ultrasound. For the calculation of reliability, two observers scored the ultrasound images for echogenicity. The first observer scored the images twice and the second observer scored the images once. The inter- and intra-observer reliability were calculated using the intra-class correlation coefficient (ICC).

Results and Conclusions: Hypo-echogenicity did not predict progression in terms of increase in nodule size one year later (Beta=-0.019, P=0.748). Sensitivity analysis showed that hypo-echogenic nodules were more likely to have grown in the past year (Beta=0.173, P=0.011). However, these results were most likely influenced by nodules that had emerged in the year prior to ultrasound.

The reliability of measurement of echogenicity of Dupuytren nodules, measured by a single observer, was excellent (ICC=0.996, 95% CI: 0.993-0.998). The reliability of measurement of echogenicity of Dupuytren nodules by different observers was less satisfying, with an ICC of 0.688 (95% CI: 0.329-0.977).

Further research is necessary to define the relation between echogenicity of Dupuytren nodules and disease activity. When measuring echogenicity, the use of a single observer leads to more consistent results.

Keywords: Dupuytren disease, ultrasound, echogenicity, disease progression, reliability
Measuring Quality in Hand Surgery using Patient Reported Experience Measures

List of authors:
Pei Yein Tong*, Dawn Cen¹, Rachel Law², Vaikunthan Rajaratnam³
¹ Khoo Teck Puat Hospital (Singapore)
² National University of Singapore, Yong Loo Lin School of Medicine (Singapore)

Objectives / Interrogation: Patient-reported experience measures are becoming an international standard for measuring quality of healthcare delivery. Studies have shown that satisfied patients are more likely to have a positive outlook on their condition, and believe that their treatment will be effective. Consequently, they are more likely to play an active role in their treatment process, including participation in their rehabilitative programme. It is thus worthwhile to study the patients' experience of their hospital journey, and to assess patients' satisfaction in a meaningful way.

A huge proportion of patients requiring treatment in our Hand Surgery unit have their procedures done as a day surgery case. Our objectives are to understand the extent to which our current work processes meet the needs and satisfaction of our patient group, and to identify potential areas for improvement.

Methods: Patients who underwent a day surgery procedure were interviewed immediately after surgery, using a validated questionnaire. Their responses were tabulated and analysed.

Results and Conclusions: Preliminary results show the experience of Hand Surgery patients (both acute and elective) treated in the day surgery setting in a tertiary district hospital is positive.

We will describe our experience and methodology to collect patient reported experience measures in a day surgery setting.

These findings show that the patients' experience in healthcare delivery is an important component to be studied to improve the delivery of healthcare to meet expectations of patients.

Keywords:
The reliability of sonographic measurement of early palmar Dupuytren nodules

List of authors:
Sanne Molenkamp*, Roel van Straalen1, Paul M.N. Werker3, Dieuwke C. Broekstra1
1 University Medical Center Groningen, Department of plastic surgery, HPC: BB81 (Groningen)

Objectives / Interrogation: In the future, it is expected that treatment of Dupuytren disease (DD) will aim at disease control or regression of early disease. Ultrasound might be an accurate method to measure the outcome of such treatment. The aim of this study was to assess the reliability of sonographic measurement of palmar nodules.

Methods: Fifty patients with early disease nodules were assessed with ultrasound by two observers. The first observer measured the nodules twice. Four different aspects were measured in the transverse and sagittal plane: width, depth, circumference and cross-sectional area. The intra- and inter-observer reliability (intra-class correlation coefficient (ICC)) and the standard error of measurement (SEM) were calculated for each aspect.

Results and Conclusions: The ICCs for the intra-observer reliability were good (ICC: 0.724 [0.562-0.833] to 0.886 [0.808-0.934]), except for width in the sagittal plane (ICC: 0.671 [0.484-0.799]). The ICCs for the inter-observer reliability were lower (ICC: 0.385 [0.126-0.596] to 0.757 [0.538-0.869]). Overall, the intra-observer ICCs of area were highest (transverse: 0.847 [0.744-0.893] and sagittal 0.886 [0.808-0.934]). The SEM of area was 6.1 mm² in the transverse and 8.02 mm² in the sagittal plane.

Sonographic follow-up of Dupuytren nodules is reliable when performed by a single observer. The measurement of area is most reliable and is therefore recommended for future studies. However, not all detected changes can be interpreted as progression or regression, since measurements of both a single and different observers have a certain dispersion. A change beyond 6.1 and 8.02 mm² in the transverse and sagittal plane respectively can be considered as regression or progression.

The Validity of PRWHE and QuickDASH as Outcome Measures Following Surgery to Treat Scapholunate Ligament Dissociation

List of authors:
Libby J Anderson*, Greg Couzens¹, Silvia Manzanero¹, Bhavana Jha¹, Susan E Peters¹, Mark Ross¹
¹Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: Injury to the scapholunate ligament is a common cause of wrist instability. As there are no specific scores to report treatment efficacy, clinicians and researchers currently rely on generic upper limb patient-reported outcome measures, such as PRWHE and the QuickDASH. This study's aim was to evaluate the validity of these measures in detecting changes in patient outcomes after treatment of scapholunate dissociation.

Methods: 92 patients (15 female, average age 40.5) were retrospectively identified from a prospective cohort treated for wrist instability. Data was collected at baseline and at least one follow-up time point (3, 6, or 12 months). At each follow-up time point, subjects were assigned to one of four groups according to their reported global rating of change (PGRC) for both the symptoms (PGRCs) and function (PGRCf) categories. Groups were labelled: 0, PGRC (-7) to (0) inclusive - no change or worse; 1, PGRC (+1) to (+3) - small improvement; 2, PGRC (+4) or (+5) - medium improvement; and 3, PGRC (+6) or (+7) - large improvement. Analysis of variance (ANOVA) and Tukey HSD test for post-hoc multiple comparisons of means were used to test differences between groups in PRWHE and QuickDASH scores at each time point. The significance level was set at p=0.05.

Results and Conclusions: At 3 months, neither PRWHE nor QuickDASH showed significant differences between the groups according to PGRCs or PGRCf. At 6 months, neither score showed significant differences between the groups according to PGRCs; as for PGRCf, both scores showed significant differences between the two extremes (group 0 vs group 3) but failed to reveal differences in the mid-ranges (groups 1 and 2). At 12 months, PRWHE showed significant differences across groups 0 and 2, groups 1 and 3, groups 0 and 3 of PGRCs, whereas QuickDASH only showed significance between group 3 and each of the other groups; as for PGRCf, both scores showed significant differences between the extremes (group 0 and group 3) but failed to reveal differences in the mid-ranges of PGRCf (groups 1 and 2).

PRWHE and QuickDASH may not be able to detect nuances in functional changes at key time points in the context of wrist instability. These preliminary findings have implications for clinicians aiming to select valid and sensitive outcome measures and suitable time points for measurement. The results suggest that the development of a reliable, valid and responsive score for patients with wrist instability may be warranted.

The Vascularized Dorsal Periosteal Curtain for Corrective Osteotomy of the Distal Radius

List of authors:
Mark Ross*1
1Brisbane Hand and Upper Limb Research Institute, Brisbane Private Hospital (BRISBANE)

Objectives / Interrogation: Corrective osteotomy of the radius frequently requires significant soft tissue releases to achieve correction. We propose a technique that utilises the releases to create a dorsal curtain of vascularised periosteum over the osteotomy site.

Methods: Surgery is performed through the usual volar approach to the distal radius. Following the usual release of brachioradialis, the periosteum is elevated over the dorsal radius for approximately 2 cm proximal to the osteotomy site. The osteotomy is performed taking care not to damage the dorsal soft tissue envelope. The proximal radius shaft is then pronated to allow further exposure and elevation of the dorsal periosteum which is then separated from the extensor tendons and divided 2 cm proximal to the osteotomy and left attached to the distal radial fragment. When the correction is made the distally based periosteal flap hangs down proximally over the osteotomy site, separating the bone graft from the extensors and providing vascularity for the graft.

Results and Conclusions: We have utilised this technique for many years without any significant complication. The correction of the radial deformity is usually straightforward because the technique ensures a thorough dorsal release. The cancellous graft appears to unite and remodel extremely rapidly and patients can usually return to activity at 6 weeks post osteotomy when union is seen.

We recommend the use of this technique for all distal radius osteotomies. It facilitates the requisite soft tissue releases, protects the extensor tendons from the bone graft, and encloses the bone graft with a vascularised layer of periosteum to expedite union and graft incorporation/remodelling.

Functional outcome of stage surgical treatment of nonunions of the distal humerus

List of authors: Igor Kurinnyi*, Aleksandr Strafun

1 Institute of Traumatology and Orthopedics of NAMS of Ukraine (Kiev)

Objectives / Interrogation: Assessment of the effectiveness of surgical treatment of nonunions of the distal humerus.

Methods: The analysis of surgical treatment of 66 patients (43 men, 23 women) with the consequences of treatment of fractures and nonunions of the distal humerus was performed. The average age of patients consisted 47.2 ± 14.9 years. All patients have undergone surgery previously, but due to various reasons, consolidation of the distal humerus was not achieved. Patients were hospitalized in 6.2 ± 4.1 months after injury. During clinical investigation all of them had pathological mobility at the level of nonunion, movements in the elbow joint were significantly limited.

Results and Conclusions: In 18 cases the skin defect of the elbow region was substituted by vascularized skin flap. Treatment was started from osteosynthesis of the distal humerus with autogenous iliac bone grafting. After surgery - early rehabilitation was performed with changeable daily splinting in flexion and extension. After bone consolidation (approximately in 1 year or more after osteosynthesis) removal of fixators was performed with the simultaneous mobilization of the elbow joint. After the operation, an early rehabilitation treatment was also carried out using cast in full extension at night and at 90 degrees of flexion for a day time.

We evaluated results of surgical treatment with MEPS scale in 7-12 months after surgery. Good results were obtained at 79.4% of cases and satisfactory in 21.6% of patients. The outcome of the treatment depended on the severity of the primary injury, the time passed from the moment of injury and level of patient motivation.

Conclusions. Complex of reconstructive interventions (skin defects substitution, osteosynthesis and bone grafting, joint mobilization) in combination with early rehabilitation, allowed to obtain good results of treatment in 79.4% of cases in patients with the consequences of severe injuries of distal humerus.

Keywords: distal humerus, nonunions, surgical treatment, functional outcome
In Idiopathic Cubital Tunnel Syndrome, Ulnar Nerve Length and Instability Can Be Reduced by Repairing Osborne's Ligament after Simple Decompression

List of authors:
Sang Ho Kwak*, Jung Yun Bae
1 Pusan National University Yangsan Hospital (Yangsan)

Objectives / Interrogation: Three approaches are commonly used in the surgical treatment of idiopathic cubital tunnel syndrome (ICTS). In an attempt to reduce the risk of nerve traction and instability after simple decompression, Osborne's modification involves repairing the Osborne's ligament beneath the ulnar nerve after decompression. In this study, we aimed to evaluate the change in ulnar nerve length (UNL) following repair of the Osborne's ligament. Additionally, we aimed to compare Osborne's modified simple decompression (MSD) and conventional simple decompression (CSD) regarding the improvement in ultrasonographic grade of ulnar nerve instability (UNI) and the clinical outcomes.

Methods: 51 patients diagnosed with ICTS underwent surgery for cubital tunnel syndrome. 31 patients underwent MSD and 20 patients underwent CSD. In the MSD group, UNL was measured intraoperatively, in full elbow flexion and extension before and after the repair of Osborne's ligament. UNI during elbow motion was measured using ultrasonography preoperatively and at 12 months postoperatively. The following were recorded preoperatively and at 24 months postoperatively: visual analogue scale (VAS) score; Quick Disability of the Arm, Shoulder, and Hand (Quick DASH) score; grip strength; pinch strength; McGowan grade; and Wilson and Krout criteria.

Results and Conclusions: Results
In patients who received MSD, the UNL in full elbow flexion reduced significantly after repair of the Osborne's ligament (from 12.4±0.79 to 11.7±0.76 cm; p<0.001). At 12 months after surgery, the grade of UNI was lower in the MSD group than in the CSD group (p=0.009). At 24 months postoperatively, the clinical outcomes did not differ significantly between the MSD and CSD groups.

Conclusions
In patients who received MSD, UNL in elbow flexion reduced significantly following repair of the Osborne's ligament, and the grade of UNI was lower than that noted in patients who received CSD, without detrimental effect on clinical outcomes at 24 months postoperatively.

Analysis of Brachial plexus injury following median sternotomy in cardiac surgery.

List of authors:
Ryo Okbayashi*, Shigeya Suzuki, Takao Omura, Takashi Ogawa, Kaori Sugiura, Yukihiro Matsuyama
1 Hamamatsu University School of Medicine (Hamamatsu)
2 Fujieda City Hospital (Fujieda)

Objectives / Interrogation: Brachial plexus injury (BPI) is a rare complication after median sternotomy. However there are only few reports with small number of cases, which describes the clinical findings in detail. The purpose of this study was to investigate BPI cases retrospectively who underwent median sternotomy for open heart surgery.

Methods: During 2014 to 2018, 1062 patients underwent cardiac surgery with median sternotomy and 10 patients (0.94%) developed BPI after surgery. All ten patients were male with an average age of 65.6 (45—72) years old. The surgical time, the affected side, the level of paralysis and the period from onset to the recovery of paralysis were investigated in these ten patients. Motor function was evaluated using Manual Muscle Testing (MMT).

Results and Conclusions: The mean surgical time was 457 (300—657) minutes. All patients had paralysis on left upper extremity. In all cases, sensory and motor nerve impairment developed in lower plexus. The average post-surgical muscle power was MMT 2.2 for extensor digitorium communis (EDC), 3.9 for flexor digitorum superficialis (FDS) and 2.7 for first dorsal interosseous muscle (IOD(1)). The average persistence of sensory deficit such as numbness or hypesthesia was 3.9 months. Two cases had persisted numbness for over a year after surgery. The average period for the recovery of motor weakness to at least MMT 4 was 4.2 months in EDC, 1.4 months in FDS and 5.6 months in IOD(1). In three cases which required 8 months for the recovery of IOD(1), the surgical time was over nine hours.

The mechanism of post-surgical BPI in cardiac surgery was reported to be due to compression of the plexus between first rib and clavicle during retraction of sternal halves and stretching of the plexus cord after median sternotomy. The risk factor of BPI after median sternotomy was reported that abduction of the arm to 90 degrees or more and the occurrence of first rib fracture. In this study, five out of ten patients' arms were fixed at abstraction of over 90 degrees during operation, and two out of ten patients sustained first rib fracture during operation. Also, we found that longer surgical time was correlated with poor motor recovery. BPI after median sternotomy is relatively infrequent complication, and not all patients recovered completely. It is necessary for the cardiothoracic surgeon should beware of this complication.

The impact of illness perceptions, psychological distress and pain catastrophizing on self-reported symptom severity and functional status in patients with carpal tunnel syndrome

List of authors:
Pepijn Sun*, Ruud Selles², Harm Slijper³, Erik Walbeehm¹
¹ Radboudumc (Nijmegen)
² Erasmus Medical Center (Rotterdam)
³ Xpert Clinic (Hilversum)

Objectives / Interrogation: Previous studies have demonstrated the influence of illness perceptions on patient outcomes. Although several psychological factors have shown to be associated with self-reported severity in Carpal Tunnel Syndrome (CTS), illness perceptions have not yet been studied. Therefore, the aim of the present study was to examine the relation between self-reported symptom severity and functional status and psychological distress, pain catastrophizing and illness perceptions.

Methods: All patients with CTS who were scheduled for surgery in 1 of our 16 specialized hand clinics between September 2017 and August 2018 were asked to fill out online questionnaires regarding demographic data, comorbidities, psychological factors and clinical severity measures. A total of 674 CTS patients completed all questionnaires and were included. Our outcome measures were the functional status scale (FSS) and symptom severity scale (SSS) of the Boston Carpal tunnel Questionnaire (BCTQ). Psychological distress was measured with the Patient Health Questionnaire, pain catastrophizing with the Pain Catastrophizing Scale and illness perceptions with the Brief Illness Perception Questionnaire. Pearson correlation coefficients were calculated and hierarchical linear regression models were used to examine the relation between self-reported severity and psychological factors, when accounting for baseline characteristics and comorbidities.

Results and Conclusions: Psychological distress, pain catastrophizing and illness perceptions were significantly correlated with the FSS and SSS scores (correlation coefficients ranged from 0.21 to 0.46). Hierarchical linear regression models showed that variance in FSS score was explained for 15% by patient characteristics and comorbidities, 11% by psychological distress and pain catastrophizing, and 9% by illness perceptions. For the SSS score 8%, 12% and 13% was explained by these same sets of variables.

This study showed that psychological distress, pain catastrophizing and illness perceptions all play an independent role in self-reported severity of CTS complaints. The relation between these factors and self-reported symptom severity and functional status is important, as these factors together explain about a quarter of the variance in BCTQ scores. Future studies should indicate if and how clinicians should take this into account when they are consulted by patients with CTS.

Functional outcomes of the Adams-Berger Ligament Reconstruction for the Distal Radioulnar Joint Instability in 95 Consecutive Cases

List of authors:
Endre Soreide*, Assaf Kadar1, Joshua Gillis1, Joseph Khouri1, Richard Berger1, Steven Moran2
1 Department of orthopedic surgery, Mayo Clinic (Rochester)
2 Department of orthopedic surgery, Division of plastic and reconstructive surgery, Mayo Clinic (Rochester)

Objectives / Interrogation: To evaluate the outcomes and complication rate for Adams-Berger anatomic reconstruction of the distal radio-ulnar joint (DRUJ).

Methods: Retrospective chart review to evaluate adult patients that had undergone reconstruction of the DRUJ for instability with the Adams-Berger procedure between 1998-2015 within our institution. Charts were reviewed for patient demographics, mechanism of injury, outcome, surgery related data and complications.

Results and Conclusions: 95 wrists in 93 patients were included. Mean (SD) age at surgery was 37.3 years (+12.7 years) and follow-up time was 65.8 months (63.2 months). At the last follow-up, 90.8% of the patients presented a stable DRUJ, 3.4% had mild laxity, while 5.3% had signs of instability. Compared to preoperative measurements, grip strength had increased, and pronation and supination decreased. Patients reported improvement in overall pain scores, and none of the patients reported severe pain of their wrist at last follow up. Six patients suffered from ulnar neuropraxia.

Overall, graft survival was 87.4%. 12 patients had undergone revision surgery, with a mean time from primary reconstructive surgery to revision surgery of 13.3 months. Female and use of interference screw for graft fixation was associated with higher failure rates.

Conclusion: Our findings demonstrate that Adams-Berger anatomic ligament reconstruction of the DRUJ provides reliable long-term functional results with an overall graft survival of 87% at >5 years follow-up.

A Significant Neuralgia caused by An Epidermoid Cyst: A Case Report

List of authors:
Hirofumi Imai*, Masatoshi Takahara2, Daichi Ota2, Mikiro Kondo2
1 International Center for Lymphedema, Hiroshima University (Hiroshima)
2 Izumi Orthopedics Hospital (Sendai)

Objectives / Interrogation: An epidermoid cyst is one of the common benign tumor-like conditions in the hand. We report the rare case that an epidermoid cyst induced significant neuralgia of the finger.

Methods: A 56-year-old female presented with significant neuralgia and mass of the right ring finger. 3 years prior to presentation, she had been bitten by a dog. After then, she recognized a growing mass at the site of bitten. 11 days prior to presentation, she recognized the sudden strong pain with her right ring finger as much as jumping up and down. On physical examination, a soft elastic mass was noted on the radial volar aspect of middle phalanx of her ring finger, with strong positive Tinel's sign from the radial volar aspect of metacarpophalangeal to middle phalanx. The Pain visual analog scale (VAS) of the ring finger was 5 / 10. MRI demonstrated a 1.1 × 1.1-cm round, well-circumscribed mass at the middle phalanx of her ring finger with low intensity on T1-weighted and high intensity on T2-weighted. We concluded the significant neuralgia was induced caused by the mass, then we performed surgical excision 6 days after from presentation. Capsule of mass adhered to surrounding tissues and the mass was filled with ash color myxoid substance. The digital nerve was wrapped by the mass and had hypertrophy from the mass to 3cm proximately. The site of nerve hypertrophy was filled with ash color myxoid substance from the mass. After excision of the mass, we squeezed the myxoid substance out from the digital nerve. After then, she had the improvement from the significant neuralgia. Histological examination confirmed the diagnosis of an epidermoid cyst. 1 and a half years following the excision, there was no evidence of recurrence and she remained the improvement that the pain VAS was 0 / 10.

Results and Conclusions: We concluded her significant neuralgia was happened when the myxoid substance of epidermoid cyst strayed into the digital nerve after epidermoid cyst adhered to the nerve.

Changes in the morphology of the triangular fibrocartilage complex (TFCC) on magnetic resonance arthrography related to disruption of ulnar foveal attachment

List of authors:
Ji Hun Park*, Young Woo Kwon2, In Cheul Choi2, Jong Woong Park2
1 Korea University Guro Hospital (Seoul)
2 Korea University Anam Hospital (Seoul)

Objectives / Interrogation: The proximal ligamentous complex (PLC) of the triangular fibrocartilage complex (TFCC) inserts into the ulnar fovea and is the primary restraint of the distal radioulnar joint (DRUJ). The aim of this study was to assess whether a PLC with a distally prolapsing morphology is associated with the presence of a TFCC foveal tear on arthroscopy.

Methods: One-hundred thirty-two patients (134 wrists) who underwent MR arthrography and subsequent wrist arthroscopy between September 2014 and March 2018 were evaluated retrospectively. Distal prolapse amount of the PLC was measured on coronal MR arthrography by calculating the height-to-length ratio (HLR). Subjects’ demographics, ulnar variance, presence of a degenerative TFCC tear, and ulnar styloid nonunion were assessed. The association between specific variables and the presence of a foveal tear was investigated.

Results and Conclusions: Arthroscopy revealed a TFCC foveal tear in 101 wrists among 134 wrists. Univariable analysis showed that the HLR of the PLC was significantly greater in the foveal tear group than the intact fovea group (p < 0.05). Multivariable analysis showed that HLR had a positive association with a foveal tear (p < 0.001). Estimated cut-off value for the HLR was 41% (area under the curve [AUC] 0.77).

Conclusion: A PLC that has a distal prolapse pattern with a large HLR is associated with TFCC foveal tears. HLR of the PLC measured on coronal MR images can therefore be used as an additional predictor of tears of the foveal attachment of the TFCC.

Ten-year outcomes of the Arpe prosthesis to treat osteoarthritis of the trapeziometacarpal joint

List of authors:
Nadine Hollevoet*, Arne De Smet, Wim Vanhove, Szabolcs Benis
1 Ghent University Hospital (Ghent)

Objectives / Interrogation: The Arpe implant is a total joint prosthesis to treat trapeziometacarpal osteoarthritis. Good survival rates have been reported at 5 years, but not many studies reported results at ten years follow-up.

Methods: Fifty patients with 66 Arpe prostheses were included in the study. Mean follow-up was ten years. It was noted if implants had been removed or revised. The Kaplan-Meier method was used to calculate survival analysis. Patients were evaluated with the disability of arm, shoulder and hand (DASH) and scores from 0 to 10 for pain, satisfaction and willingness to have the same operation again.

Results and Conclusions: At ten year follow-up, 7 out of 66 implants were explanted and revised with tendon interposition. The cup (with or without the neck) was replaced in 3 patients and only the neck was revised in 2. Ten-year survival was 87% when failure was defined as implant removal followed by trapeziectomy and tendon interposition. Ten-year survival was 82% when revision of the cup was also considered as failure and it was 80% when replacement of the neck alone was also considered as an endpoint. Of the 52 prostheses that were not revised mean DASH score was 11, mean pain score 1.2 and mean score for satisfaction 9.5.

It can be concluded that the majority of patients who did not undergo revisions were satisfied and had little or no pain. However, long-term survival of the Arpe prosthesis was moderate and patients should be warned that after ten years the risk for reoperation might be as high as 20%.

Keywords:
Variable Angle LCP Volar Rim Plate fixation for volar displaced distal radius fracture with volar lunate facet fragment

List of authors:
Shiro Suzuki*, Koji Fujita², Akimoto Nimura¹
¹ Tokyo Medical and Dental University, Department of Functional Joint Anatomy (Tokyo)
² Tokyo Medical and Dental University, Department of Orthopedic Surgery (Tokyo)

Objectives / Interrogation: The volar locking plate dramatically improved the surgical treatment of the distal radius fractures. However, some fracture patterns remain difficult to treat. The volar shearing fracture with small volar lunate facet fragments is one of fractures to treat with the conventional volar locking plate. Variable Angle LCP Volar Rim Plate (DePuy-Synthes) is designed that can be placed past the watershed line to support the rim fragments. The objective of the present study is to report clinical results of Variable Angle LCP Volar Rim Plate fixation for volar displaced distal radius fracture with volar lunate facet fragment.

Methods: Five patients with distal radius fractures were examined. Inclusion criteria were volar displaced fractures with volar lunate facet fragment and the longitudinal size of the fragments was less than 15mm (mean 11.6mm, range 9.6 - 13.8mm). The mean age at the time of surgery was 50.6 (range 32 - 66) years old. The mean postoperative follow up period was 11.4 (range 8 - 16) months. Implants removal were performed in all patients after bone union confirmed by computed tomography. The range of motion, Mayo Writ Score at the final follow up period and complications were evaluated.

Results and Conclusions: Bone union was achieved in all patients without loss of reduction. The mean active extension was 74.4 (range 72 - 80) degrees and active flexion was 70.6.0 (range 68 - 73). The mean Mayo Writ Score was 86.0 (range 80 - 90) points. The complication was a pain or feeling of strangeness at the wrist flexion in four patients. Implant removal operative finding showed the compression of the flexor pollicis longus tendon by the distal end of the plate in one patient.

The Rim plate is useful to support rim fragments and to avoid postoperative displacement because of its high buttress effect. However, plate removal must be necessary because of the risk of complications such as flexor tendon problem and plate impingement. Rim plate must be indicated to rim fractures.

Dorsal Transosseous Reduction and locking plate fixation for Articular Depressed Middle Phalangeal Base Fracture

List of authors:
Ji Hun Park*, Young Woo Kwon*, In Cheul Choi, Jong Woong Park
1 Korea University Guro Hospital (Seoul)
2 Korea University Anam Hospital (Seoul)

Objectives / Interrogation: An articular depressed fragment at the base of the middle phalanx can be an obstacle to congruent reduction and stable fixation. This study assessed the outcomes of a transosseous reduction technique combed with locking plate fixation for the treatment of articular depressed middle phalangeal base fracture.

Methods: Between 2015 and 2017, seven patients (eight fingers) with intraarticular comminuted middle phalangeal base fracture were included in this study. The mean follow-up was 19.4 months (range, 12-30 months). All patients showed depression of the articular fragment on sagittal computed tomography (CT) scan and were treated with a transosseous reduction technique and dorsal locking plate fixation. Radiographic evaluation was performed to ensure restoration of a concentric articular surface postoperatively. Total active range of motion of the fingers, grip strength, and the quick Disabilities of the Arm, Shoulder and Hand (quick DASH) score were evaluated at the last follow up. Complications were also assessed.

Results and Conclusions: All fractures obtained bony union with a concentric joint. There was no significant loss of reduction during the follow-up period. The mean active proximal interphalangeal (PIP) joint and distal interphalangeal joint motion arcs at follow-up were 89° and 61°, respectively. The mean TAM of the affected finger and mean grip strength were 94% (range, 80-100%) and 94% (range, 86 - 100%) of the contralateral side, respectively. The mean quick DASH score was 2.3 (range, 0 - 9.1). All patients returned to work. No surgery-related complications occurred.

Conclusions
This technique provides satisfactory restoration of articular congruence and enables early joint mobilization of articular depression type fractures of the base of the middle phalanx.

A Weak Part Of The Strong Hand: Hook Of Hamate Fractures

List of authors:
Claus M. Kullen1, Julian Ramin Andresen2, Sebastian Radmer3, Reimer Andresen3, Oliver Scheufler4
1 Institute of Diagnostic and Interventional Radiology, Neuroradiology, Westküstenklinikum (Heide)
2 Sigmund-Freud-University, Medical School (Wien)
3 Centre for Orthopaedics (Berlin)
4 AARE KLINIK, Aesthetic and Plastic Surgery (Bern)

Objectives / Interrogation: Some of the popular sports predispose to a specific injury: the hamate hook fracture which accounts for about 2-4% of all wrist fractures. They are not readily observed on conventional radiographic imaging and hence remain untreated or treatment is delayed. The aim was to identify sport activities that are associated with an increased risk of hamate hook fractures and to present an update on the current state of diagnostic and treatment options for these fractures.

Methods: Selective literature search was performed in PubMed and Google Scholar using the terms "hamulus ossis hamati fracture", "hook of hamate fracture", "sport injuries", "tennis", "rugby", "bouldering", and "golf". Due to the number of hits, 228 relevant original papers, case series, case reports and mainly meta-analyses, and review articles published until 2018 were included.
All relevant articles were obtained and evaluated for key points, including the mechanism of trauma, injury patterns, radiological imaging, treatment, and outcome.

Results and Conclusions: Due to popularity of classic sports, such as tennis or golf in an aging society, the risk of hamate hook fractures rises. It appears also that younger athletes performing sports such as climbing, bouldering, baseball or underwater rugby are associated with a higher injury rate to the hamate hook.
These can be caused by direct or indirect forces acting on the hamulus and the surrounding carpal ligamental structures and can occur as a single force overload or after repetitive trauma. In conventional radiographs, hook fractures are often missed on standard projections. The carpal tunnel view and special 45 degree oblique projection significantly increase the sensitivity. However, CT provides the most reliable imaging modality with a sensitivity of almost 100%. MRI offers the advantage of simultaneous detection of concomitant soft tissue injuries and microtraumas.
Non-displaced fractures near the base of the hook can be immobilized in a lower arm cast. Dislocated basal fractures and those in the middle third should be treated by internal fixation through an open or percutaneous access. Consolidation of distal fractures is unreliable with either conservative treatment or osteosynthesis. Therefore fragment excision is recommended. Overall, the results of conservative treatment are disappointing with a high rate of non-union.
In conclusion the hamate hook fracture is more relevant than you might think.

Brachial plexus injury associated with thoracic surgery

List of authors: Takashi Shimoe*, Hiroshi Iwasaki1, Shuhei Tsujimoto1, Hiroshi Yamada1
1 Wakayama Medical University (Wakayama)

Objectives / Interrogation: Brachial plexus injury (BPI) associated with thoracic surgery is a rare complication. We report the clinical feature of this condition and investigated the cause and pathophysiology.

Methods: Nine patients (8 males, 1 female) with BPI following thoracic surgery were included in the study. The mean age was 61.8 years (range 52-75). The affected side was right in 3 and left in 6 patients. Median sternotomy was performed in supine position for all patients and subclavian approach was indicated for 3 patients. We investigated the type of the palsy, clinical symptoms, factors to lead this condition, treatment and prognosis.

Results and Conclusions: The type of palsy was lower type BPI for all patients. Weakness of wrist extension and fingers flexion in 5 patients, and slight motor disturbances in 4 patients developed after the operation. Hypesthesia at the level of C7 or C8 in all patients and burning sensation in 3 patients developed postoperatively. Seven patients had the ipsilateral first rib fracture. Delay of motor nerve conduction velocity for ulnar nerve at ipsilateral cubital tunnel was found in 2 patients. All patients were treated conservatively. Pregabalin or duloxetine was administered for 3 patients who experienced burning sensation. Motor disturbances were recovered to MMT 5 in 6 patients and to MMT 4 in 3 patients after 3 - 6 months postoperatively. Sensory disturbances were recovered completely in 7 patients and slight numbness of ring and little fingers remained in 2 patients.

BPI was detected in 8 cases of 502 patients (1.6%) who underwent thoracic surgery with median sternotomy in our hospital. One case visited our clinic postoperatively from another hospital because of continuous sensory disturbance. We speculated that lower brachial plexus was compressed between first rib and clavicle due to excessive sternal retraction according with the fact that ipsilateral first rib fracture was found in 7 of 9 patients (77.8%). Before visiting our clinic, the influence of harvesting radial artery or continuous ulnar nerve compression at cubital tunnel during the surgery were suspected as the cause of the upper extremity symptoms.

After our instruction to the thoracic surgeons about this condition, diagnosis delay of BPI disappeared. All patients showed good recovery of motor and sensory disturbances within 6 months after the injury. We can contribute to prevention and early detection of BPI associated with median sternotomy by instruction to thoracic surgeons.

Fixed Flexion Deformity of the Middle and Ring Fingers in Adult Caused by Intramuscular Hemangioma of the Forearm.

List of authors:
Parunyu Vilai*1, Pratchaya Manop1, Chanagun Vanichanon1
1 Department of Orthopaedics. Srinakharinwirot University (Nakorn Nayok)

Objectives / Interrogation: Intramuscular hemangioma (IMH) of the upper extremity is extremely rare and mostly found in children. Due to its varying clinical presentations, IMH could be unrecognized. The author presents an unusual case of fixed flexion deformity of middle and ring finger in adult that was treated by surgical excision and post-operative outcomes.

Methods: The author described a 39-year-old female who presented with middle and ring finger flexion deformity that was unable to perform active and passive proximal interphalangeal (PIP) joint extension with deep forearm pain on the volar side for 3 years. After complete evaluation, the patient was diagnosed with IMH of flexor digitorum superficialis (FDS) muscle. Excision of the IMH was performed, intra-operatively passive extension of PIP joints was achieved. After 3 months follow up, no recurrence was observed and the patient regained full hand function. The patient was satisfied with the outcome.

Results and Conclusions: IMH of the upper extremity is an uncommon disease especially in adults. With vague clinical presentations, patients with finger flexion deformity and deep pain of the forearm, IMH should be one of the differential diagnosis. Early investigation should be performed and surgical removal remains the treatment of choice. Furthermore, tendon transfer should be reserved in case of functional deficits.

Combined thenar and hypothenar hammer syndromes in a professional baseball player: a case report

List of authors:
Shimpei Watanabe*1, Kazuki Sato1, Takuji Iwamoto1, Noboru Matsumura1, Taku Suzuki1, Masaya Nakamura1, Morio Matsumoto1

1 Department of Orthopaedic Surgery, Keio University School of Medicine (Tokyo)

Objectives / Interrogation: The incidence of digital ischemia of the hand is rare, although it can arise in athletes participating in baseball, volleyball, and handball.

We describe a professional baseball player with occlusion of both the radial and ulnar arteries secondary to repetitive trauma to the palm of the hand. Open release of the ulnar artery resulted in complete relief and symptomatic improvement.

Methods: A 37-year-old male, a right-hand dominant professional baseball pitcher, presented with pain, cold intolerance and numbness that were aggravated for short periods in the right ulnar digits while pitching. Conservative medical treatment at a local hospital did not adequately improve his symptoms and he was referred to our hospital two weeks after symptom onset. Angiography revealed complete occlusion of the ulnar and radial arteries at the hypothenar and thenar muscles, respectively. Collateral circulation was evident from the radial artery with the flow into the deep palmar arch. Retrograde flow from the radial artery also reached the superficial palmar arch. In addition to chronic radial artery occlusion, we considered that recent ulnar artery occlusion had disturbed blood flow to the finger on the ulnar side.

Surgical revascularization was performed under general anesthesia.

The ulnar artery was compressed by fibrous tissues at two points on the hypothenar muscle. Resection of the fibrous tissues resulted in the resumption of pulsation in the artery. The symptoms immediately disappeared thereafter, and he resumed throwing activities four weeks after the procedure. Within one year of the procedure he was able to return to the mound to pitch in official games.

Results and Conclusions: Thenar and hypothenar hammer syndromes are rare. They are characterized by digital ischemia of the hand as a result of repetitive trauma at the level of the thenar and hypothenar eminence and damage to the radial and ulnar arteries, respectively. Our patient repeatedly placed the palm of his right hand on the ground during daily baseball bunt practice and repeated microforces to the palm apparently caused digital ischemia. Non-surgical treatment is generally considered as a first line. However, this patient was surgically treated because a conservative approach did not achieve symptomatic relief and he wished to resume play as soon as possible.

Artificial Intelligence Based Distal Radius Fracture Detection

List of authors:
Turkka Anttila*, Eero Waris1, Teemu Karjalainen2, Teijo Konttila3, Jorma Ryhänen1
1 HUCS (Helsinki)
2 KSSHP (Jyväskyla)
3 HUS-Dataservice (Helsinki)

Objectives / Interrogation: Distal radius fractures (DRF) are the most common fractures of the human body. The diagnose is traditionally based on clinical examination and x-ray pictures. The primary diagnosis is often carried out by a general practitioner with varying degrees of experience. Sometimes fracture or fracture displacement may be missed. Deciding the appropriate treatment can also cause problems. The past decades advances in computer sciences have made possible to develop artificial intelligence (AI) algorithms to analyse medical images. This is shown in other studies made with hip, shoulder and chest x-rays. In this study, we present the results of a convolutional neural network (CNN) for DRF detection.

Methods: Nearly 10 000 posteroanterior and lateral wrist x-ray views were extracted from radiological archive. The x-rays were identified by ICD-10 codes correlating with DRF and wrist bruises (as a control group). The anonymized dataset was divided into a training set, validation set and a held-out test set. The x-rays in training and validation sets were labelled by one hand surgery resident. The held-out test set, that was not used in neural network training, was labelled by three experienced consultant hand surgeons. After all the x-rays were labelled a CNN was trained using the training and validation sets. The results of the CNN were compared to the test set's ground truth set by the three hand surgeons. The development of the CNN was done in co-operation with third parties and hospital's AI experts.

Results and Conclusions: The preliminary results showed that CNN has great potential in DRF detection. The details are opened and discussed in the presentation. The sensitivity and specificity of CNN for DRF detection are promising and further development into a highly efficient tool is possible. Our preliminary results indicate that with added amount of wrist x-rays and further training a CNN will be a reliable aid in DRF detection. Continuous development, tests and validation in clinical settings are needed before a CNN can be used as a medical aid. The future challenges lie in assessing fracture dislocation and the anatomical changes caused by the fracture. AI algorithms will revolutionise medical image interpretation, from x-ray to 3D imaging, in the near future.

Total Wrist Arthroplasty - Complications Management

List of authors:
Miho Nicoloff*, Agniezka Mandziuk¹, Simon Cleenewerck¹
¹Hand-Zentrum, Bonifatius Hospital Lingen (Lingen)

Objectives / Interrogation: For decades design and development of TWA has been accompanied by quite a few failures, so that it has been denied by most surgeons until today. The difficult and complex anatomy of the wrist caused different ways of development and often led into an impasse. Compared to knee and hip arthroplasties which could be conceived and developed further a consistent method could not be applied. But in the last years some new concepts established themselves, so that TWA is not only applied in individual cases. The indications could be expanded and standardized. Of course complications do occur as they also do in the other joints.

Methods: The presentation refers to more than 600 TWA's which have been performed since 2005. 44% suffered from Rheumatoid Arthritis, the remaining diseases consisted of osteoarthritis, posttraumatic arthritis and osteoarthritis, SLAC-wrist, SNAC-wrist, Kienböck's disease. Complications occurred in 4.3% of all cases. Other methods of complications management are available base on the type of TWA retrospectively. The purpose of this presentation is to demonstrate the varieties of those methods in typical cases of complications.

Results and Conclusions: The application of five different types of endoprotheses for TWA yielded an outcome of individual benefits and disadvantages.
For instance BIAX(DePuy) was soon abandoned due to insufficient fixation and subsequent loosening in the carpus. Generally good results were achieved with Universal II(KMI) with the advantage of screw fixation in the carpus. However this gain was annulled with requirement of the ulnar head resection.
With ReMotion(SBI/Stryker) ulnar head resection could be avoided. Complications occurred in the form of cystoid alteration of the metaphyseal spongyous bone of the radius and radial impingement. Maestro(Biomet) has the advantage of having a modular system with scaphoid augmentation. The superiority of Freedom(Integra), the follow-on generation of iUniversal II is demonstrated with its protection of the DRUJ. Thus complications management depends on the different types of endoprotheses. This presentation will discuss revision surgery, with and without TWA change, with view to management in infective situations. Since 2013 there have been 14 patients with TWA complications, with only one case requiring a wrist arthrodesis.
In our experience, it has showed that complications in TWA are controllable, and that TWA changes are feasible without the consequence of total wrist arthrodesis.

Lower Trapezius Transfer for Triceps Function in Obstetric Palsy; Review of Other Methods and Presentation of 15 Cases.

List of authors:
ATAKAN AYDIN*, zeynep hosbay², safiye ozkan³
¹ Istanbul University (Istanbul)
² biruni university (Istanbul)

Objectives / Interrogation: Since elbow extansion is a passive movement when shoulder is adducted and at secondary importance comparing elbow flexion, muscle transfer to triceps is not commonly mentioned in obstetrical palsy literature. This need was observed specially in patients whom had improved shoulder abduction with surgery but have limited elbow extansion.

Methods: Previously, we had operated on 13 patients with elbow extansion restoration ages between 5-16 years. We used brachioradialis muscle in 6 patients, brachialis muscle in 6 patients and posterior deltoid muscle in one patient with pros and cons of each method.
Later on depending on the anatomic studies for lower trapezius transfer in order to have better shoulder external rotation, we used ipsilateral lower trapezius muscle by elongation with tensor fascia lata graft to triceps muscle, in 15 obstetric palsy cases.

Results and Conclusions: Average elbow extansion was improved 50 degrees and shoulder abduction was improved 35 degrees in our patients. Ipsilateral lower trapezius transfer is a good tecnique for triceps function restoration with minimal donor site morbidity.

obstetric tendon transfer triceps
Psychological factors are more strongly related to pain in CMC-1 osteoarthritis patients than radiographic features

List of authors:
Lisa Hoogendam*, Mark van der Oest1, Harm Slijper2, Guus Vermeulen2, Ruud Selles1, Jarry Porsius3
1 Erasmus MC (Rotterdam)
2 Xpert Clinic (Eindhoven)
3 Erasmus MC, Harvard Medical School (Rotterdam)

Objectives / Interrogation: Conservative therapy for carpometacarpal (CMC-1) osteoarthritis is not effective for all patients. However, it is not possible to predict which patients will benefit. It is known that pain before treatment is associated with outcomes of therapy, but it is not clear which factors relate to pre-treatment pain. Therefore the aim of this study was to investigate which psychological factors are related to pain prior to conservative treatment in patients with CMC-1 osteoarthritis.

Methods: Patients were included at the start of conservative treatment for CMC-1 osteoarthritis. Pre-treatment pain was measured using the Michigan Hand Outcome questionnaire (MHQ). Psychological factors were defined as anxiety and depression, measured with the Patient Health Questionnaire-4 (PHQ), pain catastrophizing, measured with the Pain Catastrophizing Scale (PCS) and illness perception, measured with the Brief Illness Perception Questionnaire (B-IPQ). X-rays were scored on presence of osteophytes, subchondral sclerosis, subluxation, joint space narrowing, cysts and STT osteoarthritis.

Two linear regression models were fitted. Model 1 consisted of patient characteristics, such as age, gender and occupational intensity, and X-ray scores. In model 2 psychological factors were added to model 2.

Results and Conclusions: 255 patients were included in this study. 75% of the patients were female, mean age was 60 years and mean MHQ pain score was 47.1 (17.3). 7.8% of the patients reported elevated PHQ scores. The first regression model with patient characteristics and X-ray scores only accounted for 3% of the variance in MHQ-pain. After adding the psychological factors to our model, 42% of the variance could be explained.

Our results show that psychological factors are more strongly related to pain levels prior to treatment in patients with CMC-1 osteoarthritis than patient characteristics and X-ray scores. More research is needed to determine whether psychological factors will also affect treatment outcomes.

Reconstruction of Extensor Tendons in Multiple Subcutaneous Rupture of Rheumatoid Fingers

List of authors:
Masayuki Sekiguchi*, Ayako Kubota1, Tatsurou Sakurai1, Kentaro Tsuji1, Takashi Arai1, Shinji Taniguchi2, Shigeta Takeuchi3, Taisei Sako1, Hiroshi Takahashi1
1 Department of Orthopaedic Surgery, School of Medicine, Toho University (Tokyo)
2 Department of Orthopaedic Surgery, Toho University, Sakura medical center (Chiba)

Objectives / Interrogation: [Purpose]
Although various methods have been reported for reconstructing multiple subcutaneous tendon rupture in patients with rheumatoid arthritis, satisfactory results have not necessarily been obtained. We attempted a new reconstruction method in which the tendon of the proximal side was reversed and sutured to the distal side. Postoperative results and usefulness of this method were examined.

Methods: [Subjects]
The subject of this study were cases of subcutaneous rupture of multiple tendons. Twenty-seven patients with RA were able to follow up for more than one year after surgery. Two cases were men and 25 cases were women, and the age at the time of surgery was 29 to 82 years old.

[Reconstruction method]
For the two fingers on the ulna side, the proximal side tendon of either EDC 4 or EDC 5 was reversed and sutured to the ruptured tendons on the distal side. In addition, for the three tendon ruptured cases, the proximal side tendon of either EDC 3 or EDC 4 was reversed. EDC 5 tendon on the distal side was sutured to EDC 4 tendon, but in cases with short tendon on the distal side, EIP tendon was transferred to distal tendon of EDC 5 / EDM. After the surgery, the affected fingers were buddy taped with undamaged fingers, and active motion exercise was permitted from the early postoperative day. It was fixed with splint at the extension position of fingers and wrist during night.

Results and Conclusions: [Result]
At the time of investigation, the average angle of ROM (extension / flexion) of MCP joints was as follows. Cases with three tendons ruptured: long finger 0.71±9.32/73.6±9.88, ring finger 0.71±12.39/76.4±16.33, little finger 0±9.57/71.4±19.30. Two tendon rupture cases: ring finger -3.0±5.70/72.0±18.91, little finger 3.0±9.08 /70.0±23.18.

[Discussion]
Since myostatic contracture is the source of contraction force in ruptured muscle, it takes a long time to improve muscle contraction. However, excellent extension range is obtained as the muscle contraction of the ruptured muscle is recovered. In addition, it is considered that excellent range of motion is obtained because the reconstructed tendon runs similar to the normal tendon.

[Summary]
Our new reconstruction method of reversing the proximal side of torn tendon is a useful method for reconstructing multiple subcutaneous extensor tendon ruptures.

LONG HEAD OF TRICEPS TRANSFER TO GAIN ELBOW FLEXION in 25 PATIENTS

List of authors:
ATAKAN AYDIN*, omer berkoz¹, zeynep hosbay², safiye ozkan¹
¹ Istanbul University (Istanbul)
² biruni university (Istanbul)

Objectives / Interrogation: Elbow flexion is the most important function of the upper extremity, hence loss of this function leads a major disability. Elbow flexion deficit can be seen in both congenital (arthrogryposis) and acquired (traumatic / obstetric brachial plexus palsy) conditions. We describe our results for the surgical technique of transfer of the long head of triceps transfer in traumatic and congenital cases.

Methods: We performed this transfer in 25 patients, ages between 2-45 years. The nine adult patients were suffering from traumatic brachial plexus injury while 16 young patients were arthrogrypotic or obstetric palsy sequel. We achieved 85-115 degrees of elbow flexion in obstetric and traumatic plexus patients while preserving elbow extension and 60-90 degrees of elbow flexion in arthrogrypotic patients.

Results and Conclusions: All patients were happy to gain hand to mouth function, elbow extension deficit is acceptable in acquired cases while in arthrogrypotic cases since shoulder abduction is not expected, partial triceps power loss almost never effects daily living. Although there are many muscle transfer methods (lat dorsi, pectoralis etc) to reanimate elbow flexion, we conclude that long head of triceps transfer is a reliable technique in both acquired and congenital cases.

Management of shoulder internal rotation limitation in obstetrical palsy.

List of authors:
ATAKAN AYDIN*, zeynep hosbay², safiye ozkan³
¹ Istanbul University (Istanbul)
² biruni university (Istanbul)

Objectives / Interrogation: Muscle imbalance in a growing child can lead to bone and joint deformities. Obstetric palsy patients with incomplete recovery have glenohumeral joint problems because of imbalance between shoulder adductor and internal rotator(IR) muscles & abductor external rotatuar(ER) muscles. Although shoulder internal rotation contracture preventing shoulder abduction and external rotation in the most common problem in obstetric palsy patients with partial recovery; shoulder internal rotation limitation or external rotational contracture is a worse condition preventing hand to belly and back functions hence limiting daily activities.

Methods: Fourteen patients had operation to improve shoulder ER and Abduction 3-5 years ago. Although their Abd and ER degrees improved dramatically; two years after the operation they had internal rotation limitation despite vigorous physiotherapy. 15 patients did not have neither nerve nor palliative any operation before and had IR limitations preoperatively. During operation, posterior incision above spine of the scapula was performed, supraspinatus, infraspinatus and teres minor muscles, and acromion bone were encountered. The intraoperative observation was not only heavily scarred muscle fascias which needed relaxation but also shortened external rotator muscles which needed release and lateralization with V-Y fashion so that passive shoulder internal rotation movements were possible. At 3rd day postoperative rehabilitation program, active range of motion exercises were initiated. All cases were evaluated by using range of motion measurement and Mallet scale.

Results and Conclusions: Average age of the children was 6,3 years and The average follow-up period was 21 months. The preoperative values in terms of IR were 2º and postoperatively 20º. Degree of abduction was mean 136 before the surgery. After surgery, it decreased to 105º but with therapy it caught up preoperative values. Degree of external rotation value was mean 85º preoperatively. After the treatment, the external rotation value was measured 66,2º. The mean Mallet score improved from 18 preoperatively to 20 postoperatively. Although shoulder abduction, ER problems are far more common in obstetrical palsy patients, there a group of patients which had internal rotation limitations either occured spontaneously or surgically. Facing with the reality we operated on these patients to achieve better hand to midline and back functions.

NEW TECHNIQUE FOR RECONSTRUCTION OF DRUJ IN CHRONIC INSTABILITY WITHOUT ARTHROSIS

List of authors:
1 Hospital Maria Amélia Lins (BELO HORIZONTE)
2 Hospital Madre Teresa (BELO HORIZONTE)
3 HOSPITAL DA UNIMED (BELO HORIZONTE)
4 Hospital Luxemburgo (BELO HORIZONTE)
5 HOSPITAL DAS CLÍNICAS (BELO HORIZONTE)
6 FEDERAL UNIVERSITY OF MINAS GERAIS (BELO HORIZONTE)

Objectives / Interrogation: Disorders of the distal radioulnar joint (DRUJ) of different etiologies are relatively common and can severely affect wrist and forearm function. Acute lesions, if unidentified and treated, may evolve with chronic pain and instability, or degenerative disease in more advanced stages. Due to local bone characteristics, stability is mainly given by the soft tissues, among which the triangular fibrocartilage complex (TFCC) is the main structure. Restoration of DRUJ stability is the goal of treatment and the reconstructions constitute the main group when treating chronic non-arthrosic lesions. The objective of this paper is to describe a new technique of tenoplasty using a strip of flexor carpi ulnaris (FCU) tendon, for anatomical reconstruction of the DRUJ.

Methods: Five fresh cadavers without signs of lesions or previous surgeries in the upper limbs were selected and the surgical technique was applied to both wrists, totaling 10 reproductions performed by the same hand surgeon. Photographs and computerized figures were presented detailing the most important points of each steps of technique.

Results and Conclusions: The technique of this study presents several advantages when compared to the procedures already described in the literature, since it constitutes a reconstruction of the TFCC that tries to reproduce the anatomy closer to the normal, respecting the ligament origin and insertion points. This allows gain of stability in the sagittal and coronal plane, without limiting movement of pronou-supination. Other theoretical advantages of the study include performing only two bone tunnels, with reduced risk of iatrogenic fracture; maintaining a constant tension of the graft, without loosening over time characterizing a dynamic tenoplasty; conservation of the primary function of the FCU; and small need for dissection and short time to perform. The technique described is suitable for the stability restoration of the DRUJ in cadavers, with technical advantages over other described procedures, being a good alternative for the treatment of chronic instabilities of DRUJ without arthrosis.

Complications of Hardware Removal in Pediatric Upper Limb Surgery - Is It Safe?

List of authors:
Sebastian Farr1, Philipp Scheider2, Rudolf Ganger1
1 Orthopedic Hospital Speising (Vienna)
2 Medical University of Vienna (Vienna)

Objectives / Interrogation: Previous studies indicated that hardware removal may lead to increased morbidity and therefore, at least in adults, remains questionable for certain indications. However, risks such as corrosion or local reactions may be less likely in younger patients with current, improved hardware materials. We sought to determine complication rates of hardware removal in pediatric upper limb surgery, and establish potential risk factors for increased morbidity.

Methods: All children and adolescents who underwent hardware removal under sedo-analgesia or general anaesthesia after previous upper limb surgery (2006-2016) were retrospectively evaluated. Cases with ambulatory hardware removal were not included. We performed a chart review and extracted the following details at latest follow-up available: patient demographics, diagnosis, implant location (e.g. humerus, radius/ulna, phalanges), hardware material, duration of surgery, duration of hardware-in-place, complication grades according to Goslings et al. (grade 0-5) and Sink et al. (grade 1-5), respectively. Correlations were calculated to establish potential relationships between specific outcome parameters (BMI, duration of surgery, hardware-in-place) and complication grades.

Results and Conclusions: A total of 2,090 children were evaluated of whom 450 (222 males, 228 females; mean age 9.5 years) fulfilled the inclusion criteria for this study. Overall, K-wires (46%), plates (22%), external fixators (23%), intramedullary hardware (7%), screws (1%), cerclages (1%) and pins (0.2%) were removed; most common locations were the forearm (34%), humerus (24%), metacarpalia (9%), phalanges (8%) and carpalia (2%). The mean duration of surgery was 40 minutes (range, 2-620), mean time-in-place was 194 days (range, 2-4018). Complication rates were low overall, with most being grade 0 (n=373; 83%) or 1 (n=60; 13%) acc. to Goslings et al. and grade 1 (n=387; 86%) and 2 (n=43; 9%) acc. to Sink et al. No severe complications acc. to Goslings (grades 4,5) and Sink (grade 5) were observed. Five cases required postoperative ICU admission which thus classified them as Sink grade 4 (1.1%). We found no correlation between BMI, duration of surgery or hardware-in-place duration with classification grades.

To summarize, hardware removal under sedo-analgesia or general anaesthesia in the pediatric upper extremity is a safe procedure. However, despite this large group of patients analyzed, we were unable to find any particular determinants for possible complications.

Radius metastasis: an unusual form of presentation

List of authors:
Luisa Vital*, Vitor Vidinha¹, Mariana Cunha¹, Pedro Negrão¹, Isabel Pinto¹, Antonio Sousa¹
¹ Centro Hospitalar São João (Porto)

Objectives / Interrogation: Metastatic cancer is the most common reason for a destructive bone lesion in adults. The hand and wrist are less commonly affected than the axial skeleton, and acrometastasis develop in less than 0.3% of patients with cancer.

Methods: A 69-year-old white male patient presented with a 2 days history of pain, edema, and decreased right wrist ROM. The patient denied any history of trauma, recent illness or fever. On physical examination there was mild swelling over the distal forearm and no warmth increase or erythema was identified, as well as no mass was palpable. The neurovascular structures were intact. An x-ray revealed a lytic lesion of the radius metaphysis with an associated pathological fracture. A renal cell carcinoma was diagnosed, with lung metastasis and one single bone metastasis in the right wrist. The patient underwent right total nephrectomy and started chemotherapy treatment. MRI confirmed a bone lesion at the distal end of the right radius 3 cm from the radio-carpal joint with 25 mm of longitudinal extension, destruction of the cortical bone, a small extra-osseous extension of the lesion and associated reactive edema of adjacent soft tissues. The decision was to treat this metastasis with a wide, local en bloc resection of the lytic lesion excision and fill the defect with iliac autograft (tricortical) plus fixation with a palmar distal plate of the radius. In the postoperative period, a splint was maintained for 4 weeks. Radiographs confirmed bone integration of the graft at 9 months. At follow-up the patient scored a VAS of 2/10 with mobilization of the wrist and almost normal ROM. Recurrence control with annual MRI was done, with no further disease at 5 years follow-up. The systemic disease also presented good response to the treatment instituted and seems to be estabilized.

Results and Conclusions: Acrometastasis can appear in patients of any age, with men being twice as likely as women to be affected. Rarely, they may be the first presentation of an occult silent cancer, mimicking a benign condition. In cases of RCC metastasis, one must aware that this type of carcinoma has an extremely unpredictable clinical course. But, a bone metastasis may be the first sign of the disease. Patients may present with pathologic fractures because the lesions weaken the integrity of the osseous matrix. Such lesions can be misdiagnosed. Our case describes an unusual presentation of metastatic RCC where a pathological fracture was the first sign of the disease that led to all the subsequent study made and the final diagnosis.

Treatment of fracture dislocation of the elbow with Regan-Morrey Type I/II coronoid fracture: A retrospective analysis of clinical results

List of authors:
Seungho Hyun*, Yasunori Kaneshiro¹, Ryo Sasaki³, Koichi Yano¹, Hideki Sakanaka¹
¹ Seikeikai Hospital (Sakai City)

Objectives / Interrogation: The best surgical protocol to treat fracture dislocation of the elbow with coronoid fracture remains unclear. The purpose of this study was to report the clinical and radiological outcomes of fracture dislocation of the elbow with coronoid fracture.

Methods: This is a retrospective case series of 20 consecutive patients who were treated for fracture dislocation of the elbow with Regan-Morrey Type I/II coronoid fractures between 2008 and 2017. The patients’ mean age was 49 years and the mean follow-up period was 12 months. Our surgical protocol included both repair of the lateral collateral ligament (LCL) and fixation or replacement of the radial head first, then repair of the medial collateral ligament (MCL) was additionally performed if the MCL had been confirmed as injured by preoperative MRI and/or intraoperative stress test. Only after that, if the instability remained, was coronoid repair performed. Patients were evaluated both radiographically and with a clinical examination at the final follow-up. Elbow instability was defined as clinical or radiographic evidence at the final follow-up. Outcome measures included elbow range of motion, forearm rotation, elbow stability, and radiographic arthritic changes. Clinical outcomes were assessed with Mayo Elbow Performance Score (MEPS).

Results and Conclusions: All 20 patients had a coronoid fracture, 11 patients had Regan-Morrey Type I fractures and 9 patients had Type II. Among the 20 patients, 12 patients had a terrible triad injury and 8 patients had a fracture dislocation with only coronoid fracture. Repair of the LCL was performed in all 20 patients (100%), and repair of the MCL was performed in 15 patients (75%). Repair of the coronoid fracture was performed in 2 patients (10%) with Type II. Among the 13 patients with a radial head fracture, open reduction and internal fixation in 12 patients and prosthetic replacement in one patient was performed. The mean arc of ulnohumeral motion at the final follow-up was 127° and mean forearm rotation was 155°. None of the patients demonstrated instability postoperatively. Radiographs revealed no arthritic changes. The mean MEPS was 95 points. In this study, the rate of MCL injury was as high as the rate of LCL injury in fracture dislocation of the elbow. The results suggested that fracture dislocation of the elbow with Regan Type I/II coronoid fractures can be effectively treated without repair of the coronoid, when repair of the LCL/MCL sufficiently restores stability of the elbow.

Investigation of preoperative image and pathological necrotic findings in scaphoid fracture pseudarthrosis

List of authors:
Takeshi Sakai*, Keikichi Kawasaki¹, Tetsuya Nemoto², Naoya Nishinaka³, Kouji Kanzaki⁴, Katsunori Inagaki²
¹ Showa University Yokohama Northern Hospital (Yokohama)
² Showa University School of Medicine (Tokyo)
³ Showa University Research for Sports and Exercise Sciences (Tokyo)
⁴ Showa University Fujigaoka Hospital (Yokohama)

Objectives / Interrogation: Preoperative image assessment for osteonecrosis in the proximal spicula is important for selecting the surgical technique to apply to scaphoid fracture pseudarthrosis. However, synostosis may also be obtained by nonvascularized bone graft, and actual divergence from image findings has been noted. Here, we report pseudarthrosis preoperative image findings and intraoperative pathological findings in comparison with the therapeutic outcomes of vascularized bone graft.

Methods: Taken from among vascular bone graft operations for 116 hands in treatment of vascular scaphoid fracture, the subjects in this study were 22 hands presenting pathological specimens of pseudarthrosis regions. The mean age of the subjects was 28.8 years, the male:female ratio was 20:2, the mean time from injury to surgery was 52.6 months, and the position of the pseudarthrosis was proximal:medial:distal in 8:13:1 hands. Surgery was performed by the Zaidemberg technique for 21 hands and the Makino technique for 1 hand. X-ray images assessed using the Ikeda classification showed filamentary in 2 cases, cystic in 7 cases, and sclerotic or transpositional in 13 cases. The preoperative MR images (obtained for 20 cases) for proximal spicule, T1, and T2 findings were compared with the peripheral carpal bones and assessed for signal intensity. Low signal intensity was found in both T1 and T2 in 8 cases and low T1 signal intensity alone in 7 cases. In the pathologic diagnosis, samples from within the proximal spicule of the pseudarthrosis were taken and assessed for osteonecrosis. The image findings, pathological diagnoses, and postoperative outcomes were investigated.

Results and Conclusions: In the pathological investigation, osteonecrosis was found in 11 cases (50.0%), with the position proximal in 6 cases (necrosis 75.0%), medial in 5 cases (38.5%), and distal in 0 cases (0%), and thus most often proximal. In the Ikeda classification, osteonecrosis was filamentous in 2 cases (100%), cystic in 4 cases (57.1%), and sclerosal or transpositional in 5 cases (6.7%). From MRI, osteonecrosis was both T1 and T2 in 4 cases (50.0%) and T1 alone in 5 cases (71.4%). The synostosis rate was 11 cases (100%) in the necrotic group and 10 cases (90.9%) in the non-necrotic group. Osteonecrosis findings by pathological examination did not necessarily match the X-ray or MRI findings, thus indicating that determination of osteonecrosis as a preoperative finding is difficult.

Recovery Analysis of Two Point Tactile Discrimination Following Dorsal Cross Finger Flap

List of authors:
Tanveer Ahmed*, Iftekhar Mannan, Farzana B Ibrahim, Md. Abul Kalam
1 Plastic Surgery, Dhaka Medical College (Dhaka)
2 Popular Medical College (Dhaka)
3 Ibrahim Medical College (Dhaka)
4 Dhaka Medical College (Dhaka)

Objectives / Interrogation: Fingertip injuries are common among the young working group of people in a developing country posing a great concern.
Sensation in the flap is imperative to the proper functioning of the reconstructed fingertip. The study conducted to observe the way to return of two-point tactile discrimination in different stages and conditions over the flap after division is a method of identifying adequate functional re-innervation of the flap.

Methods: A prospective observational study to measure the changes during the recovery of two-point tactile discrimination (TPTD) over the dorsal cross finger flap was carried out for a period of 6 months after flap division for each case. TPTD was measured in the dorsum before flap elevation (donor control) and from the corresponding opposite fingertip (control). Then TPTDs were noted from the day of flap division, 7th POD, 15th POD and thereafter monthly up to six months. Data were analyzed and compared on those days in-relation to age, sex, hand dominance, time to repair after injury and smoking.

Results and Conclusions: In this study, it was shown that the mean TPTD on the dorsum of the middle phalanx of the flap donor site (Donor Control) was 5.31 ± 0.79 mm and on the corresponding opposite fingertip (Control) was 2.79 ± 0.78 mm.
In the 1st follow-up on the 15th POD following flap division, the mean TPTD was 15.70 ± 1.31 mm, on 30th POD was 14.66 ± 1.14 mm, on 60th POD 13.74 ± 1.00 mm, on 3 months 13.10 ± 1.12, 4th & 5th months 11.87 ± 1.01 & 09.25 ± 1.09 respectively and at 6th months was 07.70 ± 0.92 mm.
The improvement was rapid between the 4th & 6th months where the mean improvement was 4.17 mm - the most significant improvement. It had been evident, TPTD on 6th months (7.7 mm) was reached just below the protective sensation cut off value of 8 mm in 83.4% cases. But no statistically significant differences were found in the two comparing age groups (< 30 years and > 30 years). In the same time, no statistically significant differences were found while comparing between sex, reconstruction time after injury, type of injury, hand dominance and even on smoking.
So, the cross finger flap for fingertip injury reconstruction is a good option for a resource-poor developing country.

Transversal morphology of the sigmoid notch

List of authors:
Flavien Mauler¹, Sana Boudabbou², Jean-Yves Beaulieu²
¹ Kantonsspital Aarau (Aarau)
² Geneva University Hospitals (Geneva)

Objectives / Interrogation: Treatment of distal radioulnar joint instability remains challenging. The relative congruency of this joint depends among other structures on the morphology of the sigmoid notch. However, since the description on cadavers by Tolat and colleagues in 1996 there are very few data available on the morphology of the sigmoid notch in the transversal plane. The purpose of this study was to describe the shape and analyze variations of the transversal morphology of the sigmoid notch on axial T1-weighted magnetic resonance imaging (MRI) sequences in healthy patients.

Methods: 88 patients with suspected scaphoid fracture which underwent MRI and standard radiographs of the wrist were included in this study. Patients with history or proved wrist instability or prior radius surgery were excluded. The sigmoid notch was analyzed on T1-weighted MRI axial plane by two readers. Its shape was categorized in four groups according to the classification of Tolat. This rather subjective classification was confronted to more objective measurements and correlated to the shape of the radius and the curvature of the ulnar head.

Results and Conclusions: The morphology of the sigmoid notch is analyzed according to the classification of Tolat. Objective measurements of the different morphology variations, as well as correlations with the shape of the ulnar head, the ulnar variance and inclination of the distal radioulnar joint are assessed. Furthermore, the presence of a distal-volar lip on the radius is discussed; it has a similar aspect to the labrum of the shoulder and seems to correspond to a broader insertion of the volar radioulnar ligament. Its relation to the shape of the sigmoid notch is also analyzed. Transversal shape of the sigmoid notch is a potential factor influencing the stability of the distal radioulnar joint. Association with a distal-volar lip on the radius and valuable input for the surgical treatment of distal radioulnar joint instability are discussed.

sigmoid notch, distal radioulnar joint, morphology
Wrist Arthroscopy - lessons learnt from the first 100 cases

List of authors:
Sonja Cerovac*
1 St George's Hospital, Hand Unit (London)

Objectives / Interrogation: Wrist arthroscopy is technically demanding and complications-prone procedure due to intricate wrist anatomy and the steep learning curve. Published evidence suggests inverse relationship between the surgeon's experience and complication rate. This audit analysed the case-mix and outcomes of all arthroscopies performed by a single surgeon since the introduction of the wrist service within a busy plastic surgery hand unit, as well as the challenges faced during this novel process.

Methods: 113 consecutive primary arthroscopies were carried out over the 9-year period (2009-2018). 62% of the procedures were diagnostic and 38% therapeutic. The triangular fibrocartilage complex pathology was the commonest indication for investigation (47% of cases), followed by the scapho-lunate ligament injury in 27% and scaphoid fractures in 21%.

Results and Conclusions: There were no major complications - infections, neuromas, tendon or nerve injuries - in this cohort. A total of 7 (6%) minor complications were identified, 5 of which were in the first 4 years of the surgeon's practice. Iatrogenic partial thickness cartilage damage was observed intraoperatively in 6 patients (5%), all of whom were asymptomatic postoperatively. One localised postoperative synovitis at the site of 3/4 portal required subsequent surgical exploration and excision.

The first 100+ wrist arthroscopies carried out in our department have been delivered safely with complication rate comparable to that published worldwide. Wrist arthroscopy requires targeted subspecialist training, but with ongoing education and growing experience, it becomes safer and invaluably broadens the referrals to plastic surgery hand units. Lessons learnt will be covered as input to the colleagues involved in a similar practice setup.

The use of the hipotenar fat flap for recurrence of the carpal tunnel syndrome surgery

List of authors:
LUIZ VILELA¹, HENRIQUE CHAMON¹, Felipe Leao¹, Renan Reis¹, Vinicius Toledo¹, Rafael Lopes¹
¹ HOSPITAL MARCIO CUNHA (IPATINGA)

Objectives / Interrogation: Present a technical proposal and show the results of the hipotenar fat flap for the recurrence of failure or recurrence of carpal tunnel release

Methods: This is a retrospective study with a prospective data collection, all the surgeries performed by the same surgeon. Between February of 2014 and March of 2018, 20 patients were operated for carpal tunnel recurrence with the technique of hipotenar fat flap. 13 participate the study, not for exclusion criteria, but because 7 were not available to answer the questionaire or to sign up the formularie. The group were composed for 1 man and 12 women. Related to the side operated 5 were right side and 8 left side. The average time between the first and the second surgery was 3 years. The medium follow up between the surgery and final evaluation was 54 moths (6 months to 48 months). The technique consisted in a "L" approach beginning in the distal palmar crease, in line with the radial border of the 4th finger in a curve longitudinal fashion to the wrist crease, continuing transversely to the pisiform. The skin was elevated leaving the subcutaneous tissue (hipotenar fat pad) attached to the hand. Then, the carpal tunnel was open, and all the synovitis was taken off beneath the tendons, and the median nerve was cleaned as well, sometimes removing part of the epineurium. The flap was raised preserving its vascularity by branches of the ulnar artery. The flap was transposed to cover the carpal tunnel and the skin over it.

Results and Conclusions: The results were evaluated by the Quick Dash Score. The data was collect pre and pos operative. The average Quick Dash score was pre operative 80.65 (range 61.3 to 100), and pos operative 40.65 (range 11.3-70). The worst patients were those with multiple surgery in the same member or another, and those who were out of work, receiving benefits from social security (7 patients).

In this study, analysing the results, the hipotenar fat flap improves the symptoms of carpal tunnel recurrence, being a simple and low cost technique, and promotes a good coverage of the nerve and tendons, in a scared tissue surroundings, being a good option in this situation. Unfortunatelly, we observe that the results are very heterogenous, some patients that improved a lot, and some that not improved at all. The reason to that could be explained by many ways: time in between the two surgery (3 years in average), extend of impairment of the nerve, works compensation and clinical conditions in some of them.

Another neurotisation of n.axillaris

List of authors:
Margarita Kateva*, Kalin Angelov1, Iliyana Marcheva1, Desislav Vrachanski1, Eli Apostolou1, Nikola Simeonov1
1 University Hospital “Sofiamed” (Sofia)

Objectives / Interrogation: N.phrenicus is a classic extra-plexus donor of axons for re-innervation of the muscles innervated by n.musculocutaneus, n.suprascapularis, n.medianus, n.ulnaris, n.radialis, n.axillaris by performing end-to-end or end-to-side microsurgical anastomoses with nerve-grafts (n.suralis, n.saphenus). A new method of direct neurotisation of n.axillaris with n.phrenicus was presented as n.phrenicus is taken endoscopically in its full length immediately before it sank into the diaphragm. M1 contractions(MRC) of m.deltoideus was reported 2 months postoperatively. A major factor for successful neurotisation is time, most importantly, the donor / recipient nerve distance.

Methods: 4 adult patients with brachial plexus trauma are presented. Our approach to those with C5, C6, C7 avulsion and C8, Th1 neuropraxia was: 3 months after the trauma first stage of surgery treatment is presented- modified Oberlin method for restoration of elbow function is performed, as well as other nerve transfer was also carried out at the same stage:n.accessorius to n. suprascapularis. In the second stage neurotisation of n.axillaris is performed by taking full length of n.phrenicus endoscopically before it sank into the diaphragmatic musculature.

Results and Conclusions: M1(MRC) muscle contractions of m.deloideus are reported on the 2nd postoperative month. The length of the intrathoracic n.phrenicus is 22 cm. This shortens the reinnervation time with 7-12 months. For the period of March-September 2018 we have operated 4 patients with this methodology. The use of n. phrenicus as a donor nerve in the case of end-to-end coaptation does not lead to permanent impairment of respiratory capacity and pulmonary function of the patient. This is a revolutionary method of restoration of affected muscles after plexus brachialis trauma. A major factor in their successful neurotisation is the time. i.e., the donor / recipient nerve distance. The use of n.phrenicus with its full length as a donor shortens the re-innervation time of the impaired muscles. This is particularly important in patients who have not had pre-operative nerve stimulation of the denervated muscles or delayed treatment.

n.phrenicus, n.axillaris, nerve transfer
Restoring Functional Motion in the Arthritic Wrist through Circumduction

List of authors:
Maheen Nadeem∗1, Jeremy Loss1, Zong Ming Li1, William Seitz1
1 Cleveland Clinic (Cleveland)

Objectives / Interrogation: Object:
We hypothesize that functional wrist motion is lost in the arthritic wrist due to a combination of mechanical incongruity & pain. Restoration of functional motion is achieved through elimination of pain generators and reestablishment of adequate freedom of motion through a three dimensional envelope of motion allowing near-normal circumduction.

Methods: Materials:
Biomechanical studies performed in our laboratory have mapped out 3-D arcs of motion needed to carry out normal ADL tasks. These were compared to patients who underwent motion-sparing reconstructive wrist surgery (4-C-F, PRC, SHARC, TWA) who reported satisfactory wrist function following surgery / rehabilitation. Limitations in any direction were compared to the total circumductive envelope achieved clinically.

Results and Conclusions: Results:
Satisfactory ADL mobility parallels reestablishment of movement through a stable, pain-free circumductive arc of motion by means of limited arthrodesis, excision of mechanical obstruction, preservation of congruent healthy articular surfaces, or arthroplasty which restore wrist kinematics to near-normal.

Conclusion:
PRC, SHARC, TWA appear to restore central, unimpeded circumduction of roughly 60% of normal which provides adequate 3-D mobility for restoration of functional ADLs. 4-C-F results in a longer lever arm with increased stress at the R-C articulation which offers a more restrictive & less functional circumductive envelope.

Epiphyseal stress fracture of the base of the middle phalanx in adolescent sport climbers

List of authors:
Andreas Schweizer*, 1, Anne-Gita Scheibler1, Natalie Bärtschi1
1 Universitätssklinik Balgrist (Zürich)

Objectives / Interrogation: Epiphyseal stress fracture of the base of the middle phalanx is the most common injury among adolescent sport climbers and observed only in this sport. The purpose of this study was to evaluate subject characteristics, injury mechanism and clinical outcome.

Methods: All adolescent sport climbers with pain at the dorsal base of the middle phalanx with or without fractures (Salter-Harris Typ III) who were treated at our department between 2006 and 2018 were included in the study. A questionnaire was sent to all patients about their specific climbing and training habits. In climbers were the questionnaire was not sent back, the patient chart records were used only. All patients were treated conservatively with reduction of load and regular clinical and radiological control (either to document consolidation or to detect a late development of a fracture) every 2-3 months until pain disappeared.

Results and Conclusions: 28 climbers (21 male) with 67 affected fingers could be evaluated. 16 patients completed the questionnaire addressing injury details as well as training behavior before and after the injury. The mean age at the time of injury was 14.0 years (±1.4 years). Middle (58%) and ring (30%) finger PIP joint were found to be the most common sites of injury. All suffered from pain at the dorsal base of the middle phalanx while 16 patients had a fracture in 22 fingers, two of them developed the fracture only at a follow up control. Mean time for consolidation was 8 months (2-24 months). One patient who presented late showed a destruction of the epiphysis with severe joint surface incongruence and signs of osteoarthritis. 9 patients showed mild joint surface incongruence. 37.5% had only slight pain occasionally during climbing and 75% climbed still regularly at the same level or better as before. Nearly half of the patients (43.7%) included campus board exercises and one fourth of the patients (25%) trained specifically on small holds.

Epiphyseal fatigue fracture of the base of the proximal phalanx is a unique injury in adolescent sport climbers which can lead to severe damage of the growth plate with a joint surface incongruence when left untreated resulting in permanent impairment of the affected finger. Dorsal finger pain at the PIP joint in adolescent climbers must be assessed carefully and consultation of an experienced physician should be considered at an early stage and patients should be followed until the pain disappears, which may take several months.

Nitinol Intramedullary Fixation for DIP Arthrodesis Restores Biomechanically Stable Pinch and Grasp

List of authors:
William Seitz*1
1 Cleveland Clinic (Cleveland)

Objectives / Interrogation: Objective
The authors have hypothesized that an alternative technique for arthrodesis of the DIPJ of the fingers or IPJ of the thumb using pre-tensioned implants for intramedullary fixation can provide a high rate of satisfactory union and anatomic position with a minimal complication rate.

Methods: Methods
Twenty-one distal interphalangeal joint arthrodesis and 11 thumb interphalangeal joint arthrodesis were performed in 16 patients (10 women and 6 men). Age range between 6 and 79 years with a mean age of 62 years. In five patients a single joint arthrodesis was performed whereas in 11 patients more than one arthrodesis was performed. All patients included in this study were followed for a minimum of two years.

Results and Conclusions: Results
The mean time to healing was eight weeks with a range of six to ten weeks. By ten weeks, healing was noted in 31 of 32 digits. The healing was eight weeks with range of 6-10 weeks. By ten weeks there was healing noted in 31 of 32 digits. Only one patient with a delayed union after ten weeks demonstrated a fibrous union that was stable and non-tender. In all cases patients reported no pain at the arthrodesis site by three months postoperatively. There have been no hardware related problems and in no case was the hardware removed. The one patient with delayed union after ten weeks appeared to have formed a fibrous union which was stable and non-tender. All patients described complete absence of pain at the site of arthrodesis and complained of no significant pain or dysfunction by three months post-operatively. There have been no hardware problems and in no case was hardware removed. Functional pinch & grip strength was 80% of normal.

Conclusion
The surgical technique for arthrodesis of the distal joint of the fingers and thumb is straightforward. The technique employed in this series utilizes instrumentation which further simplify the surgical procedure, affords excellent apposition of bone, and intramedullary fixation of the arthrodesed joint. Variability in angle of the implants affords the surgeon the ability to place the fused joint in neutral 15 or 25 degrees of flexion as is needed for patient function. The absence of any hardware related problems, lack of infection and high rate of union, & excellent function indicates this to be a viable and attractive option for arthrodesis of the distal joints in the hand.

Objectives / Interrogation: Objective
Historically, attempts to surgically treat recalcitrant lateral epicondylitis have been associated with significant post-operative pain and a prolonged period of dysfunction. The authors have hypothesized that use of a minimally invasive radiofrequency coblation technique & arthroscopic synovectomy can provide enhanced early pain relief as compared to prior techniques.

Methods: Methods
The authors have prospectively evaluated 35 patients surgically managed with radiofrequency coblation of the lateral epicondylar tendon insertion and arthroscopy with synovectomy of a synovial "plica" when noted.

Thirty patients have been followed for a minimum of two years and up to five years. All patients were treated conservatively pre-operatively for a minimum of six months. In all cases, symptoms were present for a minimum of eight months and in some, up to four years. Pre-operatively patients rated their level of pain on a visual analog scale a mean of 8.6. Twenty-eight patients were found to have radiocapitellar synovitis which was arthroscopically resected. All patients were treated with the Topaz (ArthroCare, Sunnyvale, CA) Radiofrequency Coblation instrument. Perforations were made at 5mm intervals over a 3.5 X 2.5cm grid at the denervated insertion of the extensor musculature along the lateral epicondylar ridge.

Results and Conclusions: Results
Twenty-eight of thirty-five patients were found to have an inflamed synovial plica with erosive changes of the radial head. Post-operative pain ratings on the first day post-operatively averaged 6.3, by the second week 4.8, by six weeks 3.8, by 12 weeks 2.7, by six months 1, and by 12 months 0.9. Twenty-nine returned to pre-injury activities and sports by 12 weeks. Six patients stated that they have not returned to their pre-injury level of function and have had incomplete pain relief. All six of those patients were Workers Compensation patient who had other outstanding Workers' Compensation claims. But five said that they were substantially improved and would go through the surgery again.

Conclusion
Radiofrequency coblation has been shown in areas of tendinosis to enhance neovascularization in the area of treatment. Radiofrequency coblation along the lateral epicondylar ridge in conjunction with an arthroscopic synovectomy appears to enhance healing while minimizing post-operative pain experience, thus allowing a rapid return to functional activities.

The effect of nitric oxide-releasing silica nanoparticle on revascularization and functional recovery in rat sciatic nerve crush injury

List of authors:  
Ji Hun Park*, Jung Il Lee2, Jong Woong Park3, Myoung-Ryul Ok4, Jae Ho Shin5, Joo Yup Lee6  
1 Korea University Guro Hospital (Seoul)  
2 Hanyang University (Seoul)  
3 Korea University Anam Hospital (Seoul)  
4 Korea Institute of Science and Technology (Seoul)  
5 Kwangwoon University (Seoul)  
6 The Catholic University of Korea (Seoul)

Objectives / Interrogation: Nitric oxide (NO) is a pivotal biological molecule in revascularization and nerve regeneration process after peripheral nerve injury. Recently, biomaterial advances introduce NO-releasing silica nanoparticle, which may offer the controlled and sustained delivery of NO to the targeted tissues. We hypothesized that NO-releasing nanoparticle promotes revascularization and functional recovery in rat sciatic nerve crushing model.

Methods: Forty-eight Lewis rats were divided in two groups of 24 rats each. A standardized crushed sciatic nerve of group I was treated with NO-releasing silica nanoparticle in fibrin glue carrier. The crushed sciatic nerve of group II was augmented in fibrin glue without NO nanoparticle. Four rats from each group were sacrificed and micro-angiography using a colored polymer dye was performed to evaluate the neural capillary density of sciatic nerve. We evaluated the sciatic functional index (SFI) using the walking tract test weekly. We measured maximum isometric tetanic force of tibialis anterior (TA) muscle and posterior calf muscle weight at 3 and 6 weeks after injury. All results of TA muscle force and muscle weight were normalized to the contralateral side. We also evaluated the histomorphometry of sciatic nerve.

Results and Conclusions: Microangiography showed that NO-releasing silica nanoparticle increased the neural capillary density of the crushing site of sciatic nerve 3 days after injury. Sciatic function index of animals treated NO-releasing silica nanoparticle was better than that of animals without NO on 4 weeks after injury. NO-releasing silica nanoparticle reduced muscle atrophy on 3 weeks after injury in terms of wet muscle weight. NO- nanoparticle enhanced the TA muscle force on 3 and 6 weeks after injury, but a significant effect was apparent with a mean intergroup difference on 6 weeks after injury. The number of myelinated axon and muscle weight of animals treated NO-nanoparticle was higher on 3 weeks after injury.

In conclusion, our results suggest that NO releasing silica nanoparticle enhance the revascularization of rat sciatic nerve in early phase after crushing injury, promote axonal regeneration and functional recovery in the early phase based on evidences from morphometric analysis and sciatic functional assessment. These findings provide a possible new avenue of using exogenous nitric oxide therapeutically.

FUNCTIONAL ASSESSMENT, QUALITY OF LIFE AND ASSOCIATED COMPLICATIONS OF RADIAL HEAD PROSTHESIS.
EXPERIENCE OF OUR CENTER

List of authors:
Cristina Llarena Barroso¹, Jose A. Oteo³, Patricia Merino¹, Pedro Jiménez³, Francisco Javier Garcia Lazaro¹
¹ Hospital Universitario de Fuenlabrada (Fuenlabrada)

Objectives / Interrogation: Radial head arthroplasty (RHA) is an increasingly frequent surgical intervention in our country, usually as treatment for radial head fractures or sequela. The objective of our work is to describe the functional results, complications and quality of life of patients who underwent RHA in our center.

Methods: All cases of RHA (Mason type III-IV radial head fractures) in our center have a minimum duration of follow-up of one year.

Next data was obtained from each patient: age, gender, laterality and type of fracture, type of stem, complications and associated fractures, range of motion and strength of both hands, and radiographic presence of loosening, osteoarthritis and heterotopic calcifications. Pain was evaluated according to the visual analogic scale (VAS). Functionality and quality of life of patients were assessed with DASH and SF-36 questionnaires, the satisfaction of the patient was evaluated with a subjective scale ranged from 1 to 10.

For the statistical calculation we use the S of Spearman (Correlations) and Mann Whitney U and Chi-square tests (Differences)

Results and Conclusions: 10 patients (4 women, 6 men), the mean age was 57.4 years. 2 fractures affected the right side. In 6 cases a long stem was used. Loosening, osteoarthritis and calcifications appeared in 30, 50 and 50% respectively. Average values of VAS, DASH and SF-36 were 3.1, 28.4 and 62.5% respectively. Personal average satisfaction was 8.5. There was an 80% of associated fractures, being olecranon and coronoid apophysis the most frequent ones. Complications occurred in 30% of cases.

Significative differences between both hands were only found on supination (p0.043), extension (p0.042), and pinch (p0.043) and grip strength(p0.037).

A significative correlation was found between grip strength of affected hand and DASH scale (s-0.705,p0.023).

A correlation was found between subjective satisfaction and next scales: DASH(s-0.772,p0.009) and VAS(s-0.665,p0.036), but satisfaction did not correlate with SF-36(s0.601,p0.066).

We found no relationship between SF-36, DASH, VAS and personal satisfaction and presence of loosening, osteoarthritis and heterotopic calcifications, as well as between type of stem and presence of loosening.

We concluded that RHA (Acumed®) achieves a high degree of satisfaction in our patients, nevertheless a decrease in their capacity for extension, supination and pinch and grip strength in affected hand was found. The subjective scale used to assess personal satisfaction correlates with DASH and VAS.

Measurement of the distance between a line extending along the volar aspect of the radial shaft and the lunate rotation center on lateral view X-ray of the wrist

List of authors:
Souichi Ohta*, Ryosuke Ikeguchi1, Hirofumi Yurie1, Hisataka Takeuchi1, Sadaki Mitsuzawa1, Shuichi Matsuda1
1 Department of Orthopaedic Surgery, Kyoto University (Kyoto city)

Objectives / Interrogation: Changes of radiocarpal alignment occur after severe Smith fractures or fracture malunion, and sometimes cause pain, limited wrist motion, or functional disability. On lateral view X-ray of the wrist, a line extending along the volar aspect of the radial shaft is considered to roughly bisect the radial articular surface and the lunate. However, detailed measurements have not been reported. We expect such measurements to be useful in treatment of severe Smith fractures or fracture malunion. We measured the distance between a line extending along the volar aspect of the distal radius diaphysis and the lunate rotation center on lateral view X-ray of the wrist.

Methods: A total of 151 lateral wrist radiographs were randomly extracted from medical records of our institution between 2010 and 2017. Patient ages ranged from 12-92 years. Fractures, osteoarthritis, tumors, and rheumatoid arthritis were excluded. A lateral wrist radiograph was defined by the pisoscaphocapitate relationship, where the palmar cortex of the pisiform should lie between the anterior surface of the distal pole of the scaphoid and the capitate. After 3 points on the proximal articular surface of the lunate were randomly selected, we found a center of a circle passing through the 3 points as a lunate rotation center. A line parallel to the axis of the distal radius was drawn along the volar aspect of the distal third of the radial diaphysis. We measured the distance between the lunate rotation center and the extended line along the volar aspect of the radius. If the lunate center was posterior to the line, it was expressed as a minus value and if anterior, it was expressed as a plus value. Data were expressed as the mean ± standard error.

Results and Conclusions: The mean age was 55.5 ± 1.7 years old. Fifty-three were male and 98 were female. The right wrist was involved in 71 cases and the left wrist in 80. Most of the lunate rotation center was located at the center of the distal articular surface of the lunate. The distance between the lunate rotation center and a line extending along the volar aspect of the distal radius diaphysis was 0.09 ± 0.1 mm (-2.34-3.97 mm).

The lunate rotation center was approximately on a line extending along the volar aspect of the distal radial diaphysis. However, because of individual variation, the distance on the unaffected side should be used as a basic reference value.

Contusion Neuropraxia of Cutaneous Sensory Nerves: Early Diagnosis and Treatment Reduces Chronic Pain Syndromes (Early Diagnosis Shortens Recovery Time)

List of authors:
Lingyi Chia*, Dawn Sinn Yii Chia¹, Fok Chuan Yong¹
¹ TAN TOCK SENG HOSPITAL (Singapore)

Objectives / Interrogation: Contusion neuropraxia of cutaneous sensory nerves in the upper limb is an under-recognised cause of chronic neuropathic pain. This study recommends a diagnostic criteria, and assesses if early diagnosis and treatment can lead to better outcomes.

Methods: Thirteen patients with contusion neuropraxia of cutaneous sensory nerves in the upper limb were recruited. Each case had clear inciting injury: blunt trauma, stretch injury, or chronic repetitive compression. Two of three were present: (1) local hyperalgesia, (2) distal paraesthesia and (3) a positive Tinel's sign. Clinical findings corresponded to a cutaneous nerve in the upper limb. Patients with concurrent fractures, muscle, tendon, ligamentous or open wound injuries were excluded from the study. All patients were treated conservatively and assessed at monthly intervals for up to three months.

Results and Conclusions: All patients experienced neuropathic pain with local hyperalgesia and sensitivity at the site of nerve injury. Ten participants (76.9%) fulfilled two out of three criteria with the rest of the participants (23.1%) fulfilling all three criteria. The interval between injury and definitive treatment averaged 9.5 weeks (range 0 - 48 weeks). The superficial radial nerve was the most commonly involved nerve (38.5%) followed by the median antebrachial cutaneous nerve (30.8%). At the end of the study period, four patients achieved excellent outcome (30.8%) and nine patients achieved good outcome (69.2%). Amongst patients who achieved an ‘excellent’ outcome, patients who presented earlier (mean 6.5 weeks, range 5 - 8 weeks) achieved their final outcome earlier than those who presented later (mean 21.70 weeks, range 8 - 48).

Contusion neuropraxia of cutaneous sensory nerves is a disease entity that can result in significant neuropathic pain that interferes with quality of life. Early recognition and definitive treatment can expedite the recovery process, lead to better outcomes, and avoid progression to complex regional pain syndrome. This diagnosis should be considered in all patients with a history of trauma who experience unremitting neuropathic pain and fulfil our diagnostic criteria.

Enzymatic Debridement for Hand Burns: Function and Quality of Life One Year After Trauma

List of authors:
Tomke Cordts*, Benjamin Ziegler¹, Yannick Diehm¹, Sebastian Fischer¹, Leila Harhaus¹, Ulrich Kneser¹
¹ BG Klinik Ludwigshafen, Hand, Plastic and Reconstructive Surgery, Burn Center (Ludwigshafen)

Objectives / Interrogation: Over the last years, Enzymatic Debridement has become an accepted alternative for the treatment of severe burns. A topical burn eschar removal by the proteolytic enzyme mix NexoBrid® has certain important advantages when compared to Standard of Care. Most notably, it allows for a selective debridement, conserving adjacent tissue. This appears to be especially beneficial in severe burns of the hands, where conventional, “sharp” nectrectomy by knife or blade is usually accompanied by extensive functional damage.

Methods: Patients that were admitted to our hospital and had received Enzymatic Debridement on at least one burned hand between 2016 and 2017 were reexamined in our outpatient clinic one year after trauma. Range of Motion and grip strength were evaluated on both hands. Firmness and elasticity parameters were obtained by comparing scarred and unaffected skin by Cutometer® measurement. Patients were asked to complete DASH, SF-36 and the Ludwigshafen version of the Burn Specific Health Scale-Brief (BSHS-B) questionnaires to assess remaining functional deficits and present quality of life.

Results and Conclusions: Results:
As of today, 14 patients (9 male, 5 female) could be included in the study. Average TBSA was 12.6 %, 2.2 % TBSA were attributed to burns of the hands. As assumed, grip strength and range of motion were reduced on burned extremities. Firmness was increased, most elasticity parameters were decreased in the originally injured area when compared to unaffected skin. DASH showed significant functional impairment when compared to the average population, scores for emotional and psychological well-being were lower in the SF-36 questionnaire. However, BSHS-B scores were equivalent to those of a reference collective of burn patients.

Conclusions:
One year after trauma, patients with hand burns that were treated with Enzymatic Debridement still showed significant morbidity. Functional and psychological impairments were higher than in the average population but comparable to values observed in a reference collective of burn patients. Further examinations in the next couple of weeks, that will gain more results from a larger number of patients as well as a control group, are needed to clarify the current conclusions.

VOLAR PLATE RETENSIONING AFTER TRAPZIECTOMY AND LIGAMENT RECONSTRUCTION TENDON INTERPOSITION IN BASAL THUMB ARTHRITIS WITH HYPEREXTENSION METACARPOPHALANGEAL INSTABILITY

List of authors:
Enrico Carità*, Alberto Donadelli², Landino Cugola²
¹ Clinica San Francesco, Ospedale Volta Mantovana (Verona)
² Clinica San Francesco (Verona)

Objectives / Interrogation: Hyperextension instability of the metacarpophalangeal (MCP) joint of the thumb leads to malfunction and bad outcomes of basal thumb arthritis surgical treatment. Loss of metacarpal height after trapeziectomy and ligament reconstruction tendon interposition (LRTI) can get MCP instability worse. Various techniques have been used to address this hyperextension depending on its severity.
In this study the authors describe their experience with the use of a volar capsular flap fixed with suture-anchor to the neck of first metacarpal bone to restore normal extension in grade 3 instability during basal thumb arthritis surgery.

Methods: From January of 2013 to January of 2018 12 thumb of 10 patients affected by basal thumb arthritis and MCP hyperextension were treated in the same time by trapeziectomy and (LRTI) and volar capsular retensioning. All cases were evaluated pre and post-operatively with VAS, ROM, MCF hyperextension, Jamar and Pinch Test, personal satisfaction and DASH scores with an average follow-up of 39 months (min 6 - Max 62). MCP arthritis was a contra-indication for this technique.

Results and Conclusions: 11 of 12 reported relief from pain, no hyperextension and improvement grip and pinch strength. At the follow-up there was an average reduction of pain from 8,2 to 2,1 VAS. MCF extension was from -10 to 5°; 9 of 10 patients were very satisfied with the results and were able to return to the precedent activities better than before. Improvement of DASH scores was detected. Radiographic controls revealed reduction of scaphoid-metacarpal height from 20 to 50% at follow-up.

We believe that volar plate retensioning is a good way to improve stability of metacarpophalangeal joint preserving motion in alternative to arthrodesis and simultaneous trapeziectomy and LRTI and volar plate retensioning is an appropriate way to treat basal thumb arthritis associated to Z deformity improving functional and subjective outcomes.

PRELIMINARY RESULTS OF LUNATE PIROCARBON PROSTHESIS - Multicentric Study

List of authors:
Enrico Carità*, Alberto Donadelli†, Alberto Sgarbossa‡, Massimo Corain§, Landino Cugola
1 Clinica San Francesco, Ospedale Volta Mantovana (Verona)
2 Clinica San Francesco (Verona)
3 Istituto Sant'Anna (Brescia)
4 Ospedale Policlinico GB Rossi (Verona)

Objectives / Interrogation: Current indications for treatment of post-traumatic or avascular necrosis of the collapsed lunate are proximal row carpectomy or proximal capitate resurfacing or TWA or wrist arthrodesis. Replacing of lunate can restore carpal height and delay major surgeries.
AIM: In this study the authors describe their experience with the use of a Pirocarbon implant for replacing of lunate in Kienbock stage IIIA-B and in post-traumatic avascular necrosis.

Methods: From September of 2016 to September of 2017 10 wrists were treated (3 III-A; 5 III-B and 2 failure of previous surgery for Kienbock disease). All cases were evaluated pre and post-operatively with MMWS, PRWHE and DASH scores with an average follow-up of 13 months (min 6 - Max 30).

Results and Conclusions: 9 of 10 reported relief from pain, small improvement in ROM and improvement strength. At the follow-up there was an average reduction of pain from 7,01 to 3,4 VAS. There was an improvement of grip and pinch force. 80% of the patients were satisfied with the results and were able to return to the precedent activities. Improvement of DASH and of PRWHE scores were detected. Radiographic controls revealed 5 cases of S-L diastasis especially in Kienbock III-B stage; no dislocation of the implant, no reduction in carpal height nor worsening of capito-lunate angle were founded.

Pathologic Adipose Infiltration in Macrodactyly: the Mechanisms and Treatment Options

List of authors:
Bin Wang*1

1 Shanghai 9th People's Hospital, Shanghai Jiaotong University (Shanghai)

Objectives / Interrogation: Macrodactyly is a rare congenital disease with manifestations involving overgrowth of soft tissues and bones. The abnormal overgrowth with or without hyperostosis and nerve enlargement seriously affects the appearance and function of digits or limbs, which poses a great challenge for plastic and hand surgeons. Due to a lack of understanding of the molecular mechanism and pathological features of adipose invasion in the disease, there has been controversy regarding the surgical strategy and timing of debulking. The biological characteristics including the genomic profiles and cytological markers of Mac-ADSCs and fat infiltration of nerve tissue of the macrodactyly were investigated in the study.

Methods: Whole exome sequencing, Sanger sequencing, cDNA microarray and bioinformatics analysis were performed to identify mutations, gene expression patterns and signal transduction pathway changes in the pathological adipose tissues. The cellular characteristics of adipose-derived stem cells in macrodactyly (Mac-ADSCs) were studied using normal abdominal subcutaneous adipose-derived stem cells (Sat-ADSCs) as control, including features of cell cycle, apoptosis and differentiation induction of adipocytes, osteoblasts and cartilage. Electromyography (EMG) in patients with type II macrodactyly was examined, with the expression of neural proteins and ultrastructural changes evaluated.

Results and Conclusions: The PIK3CA-C420R and E81K mutations were identified in macrodactyly patients. The expression of EGFL6, ANGPTL7, PTN, FGF1, SFRP4 and other relevant genes was significantly up-regulated. Mac-ADSCs showed increased proliferative activity as well as osteogenesis and cartilage differentiation potential, while the adipogenic differentiation capability was decreased. Co-existence of myelin sheath injury, nerve regeneration and functional compensation was found in type II macrodactyly patients. Dysfunction of PI3K-AKT pathway activation which interferes with cell secretion and extracellular matrix - receptor interactions is an important mechanism for the development of macrodactyly, suggesting PI3K-AKT as a potential target for medical intervention; The enhancement of osteogenesis and cartilage differentiation potential in Mac-ADSCs indicates that early defatting could potentially ameliorate the disease progression; The surgical decision to preserve or resect the enlarged nerve for type II macrodactyly patients should be determined according to the nerve injury and compensation situation of the digits.

The outcomes of the avulsed thumb's reconstruction

List of authors:
Oxana-Madalina Grosu¹, Sorinel Lunca², Mihaela Pertea¹
¹ University of Medicine and Pharmacy”Gr. T. Popa” Iasi, “Sf. Spiridon” Emergency Hospital Iasi (Iasi)
² University of Medicine and Pharmacy”Gr. T. Popa” Iasi, Institute of Oncology Iasi (Iasi)

Objectives / Interrogation: The aim of this paper is to present the functional and esthetic results when using different types of known flaps and, also, when using a combined of these techniques, for thumb reconstruction without microsurgery.

Methods: Our study is based on 42 patients, aged between 25 and 68 years old, who suffered an avulsion trauma and presented complete thumb amputation. In 12 cases, the amputation was at the level of the first phalanx, in 18 cases at the level of interphalangeal joint and in 12 cases at the level of the distal phalanx. For distal amputation, we used H. Rose technique in 5 cases and Hueston flap in 9 cases. In 10 cases of interphalangeal joint amputation, we used Mantero-Bertolotti technique with O’Brien flap. For the other 8 cases of interphalangeal joint amputation and for all cases of the first phalanx amputation, we designed a technique which associated decortication of the amputated segment, its osteosynthesis to the amputation stump and coverage with a neurovascular heterodigital flap (Littler), harvested from the nonfunctional board of the 4th finger, with the length of two phalanges.

Results and Conclusions: Results
We evaluated the patients in terms of age, trauma mechanism, surgical technique, mobility, sensitivity, cortical reintegration of the new thumb in those cases in which we used Littler flap, the donor site morbidity, number of days of hospitalization, social and professional reintegration, as well as the patient’s satisfaction. In order to test the cortical reintegration of the new thumb, one year after the trauma and reconstruction, we used the light touch deep pressure test, using the minikit Semmens Weinstein monofilaments test. We obtained a low value of the protective sensitivity, but satisfactory. The media of the 2PD (2 point discrimination) test was 6 mm, which is considered to be a good result. For the mobility, we used the Kapandji score, and we obtained values between 7 and 10.

Conclusions
For all of the cases the results in terms of functionality and aesthetics are very good. Using homo or heterodigital flaps, as unique or in association of different techniques, represent a very good solution to reconstruct the amputated thumb whenever the microsurgical replantation is not possible.

thumb, flap, reconstruction
Socioeconomic Factors predicting Outcome after Open Carpal Tunnel Release

List of authors:
Malin Zimmerman1, Erika Nyman2, Lars B. Dahlin1
1 Department of Translational Medicine - Hand Surgery, Lund University, Skåne University Hospital (Malmö)
2 Department of Clinical and Experimental Medicine, Department of Hand Surgery, Plastic Surgery and Burns (Linköping)

Objectives / Interrogation: We aimed to investigate the influence of socioeconomic factors, such as, education level, employment status, marital status, being foreign born and income, on the outcome after open carpal tunnel release (OCTR) for primary carpal tunnel syndrome (CTS).

Methods: Data from the National Quality Register for Hand Surgery Procedures (HAKIR) were combined with data from Statistics Sweden (SCB) to evaluate OCTRs performed 2010 - 2016. QuickDASH (Disabilities of Arm, Shoulder and Hand) questionnaires were filled out by the patients preoperatively and at three and 12 months postoperatively. Each treated hand was considered a separate statistical entity. Kruskal-Wallis, with post-hoc Bonferroni correction, or Chi2 were used to compare groups. In the linear regression analysis, all calculations were adjusted for age at surgery and gender.

Results and Conclusions: A total of 10770 OCTRs were performed during the study period. The regression analysis showed that patients with education from upper secondary school scored on average 6 (95% CI 3-8; p<0.0001) points lower in the 12 months postoperative QuickDASH than patients who had only gone to elementary school. Patients with higher education scored on average 13 (95% CI 10-15; p<0.0001) points lower on the 12 months postoperative QuickDASH than patients who had only gone to elementary school. Patients who had employment scored on average 13 (95% CI 10-15) points lower on the 12 months postoperative QuickDASH than patients without employment (p<0.0001). Patients who were born outside of Sweden scored on average 13 (95% CI 10-16) points higher on the 12 months postoperative QuickDASH than patients who were born in Sweden (p<0.0001). Widowed patients scored on average 6 (95% CI 2-11; p=0.007) points higher in the 12 months postoperative QuickDASH than patients who were not married. Patients with higher income had lower QuickDASH scores at 12 months. Relative change in QuickDASH between 0 and 12 months postoperatively did not differ between any of the groups, except between unemployed (median 23 [IQR 9-39]) and employed (27 [14-43]; p=0.004).

We conclude that lower education levels, being a widow, low income and immigrant status are associated with more persisting symptoms 12 months after OCTR for CTS, but these factors do not affect the relative improvement in QuickDASH. However, unemployment is associated with a smaller improvement in QuickDASH scores.

Late shoulder anterior release in birth brachial plexus injury sequelae. Prospective study

List of authors:
abdellaziz boulahouache*1, mohamed lamine lardjane2, rachid hadad2, zoubir belkheyar3
1 orthopedic surgery center (bOUIRA)
2 orthopedic surgery center boudouaou (BOUMERDES)
3 lestre clinic paris (Paris)

Objectives / Interrogation: Among birth brachial plexus injury sequelae, the lack of external rotation is common and responsible of clairon sign, which impair the whole upper limb. The shoulder was fixed in medial rotation thanks to external rotators weakness and medial soft tissue retraction. The humeral external osteotomy with muscles transfer was usually applied, but still not achieving correction in every kind of shoulder deformities, more over with results loss through time life. In this prospective study, we aim to evaluate the functional and anatomic results of late anterior release of old child and teenager.

Methods: Our series included 8 patients (1 male and 7 females), aged from 9 to 17 y.o. with different level of plexus injury. The follow up were from 1 to 36 months. The clairon sign was constant, associated sometimes to elbow, forearm and hand impairment. All of them had daily living and clothing difficulties with lack of autonomy, eating, and hygiene. Also suffering from cosmetics, less strength, and pain, involving social live and school education.

Patients were assessed at follow up regarding life quality enhancement, daily living, clairon sign correction, mallet score, range of movement, satisfaction and radiology results.

Results and Conclusions: We had five good results and patients were improved in terms of all criteria’s, and three of them with total plexus injury sequela had mild and bad results.

Our results of late anterior shoulder release in birth plexus injury are promising, and enable us to avoid sometimes using muscles transfer and humeral osteotomy in late childhood which neglect dislocation correction.

Volumetric, cellular and genic expression modifications of FDP striated muscle following flexor tendon division in a rodent model.

List of authors:
Guillaume Bacle*, David McCombe², Eugene Ek², Stephen Tham²
¹ CHRU de Tours, Hôpital Trousseau, Inserm U1253 (Tours)
² Bernard O’Brien Institute Of Microsurgery, VHSA (Melbourne)

Objectives / Interrogation: Background
Repairing of divided flexor tendons with an ad integrum hand flexion function is still a challenge. Moreover, due to initial extensive lesions or misdiagnosed injuries, repairs could be delayed or need tendon reconstruction with lower functional results than acute management.
Tenotomy has been studied across a wide range of species and always results in decreased muscle mass. Apart from the rotator cuff muscles in shoulder, fiber type and fat composition, myogenic and adipogenic expressions have not been investigated about digit flexor muscle bellies following tendon division.

Objectives and interrogation
In order to explain the lower results following delayed repair or flexor tendon reconstructions, we hypothesised that flexor tendon division are linked to muscle impairment with decreased muscle mass, decreased cross sectional area of muscle fibers and increased fatty invasion.

Methods: We used a rodent as animal model. Thirty two white New Zealand rabbits have been used and shared in eight groups of 4 rabbits after approval of the local Animal Ethics Committee. A complete division of FDP tendon has been made and four time points assessment at 1, 2, 4 and 6 weeks. A control group with only a skin incision (SHAM procedure) for each time point has been assigned.
The muscle wet mass, muscle volume, adipogenic and myogenic gens expression and histology have been assessed for each group.

Results and Conclusions: The muscle wet mass and volume decreased significantly at one week, four weeks and six weeks between experimental and sham groups. We noted a highly significant increase of myogenic master genes expression at two weeks with a likely inhibition feedback afterward. Adipogenic genes expression were slightly increased within the two first weeks and down regulated thereafter.
Histologic works showed decreased cross sectional area of muscle fiber without fatty invasion. We assisted also to a switch between the overall amount of slow and fast muscle fibers with a significant increase of fast fibers.

Conclusions
Decrease of mechanical stress applied in the muscle by tendon division is related to decreased muscle mass and volume from the first week. An attempt to reverse alterations is shown by upregulation of master myogenic genes within the two first weeks and fast fiber type increase. On the other hand, no muscle fatty invasion has been noted.

Forearm Skin Degloving. A case report

List of authors:
abdelaziz boulahouache1, mohamed lamine lardjane2, rachid hadad2, zoubir belkheyar3
1 orthopedic surgery center (bOUIRA)
2 orthopedic surgery center boudouaou (BOUMERDES)
3 lestre clinic paris (Paris)

Objectives / Interrogation: Skin degloving is well known in hand as "ring finger" with bad prognosis. It usually leads to finger necrosis and amputation. Recently some replantation were done with mild results. We aim to report a rare case of forearm degloving, with bonne, nerves, and tendons injuries. The skin was freed from muscles in removed-glove-shape with its fascia, leaving bare muscles, from elbow to the wrist. It was caused by violent car accident and the patient was passenger in the front seat. We call the mécanisme "car-door-forearm"

Methods: The skin was cleaned, and reimplanted as skin thin graft, after removing the whole fascia we fixed the associated lesions in the same time

Results and Conclusions: At the follow up of three years and half, the graft had completely healed with good function of the whole upper limb. The range of movement was good too with good hand function in terms of grip, pinch, and strength. Our good results in this rare case are encouraging. We can propose this procedure in such cases unless the skin is not too much damaged by the crash, and the underneath muscles are good enough likes to that the origin of the ongoing graft vessels. The associated injury reparation as a whole in the same time is a requirement in such case for the sake of limb salvage, and good function as the final purpose to this surgery.

Correction of the postoperative deviation deformity in duplicated thumbs

List of authors:
Yongkang Jiang\textsuperscript{1}
\textsuperscript{1} Shanghai Ninth People's Hospital (Shanghai)

Objectives / Interrogation: Residual deformities are often seen in thumb duplication after reconstruction, where the axis deviation is the most common. The purpose of this study was to describe our operation for correcting the postoperative deviation deformity, and to evaluate the appearance and function outcomes.

Methods: 54 thumbs with deviation deformity in 45 patients with thumb duplication after reconstruction in other hospitals were enrolled and operated between 2014 and 2017 in our hospital. The average age at time of surgery was 13.1 years old and the average time of follow-up was 31 months. The surgical procedures included osteotomy, reconstructing the joint capsule, tightening the collateral ligament, centralizing the extensor pollicis longus tendon, repositioning the abductor pollicis brevis muscle and arthrodesis. Kirschner wire fixation was applied for 4-6 weeks and brace fixation for 3 months. The subjective evaluation was given by patients or patients' parents on both the functional and cosmetic results. The modified Tada scoring system was used for objective evaluation.

Results and Conclusions: Results: In these patients with thumb duplication, the most common type was type IV (26/54) preoperatively according to the Wassel classification, and the right thumb was more affected (36/54). The mean range of motion (ROM) for the metacarpophalangeal joint (MCPJ) was 78° and at the interphalangeal joint (IPJ) was 56°. No joint instability in the MCPJ and IPJ was found, and slight mal-alignment was observed in 4 thumbs at the MCPJ and 7 thumbs at the IPJ. 39 good (72.2%), 13 fair (24.1%) and 2 poor (3.7%) was obtained based on the modified Tada scoring system. The patients or patients' parents were satisfied with the function and appearance of the reconstructed thumbs in 49 patients (90.7%).
Conclusions: Multiple surgical techniques should be chosen and applied according to the patients individually to achieve a satisfactory appearance and good function for patients with thumb duplication with postoperative deviation deformity.

Functional and aesthetic reconstruction of the digital flexion contracture with full-thickness plantar skin grafting in children

List of authors:
Yongkang Jiang*1
1 Shanghai Ninth People's Hospital (Shanghai)

Objectives / Interrogation: Finger burns are often seen in children, and some patients with deep hand burns are treated with split-thickness or full-thickness skin grafts. The typical split-thickness or full-thickness skin grafts leave a notably different skin texture and hyperpigmentation. The purpose of this study was to describe our operation for treating the digital flexion contracture with full-thickness plantar skin grafting, and to evaluate the appearance and function outcomes.

Methods: The hematoxylin and eosin (HE) staining, Masson trichrome staining and Melan A immunohistochemical staining was tested for palmar skin, plantar skin, groin skin and burn scar. Full-thickness plantar skin grafting was performed between 2008 and 2015 for 18 fingers in 12 hand burn patients with digital flexion contracture. The average age at time of surgery was 14 months and the average time of follow-up was 5.6 years. The subjective evaluation was given by patients' parents on both the functional and cosmetic results. Scar appearances were assessed using a Vancouver Scar Scale (VSS). The modified Tada scoring system was used for objective evaluation.

Results and Conclusions: Results: The plantar skin shared similar attribute with the palmar skin histologically. Both the plantar skin and the palmar skin did not express the Melan A. The color of the grafts became similar to adjacent tissues. The average active range of motion (ROM) for the fingers was improved from 32° to 86° in MCP, from 23° to 84° in PIP, from 42° to 77° in DIP. 10 good (83.3%), 2 fair (16.7%) and no poor was obtained based on the modified Tada scoring system. There was no hypertrophic scar on the plantar donor site. The patients' parents were satisfied with the function and appearance in 11 patients (91.7%). Average VSS score was improved from 9.62 to 2.16.

Conclusions: The full-thickness plantar skin grafting could achieve a satisfactory appearance and good function for hand burn patients with digital flexion contracture.

Early Outcome of AO type C2 & C3 Distal Radius Fractures Treated with Single Broad Dorsal Plate Fixation. A Case Series.

List of authors:
Siew Khei Liew†¹, Ikhwan Abdul Samad², Firdati Mohamed Saaid², Manohar Arumugam¹
¹ University Putra Malaysia (Kajang)
² Serdang Hospital (Kajang)

Objectives / Interrogation: Intra-articular dorsal distal radius fractures were conventionally treated with volar plating. Recent studies described the use of dorsal plating but most often used fragment specific plates.¹ Our goal was to evaluate the early outcome of broad dorsal plating of distal radius using low-profile, titanium, fixed angle locking plate system (Acu-Loc dorsal distal radius plate, Acumed) in AO C2 and C3 types of fractures.

Methods: 7 patients with distal radius fractures AO types C2 and C3 due to motor-vehicle accidents from 2015 to 2017 were managed surgically via dorsal plating using the above plate (broad dorsal engaging both radial and intermediate columns). Patient with brain injury was excluded. All surgeries were done by a single senior hand surgeon. Pre-operative CT wrist were performed. Pre- and post-operative wrist AP and lateral X-rays were evaluated. Clinical assessment of range of movement of the wrist, grip strength, QuickDASH, Patient-rated Wrist and Hand Evaluation (PRWE) and Modified Mayo Wrist Score (MMWS) were done at 12 months post-op.

Results and Conclusions: All patients were male. Median age was 27.6 years (range 15 to 59), 3 with AO type C2 and 4 AO type C3. Mean follow up was 28.4 months. 3 patients were referred after initial wrist external fixator application for dorsal subluxation, 1 of them was an open fracture Gustilo grade 1. Mean time from trauma to plating was 20.8 days, mean from external fixation to plating was 9.7 days. Mean pre-plating radial height was 7.3mm, radial inclination 14.3°, sagittal tilt -4.7°, intra-articular step was 4.6mm. Mean post-op radial height was 11.4mm, radial inclination 19.1°, sagittal tilt 0.6°, intra-articular step was 0.5mm. 2 patients required iliac bone grafting. Mean wrist movements post-op 1 year were flexion 60°, extension 59.3°, radial deviation 27.9°, ulnar deviation 27.9°, supination 85.7°, pronation 85.7°. Mean grip strength was 89.6% of the unaffected hand, corrected according to the 10% rule. QuickDASH score was 4.5, PRWE was 13.5, MMWS was 87.5 (good). At 1 year follow-up, there was no loss of reduction, no bone graft donor site or hardware-related complication and thus none required removal of implant. Patient self-reported average return to work with similar intensity was 4.5 months, mean self-reported satisfaction on visual analogue scores (0-10) was 8.1 (Good).

We conclude that single broad dorsal plating is effective in treating AO type C2 and C3 distal radius fractures.

The effect of surgery for base of thumb osteoarthritis on range of dart thrower's motion at the wrist in cadavers.

List of authors:
Mohamed Elajnaf\(^1\), Philippa Rust\(^2\), Robert Wallace\(^3\)

\(^1\) Anatomy, Edinburgh Medical School: Biomedical Sciences, University of Edinburgh (Edinburgh)
\(^2\) Hand Surgery Unit, St John's Hospital (Livingston)
\(^3\) Department of Biomechanical Engineering, University of Edinburgh (Edinburgh)

Objectives / Interrogation: Dart thrower's motion (DTM) is considered the functional plane of motion at the wrist used in most activities of daily living. DTM is the plane of oblique motion from radial extension to ulnar flexion (Moritomo et al., 2007). It occurs at the midcarpal joint, specifically at the scaphotrapeziotrapezoid (STT) joint, guided by an oblique ridge on the distal scaphoid (Moritomo et al., 2000). The articular surfaces of the scaphoid, trapezium and trapezoid bones allow the wrist the characteristic DTM plane of oblique motion (Slutsky, 2010). Surgical treatment of thumb osteoarthritis is commonly performed, but their effect on DTM is not documented in the literature. It is therefore important to assess how this plane of motion is affected by surgery, to provide patient information for better outcome. The aim of this study is to identify the range of DTM and compare it with the effects of simulated basal thumb osteoarthritis surgeries (STT joint fusion, distal pole of scaphoid excision and trapeziectomy).

Methods: Thirteen fresh-frozen cadaveric specimens were dissected and placed in a specially designed jig to measure the range of DTM.

Specialised Jig for DTM

Jig for producing and measuring DTM

Simulated STT fusion was performed on all specimens and DTM measured. Post STT fusion measurements were recorded afterwards to ensure fusion did not alter control range. Distal pole of scaphoid excision was then performed on left side specimens and trapeziectomy on right side specimens. Measurements taken for each and all results were compared using t-tests.

Results and Conclusions: Arc of dart thrower's motion averaged 117° in intact wrists. Simulated STT fusion reduced the range of DTM significantly to an average of 104° (87% of control, \(P=.00004\)). Neither distal pole of scaphoid excision (average 117°) nor trapeziectomy (average 121°) significantly altered the range of DTM.

Theories on DTM suggest that free movement occurs between the scaphoid trapezium trapezoid through range. Our results of STT joint fusion are consistent with this theory. However, DTM is not be affected by distal pole of scaphoid excision or trapeziectomy, providing better pre-operative decisions.

SARCOMA SINOVIAL OF THE HAND: DIAGNOSIS AND TREATMENT. A RARE CASE REPORT AND LITERATURE REVIEW

List of authors:
Monica Fernandez Alvarez¹, Maria de los Angeles De La Red Gallego³, Manuel Ruben Sanchez Crespo¹, Jose Couceiro Otero¹, Higinio Ayala Gutierrez², Olga Maria Velez Garcia³, Fernando Javier Del Canto Alvarez¹
¹Hospital Universitario Marqués de Valdecilla (Santander)

Objectives / Interrogation: Soft tissue sarcoma (STS) of the hand is rare. To achieve the best possible functional and cancer-related outcomes, surgical excision must be combined with early reconstructive surgery and multidisciplinary care.

Methods: A 30-year-old man was presented complaining of painless mass over thumb finger of the right hand. At physical examination he had pulsatile pain over the thenar eminence and positive Tinel sign. Ultrasonography and MRI study showed a highly vascularized nodule. Extirpation was carried out, showing compression of the tenar motor branch of the median nerve and both collateral nerves of the thumb. Pathological anatomy (PA) and immunohistochemically proved diagnosis of synovial sarcoma grade 2 of the FNCLCC system. Local study was performed and malignant edge was observed. No malignant extension lesions were identified. Surgical block resection was performed including thenar musculature, both collaterals and ulnar collateral bundle. ALT flap of the left limb was used to covered the skin defect. PA confirmed the diagnosis of synovial sarcoma and treatment with adjuvant RT was completed. The patient had a good functional outcome and at 6 months of follow-up no local or distance recurrence is observed.

Results and Conclusions: Synovial sarcoma is one of the most misdiagnosed malignancies of soft tissues, due to slow growing pattern, benign radiological features and pain similar to traumatic pain. STS are initially diagnosed as myositis, haematoma, synovitis, bursitis and delay in diagnosis is common. There is no significant correlation between previous surgical excision and risk of local recurrence. According to Gaurish SKS et al. regional lymph node dissection is not required. Treatment involves excision with a margin of clearance (1-2 cm) followed by reconstruction. Success reconstruction is determined by stable wound coverage, preservation of health, function and sensation. Free flaps offer durable and well-vascularized tissue of sizes greater than those achievable with local or regional flaps. They can provide coverage of vital anatomical structures, as well as minimize the effects of radiation injury on these structures. Awareness of this rare tumor can hasten diagnosis, and this can increase survival. Therefore, a high index of suspicion should be kept in mind, particularly when evaluating young people. Physical examination as well as correct imagen tests, would improve the diagnosis, associated with a multidisciplinary care.

Effect of wrist injury and treatment on the dart throwing motion

List of authors:
Vasiliki Vardakastani, Joelle Chalmer, Angela Kedgley
1 Imperial College London (London)
2 St Mary's Hospital, Imperial College Healthcare NHS Trust (London)

Objectives / Interrogation: This study aims to investigate the effect of both conservatively and surgically managed wrist trauma on the dart throwing motion (DTM) and to explore any relationship between DTM and patient-rated wrist evaluation (PRWE) scores.

Methods: For this study, 21 patients with unilateral wrist trauma were recruited during their first appointment to the hand therapy clinic. Patients were categorised in three groups based on their injury and type of treatment. Each patient was asked to perform DTM using a dart-like object, including object release, with both hands. Clinical measurements, including goniometric measurements of DTM range of motion and PRWE scores, were recorded by hand therapists at each appointment. Grip strength measurements were performed if it was considered appropriate by the therapist. Wrist kinematics were measured using a nine-camera optical motion capture system and a robust regression analysis was used to define the DTM plane orientation. All measurements were repeated on ten patients during a follow-up appointment, once they were discharged from the clinic. Wilcoxon signed-rank tests were used to assess all differences.

Results and Conclusions: Regardless of the type of the injury, all patients were able to perform DTM. Significant differences were found in the range of motion along DTM between the injured and the healthy hand at the start of the therapy (p=0.001). At the time of discharge, no differences were observed between the two hands (p>0.5). No significant differences were found in the DTM plane orientation between the injured and the healthy hand at early stages of the rehabilitation (p>0.8). The PRWE scores presented significant differences at the two stages of the therapy (p=0.008). A correlation was defined between the PRWE scores and the product of the range of motion along DTM and the grip strength measurements. These findings suggest that although wrist injury has a significant effect on the range of motion of the wrist, the orientation of the DTM plane is not affected equally. The correlation of patient-rated scores with objective functional measures, such as the range of motion along DTM and the grip strength, can further confirm their validity and improve our understanding of the underlying factors affecting these questionnaires.

EXTRAVASATION OF RADIOGRAPHIC CONTRAST MATERIAL IN THE HAND: CASE REPORT AND LITERATURE REVIEW

List of authors:
Monica Fernandez Alvarez¹, Maria de los Angeles De La Red Gallego¹, Manuel Ruben Sanchez Crespo¹, Jose Couceiro Otero¹, Higinio Ayala Gutierrez¹, Olga Maria Velez Garcia¹, Guillermo Menendez Solana¹, Fernando Javier Del Canto Alvarez¹
¹Hospital Universitario Marqués de Valdecilla (Santander)

Objectives / Interrogation: Contrast extravasation is a known but rare complication of imaging test. Various studies consider the rate of extravasation during CT in figures ranging from 0.03%-0.17%

Methods: A 73-year-old man was programmed for another contrast tomography scan to monitor his portal hypertension disease. At the start of the contrast injection, the patient experienced swelling and pain in the hand. No contrast was visible in the thoraco-abdominal images. Local ice and analgesic treatment was recommended. 4 hours after the scan, given increasing pain and swelling of the hand, the patient presented at the emergency department. Physical examination showed tense and swollen hand, with blisters and no loss of sensation. Capillary refill was normal and pain not increased with passive movements. No signs of compartment syndrome were present. We considered conservative approach measures as our first option. Ice, elevation of the forearm, intravenous administration of corticosteroids, analgesic treatment and empiric antibiotic with amoxicillin/clavulanic acid. Evacuation of the multiples blisters at dorsal and volar aspect of the hand and the forearm was carried out. After 24 hours, the symptoms and physical examination improved. Swelling and pain had significantly decreased. There were no new blisters. Two days after, his hand recovered the normal aspect and full active mobilisation of the hand commenced and the patient suffered no long-term sequelae.

Results and Conclusions: There is no general agreement regarding the best approach for the management of extravasation. Elevation of the limb is often useful to reduce edema and cooling the injection site with ice packs is useful in limiting inflammation. The injection of hyaluronidase has also been recommended for patients with large extravasation volumes. Corticosteroids, vasodilators, and other drugs have also been proposed, but most studies have not shown its efficacy. Review of the literature reveals that extravasations of non-ionic contrast of up to 150 ml can be managed conservatively without long-term sequelae. Surgical drainage or liposuction within 6h can be effective, and saline washout as originally describe by Gaul has been shown to be helpful. Urgent surgical drainage and aspiration has been effective when a compartment syndrome has occurred.

Early identification and appropriate management are essential when extravasated volume is large and the clinical signs and symptoms suggest severe injury including compartment syndrome and soft tissue necrosis.

ZASH: The Zurich appearance score for hands. A validated instrument to assess appearance of hands with and without malformations. Preliminary results

List of authors:
Daniel Weber*, Rafael Koss², Helene Werner³
¹ University Children's Hospital, Division of Hand Surgery (Zurich)
² Dimensional - 3D and VFX Solutions (Aeugst)
³ University Children's Hospital, Division of Psychology (Zurich)

Objectives / Interrogation: Surgical corrections of hand malformations modify function and appearance, with the latter often being the main indication for surgery. Outcome measurements must therefore include quantitative assessment of hand appearance with patient and parent related outcomes (PRO) to appreciate the effectiveness of therapy. The aim of this study was to develop and validate an instrument for assessing hand appearance in children with hand malformations.

Methods: An instrument, called the Zurich Appearance Score for Hands (ZASH), was developed based on previous literature and expert meetings. It is the sum score of 5 questions with items regarding overall appearance, skin and scarring, proportions, number of digits and distortion of fingers. Items were rated on a 5-point-Likert scale ranging from 'not good at all' to 'very good' and added to a sum score. 3D photorealistic images of 18 hands with and without hand malformations were developed with Maxon Cinema 4D for validation of the instrument. Three standard views of each hand, including the palm, the back of the hand and a lateral view, were embedded in the questionnaire and presented to participants on a tablet computer. Up to now, these images have been rated by 267 healthy lay persons (14-78 years).

Results and Conclusions: The ZASH had good internal consistency (alpha=0.69) and was most strongly correlated with "overall impression", followed by "skin and scarring", "number of fingers", "distortion of fingers" and "proportion of individual parts". Furthermore, statistical analysis of the ZASH revealed good interrater reliability (intraclass correlation 0.59 to 0.76) and good stability over 2-4 weeks (mean r = 0.47). No gender effects were found, while age effects were present, with older participants rating the appearance of hands more favorable than younger participants.

Conclusions:
The ZASH is the first validated instrument for quantitatively assessing hand appearance. It is suitable for parents and proxies to assess children's hands and as a PRO for older patients with congenital malformations. Further testing among age groups and professionals is ongoing to finalize the instrument.
The ZASH has the potential to be useful to assess the appearance of adult hands with other conditions as well. However, specific validation for these conditions must be performed before it can be recommended more universally.

COMBINED IPSILATERAL FRACTURE OF DISTAL RADIUS AND SCAPHOID TREATED WITH LOCKING PLATES. WHEN IS IT NECESSARY? CASE REPORT AND LITERATURE REVIEW

List of authors:
Monica Fernandez Alvarez*, Manuel Ruben Sanchez Crespo1, Maria de los Angeles De La Red Gallego1, Jose Couceiro Otero1, Higinio Ayala Gutierrez1, Olga Maria Velez Garcia1, Fernando Javier Del Canto Alvarez1
1 Hospital Universitario Marqués de Valdecilla (Santander)

Objectives / Interrogation: Ipsilateral fractures of the distal radius and scaphoid are rare, approximately 0.7 to 4% of all upper extremity fractures, with few reports described. Headless screw fixation is the current gold standard of surgical repair for scaphoid fractures. However, maintaining reduction of certain types of scaphoid fractures is challenging with a compression screw.

Methods: 44-year-old woman arrived into our hospital due to precipitation of second floor. Radiographs showed pelvic fracture and closed left distal radius fracture (type A3 of AO classification) and left scaphoid fracture (type B2 of the Hebert classification). After stabilization of the patient and performed the first damage control; definitive surgery was performed 5 days later. Open reduction and internal fixation of radius fracture was performed with an Aptus plate. Initially, percutaneous reduction of the scaphoid fracture was attempted with percutaneous screw, but stabilization was not achieved due to poor bone quality. Intraoperative radiographs showed comminution and third fracture fragment, so volar approach and open reduction and internal fixation reduction with AptusHand was performed. After a rehabilitation program, excellent functional result was achieved, with a joint balance of supination/pronation 80º-85º, radial/ulnar inclination 25º-30º, full fist closure and 6mm sensibility discrimination in all fingers. No pseudoartrosis was observed.

Results and Conclusions: Recent series, reintroduced volar plating as a valid fixation option in a small subset of scaphoid fractures. Plate fixation may offer superior fixation, particularly those with comminution, nonunion, segmental bony defects, and osteopenic or osteoporotic bone. CT scan could by necessary in this type of radius associated with scaphoid fracture because of usually result of high-energy mechanisms and radiographs cannot see the comminution, specially on scaphoid bone. Goodwin J et al. reported this year that there were no differences in load to failure between fixation methods In simulated osteoporotic bone, the locking plate had a 28% greater load to failure as compared with screw fixation.

Consideration of bone quality is also important when choosing a method of fixation. In cases of comminution scaphoid fractures, locking plate fixation is better to achieved a good anatomic reduction and stabilization of the fracture with excellent functional outcomes.

DISTAL RADIUS FRACTURE NONUNION: SERIES OF COMPLICATIONS IN A CASE REPORT

List of authors:
Monica Fernandez Alvarez*, Manuel Ruben Sanchez Crespo¹, Maria de los Angeles De La Red Gallego¹, Jose Couceiro Otero¹, Higinio Ayala Gutierrez¹, Olga Maria Velez Garcia¹, Fernando Javier Del Canto Alvarez¹
¹Hospital Universitario Marqués de Valdecilla (Santander)

Objectives / Interrogation: Distal radius fracture nonunion is uncommon, occurring in less than 1% of fractures. Healing problems in the distal radius seem to be related to unstable situations, such as concomitant fracture of the ulna, and to an inadequate period of immobilization.

Methods: A 60-years old female was presented into our department with a distal radius fracture (23-A2 of OTA classification) of her right wrist. According to the characteristics of the fracture cast immobilization was applied. After removed it, she complained about pain at pronosupination movement and physical examination revealed pain at the triangular fibrocartilage complex (TFCC). 3 months later, NMR showed no signs of consolidation of distal radius fracture and a rupture of fibrocartilage type 1B of Palmer classification. We performed a correction osteotomy of the distal radius length. In addition, arthroscopy was performed showing normal status of TFCC. Rehabilitation program was completed, and she complained about persistent pain at distal radioulnar joint (DRUJ). We decided to perform a shortening osteotomy of the distal ulna by an acquired ulnar impaction, 1 month later, radiographs showed a rupture of the osteosynthesis plate and screws. CT scan confirmed the diagnosis of non-union. Osteosynthesis plate was removed and curettage, bone graft substitute and new osteosynthesis with longer plate was performed. 8 months later, CT scan showed complete consolidation of ulna osteotomy but no signs of union at radius. Ulna plate was removed and debridement of the focus fracture with autologous iliac cancellous bone graft was performed, 8 months later, the patient achieve good functional outcome and no pain was documented.

Results and Conclusions: Nonunion should be suspected if there is continuing pain after immobilization in combination with a progressing deformity. The low incidence of distal radius nonunion can be attributed to many factors, including impact of the fracture fragments, their location in the metaphyseal bone, and the fact that they typically result from low-energy falls, indicating less soft-tissue disruption. The main surgical procedure for nonunion distal radius is open reduction, freshening of nonunion, iliac crest bone grafting to achieve as much radius length as possible and stable internal fixation using a plate construct.

Non-union of distal radius fracture is rare. Carefully planned open reduction and fixation can help to achieve rapid bone union with satisfactory functional outcome.

Keywords: nonunion, radius, fracture, complications
ACTUALIZATION RESULTS OF OUR PROSPECTIVE STUDY WITH COLLAGENASE CLOSTRIDIUM HISTOLYTICUM: SERIE OF 100 CASES, 5 YEARS FOLLOW-UP

List of authors:
Monica Fernandez Alvarez¹, Maria de los Angeles De La Red Gallego¹, Manuel Ruben Sanchez Crespo¹, Jose Couceiro Otero¹, Higinio Ayala Gutierrez¹, Olga Maria Velez Garcia¹, Fernando Javier Del Canto Alvarez¹
¹Hospital Universitario Marqués de Valdecilla (Santander)

Objectives / Interrogation: Collagenase injection is a non-surgical option for Dupuytren disease. We ought to analyse the results in our prospective serie of cases at 5 years of follow-up.

Methods: Prospective study collected data was performed from the first 100 CCH injections performed at our institution since 2012. Statistical analysis was made for 18 variables. We'll focuse specially in the recurrence rate and necessity of a new infiltration or surgery. Recurrence was defined as the apparition of a palpable cord with retraction greater than 20º

Results and Conclusions: 89% male, with a mean-age of 64'27. 94% right-handed. Fifth finger was affected in 47%, fourth 27%, both 11% and others 15%. MCP were the most injected joints, 79% of cases, followed by PIP 18%. Complete extension was achieved in the 83'54% of cases (86% of MCP joints and 56% of PIP joints), incomplete extension in 12'66%, and in 3'8% of cases there was no extension. There were statistical significant differences (p= 0,008) between treated joints and extension achieved. Nor statistical significant differences (p=0'462) were found between treated finger and extension achieved, neither between treated joint and complications rate (p; 0'248). In total the rate of recurrences was 16%; 1% at 6 months, 5% at 1 year, 4% at 2 years, 3% at 3 years, 1% at 4 years and 2% at 5 years' follow-up. Recurrence affected the Fifth finger in 75% of cases. In 43,75% of cases, PIP were the affected site, MCP joints in 18,75% and combination of both in the rest of the cases. PIP joint mean recurrence degrees was 42,3º, and 40,5º at MCP. Treatment after recurrence consisted in open surgery procedure for 31,25% of the cases, new collagenase injection for 31,25% and no procedure in other cases.

CCH is effective in the treatment of Dupuytren MCP and PIP joint contractures, in mid-term follow-up. Most studies are short term and there are few data on recurrence, however, recurrence PIP rate are high and we should consider this at long follow-up because the advantage of initial lower cost and quick recovery of CCH comparing to surgery might be dud if those patients need another infiltration or surgery.

Treatment of Bennett Fractures with Tension Band Wiring Technique through a Small Incision in 32 Patients

List of authors:
Xu Zhang*, Yadong Yu1, Guisheng Zhang1, Xinzhong Shao1
1 Third Hospital of Hebei Medical University (Shijiazhuang)

Objectives / Interrogation: Objective: To introduce a tension band wiring technique for the treatment of Bennett fractures through a small incision, which allows early motion of the first carpometacarpal joint.

Methods: From January 2015 to May 2017, 32 Bennett fractures in 32 patients were treated with open tension band wiring. The mean age of the patients was 34 years (range, 20 to 52 years). There were 30 male and 2 female patients. There were 31 dominant hands and 1 nondominant hand. The mean time between the injury and operation was 7 days. The average joint surface involvement was 41%. All injuries were associated with carpometacarpal joint subluxation. We prefer a small dorsal incision 0.5 cm in length. The volar fragment was fixed to the first metacarpal with tension band wiring. Joint motion was started 2 days after surgery. At the final follow-up, motion of the thumbs and pinch and grip strength of the hands were assessed.

Results and Conclusions: Results: No fixation failure was noted. Radiographic fracture healing was attained in all patients at an average period of 4 weeks. Patient follow-up lasted 26 months (rang, 24 to 29 months). At the final follow-up, the mean extension-flexion arc of the first carpometacarpal joint was 46° (range, 39° to 52°). The mean thumb abduction was 85° (range, 75° to 93°) and mean pinch and grip strength of the injured hands were 7.2 kg (range, 4.6 kg to 9.3 kg) and 47 kg (range, 32 kg to 52 kg), respectively. The measurements were similar to those on the opposite side. There were no significant differences between two groups regarding the extension-flexion arc of the first carpometacarpal joint and grip strength (p > 0.05). The two groups were similar regarding thumb abduction and pinch strength (p > 0.05).

Conclusions: Open tension band wiring through a small incision is a minimally invasive technique that is reliable and presents another fixation option for the treatment of Bennett fractures.

Reconstruction of a Nail Unit Using a Free Composite Flap Harvested from the Great Toe with Nerve Repair in 25 patients

List of authors:
Xu Zhang*, Yadong Yu¹, Guisheng Zhang¹, Xinzong Shao¹
¹ Third Hospital of Hebei Medical University (Shijiazhuang)

Objectives / Interrogation: Objective: To introduce reconstruction of a nail unit defect in the finger using a free composite flap taken from the great toe, including neurorrhaphy between the dorsal digital nerve of the great toe and the dorsal branch of the proper digital nerve of the injured finger.

Methods: Methods: From May 2015 to May 2017, 25 fingers in 25 patients with traumatic nail unit defects were treated. The mean size of the germinal matrix and sterile matrix defects was 6 mm × 8 mm (range, 4 mm × 6 mm to 7 mm × 10 mm), and the mean size of the nail bed flaps was 7 × 9 mm (range, 5 mm × 7 mm to 8 mm × 11 mm). The mean length of the arteries that the flap based was 2.4 cm (range, 1.9 cm to 3.1 cm). For comparison, we also collected 21 patients without nerve repair from January 2012 to January 2015. Outcomes were rated using the Zook et al.'s method. In the study group, full flap survival was achieved in all patients.

Results and Conclusions: Results: At the mean follow-up period of 28 months (range, 24 to 31 months), there were 15 excellent, 6 very good, 4 good results. In the comparison group without nerve repair, there were 7 excellent, 3 very good, 2 good, 6 fair, and 3 poor results. Donor site morbidities were similar in both groups.

Conclusions: The use of a free composite flap taken from the great toe is a useful technique for reconstructing nail unit defects in the finger, and no obvious donor site morbidity exists with the use of the dorsal branch of the proper digital nerve.

Keywords:
Nail unit; free composite flap; great toe; nerve repair.
Do national randomised controlled trials change international clinical practice?

List of authors: Rosie Mc Colgan*, David M. Dalton¹, Adrian J Cassar-Gheiti², Michael E O’ Sullivan¹
¹ University Hospital Galway (Galway)

Objectives / Interrogation: The Distal Radius Acute Fracture Fixation Trial (DRAFFT) was a randomised controlled trial performed in the United Kingdom (UK). The authors concluded that there was no difference between locking plate versus Kirschner-wire (k-wire) fixation in fractures of the distal radius. This trial had a significant impact on clinical practice in the UK. The number of patients in treated with plate fixation fell from 75% to 48% before and after publication of the trial. The number of patients treated with k-wire fixation rose from 12% to 42%.

Our aim was to assess whether DRAFFT affected clinical practice in Ireland.

Methods: Data was obtained from the Hospital Inpatient Enquiry system (HIPE). It was grouped into annual intervals from 2012 until 2017. All in-patient episodes involving emergency surgery for fractures of the distal radius were included.

Results and Conclusions: In 2012, before publication of DRAFFT, 38% of patients in Ireland were treated with plate fixation versus 49% with k-wire fixation. In 2017, after publication of DRAFFT, the proportion of patients who underwent plate fixation rose to 62% with a concurrent fall in the number who underwent k-wire fixation to 30%.

It appears that surgeons in Ireland do not change their practice in response to randomised controlled trials performed in the UK. National randomised controlled trials performed in the UK have a significant impact on practice in the UK, however they do not appear to influence practice in similar international populations.

Keywords: clinical trial, change in practice, distal radius
The effects of porcine extracellular matrix nerve wrap as an adjunct to primary epineurial repair

List of authors:
Philip Hanwright*, Jennifer Rath¹, Nicholas von Guionneau¹, Benjamin Slavin², Dan Zlotolow³, W.P. Andrew Lee¹, Jaimie Shores¹, A. Lee Dellon¹, Sami Tuffaha¹
¹ Johns Hopkins University School of Medicine (Baltimore)
² University of Miami, Miller School of Medicine (Miami)
³ Shriner's Hospital for Children (Philadelphia)

Objectives / Interrogation: The use of nerve wraps has been advocated as a means of protecting and isolating the neurorrhapy site; however, there is a paucity of data to support their use. The most commonly used commercially-available nerve wrap is an extracellular matrix (ECM) membrane derived from porcine small intestine submucosa (AxoGen, Alachua, FL). The purpose of this study is to characterize the effects of using this wrap as an adjunct to primary epineural repair.

Methods: Lewis rats were randomized to undergo median nerve transection and epineural suture repair, either with or without the use of a wrap around the coaptation site (n=10 per group). Animals were sacrificed at five weeks for quantitative histologic analysis of intraneural scar formation and inflammatory cell infiltration at the repair site, as well as distal axonal regeneration and neuromuscular junction reinnervation. These groups were repeated with a 15-week endpoint to allow for weekly assessments of functional recovery with grip strength testing.

Results and Conclusions: The wrapped group demonstrated significantly less intraneural collagen deposition at the coaptation site at five weeks (Figure 1, p=0.01). There were no statistically significant differences for inflammatory-cell density, number of regenerating axons, or percent reinnervation of neuromuscular junctions at either endpoint. Initial functional recovery was observed earlier in the wrapped group than the unwrapped group (5 weeks vs. 6 weeks, p=0.090); at the 15-week endpoint, there was no statistically significant difference between wrapped and unwrapped grip strength (1.29±0.12N vs. 1.06±0.10N, p=0.17). No deleterious effects were observed with use of the wrap.

Figure 1. (A) Intraneurial collagen content; * denotes significances. Representative images of coaptation sites stained with picrosirus red for unwrapped (B) and wrapped (C) repairs.

The use of the porcine ECM nerve wrap as an adjunct to primary epineural repair is safe and effective in reducing the rate of intraneural collagen deposition at the neurorrhapy site. Potential trends towards modest improvement in inflammatory cellular infiltration, motor reinnervation and functional recovery were noted that did not reach statistical significance.

Sonoelastography in carpal tunnel syndrome diagnosis: A Systematic Review of diagnostic value

List of authors:
Che-Hsiung Lee¹, Yu-Te Lin²
¹ Chang Gung Memorial Hospital (Linkou)
² Chang Gung Memorial Hospital (Keelung)

Objectives / Interrogation: Sonoelastogram (SEL) has been widely used in many aspects, including musculoskeletal and vascular application. Its biomechanical properties could somehow reflect the degree the pathophysiology of the breast, liver and musculoskeletal disorder. Sonoelastogram has been used to diagnose the carpal tunnel syndrome (CTS). However, the current criteria for CTS diagnosis was diverse. The authors reviewed the literature and provide extratable of the specific value on diagnosis by using sonoelastogram in CTS patients.

Methods: A literature review was performed using MEDLINE (PubMed), EMBASE, and the Cochrane Collaboration Library for primary research articles on sonoelastogram and carpal tunnel syndrome as the key word. The inclusion criteria were primary journal articles examining CTS by using sonoelastogram based on any modality. Data related to diagnostic value, cross section area and cutoff value were extracted. Bias assessment was performed.

Results and Conclusions: A total of 59 publications were reviewed. Fourteen primary case series were selected for full analysis with 2 diagnose with acoustic radiation force impulse (ARFI) with the cutoff value of 3.25 and 3.0 m/s for diagnosing the CTS. Three diagnose with mean shear modulus (kPa), ranged from 38.25 to 70 kPa. Eight articles with strain ratio (SR) between the median nerve and nearby tissue for CTS diagnosis were reviewed revealed diverse results due to different reference points. The other one diagnostic tool was discussed with pixel value on SEL. Sonoelastogram was a useful tool to diagnose carpal tunnel syndrome. It can itself reflect not only the condition of soft tissue scarring, but also specific diagnostic value for CTS in reflection of median nerve stiffness. From our review, SEL provides a non-invasive and reliable modality for CTS evaluation.

Pyrocarbon Interposition with PyroDisk Implant for Trapeziometacarpal Osteoarthritis: A Ten-Year Follow-Up study

List of authors:
Alexandre Petit*, Guy Raimbeau, Bruno Cesari, Raphaëlle Gibaud, Nicolas Bigorre, Fabrice Rabarin, Yann Saint-Cast

1 CENTRE DE LA MAIN (ANGERS)
2 CHU Angers (ANGERS)

Objectives / Interrogation: The aim of the study was to report outcomes after around 10 years following pyrocarbon interposition (PyroDisk) trapeziometacarpal joint implant with partial trapeziectomy for carpometacarpal osteoarthritis of the thumb in a single center.

Methods: We retrospectively reviewed the longterm clinical and radiological outcomes of 16 patients who had a pyrocarbon interposition implant (PyroDisk; Integra Life Sciences, Plainsboro, NJ) arthroplasty, with partial trapeziectomy. The rate and causes of repeat surgeries, and complications were examined.

Results and Conclusions: Results: The mean follow-up period was 115 months. Patient satisfaction was high. The mobility of the operated thumb was restored to a range of motion comparable to the contralateral thumb. Grip strength was improved. Overall function, according to the Quick DASH and PWRE scores, showed a good improvement. Pain decreased in all cases according to the numerical rating scale. Radiological evaluation revealed no progression of the periprosthetic lucency of the implant after 2 years in 11 of 16 patients. Progression of lucency did not predict implant loosening or failure at 10 years. Scaphotrapeziotrapezoid joint was preserved in all cases. No patient had symptomatic instability that required revision. No dislocations occurred. The 10-year survival of the prosthesis was 100%, but only 8 patients (50%) have forgotten their thumb.

Conclusions: The PyroDisk implant for treating advanced trapeziometacarpal arthritis did not demonstrate superiority over published outcome data of other prosthesis or total trapeziectomy with or without ligament reconstruction and tendon interposition. Indeed, the perceived expectation of these procedures is to be able to achieve the "forgotten thumb". However, in several particular cases, like nickel allergy for example, Pyrodisk can be still proposed.

Proximal Interphalangeal Joint Adipofascial Flap (PIPJAF) Resurfacing Improves the Active Motion of the Proximal Interphalangeal Joint after Contracture Release

List of authors:
Che-Hsiung Lee*1, Charles Yuen Yung Loh2, Yueh-Hsia Chen3, Yu-Te Lin4
1 Chang Gung Memorial Hospital (Linkou)
2 Broomfield Hospital (Chelmsford)
3 Chang Gung Memorial Hospital (Taoyuan)
4 Chang Gung Memorial Hospital (Keelung)

Objectives / Interrogation: Post-traumatic proximal interphalangeal joint (PIP) contracture of the digit is common and is associated with impaired function of the hand. After surgical release of PIP contractures, relapse often occurs. We performed a novel treatment strategy with a PIPJ adipofascial flap (PIPJAF) to resurface the PIPJ after release. This study examines 2 groups of patients with similar joint contracture release where one group is resurfaced with a flap and the other without.

Methods: During January 2010 to January 2018, 10 patients received single-digit PIPJ flexion contracture release and PIPJAF resurfacing whereas 20 patients received a stepwise release as a control group. A total of 30 joints were compared and the degree of extension lag improvement over time was measured during over an average of 292.4 days.

Results and Conclusions: In the PIPJAF group, greater extension lag improvement was observed compared to control group (37.0±19.2 vs. 21.0±19.5, p=0.055). The ratio of improvement was also significantly higher in the PIPJAF group (0.79±0.26 vs. 0.49±0.46, p=0.049). PIPJAF group appeared to have beneficial effect (p=0.042) while following number of operations, associated fractures and maximum VAS scores one week postoperatively were negatively associated in univariate analysis (p<0.05). From generalized estimating modelling, PIPJAF resurfacing has a significantly positive effect on extensor lag improvement along with time ($###$=2.235, p=0.04). Patients that receive PIPJAF resurfacing following PIPJ contracture release may have a better result in improving extensor lag and maintaining it. Recovery of the PIPJ motion may be quicker as well compared to conventional release alone.

IGF-1 Nanoparticles to Ameliorate Effects of Chronic Denervation Following Peripheral Nerve Injury

List of authors:
Philip Hanwright*, Chenhu Qiu, Jennifer Rath, Nicholas von Guionneau, Karim Sarhane, Thomas Harris, Harsha Malapati, Ahmet Hoke, Hai-Quan Mao, Sami Tuffaha
1 Johns Hopkins University School of Medicine (Baltimore)
2 Johns Hopkins Whiting School of Engineering (Baltimore)

Objectives / Interrogation: Insulin-like growth factor 1 (IGF-1) is a potent mitogen with well-described trophic and anti-apoptotic effects on neurons, myocytes, and Schwann cells (SC). Local delivery of IGF-1 is limited by its short-half life. The aims of this study are to (1) encapsulate IGF-1 into biodegradable nanoparticles (NP) that stabilize IGF-1 in its bioactive state and enable sustained release at target tissue sites; and (2) assess the efficacy of locally delivered IGF-1 NPs in augmenting axonal regeneration while also reducing denervation-induced muscle and SC atrophy to thereby improve functional recovery following nerve injury.

Methods: (1) NP Fabrication: IGF-1 was first complexed with dextran sulfate to create hydrophobic ionic paired (HIP) complexes, which were then encapsulated in biodegradable PGLA NPs. Varying ratios of HIP:polymer were evaluated to maximize loading efficiency and release kinetics. In vitro NP release kinetics were evaluated and mitogenic activity of released IGF-1 was compared to native IGF-1. (2) The effects of locally-delivered IGF-1 NPs on denervated muscle and Schwann cells were assessed in a rat median nerve transection-without-repair model. The effects of IGF-1 NPs on axonal regeneration, muscle atrophy and reinnervation, and recovery of forepaw function were assessed in a model in which chronic denervation is induced prior to nerve repair; functional recovery was assessed weekly with stimulated grip strength testing prior to sacrifice at 15 weeks.

Results and Conclusions: (1) Fabrication of uniform NPs with an encapsulation efficiency of 83.2% was achieved. 1:5 PEG5k-PCL40k formulation yielded optimal release of IGF-1. Near-zero-order release of IGF-1 can be achieved for at least 70 days, and released IGF-1 exhibits comparable bioactivity to native IGF-1. (2) IGF-1 treated animals recovered significantly more forceful grip strength compared to negative controls (Fig. 1). IGF-1 NP treatment limits muscle atrophy during periods of denervation compared to negative controls (620 vs. 340um2; p <0.05) and enhances neuromuscular junction reinnervation (41 vs. 27%, p <0.05).

Figure 2: Animals undergoing chronic denervation (CD) with IGF-1 nanoparticle therapy (red) demonstrate more robust recovery of grip strength compared to untreated negative controls (blue). * denotes p<0.05.

FIFTH FINGER COMMINUTED SPIRAL FRACTURE IN HORSE RIDERS RELATED TO REIN HOLD TECHNIQUE

List of authors:
Eduardo Pereira*, Laura Filippini Lorimier Fernandes¹, Luciano Pereira¹
¹Hospital Albert Einstein (São Paulo)

Objectives / Interrogation: Horse riding is a highly dangerous sport. The athlete's partner is an unpredictable and independent animal over 600 Kg and 2,7 m that can reach 60Km/h. Some studies discuss whether riding horses may be riskier than a motorcycle.

The most common mechanisms of injuries are falling from the horse. From all the injuries, upper limbs seems to be the one with higher prevalence.

The riders usually wear helmet for head protection and boots and specially designed trousers for lower limb protection, while the upper body and limbs remains unprotected. The gloves protect from attritional damage, but they are not useful for rotational finger injury caused by the reins.

The horse riders usually grip the rein in their first and forth interdigital commissural space, leaving the fifth digit out. In the event of twist or a fall, like after a runout, the rider can easily release the rein from the first commissure, but opening up the forth space isn't as easy, and the rein may wrap around the small finger rotating it.

The aim of this study is to report a series of fifth finger fracture in horse riders.

Methods: We retrospective reviewed 204 cases of hand injury in a single center among horse riders from 1994 to 2018. We evaluated epidemiologic data and the pattern of injury.

Results and Conclusions: There was a male: female rate of 18.25, the mean age was 26.3 (S.D 13.4) years old. The non-dominant hand presented most lesions 57.8%.

Of all injuries 73 (35.7%) were fractures and 21 (28.76%) affected the fifth ray. There were 12 metacarpal, 6 proximal phalanx and 3 middle phalanx fractures.

We would like to call attention to this particular injury - fifth finger's comminuted rotational fracture - related to rein holding technique in horse riding

EXTERNAL FIXATOR WITH DISTRACTOR FOR TREATMENT OF THE RETRACTION IN FLEXION OF FINGERS

List of authors:
Kleber Oliveira Barboza*
1 Hand club Pernambuco, SOS Mãos Recife, Hospital Regional do Agreste (Caruaru - Pernambuco)

Objectives / Interrogation: Skin retraction at palmar 2 zone level fingers may happen sometimes in case of injury, burn or infection, when it needs surgical treatment for flexion deformity more than 45 grade. There are any methods to treat it, as zetaplasty, skin flat, expansor, skin autograft, Ilizarov method. That our technic, with external distractor, can be used to treatment at various types of finger flexion contracture. As well as first treatment for botoniere deformity and dupuytren contracture. That technic is very easy, may be used with local anesthesia, by day clinic.

Objectives
To describe a serial of patients with retraction in flexion finger, by any reasons, treated by progressive stretch using a mini external fixator as a Hoffa.

Methods: 50 patients were operated from january 2000 to december 2017, 36 male and 14 female, with middle age of 28 years-old, between 15 and 42 years-old. 04 cases in thumb, 16 cases in 2º finger (QD), 08 in 3º QD, 08 in 4º QD and 14 in 5º QD. The patient, after asepsis, receives a local anesthesia for the finger flexioned. So two pins are putting with a Hoffa fixator articulated with distractor. One pin, perpendicularly, in each side of joint. Hangs the screws for block the pins and gives the tool for the patient or parent that will turn, on clockwise, the principal axis to correct the deformity, by progressive strech of 01 mm per day (one complete turn). After the total correction, the patient goes back to the clinic for withdraw the pins and fixator. So the patients were available by total active motion (TAM) and satisfaction.

Results and Conclusions: Results
We had 100% of correction, with TAM recuperated for all patients. About the method, 80% patients are pleased. 10 patients complained about the delay, middle time of 36 days. Had 02 cases with recidive in 5º QD, but retreated with a total correction.

Discussion
That Hoffa fixator is better to use in the thumb, second and fifth finger. In the third and fourth fingers, the interdigital space is more difficult to apply it.
Years ago, an american company produced a model circular very narrow, but they abandoned it, I don't know why. Actually we can use anothers fixators more narrow, as Miniflo.

Conclusions
We conclude that it is a good alternative for treatment of the retraction in flexion of fingers, But to keep the protocol is indispensable, With a attentive and cooperative patient.

HAND IN STREET ART AROUND THE WORLD

List of authors:
Eduardo Pereira*, Laura Filippini Lorimier Fernandes¹, Luciano Pereira¹
¹Hospital Albert Einstein (São Paulo)

Objectives / Interrogation: Since the beginning of human civilization, under the Caveman era, the man had a necessity to represent the human figure, drawing it on the cave, and the hand was always an important part, due to its function as our first tool, for hunting, fighting and daily life activities.

In urban centers, a creative phenomenon is taking place, alongside to buildings and traffic, a personal expression of the modern human condition in the form of works of art on the street (Street Art), is available for everyone to see.

Nowadays, hand keeps present in the art in general; and drawing hand is known to be one of the most difficult forms our body.

In urban centers, a creative phenomenon is taking place, alongside to buildings and traffic, a personal expression of the modern human condition in the form of works of art on the street (Street Art), is available for everyone to see.

Methods: The author, a Hand Surgeon presents photographs of street art, whose theme is hand, around the world, taken by him, with his camera, during bike rides.

Results and Conclusions: We present 50 photographs of street art taken in several cities around the World like Berlin, London, Miami, New York, Paris, Sao Paulo.
The beauty and importance of a hand are expressed in the streets by many artists around the world, sometimes we pass in a hurry, by car and don't notice it. The author passionate by hands wanted to share with other hand surgeons his experience discovering hand in art in our big metropolis.

Variation Amongst Pediatric Orthopedic Surgeons in the Use of Pre-operative Antibiotics in Percutaneous Pinning Procedures of the Upper Extremity

List of authors:
Joshua Abzug*, Alexandria Case¹, Jennifer Ty², Alice Chu³, Christine Ho⁴, Andrea Bauer⁵
¹ University of Maryland School of Medicine, Department of Orthopaedics (Baltimore)
² Alfred I. duPont Hospital for Children (Wilmington)
³ New York University Langone Health (New York)
⁴ Texas Scottish Rite Hospital for Children (Dallas)
⁵ Boston Children's Hospital (Boston)

Objectives / Interrogation: Pre-operative antibiotics use in percutaneous pinning procedures of the upper extremity is commonly prescribed by many orthopedic surgeons. However, the use of the antibiotics may not be necessary given the low infection rates associated with these procedures. Numerous studies have investigated the need for pre-operative antibiotics in soft-tissue procedures of the upper extremity and found that they did not reduce the overall infection rate. The purpose of this study was to determine the patterns and variation among pediatric orthopedic surgeons in pre-operative antibiotic prescribing practices when performing percutaneous pinning procedures of the upper extremity.

Methods: A survey was sent to all members of the Pediatric Orthopedic Society of North America to assess the current practices and surgeon's thoughts regarding pre-operative antibiotics use for percutaneous pinning procedures of the upper extremity based on location of the procedure. Simple statistics were utilized to analyze the data.

Results and Conclusions: Two hundred ninety-seven surgeons responded to the survey, only 34% reported that their institution had protocols in place to routinely receive pre-operative antibiotics for percutaneous pinning procedures of the upper extremity. Eighty-one percent of surgeons described that they routinely provide antibiotics for all percutaneous pinning procedures of the upper extremity. However, only 60% of surgeons felt that patients undergoing percutaneous pinning procedures of the upper extremity must receive pre-operative antibiotics. When assessing individual joint procedures, 81% of surgeons felt that shoulder procedures required pre-operative antibiotics, 70% of surgeons felt that elbow procedures required pre-operative antibiotics, 66% of surgeons felt that wrist procedures required pre-operative antibiotics, and 62% of surgeons felt that hand/finger procedures required pre-operative antibiotics.

Currently, the majority of institutions do not have protocols for the use of pre-operative antibiotics in percutaneous pinning procedures of the upper extremity. The vast majority of pediatric orthopaedic surgeons (80%) routinely prescribe antibiotics for percutaneous pinning procedures of the upper extremity despite the fact that 40% of surgeons felt that antibiotics were not necessary for all procedures. As the percutaneous pinning procedure is performed more distally on the upper extremity, less surgeons feel pre-operative antibiotics are necessary.

Analysis of BSSH UK Hand Registry shows no difference in outcomes between simple trapeziectomy and trapeziectomy plus LRTI

List of authors:
Matthew Gardiner*, Jennifer Lane, Jeremy Rodrigues, Robert Poulter, Dominic Furniss

* Kennedy Institute of Rheumatology, NDORMS, University of Oxford (Oxford)
2 Botnar Research Centre, NDORMS, University of Oxford (Oxford)
3 Royal Cornwall Hospital (Truro)

Objectives / Interrogation: Surgery for thumb base osteoarthritis (TBOA) is common. It is one of the domains recorded by the UK Hand Registry (UKHR). The aim of this study was to analyse the TBOA registry data to assess the impact of surgical procedure type on patient reported outcome measures (PROMs) and EQ5D.

Methods: The UK Hand Registry (UKHR, formerly called the BSSH Audit Database) prospectively collects data from patients undergoing hand surgery as part of an approved national quality assurance process. This study involved secondary analysis of fully anonymised data from inception of the registry. Exemption from ethical approval was confirmed by University of Oxford Clinical Trials and Research Governance prospectively. Prospectively collected data from patients undergoing TBOA surgery were analysed from February 2012 to January 2018 inclusive. Outcomes were evaluated using EQ5D index and Patient Evaluation Measure part 2 (PEM) outcome measures at baseline, three, six and 12 months post-operatively. Regression analyses were conducted with procedure type, age and gender as factors.

Results and Conclusions: A total of 1456 TBOA procedures were added during the study period. Most were simple trapeziectomy (51%) or trapeziectomy plus ligament reconstruction and tendon interposition (LRTI) (45%). Other procedures were excluded from our analysis. There was no statistical difference between the demographics (age, gender) or baseline PROMs (EQ5D; Patient Evaluation Measure, PEM) for the two groups. The mean age was 65 years (SD 9); 78% of the population was female.

There was a significant improvement in EQ5D index and PEM for each postoperative time point up to 12 months for both groups. However, there was no significant difference between the two groups at any time point.

Regression analysis showed gender to be a significant contributing factor to outcome. Male patients had less improvement following surgery at each time point.

This study showed surgery for TBOA significantly improved patient outcomes. Our findings support previous studies suggesting no difference in outcomes between the two most common surgical procedures.

Distal radius fractures: is rotation an important factor in fixation?

List of authors:
Joshua Filer¹, Adam Smith², Grey Giddins²
¹ North Bristol NHS Trust, Southmead Hospital (Bristol)
² Royal United Hospital (Bath)

Objectives / Interrogation: Hypothesis: the distal fracture fragment in distal radius (wrist) fractures very commonly rotates as well as shortens and angulates.
Aim: To assess the frequency and degree of rotation of the distal fracture fragment on CT scans.

Methods: Retrospective radiological assessment of 85 CT scans of the distal radius: 35 following a fracture and 50 normal radii. A simple method for measuring rotation of the distal radius relative to the diaphysis using routine CT scans was developed and applied. Mann-Whitney analysis was used to identify differences in radial rotation between fractures and controls. Intra- and interobserver reliability were analysed using intraclass correlation coefficients and Bland-Altman plots.

Results and Conclusions: The distal fracture fragment could rotate into pronation or supination relative to the diaphysis, both normally and following a fracture. The median radial rotation angle was -1° (pronation, range -15°-4°) in the control group compared to -3° (pronation, range -24°-31°) in the fracture group. The absolute rotation angle was significantly greater in the fracture group (median 10°, range 0-31° vs to 3°, range 0-15°; U = 291.50, Z= -5.21, p < 0.001) and outside the "normal range" of this study in 26 cases indicating that at least 75% had rotated appreciably following injury.
Both intra and interobserver reliability was very good with intraclass correlation coefficients of 0.99 and 0.98 respectively.

Malrotation of the distal radius is common following a distal radius fracture. Malrotation of the distal fracture fragment has been shown to affect DRUJ function. Despite this rotational deformity is often overlooked in clinical practice. The simplified method described in this study is both easy to use in routine clinical practice and reliable. Measuring radial rotation angle using such a method may be an important consideration when planning primary treatment and corrective osteotomy for patients with distal radial malunion.

Keywords: Radius; Fracture; Rotational deformity; Malrotation
RARE TUMOURS IN HAND AND FOREARM: A SERIES OF 18 CASES.

List of authors:
ELENA DELGADO*, HERNANDO LAVERDE2
1 HOSPITAL UNIVERSITARIO MAYOR MEDERI, EJERCITO NACIONAL DE COLOMBIA, UNIVERSIDAD NUESTRA SEÑORA DEL ROSARIO (BOGOTA)
2 HOSPITAL CENTRAL DE LA POLICIA NACIONAL (BOGOTA D.C.)

Objectives / Interrogation: Purpose: To report 18 case of patients with rare tumours in hand and forearm and review the related literature.

Methods: Methodology: The sample consisted of 18 patients, who consulted for mass in hand and forearm who were taken to excresis and the pathology report rare tumours for locating.
The sources of data for the literature review were obtained from Medline, Cochrane and Pubmed.

Results and Conclusions: Results: 18 patients aged 8-74 years old, the tumours were:
- 1 endometrioma,
- 1 squamous cell carcinoma type Keratoacanthoma
- 2 necrotizing synovitis,
- 1 Multiple Osteocondromas,
- 1 Schwannoma with metacarpal intraosseous osteochondroma,
- 3 atypical Schwannoma,
- 1 Nodular fascitis,
- 1 Keratoacanthoma type cutaneous horn,
- 1 cavernous hemangioma,
- 1 villonodular synovitis,
- 1 melanocytic lesions parallel ungual,
- 1 intravascular papillary endothelial hyperplasia,
- 1 aneurysmal bone cyst,
- 1 fibrokeratoma,
- 1 papillary digital adenocarcinoma.

Discussion and Conclusions: Because of rare occurrence of these tumours diagnostic and operative experience is relatively small. There is also a few number of publications regarding strange tumours of hand and forearm. Therefore the aim of the study was present our experience in the surgical treatment of the unusual tumours of the hand and forearm basing on the material of 18 cases treated in the years 1999-2016.
In the literature there is no record of endometrioma in upper extremity, during our literature review we found only one case in lower limb. The present authors have 589 cases of resection tumours in 13 years, and these 18 cases represent 3% of them. Generally these rare tumours are average 2% of report in the literature review without significant experiences have registered.
Unusual tumours pathologies in hand and forearm are part of the differential diagnosis the hand surgeon must be present.

Treatment of Painful Neuroma by Nerve Capping Using Nerve Conduits in a Rat Model

List of authors:
Ema Onode¹, Takuya Uemura², Kosuke Shintani¹, Takuya Yokoi¹, Mitsuhiro Okada¹, Kiyohito Takamatsu³, Hiroaki Nakamura¹
¹ Osaka City University Graduate School of Medicine (Osaka)
² Osaka General Hospital of West Japan Railway Company, Osaka City University Graduate School of Medicine (Osaka)
³ Yodogawa Christian Hospital, Osaka City University Graduate School of Medicine (Osaka)

Objectives / Interrogation: Although peripheral nerve stump (PNS) capping using nerve conduits for the treatment of painful neuroma has attracted attention, details of the underlying mechanisms of pain relief and appropriate nerve conduit length remain unclear. Thus, we aimed to investigate the effectiveness of nerve capping and to identify the appropriate nerve conduit length in a rat neuroma model.

Methods: In male SD rats (n=45), the sciatic nerve (diameter, 1.5 mm) was sharply transected to create a 15 mm nerve defect (rat neuroma model). In the nerve capping (NC) group, the PNS was inserted to a depth of 2 mm into a 3 mm (n = 15) or 6 mm (n = 15) bioabsorbable nerve conduit (internal diameter, 2 mm), whereas in the no capping group (n = 15), no tube was inserted. Autotomy scores were measured to evaluate neuropathic pain, and the PNS was evaluated grossly and histologically at 12 weeks after the surgery. PNS were stained with HE and Masson's trichrome and immunohistochemically stained using anti-neurofilament protein antibody to evaluate the axons, anti-alpha-smooth muscle actin (α-SMA) antibody to evaluate areas of scarring surrounding the PNS, and anti-sigma-1 receptor (S1R) antibody to examine neuroinflammation. Positive areas were morphometrically analyzed using computer-assisted imaging.

Results and Conclusions: At 12 weeks after surgery, the autotomy scores in the 6 mm NC group was significantly lower than that in the no capping group (p < 0.01). In the gross appearance, PNS was swollen and adhered to the surrounding tissues in the no capping group; meanwhile, the PNS remained wrapped with nerve conduits protectively in NC groups. Histologically, neuroma was formed in the no capping group, and regenerating nerves were exposed from the distal end of the nerve conduit in the 3 mm NC group, whereas they converged within the nerve conduit in the 6 mm NC group. Notable perineural scar tissue was found in the no capping and the 3 mm NC group, whereas minimal perineural scar formation was present around the terminated axonal fibers in the 6 mm NC group. Morphometric analysis revealed that the % area of α-SMA and S1R positive expression in the PNS were significantly lower in NC groups than in the no capping group (p < 0.05).

Nerve capping of the PNS using nerve conduits successfully relieved neuropathic pain in the rat neuroma model. Neuroma was not formed, and the peripheral scar formation around the PNS was suppressed. The appropriate length of the nerve conduit is more than 4 times the diameter of the nerve.

Pathology and treatment of deviation deformity of thumb after radial polydactyly resection

List of authors:
Yanhua Chen*, Zhengbin Chen¹, Guangxiang Hong¹, Xiaobing Cong¹
¹Department of Hand Surgery, Union Hospital (wuhan)

Objectives / Interrogation: Radial polydactyly is one of the most common congenital deformity that affect the hand. It has complex anatomic and morphologic features. So the residual thumb deformities usually be seen after radial polydactyly resection. The deviated thumbs are the most common. To the thumb, axis deformity can not be accepted by patients and parents because this kind of deformity seriously affects the function and aesthetics of the hand. We analysis the pathology of deviated thumbs to prevent and treat the axis deformity of the residual thumb.

Methods: A total of 62 deviated thumbs in 58 patients who were treated surgically from 2013 to 2018 were included in this series. The abnormal bone, ligament and tendon were recorded. All patients underwent surgical treatment based on the pathology of deviation. The surgical outcomes were assessed using the Modified Tada score.

Results and Conclusions: Of the 62 deviated thumb cases, 34 (55%) had a abnormal tendon insertion into distal phalanx from flexor pollicis longus, 26 (42%) had no normal insertion of abductor pollicis brevis, and 16 (26%) were triphalangeal thumb. In the evaluation of the surgical outcomes, 51 (82%), 9 (15%) and 2 (3%) were rated as good, fair and poor, respectively. In the thumb that has two phalanges, the main reason contributed to thumb deviation is the abnormal insertion of the thumb muscles. In the children, resetting the insertion of the thumb muscles can avoid the remarkable axis deformity.

Keywords: polydactyly, axis deformity, deviation, pathology, treatment
**Thumie and other Non-Conventional Treatments**

⁴Hospital Militar Campo de Mayo (Campo de Mayo, Buenos Aires)
⁵Hospital Militar Central (CABA)

**Objectives / Interrogation:**
1. Is it possible to achieve good results with certain non conventional treatments for severe hand injuries?
2. Is it possible for serious wounds to heal in presence of bacteria?

**Methods:**
Between Sept 24/14 and Sept 24/18 90 patients consulted of important injuries in the upper limb. Among them were selected 5 with tissue loss, so important that despite complex surgical procedures would be performed it was predictable that there would persist very limiting sequelae. The 5 patients, lucid hand worker males, who averaged 32 y/o (23-41) (2 wounds by circular saw of thumb; 1 blast injury in hand; 1 gunshot on wrist; 1 devascularization of half a phalanx of the thumb by motorcycle chain), were warned about the possibility of not achieving good results by any indicated conventional treatment; the alternative to implementing non-conventional methods which had provided excellent results in previous less severe cases and, in the event of adverse evolution, would not impede the resolution by the same traditional procedure already indicated.

All fractures were stabilized, and tendons and nerves repaired or replaced by convenient grafts. In all cases, the open wounds were covered by a waterproof element that acted as a secretion-preserving chamber, keeping the exposed tissues in a liquid environment. Patients did not receive antibiotics even when they presented purulent secretion, except in cases of deep infection. The wounds were cleaned only when their odor was fouled and the purulent secretions overflowed in outer bandages.

**Results and Conclusions:**
Two patients required intravenous antibiotics for a short time, due to systemic infection. In 4 of the 5 patients was achieved the regeneration of cutaneous tissues in an average of 14 weeks (8-32), despite the contamination with Pseudomonas Aeruginosa and/or Staphillococcus Coagulas Neg. The finger degloved by the blast had to be rescued by a skin-graft. No signs of infection have been detected since then in any patient.

**Conclusions:**
1. It is possible to heal serious wounds in presence of bacteria.
2. Maintaining wounds moist facilitates joints mobility during the healing process.
3. It is possible to achieve the regeneration of some tissues maintaining a humid environment.
4. Bacteria such as Pseudomonas or Staphillococcus does not prevent the healing of hand and wrist wounds.
5. A history of infection does not preclude survival of bone, tendon, or nerve grafts in hand and wrist.
6. Is it possible to achieve good results with certain non conventional treatments.

WOUND INFECTION. TISSUE LOSS. NON-CONVENTIONAL
Castleman's Tumor associated brachial plexus, literature review a propos a case

List of authors:
ELENA DELGADO*, 1 RODOLFO COSENTINO2, SERGIO DARODA2, PAUL PEREIRA2, FERNANDO MENVIELLE2
1 HOSPITAL UNIVERSITARIO MAYOR MEDERI, EJERCITO NACIONAL DE COLOMBIA, UNIVERSIDAD NUESTRA SEÑORA DEL ROSARIO (BOGOTA)
2 GAMMA- CLINICA DE LA MANO (LA PLATA)

Objectives / Interrogation: Objective: To report a case of a patient with Castleman's disease associated with brachial plexus injury and review the related literature.

Methods: Methodology: The sample comprised a male patient aged 37, who consulted for feeling mass in left infraclavicular region associated with dysesthesia inner side of forearm and wrist, referred history of blunt trauma to that location.

The sources of data for the literature review were obtained from Medline, Cochrane and the annals of the our Association of Hand Surgery.

Results and Conclusions: Results and Conclusions: In the literature there is no record of these lesions in relation to the brachial plexus. The present authors reported a similar case in a woman in her fourth decade of life, with symptoms of brachial plexus compression.

According to the histological types should be directed treatment, when localized disease is surgical resection definitive management.
Recent findings of cytogenetic alterations in stromal cells of hyaline vascular type and the role of IL-6 and HHV 8 in the pathogenesis suggest that the hyaline vascular and plasma cell may even be considered as separate diseases.

Patients with multicentric disease should undergo extension studies for immune status.

Preliminary Study Using A Synthetic Ligament in DRUJ reconstruction

List of authors:
Shalimar Abdullah¹, Levin Kesu Belani¹, Mohd Zaim Rashid¹, Jamari Sapuan¹
¹Universiti Kebangsaan Malaysia (Kuala Lumpur)

Objectives / Interrogation: In chronic DRUJ instability, one of the popular methods is utilizing the palmaris longus as a graft in techniques such as the Adams techniques. However we have found that the palmaris longus can be short. We have exchanged the palmaris longus with a synthetic tendon named Orthotape - polyethylene teraphtalate mesh¹.

Methods: A 45-year-old male had a poorly treated comminuted distal end radius fracture and DRUJ instability fixed with a 1/3 tubular plate and K-wires by a private surgeon. Due to the poor fixation physiotherapy was not instituted. After 3 months, he presented to us and we revised the fixation with a locking distal radius system and instituted immediate physiotherapy. His progress went well and 3 months later, his only concern was the DRUJ instability. We opted for the Adams DRUJ reconstruction utilizing a synthetic ligament.

Results and Conclusions: At 6 months post-operatively, his wrist stability had improved and his DASH score has reduced from 39 to 7.5. However radiographically the DRUJ space which immediately post-operatively was obliterated has reopened. Synthetic ligament remains as an alternative in DRUJ reconstruction and can offer good functional outcome to the patient. However a longer follow-up study needs to be done.

TREATMENT OF RADIOCUBITAL DISTAL INSTABILITY WITH ENDO BUTTON SYSTEM

List of authors:
Willian Alvarez*
1 Hospital Militar N°1 Quito Ecuador, Escuela de Medicina Universidad Central del Ecuador, Quito Hand Center (Quito)

Objectives / Interrogation: Determine the results achieved in the short term with the Álvarez - Hidalgo Technique with the Tight Rope endoboton anchor system of small joints.

Methods: Patients with clinical symptoms and positive signs consistent with IRCD, admitted to the No.1 General Hospital of the Armed Forces (Quito-Ecuador), between January 2013 and December 2015.

Design
Prospective cohort.

Main measurements
Clinical controls performed at 7, 15, 30, 60 and 90 days postoperatively.

Results and Conclusions: Results
We studied 34 patients surgically treated with the Álvarez - Hidalgo Technique with the Tight Rope endoboton anchor system for the stabilization of the distal radio-ulnar joint. The proportion of men was significantly higher than that of women (61.7% vs. 38.2% p <0.001) in the total group, the average age was 38 ± 12.5 years, with a range of 20 to 56 years. The largest number of patients was agglutinated in the age group of 27 to 45 years (48.9%, 95% CI = 40.4% - 57.5%), with significant differences compared to the other age groups.

The location of the IRCD was usually the right hand (n = 102, 73.4%). There were no surgical complications. Six months after the postoperative period, most of the patients who had undergone surgery had achieved a significant clinical improvement in the parameters evaluated; Complete normality was reached in 96.47% of the cases, with respect to pain, 97.05% reported a total decrease, only one patient reported pain on the EVa scale of 2/10. The mobility arcs were recovered within the normal parameter by 94.11%, 5.88% was classified within a degree of medium. Stability (absence of the key sign) was observed in 100% of the patients. The capacity to hold weights-force was established at 91.17%. Total postoperative satisfaction was reported by 100% of the patients. Considering the clinical results classified as excellent and good (Tables 2 and 4), the overall frequency of surgical successes was 97%.

Conclusion
The technique of Alvare - Hidalgo with the Tight Rope endoboton anchor system of small joints used for the IRCD achieves favorable clinical results. The wrist arthroscopic procedure is of the utmost importance, since it allows to visualize complementary lesions of the FCTC and to apply an opportune treatment.

Flexor Pollicis Longus Tendon Rupture after Volar Plate Fixation of Distal Radius Fracture.

List of authors:
Daiki Yamamoto*, Kaoru Tada
1 Department of Orthopedic surgery, Keiju Medical Center (Nanao city, Ishikawa)
2 Department of Orthopaedic Surgery, Kanazawa University (Kanazawa city, Ishikawa)

Objectives / Interrogation: Flexor pollicis longus (FPL) tendon rupture is known as a complication after volar plate fixation of distal radius fracture caused by volar plate prominence. We experienced some cases of FPL tendon rupture without plate prominence significantly, so we evaluated other risk factors of FPL tendon rupture.

Methods: Patients who had been undergone volar plate fixation for distal radius fracture between 2006 and 2012 were included in this case-control study. Eight patients with FPL tendon rupture (case group) and forty-five patients who were observed for more than two years without hardware removal (control group) were included. All patients were female. We investigated age, body height and weight, range of motion of the operated wrist, medical history of rheumatoid arthritis and diabetes mellitus, history of oral administration of steroids, smoking, and alcohol use in the patients. Post-operative X-rays were used to identify parameters of reduction (volar tilt, radial inclination, and ulnar variance) and of volar plate prominence (Soong’s grade, plate to critical line distance, and plate to volar rim distance).

Univariate analysis with Mann-Whitney U tests or chi-square tests was performed. Factors with a P-value > 0.2 by univariate analysis were introduced to multivariate logistic regression.

Results and Conclusions: In univariate analysis, body height (p=0.014) and plate prominence (Soong’s grade 1, p=0.041) revealed statistically significant differences. In multivariate logistic regression, only the odds ratio (OR) for body height was statistically significant (OR = 1.32 per 1 cm less in body height, p=0.027). We created a receiver operating characteristic curve of FPL tendon rupture and body height, and established a cutoff value of 150 cm, calculated from the national statistical chart of body height of Japanese women (50-80 years old, average 154.36 cm, and the standard deviation of 2.23). As a result, the sensitivity was 75% and the specificity was 58% for using body height as a risk predictor for FPL tendon rupture. In this study, volar plate prominence value of case group (FPL tendon rupture) were not so significantly different from those of control group. It is suggested that the risk of FPL tendon rupture after volar plate fixation is greater not only with plate prominence but also with physically smaller women in this case-control study.

Transfer of contralateral C7 nerve to upper trunk via prespinal route for neuropathic pain after total brachial plexus avulsion: A novel and effective approach to relieving the intractable pain

List of authors:
Zhonggen Dong*, Jianwei Wei1, Lihong Liu1, Zhaobiao Luo1, Ping Peng1, Xinyu Peng1, Chaodong Yin1
1 The Second Xiangya Hospital, Central South University (Changsha)

Objectives / Interrogation: To report the efficacy of transferring contralateral C7 nerve to the upper trunk via the prespinal route for neuropathic pain after total brachial plexus avulsion, and evaluate the value of this procedure for the intractable pain.

Methods: Between December 2014 and March 2016, 6 patients with refractory pain after total brachial plexus avulsion underwent the procedure of transferring CC7 nerve to the upper trunk via the prespinal route. The curative effects of this procedure for these patients were observed and studied prospectively. The questionnaire of DN-4 was used to determine if the pain in these patients was the neuropathic pain. These patients were followed up regularly, and their pains were evaluated preoperatively and postoperatively using the VAS, pain relief rate, SF-MPQ-2, territory and frequency of the pain, and HADS. The motion and sensation of the affected limb were assessed using the BMRC grading system.

Results and Conclusions: Preoperative scores of DN4 ranged from 5 to 8 in 6 patients who were followed up for a period from 24 to 38 months (average, 29.9 months). There was a descending tendency of the VAS scores over time in the six patients. The VAS scores at the 6 month, 12 month and the last time follow-up postoperatively decreased in order (P<0.05), and were significantly lower than that preoperatively (P<0.05). At the last follow-up, the curative effect of relieving pain was excellent in 4 and good in 2 patients. The total score of the SF-MPQ-2 (32.2±14.1) were significantly lower than that before operation(65288;74.0±9.5)(65289;P<0.05). The territory and frequency of the intractable pain decreased at the last time follow-up. The total score of the HADS was significantly lower at the last time follow-up than before operation (P<0.05).The muscle strengths of both the deltoideus and supraspinatus were grade M3 in five patients, and the mean angle of the shoulder abduction was 27.5°(20°-30°) in six patients. The muscle strengths of the biceps brachii were grade M3 or greater in five patients, and the angle of flexor elbow ranged from 0°to 130°(mean, 81.7°). The sensation in affected upper limb recovered to grade 3 in four patients and grade 2 in two patients.

Transferring CC7 nerve to upper trunk via prespinal route can significantly alleviate neuropathic pain after total brachial plexus avulsion, and this procedure is a novel and effective approach. Meanwhile, it has the advantage of recovery in both motions and muscle strengths of the affected shoulder and elbow.

Forearm diaphyseal bone strength recovers three months after plate removal

List of authors:
Yusuke Matsuura*, Tomoyuki Rokkaku, Kazuki Kuniyoshi
1 Chiba university (Chiba)
2 Chiba municipal hospital (Chiba)
3 Nagareyama central hospital (Nagareyama)

Objectives / Interrogation: Forearm diaphysis fractures are usually treated by open reduction internal fixation with plates. Long after surgery, some patients present with bone atrophy adjacent to the plate, occasionally leading to refracture. Because we have an incomplete understanding of when bone strength recovers, the aim of this study was to investigate changes in forearm bone strength after plate removal using a computed tomography (CT) based, specimen-specific finite element model (FEM).

Methods: We included 13 forearm fractures from 7 patients treated with locking plates. CT imaging of both forearms was performed before plate removal, and at 1, 3, and 6 months after plate removal to assess local bone mineral density and predict bone strength. We created a 3-dimensional FEM with Mechanical Finder software, using a previously-reported CT data.

Results and Conclusions: Mean patient age at plate remove was 33.5 years. The mean period of plate fixation was 33.2 months. The mean bone strength of the healthy contralateral side was 7910.2N. The mean strengths of the injured side before plate removal, and 1, 3, and 5 months after plate remove were 4093.1N, 4178.3, 6139.7, and 7220.7N, respectively. The injury-healthy ratios were 49.0% (baseline), 62.7% (1 month), 88.0% (3 months), and 95.2% (5/6 months). Compared with the healthy side, bone strength was significantly decreased after removal. By 3 months after plate removal, bone strength was significantly recovered.

In conclusion, bone strength decreases after plate fixation, often recovering by 3 months after plate removal. It may be necessary for patients to restrict potentially injurious activities for approximately 3 months or until bone strength recovers.

Reversed Dorsal Metacarpal Adipofascial Flap Resurfacing the Metacarpophalangeal Joint Capsule after Dorsal Capsulotomy in Posttraumatic Contractures

List of authors:
Yu-Te Lin*, Che-Hsiug Lee
1 Chang Gung Memorial Hospital (Keelung City)

Objectives / Interrogation: After dorsal capsulotomy or capsulectomy for the extension contracture of the metacarpophalangeal joint (MCPJ), the divided capsules were left for secondary healing. Despite vigorous rehabilitation postoperatively, reemergent fibrotic capsule restricting the motion was inevitable. In this study, the reversed dorsal metacarpal adipofascial flap was used to resurface the MCPJ capsule in the cases with posttraumatic contracture.

Methods: Dorsal approach with a curvilinear Incision was performed. Tenolysis of the extensor tendon was undergone from zone 4 to zone 6. The proximal sagittal slings could be divided to expose the MCPJ. Capsulotomy and division of dorsal collateral ligaments was continued to ensure least resistance with passive flexion of the joint. The reversed dorsal metacarpal adipofascial (RDMA) flap was dissected superficial to the extensor tendon. The longitudinal axis of the flap locates in the center between two metacarpi, and the pivot point is the midpoint between the two metacarpal necks. The flap was turned and inset to the joint capsule with passive flexion of the MCPJ.

Results and Conclusions: Results
The technique was performed in 4 cases, including one 3rd MCPJ and three 5th MCPJs. All contracture were resulted from previous metacarpal fracture. Pre-operative active motion of the involved MCPJ was from 0 to 35 degrees. The patients were followed for 6 to 17 months. The final active motion was from 55 to 82 degrees. The improvement of active motion was from 40 to 70 degrees.

Conclusions
The RDMA flap resurfacing the divided MCPJ capsule provides primary healing of the defect and a better gliding surface for the extensor tendon on the dorsal MCPJ. All the patients got improvement without relapse of extension contracture.

**WALANT Surgery, Advanced techniques in wrist surgery**

**List of authors:**
Carlos Ramos Pina*¹, Ana Daniela Lousada¹, Carlos Ferreira¹, Vitor Rodrigues¹, Sergio Figueiredo¹, Luis Machado¹
¹ Centro Hospitalar de Leiria (Leiria)

**Objectives / Interrogation:** Wide Wake Local Anesthesia No Tourniquet Surgery recently changed the way hand procedures are done and contributed definitely to improve our functional results in some of the hand conditions. Recently, the technique for distal radius fracture treatment by WALANT were described.
We asked if the same principles and rationale of WALANT could be applied to wrist surgical techniques and what would be the advantages of Wrist Surgery done by WALANT.

**Methods:** We developed a technique of local anesthesia technique to apply the principles of WALANT Surgery in Wrist Surgery. 6 Patients were selected and included in the study. All patients gave their informal consent.
Carpal row carpectomy, four corner fusion, scaphocapitate arthrodesis and perilunate dislocation were the procedures done by technique.
We had no complications from using WALANT techniques for these more advanced wrist procedures.
Dynamic motion allowed additional procedures and adjustments made peroperatively based on intraoperative findings.

**Results and Conclusions:** We operated 6 patients with no formal complications of the local anesthetic technique.
In 3 patients additional procedures decisions were done by direct visualization of their need dynamically.
Motion could be very reliably anticipated by intra-op motion by the patient.
WALANT is possible in more advanced Wrist surgery and can permit several important technical decisions during surgery regarding additional and concomitant procedures, this could improve surgical functional results and patient satisfaction.
This study adjoin new possible procedures that can be done with Walant technique, expanding the armamentarium of surgeries already described.
We present our anesthetic technique and surgical results.

Comparison of open surgical release versus ultrasound-guided percutaneous release using new instrument for trigger finger

List of authors:
Ryotaro Fujitani*1
1 Ishinkai Yao General Hospital (Osaka)

Objectives / Interrogation: We used new ultrasound-guided instrument for percutaneous release with 18-gauge needle for trigger finger. This instrument was developed to avoid the complications of incomplete release and flexor tendon, digital nerve, and digital artery damage under ultrasound-guided. (Double guide-type tendon sheath incision instrument, Nara Seiko INC®, Japan).
We compared open surgical release (Group A) with ultrasound-guided percutaneous release with this instrument (Group B) for trigger finger.

Methods: 18 fingers were treated with open surgery (Group A) and 16 fingers were treated with ultrasound-guided percutaneous release with this instrument (Group B). Functional and clinical outcomes of the both groups were evaluated at 1.5, 3, and 6 month postoperatively and were compared between the patients with the Group A and B.
Group A patients allowed wetting hands after the stitches have been removed. Group B patients allowed soaking hands the second postoperative day.

Results and Conclusions: The groups were similar at base line in terms of sex, age. There are no postoperative complication and secondary operation procedures. At 1.5 months postoperatively, the average VAS score was 32 mm in the Group A, and 15mm in the Group B, respectively. There was a significant difference between the two groups (p<0.05). The average extension of PIP joint at 3 months postoperatively was -10 degree in the group A, and -3 degree in the group B, respectively. There was a significant difference between the two groups (p<0.05). At 6 months postoperatively, there was no significant difference between the two groups regarding the pain level on a visual analogue scale, the Quick DASH, range of motion of PIP. Our data indicate that both procedures are highly effective for treatment of trigger finger without postoperative complication. While, release with new ultrasound-guided instrument yielded better results compared to the open technique in the early postoperative period, in respect of improvement of VAS and extension of PIP joint. Besides, after 6 months, this study shows the functional outcomes are comparable between two groups.
The ultrasound-guided percutaneous release with this instrument may make sure to complete release and provide earlier recovery of the finger function in the early postoperative period.

10 Questions About Scaphoid Fractures - Revisited: A case based discussion

List of authors:
Amit Gupta*, Kyle Bickel¹, Chaitanya Mudgal³
¹ Assoc Professor, Dept of Orthopedic Surgery, University of Louisville (Prospect, KY)
² The Hand Center of San Francisco, Assistant Clinical Professor, UCSF School of Medicine (San Francisco, CA)
³ Assoc. Professor, Hand Surgery Service, Massachusetts General Hospital, Harvard School of Medicine (Boston, MA)

Objectives / Interrogation: The 1992 article “Twenty questions about scaphoid fractures” by Nicholas Barton was a seminal work in wrist surgery. Twenty-five years of progress in the treatment of this common wrist injury have made the revisiting of this work with current methods, materials, and analyses an important endeavor. [1]

Methods: An international panel of experts will discuss the following 10 questions:

1. What is the diagnostic algorithm for a painful wrist injury?
2. What characteristics of scaphoid fractures lead to a poor prognosis?
3. What is the current treatment algorithm for scaphoid fractures?
4. What techniques are currently used to treat scaphoid fractures?
5. How is delayed union of scaphoid fractures diagnosed and treated?
6. What is the best treatment for scaphoid nonunion?
7. What is the role of vascularized bone grafts in scaphoid nonunion?
8. What is the role of free microvascular grafting in scaphoid nonunion?
9. What is SNAC wrist?
10. How is SNAC wrist best treated?

Results and Conclusions: Each question will be discussed by an expert surgeon, using currently available diagnostic tools, treatment methods and techniques, and discussing published data related to outcomes of treatment.

The panel will then present cases in a discussion format to illustrate the current state-of-the-art in the treatment of scaphoid fractures, including acute fractures, non-unions, and SNAC wrist.

Analysis of the risk factors that determine composite graft survival for fingertip amputation

List of authors:
SuRak Eo*, GyeongHyeon Doh¹, KiYong Hong¹
¹Plastic Surgery, DongGuk University Medical Center (Goyang)

Objectives / Interrogation: The composite graft is the only surgical method that is able to maintain digital length and provide soft tissue coverage without donor site morbidities in microsurgically non-replantable fingertip amputations. This study aimed to explore the risk factors that determine the survival of composite grafts.

Methods: Clinical characteristics associated with graft survival were retrospectively analysed by a comparison between the graft survival and failure groups.

Results and Conclusions: Of 94 patients who underwent a composite graft for fingertip amputation, the graft survived in 84 (89%). Surviving grafts showed reperfusion within 1 week. Multivariate analysis revealed that graft failure was independently associated with a crushing injury. Based on the risk factors from the comparison analyses and a review of previously published studies, a cutting injury, grafting the injured finger within 5 hours of injury, and being a non-smoker are associated with good results.

In these circumstances, excellent outcomes with a high success rate can be achieved by composite graft in most adult patients as an alternative treatment to microsurgical replantation.

- This paper is in the process of publication on the J Hand Surg Eur Vol. -

Midterm outcome of costo-osteochondral graft reconstruction of proximal pole of scaphoid fractures

List of authors:
Wolfgang Heiss-Dunlop¹, Adam Durrant¹, Nadja Zechmann-Müller¹
¹Middlemore Hospital, Regional Hand Service (Auckland)

Objectives / Interrogation: We present the midterm outcome of patients that were treated for an irreparable proximal pole fracture of the scaphoid with a costo-osteochondral graft (rib graft). The surgical technique itself as well as our rational for the use of this technique are outlined.

Methods: A prospective non-randomised series of 30 consecutive patients with irreparable proximal pole of scaphoid fractures were treated with a rib graft reconstruction. The average follow-up was 25 months. All patients were male with an average age of 25 years.

Subjective outcome measures are Patient Rated Wrist Evaluate (PRWE) and Disability ARM Shoulder Hand (DASH) scores, objective outcomes include clinical range of motion and grip strength.

Post operative x rays were assessed for union and carpal alignment.
Complications are reported.

Results and Conclusions: We noted a statistically significant and clinically relevant improvement of the PRWE from 42 to 23 and of the DASH score from 33 to 16.

The grip strength, measured as percentage of strength of the uninjured arm, improved significantly from 63 to 84%. The average postoperative range of motion arc for flexion/extension was 114 degrees.

Radiologically we noted union of the graft in all but one patient. The scapholunate gap, created by the chondral portion of the graft was maintained in all patients. The capitolunate angle, as marker for carpal alignment, was 82 degrees (range 75-90).

There were no donor site complications noted, i.e. no pneumothorax after rib harvest. One patient needed revision to a four corner fusion for persistent pain due to poor graft quality.

In conclusion we found the cost-osteochondral graft reconstruction a reliable solution for an otherwise difficult problem. Standard salvage procedures remain an option for the patients in the future.

Proximal pole scaphoid fracture, rib graft, costo-osteochondral graft
OPEN CARPAL TUNNEL RELEASE WITH LOCAL ANESTHESIA: ISQUEMIA VS WALANT COMPARATIVE STUDY

List of authors:
José Joaquin Diaz*1, Juan José Cruz2, Ma. Francisca Vazquez2
1 IMSS UMAE LOMAS VERDES (NAUCALPAN DE JUAREZ, ESTADO DE MEXICO)
2 IMSS HOSPITAL DE TRAUMATOLOGIA Y ORTOPEDIA LOMAS VERDES (NAUCALPAN,ESTADO DE MEXICO)

Objectives / Interrogation: To evaluate the effectiveness and acceptability of the use of adrenaline as a mean to achieve hemostasis in open release of median nerve compared to the use of tourniquet in the arm.

Methods: Prospective, experimental, controlled, randomized study was made up of 50 participants; divided into two groups of 25 each. Group 1 operated with application of local anesthesia under transverse carpal ligament and with tourniquet (WT) and 25 with WALANT technique. In the WT, 2% lidocaine 10ml was injected, and in the WALANT 2% lidocaine plus epinephrine was injected at a concentration of 1: 200,000 in total of 10ml, below the dermis. Pain was measured at the time of anesthesia with the analogous visual scale, surgical time, amount of bleeding, heart rate, blood pressure and pulse oximetry, pre, trans and postoperative.

Results and Conclusions: RESULTS: The analysis of association by groups between the 2 kind of treatments showed significant differences in the heart rate (HR) pre, trans and postsurgical (p: 0.045, 0.001, 0.001, respectively), the other variables studied did not show significant p values , when associating the quantity of bleeding with the used methods, patients with WALANT obtained significantly higher values with respect to WT, when performing the correlation analysis in groups the relationship of bleeding with WALANT was lost, while patients wearing a tourniquet maintained a P < 0.05, showing a relative benefit. CONCLUSION: WALANT is a good alternative of anesthetic technique for the release of the median nerve, since it presents fewer complications, absence of pain by the tourniquet, without the need of an operating room for the procedure, support from a single assistant, short hospital stays, the patient stays awake during the surgery without pain, as well as, decrease in costs and increase in the benefits for the patient and the surgeon, being a simple, safe and effective anesthetic technique to achieve haemostasis in the surgical site.

Keywords: wide awake, hand surgery, local anesthesia, epinephrine, no tourniquet, carpal release
Role of arterial supply and venous drainage of fasciocutaneous pedicle in saphenous artery perforator-plus fasciocutaneous flap in rabbit

List of authors:
Jianwei Wei*, Zhonggen Dong1, Lihong Liu1, Ping Peng1, Zhaobiao Luo1, Chaodong Yin1
1 The Second Xiangya Hospital, Central South University (Changsha)

Objectives / Interrogation: Based on the models of saphenous artery septocutaneous perforator pedicled (SPP) flap and perforator-plus fasciocutaneous (SPF) flap in rabbit, the purpose of the present study is to illuminate the role of the fasciocutaneous pedicle in arterial blood supply and venous drainage of the perforator-plus fasciocutaneous flap, and provide experimental evidences for optimal application of both flaps during operation.

Methods: The flaps harvested in twenty legs of 10 New Zealand rabbits were randomly divided into 2 groups: the perforator group including saphenous artery perforator flap (n=10), and the perforator-plus group including saphenous artery perforator-plus fasciocutaneous flap (n=10). The blood perfusions in five zone of both flaps were measured using Laser Doppler flowmeter before operation, and 1h, 6h, 1d, 3d, 5d, 7d and 10d postoperatively. The survival rates of both flaps was measured at 7 days postoperatively. The flaps harvested in 50 legs of 25 rabbits were randomly divided into 5 groups: group A consisting of the SAP flap (n=10), group B consisting of the SAPPE flap (n=10), group C consisting of fasciocutaneous flap without the perforator (n=10), group D consisting of the fasciocutaneous flap with perforator artery but without the perforator vein (n=10), and group E consisting of the fasciocutaneous flap with perforator vein but without the perforator artery (n=10). The survival rates of these flaps was measured at 7 days postoperatively.

Results and Conclusions: The blood perfusions in five zones of the flaps were not statistically significant at every time point between perforator group and perforator-plus group (P>0.05). The survival rates of the SAP flap and the SAPPE flap were 94.0%±11.8% and 96.7%±6.9%, respectively (P>0.05). The survival rates of groups A, B, C, D and E were 86.5%±18.2%, 97.7%±4.6%, 32.8%±26.8%, 60.8%±38.4% and 51.2%±31.3%, respectively (P<0.05). The survival rate was higher in group A than in group C, in group B than in group C and group E, and these differences were not statistically significant (P>0.05). There is no statistically significant difference between other two groups (P>0.05).

Converting the SAP flap into SPF flap can not significantly improve both the survival rate and blood perfusion of the SAP flap. The perforator plays a key role in the survival of the SAPPE flap, and the fasciocutaneous pedicle plays a minor role. The fasciocutaneous pedicle is an approach for venous drainage in the SAPPE flap.

The clinical results of Kirschner wire fixation after closed reduction for Gertland type II and III supracondylar humerus fractures in children

List of authors:
Takanori Inoue*1, Daisuke Kaji1, Kenji Kawamura2, Keiichi Murata1, Hiroshi Yajima1, Yasuhito Tanaka2
1 Nara City Hospital (Nara)
2 Nara Medical University (Kashiwara)

Objectives / Interrogation: Supracondylar humerus fracture is the most common fracture around elbow in children. Closed reduction and percutaneous Kirschner wire fixation is a standard method of managing displaced extension type (Gartland Type II and Type III) supracondylar humerus fractures. In our hospital, we perform these operations as much as possible on the day of injury. We hypothesized that emergency operation for this fracture might bring more feasible results.

Methods: Twenty male and five female children injured with supracondylar humerus fracture were included in this retrospective study. The patients' age was averaged 6 (ranged 3-10) and the follow up period was averaged 20 months (ranged 3-56). 10 patients were distributed as Gartland type II and 15 patients were Type III. Percutaneous Kirschner wire fixation after closed reduction under general anesthesia was performed on the day of injury for 21 patients (emergency group) and on the following day for 4 patients (control group). Operations were performed in the spine position for 8 patients (group S) and in the lateral recumbent position using with the reduction bar for 17 patients (group L). We evaluated for the difference of operation time, carrying angle, forward tilting angle and Flynn's criteria at the time of final follow up between each groups.

Results and Conclusions: In previous reports, performing operation on the day of injury with supracondylar humerus fracture in children reduced complications such as compartment syndrome and facilitated the reduction. But there were no significant differences of these outcomes between emergency group and control group. There was a tendency that the average of operation time of group S was slight longer than that of group L. Forward tilting angle of group S was smaller than that of group L (p<0.05: statistically significant). Regarding to the Flynn's criteria, 22 patients were excellent, one patient in the control group was good and the other patients with neurological symptoms at the first visit were fair. We thought that there were some difficulties of the bending reduction for the fracture in the lateral recumbent position. Reduction bar would inhibit the bending reduction and this incomplete reduction might become the result of small tilting angle. An operation in the spine position is desirable if we aim at the more feasible flection. But the results of Flynn's criteria in the group L were almost excellent because the average of forward tilting angle was within the acceptable range.

Reconstruction of the Extensor Tendon of the Proximal Interphalangeal Joint (PIPJ) using a distally based slip of Flexor Digitorum Superficialis (FDS)

List of authors:
Karen Smith*, Shirley Collocott
1 Middlemore Hospital (Auckland)

Objectives / Interrogation: Objective
In 1971, H Graham Stack described a case report using a slip of FDS as a distally based tendon transfer to reconstruct the central slip of the extensor mechanism of the PIPJ. Essentially overlooked since then, this technique provides an excellent option for uncomplicated central slip reconstruction but can also be used, with more limited outcome, in more complex cases with extensor tendon or intrinsic muscle loss. We present a small prospective series of 6 patients who underwent this procedure.

Methods: Method
Six patients, identified as suitable for extensor tendon reconstruction with this technique were entered into the study.

The surgical technique was a modification of that originally described by H Graham Stack. Only one distally based slip of FDS was used; this being passed via a drill hole at the base of the middle phalanx to its dorsum, at the site of the original insertion of the central slip. The FDS slip was then woven (Pulvertaft weave) under appropriate tension, into the extensor mechanism over the proximal phalanx. A very strong repair was obtained allowing immediate protected mobilization

The six patients were prospectively reviewed.

Results and Conclusions: Results/Conclusions
Follow up averaged 18 months (3-48)

There were 4 patients who had central slip injuries of which one patient had multiple operations before his reconstruction procedure and one other had a simultaneous PIPJ release. Their mean gain in active extension was 73 degrees with a mean loss of 15.5 degrees of flexion.

In the 2 patients with major trauma, improvement was less; the active PIPJ extension gained was 28 and 21 degrees respectively with both patients each loosing 15 degrees of flexion; while seemingly a small net gain the improvement in arc of movement in these very injured fingers was thought to be, from the patient’s perspective, worthwhile.

In conclusion; this surgical technique provides a strong reconstruction suitable for early mobilization, with satisfactory early results. Better in simple central slip defects, the technique is robust enough to use in severe injuries, even those with loss of intrinsic function, but a more modest outcome should be expected

Smoking as risk factor for carpal tunnel syndrome: a birth cohort study

List of authors:
Sina Hulkkonen*, Juha Auvinen2, Jouko Miettunen2, Jaro Karppinen2, Jorma Ryhänen1
1 Helsinki University Hospital (Helsinki)
2 University of Oulu (Oulun yliopisto)

Objectives / Interrogation: The aim of this study was to determine whether smoking is associated with carpal tunnel syndrome (CTS) from two perspectives: if maternal smoking and offspring's own smoking affect the offspring's risk for CTS.

Methods: The study sample consisted of the Northern Finland Birth Cohort 1966 (N=8703). Prenatal data collected from mothers at 24 to 28 weeks of gestation and 31-year follow-up data were used, combined with data for hospitalization due CTS from the Finnish Care Register for Health Care during follow-up from 1997 to 2016. Hazard ratio (HR) with 95% confidence intervals (CI) and population attributable risk (PAR) for smoking was calculated and adjusted for body mass index and socio-economic status.

Results and Conclusions: During the follow-up between 1997 and 2016, altogether 308 participants were diagnosed with CTS.

Basic demographic features of the study population stratified by gender.

Maternal smoking was not associated with increased risk of CTS in offspring. Offspring's own smoking was associated with elevated risk for CTS, especially in women. Before the age of 31 years, regular smoking of ten or less pack years (HR=1.51, 95% CI=1.09-2.10) and over ten pack years (HR=1.82, 95% CI=1.15-2.89) among women and over ten pack years (HR=1.93, 95% CI=1.16-3.21) among men was associated with increased risk for CTS compared to non-smokers. PAR for smoking was 13.9% for men and 20.9% for women.
In this birth cohort study, we found that maternal smoking was not, but offspring's own smoking was, associated with elevated risk for CTS.

⁴ Department of Orthopaedic Surgery, Hokkaido University Graduate School of Medicine (Sapporo, Hokkaido)
⁵ Department of Orthopaedic Surgery, Yokohama City Minato Red Cross Hospital (Yokohama, Kanagawa)
⁶ Department of Orthopaedic Surgery, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (Tokyo)
⁷ Department of Orthopaedic Surgery, Chiba University School of Medicine (Chiba)
⁸ Department of Orthopaedic Surgery, Sapporo City General Hospital (Sapporo, Hokkaido)

Objectives / Interrogation: Pathological lesions of the elbow are often complicated by ulnar neuropathy at the elbow (UNE); however, detailed pathological and neurological features of these lesions remain unidentified. We investigated the elbow pathology and neurological severity of UNE in Japanese patients.

Methods: We retrospectively examined the medical records of 457 patients aged 15 years or more who were diagnosed with UNE and surgically treated by certified hand surgeons between 2000 and 2012 at six participating institutions. UNE of eligible patients were diagnosed by physical findings and nerve conduction studies. Elbows were analyzed for age, gender, occupation, elbow pathology, entrapment site of the ulnar nerve, and severity of nerve palsy.

Results and Conclusions: A total of 413 UNE elbows in 398 patients with a median age of 63 years (range: 15-87) were included. UNE elbows were predominantly male (69%). Of 310 elbows, 75% had 1 or more lesions: single lesion, 238 elbows (77%); 2 or more lesions, 72 elbows (23%). Common lesions were as follows: primary elbow osteoarthritis (EOA), 55% of elbows; medial elbow ganglion, 9%; cubitus valgus, 7%; dislocation of the ulnar nerve, 6%; prior elbow trauma, 3%; cubitus varus, 2%. Medial elbow ganglion and cubitus valgus or varus were generally associated with EOA (91% and 67%, respectively). UNE with primary EOA exhibited older age, higher prevalence of manual laborers and severe ulnar nerve palsy, and longer symptom duration compared to those with no lesion. Common entrapment sites were: cubital tunnel, 86%; medial epicondyle, 5%; deep flexor pronator aponeurosis, 4%; medial intermuscular septum, 2%. Incidences of primary or secondary EOA and severe motor weakness (McGowan grade III) were 62.2% and 47.2% in this study, respectively; in contrast, 9.5 to 19.7% and 15.0 to 26.4% have been previously reported for the Caucasian population, respectively.

Conclusions: This study showed that 75% of UNE had isolated or combined pathological lesions, and 85 to 90 % of UNE had an entrapment site at the cubital tunnel regardless of the lesion. In Japanese patients, EOA was highly associated with UNE, and clinical features of UNE with EOA differed from UNE with no lesion. In contrast to Caucasians, the UAE of Japanese patients showed high incidences of EOA and severe ulnar nerve palsy.

Radioscapholunate Fusion following Resection of Giant Cell Tumours of the Distal Radius

Objectives / Interrogation:
The objective of this study was to review the oncologic and functional outcomes of patients who underwent en bloc resection of distal radius giant cell tumours followed by radioscapholunate fusion with either a vascularised or non-vascularised bone graft.

Methods:
A retrospective review of patients with tumours of the hand and upper extremity that were treated at our institution from 2010 to 2018 was conducted. Patients with giant cell tumours of the distal radius that had undergone en bloc resection of the distal radius, and had reconstruction with either vascularised fibular graft or non-vascularised iliac crest bone graft and radioscapholunate fusion were selected for this study. The oncologic outcomes that were assessed were the presence of local and distant recurrence. Functional outcomes were assessed after patient's function had stabilised (more than one year after surgery) using the Musculoskeletal Tumor Society (MSTS) rating score of limb salvage and Short Form (SF)-36 scores.

Results and Conclusions:
5 patients were identified (1 male, 4 female). 3 presented with primary tumours, while 2 presented with recurrent tumours. Median age at the time of presentation to our centre was 35 years (range, 23 to 47 years). The 3 patients with primary disease had Campanacci Grade 3 disease. None had distant metastases at the time of surgery.

After a median follow up of 4 years (range, 4 months to 5 years), none of the patient had developed local or distant recurrence. One patient developed a peri-implant fracture requiring repeat fixation, while another developed complex regional pain syndrome that resolved with medication and aggressive hand occupational therapy. MSTS and SF-36 scores were available for the 3 patients that were more than 1 year post-op. The mean MSTS score was found to be excellent at 91.3% (range 86.7% to 96.7%) and the mean SF-36 score was 70.3% (range 59.5% to 78.5%). Assessment of range of motion of the affected wrist at mid-carpal joint revealed an average of 34.3 degrees (range 0° to 60°) of palmar flexion, 41.7° (range 40° to 45°) of dorsiflexion, 81.7° (range 65° to 90°) of supination and 78.3° (range 60° to 90°) of pronation.

Conclusion
En bloc resection and radioscapholunate fusion is a viable treatment option for patients with large and / or recurrent giant cell tumours of the distal radius.

Patient that had tendon transfers under WALANT

Author (1) was the lead surgeon for all cases. We present our injection method for each of these procedures.

All transfers were performed with 2.0 or 3.0 braided non absorbable suture using the side to side tendon weave as per Jan Friden. A temporary stay suture was placed for each transfer and passive tenodesis was used to check the tension. The patient was then asked to use the transfer muscle in order to check the tension. In a number cases, although the passive tenodesis tension appeared satisfactory the tension needed to be readjusted after assessment of active motion as tenodesis may not always be accurate for setting the tension.[1]

All patients were referred for early protected active mobilization. We present our outcomes based on patient satisfaction (questionnaire) and complications.

Results and Conclusions: One of our patients developed a wound breakdown due to postoperative infection that required surgical debridement. However his transfer was not compromised and his wound eventually healed. Another patient suffered a rupture of the transfer (ECRB to Adductor pollicis using PL graft) 11 weeks post surgery. All patients were very happy to see the outcome of their procedure on the table and this reassured them about their outcome. Also, rehabilitation was started on the table as patients were taught how to fire the transfers during surgery. No patient required sedation during surgery.

From a surgeon's perspective, the ability to witness the tension of the transfer during active range of motion was invaluable, making WALANT our preferred method of anaesthesia for carrying out tendon transfers. Conclusion: WALANT is a safe method of anaesthesia for tendon transfer surgery and if a surgeon is proficient in administering it, then the benefits of active motion can lead to good outcomes and increased patient reassurance and satisfaction.

Mutational spectrum and targeted therapy for isolated macrodactyly

List of authors:
Hengqing Cui*, Gang Han¹, Bin Wang¹
¹ Shanghai 9th People's Hospital, Shanghai jiaotong University (Shanghai)

Objectives / Interrogation: Macrodactyly is a congenital condition characterized by continuous overgrowth of fingers or toes. It is a symptom of PIK3CA-related overgrowth spectrum (PROS), which is caused by mosaic somatic mutation of PIK3CA gene. This study aimed to reveal the mutational spectrum and the targeted drug sensitivity of isolated macrodactyly.

Methods: We included 52 patients diagnosed with isolated macrodactyly from June 2014 to August 2018 in our hospital. Genomic DNA were prepared from different tissues including adipose, skin, bone, nerve, tendon, and vessel of surgically debulked or amputated macrodactylous digits. All exons of PIK3CA were PCR-amplified and sequenced by Sanger sequencing. Clinical manifestations of the patients were recorded. Adipose-derived stem cells from 9 patients with macrodactyly and 3 patients with polydactyly were isolated and cultured. The half maximal inhibitory concentration (IC 50) of rapamycin and BYL719 for these cells were determined.

Results and Conclusions: PIK3CA mutations were detected in 90.4% (47 in 52) of the patients in our cohort of isolated macrodactyly. These mutations clustered into three hotspots, p.His1047Arg (46.2%, 24/52), p.Glu542Lys (17.3%, 9/52), and p.His1047Leu (9.6%, 5/52), which differed from that was found in PROS. Mutations were detected in all tissue types including adipose, skin, bone, nerve, tendon and vessel, irrespective of the overgrown phenotype. Interestingly, the PIK3CA inhibitor BYL719, but not the mTOR inhibitor rapamycin, displayed lower IC50 for macrodactylous adipose-derived stem cells than normal adipose-derived stem cells, indicating selective inhibition of macrodactylous cells. In conclusion, through investigation of the largest cohort of isolated macrodactyly up to date, we revealed a unique mutational spectrum of this condition that differed from other PROS. Moreover, all tissue types in macrodactylous digit could serve as a DNA source for mutation detection. Finally, BYL719 was a potential selective drug for suppression of the overgrowth of the macrodactylous digit. This study will shed light on genetic diagnosis and targeted therapy for isolated macrodactyly.

Concurrent endoscopic carpal tunnel release and volar locking plate osteosynthesis for distal radius fractures

List of authors:
Junichiro Shibuya¹, Masatoshi Takahara², Mikiro Kondo², Daichi Ohta², Hiroshi Satake³, Michiaki Takagi¹
¹ Yamagata University (Yamagata-city)
² Izumi Orthopaedic Hospital., Center for Hand, Elbow and Sports Medicine (Sendai-city)

Objectives / Interrogation: Carpal tunnel syndrome (CTS) is a common complication associated with distal radius fractures (DRFx). We performed a median nerve electrodiagnostic study before surgery. In addition, we have undergone endoscopic carpal tunnel release (ECTR) in the same setting as open reduction and internal fixation (ORIF) of the radius fractures, on the following cases who is developing CTS or is potentially present CTS. The purpose of this study was to report the outcome of ECTR concurrent with osteosynthesis for DRFx.

Methods: We retrospectively reviewed 10 (mean age, 65 years; 80% women) patients treated with DRFx between 2011 and 2015. Radiographs showed the following distribution in the AO/OTA classification system: one case of type A3, one case of C1, four cases of C2, and four cases of C3. The case of type A3 was an open fracture. We performed ECTR in the same setting as ORIF using a volar locking plate for DRFx. The clinical examination served to collect data on presence of numbness, preoperative abductor pollicis brevis-distal latency (APB-DL), range of motion at the final examination, radiographic evaluation, and complications. Average follow-up period was 7.7 months (range, 3-24 months).

Results and Conclusions: Eight of the 10 patients preoperatively complained the numbness of the affected hand. The preoperative APB-DL of the affected side was 5.1 (3.5 to 7.1) msec. We preoperatively diagnosed Four patients were preoperatively diagnosed to have CTS before the injury, four patients as acute onset CTS, and two patients as asymptomatic CTS on the basis of delayed APB-DL > 6.0 msec. Mean range of motion at the final follow-up was as follows: forearm 79° pronation/77° supination, and wrist 57° palmar flexion/62° dorsal flexion. The final radiographic measurements averaged 14 degrees of volar tilt, 24.7 degrees of radial inclination, and 1.3 mm of ulnar-positive variance. We confirmed 4 trigger digits as a complication. However, there were no numbness recurrence, CTS onset, or other complications. Concurrent ECTR in distal radius ORIF using a volar locking plate was efficacious and safe.

Volar Plating of Distal Radius Fractures: Comparison of the Functional Outcomes of the Pronator Quadratus Muscle Repair, Non-repair, and Preserving Techniques

List of authors:
Ja Hea Gu¹, Jong-Pil Kim¹*, Jae-Uk Jung¹
¹ Dankook University (Cheonan)

Objectives / Interrogation: To demonstrate how the pronator quadratus(PQ) muscle function is affected in terms of forearm pronation after volar plating of distal radius fracture with PQ preservation and whether clinical outcomes would be affected by any pronation strength decrease compared to conventional technique.

Methods: A randomized controlled prospective study was performed by gathering data from all sixty-six patients treated with volar locking plate fixation for distal radius fractures divided into three groups: Group 1 with PQ preserving, Group 2 with PQ repair after splitting, and Group 3 with PQ non-repair after splitting. Clinical outcome measurement included the visual analogue scale(VAS), the disability of the arm, shoulder and hand(DASH) score, the patient-rated wrist evaluation(PRWE) score, range of wrist motion, grip strength at 12, 24, 48 weeks after surgery, and the isokinetic force of forearm pronation strength at 48 weeks after surgery. Radial height, radial inclination, ulnar variance, and palmar tilt were measured on wrist radiographs which takes immediately after surgery and at last follow-up for the radiologic outcomes.

Results and Conclusions: At 12 weeks after surgery, the average grip strength was 34.5±18.43N in group 1, 45.5±21.57N in group 2, and 31.91±15.4N in group 3.(P=0.043) At 24 weeks after surgery, the average extension was 71.32±11.94º in group 1, 79.91±6.49º in group 2, 73.05±12.56º in group 3.(P=0.031) Radial deviation was 19.55±4.21º in group 1, 22.91±6.49º in group 2, 17.95±5.46º in group 3.(P=0.012) Ulnar deviation was 26.55±6.1º in group 1, 31.14±4.86 in group 2, 27.36±6.97 in group 3.(P=0.033) The average grip strength was 42.23±21.62N in group 1, 60.23±23.68 in group 2, 47.45±21.97 in group 3.(P=0.029) At 48 weeks follow up, the average PRWE score was 16.82±23.06 in group 1, 11.68±14.90 in group 2, 31.77±30.49 in group 3.(P=0.018) Radiologic parameters were no statistically difference among the three groups. There were no complications such as complex regional pain syndrome(CRPS), post-traumatic arthritis, malunion, nonunion, delayed union, and reduction loss. PQ preservation with volar plating in distal radius fracture does not have benefit of forearm pronation strength, clinical and radiologic outcomes. Instead of preservation, pronator quadratus muscle repair is suggested when volar plate fixation is done in distal radius fractures.

THE CHIMERIC SUPERFICIAL CIRCUMFLEX ILIAC ARTERY PERFORATOR FLAP IS AN EFFECTIVE OPTION FOR RECONSTRUCTION OF OSTEOCUTANEOUS DEFECTS OF THE HAND OR FOOT

List of authors:
Hong Chen*, Jiadong Pan¹, Xin Wang¹, Yaopeng Huang¹, Miaozhong Li¹
¹Ningbo Sixth Hospital (Ningbo)

Objectives / Interrogation: Osteocutaneous defects of the hand or foot often necessitate multiple donor sites to address soft tissue and bony defects. We believe that a single chimeric perforator flap based on the superficial circumflex iliac artery (SCIA) is a reliable option for effective reconstruction of osteocutaneous defects of the hand and foot.

Methods: A retrospective review of all patients with osteocutaneous defects of the hand or foot reconstructed with a chimeric SCIA perforator (cSCIP) flap were included in this study. The SCIA is the common pedicle in the cSCIP flap which contains a perforator to skin and another vascular branch to the iliac crest. Demographic information, soft tissue defect size and location, bony defect size, chimeric flap size, and post-operative complications were collected. Success of soft tissue coverage and bony union were the primary outcome measures.

Results and Conclusions: A total of 15 patients were reviewed with a mean follow of 14 months (8-21 months). Average skin defect size was 27.8cm² (4.8-91.0 cm²) and average bony defect length was 3.35 cm (1.5-6.2 cm). In the cSCIP flap, average bone length was 3.40 cm (2.0-6.5 cm) and average skin area was 34.7 cm² (6.4-105.0 cm²). Bony union was successful in 13/15 of the cases at an average of 11.5 weeks (8-16 weeks) with the remaining two patients requiring second stage non-vascularized ICBG. 14/15 patients had complete flap survival. The remaining patient required a secondary skin graft for partial superficial necrosis. Donor site morbidity for the cSCIP flap is minimal and similar to that of non-vascularized ICBG harvest and groin flap. With a single stage procedure, the cSCIP flap provided successful soft tissue coverage and bony union in 93.3% and 86.7%

Keywords:
perforator flap; osteocutaneous defect; superficial circumflex iliac artery
Reconstruction both of hand and donor foot with a variety of wrap around flaps and free perforator flaps respectively

List of authors:
Xin Wang*, Jiadong Pan¹, Yaopeng Huang¹, Weiwen Zhang¹, Hong Chen¹
¹ Ningbo sixth Hospital (Ningbo)

Objectives / Interrogation: Objective To explore the surgical indications, techniques and curative effects of both hand and donor foot reconstruction with different types of big toe wrap-around flap and free perforator flap.

Methods: From February 2012 to October 2017, 102 fingers in 65 cases were reconstructed. A variety of wrap around flaps and perforator flaps were designed and transferred to reconstruct the hands and donor feet respectively. Single thumb reconstruction: I degree (11 fingers in 11 cases), II degree (25 fingers in 24 cases), III degree (5 fingers in 5 cases). Fingers reconstruction including thumb: two fingers (12 fingers in 5 cases), three fingers (12 fingers in 4 cases), four fingers (8 fingers in 2 cases). Fingers reconstruction except thumb: single finger (5 fingers in 5 cases), two fingers (6 fingers in 3 cases), three fingers (18 fingers in 6 cases). Secondary foot skin or bone defect: repaired with perforator flap (49 cases) or chimeric superficial circumflex iliac artery perforator flap (16 cases).

Results and Conclusions: Result All reconstructed fingers survived at last. Most of flaps for foot repair survived except partial necrosis in 3 cases and complete necrosis in 1 case. The follow-up ranged from 5 to 28 months. According to evaluation criteria from Chinese Medicine Association for hand surgery: excellent in 47 cases, good in 18 cases. According to the Maryland foot function score standard: excellent in 52 cases, good in 13 cases. Conclusion These described procedures can not only get the excellent outcome of reconstructed fingers based on minimal morbidity in the donor site but also provide a new treatment option for degloving hand that need multiple fingers reconstruction.

Short to mid-term result of Pyrocarbon implant in the TMC 1 joint for osteoarthritis

List of authors:
Allan Ibsen Sorensen\textsuperscript{1}, Anders Nilsson\textsuperscript{1}
\textsuperscript{1} Sahlgrenska University Hospital (Gothenburg)

Objectives / Interrogation: The aim of the study is to present short to mid-term results of a Pyrocarbon implant (Pyrocardan) in the trapeziometacarpal joint (TMC).

Methods: A pyro-disc was used as a spacer in the TMC joint between first metacarpal bone and trapezium bone to treat osteoarthritis. Minimal resections performed of the base of first metacarpal and trapezium bone. A cast was used for 4 weeks, and then unloaded rehabilitation of exercises in 3 weeks followed by 3 weeks with gradually loading. Heavy load was allowed 12 weeks postop.

All patients were evaluated preop, 6, 12 and 26 weeks postoperatively and then yearly with ROM, grip strength, pinch, key-pinch, VAS scores for pain, Quick-DASH and patients satisfaction. X-Ray performed preop, 3 months postop and thereafter yearly.

Thirty-six patients were operated 18 men and 18 women. Median age 59 years (45-79). Four additional operations of IP and or MP1 joint and seven on wrist or hand. One patient operated later with arthrodesis in MP1 joint in same thumb. Mean values are used.

Results and Conclusions: Follow-up was 21 months (range 3-52). Radial abduction/palmar abduction was preop 38/39 degrees and at follow-up 40/40. Thumb opposition was .5 cm (0-3.0) versus .7 (0-6.0) Last follow-up (LFU) (P=NS). Grip strength in KgF preop was 22 (range 1-76) and at LFU 24 (7-69) (P=NS). Pinch/key-pinck (Kg) preop were 4.3/3.4 and at LFU 4.5/5.1 (P=NS). VAS pain (mm) was preop at rest/activity: 47/78 and at LFU: 20/35 (P<.01). Quick DASH preop; 52 (16-86) and at LFU; 33 (0-86) (p<0.01). Satisfaction (mm of 100) preop: 17 (0-94) was improved at LFU: 71 (0-100) (p<0.01). Radiographic migration occurred in two implant but it was not dislocated.

No infection. Four implants were revised, two to tendon interposition arthroplasty and two to change of the size of the implant and MiniTightRope joint stabilization. One MiniTightRope joint stabilization were performed due to instability.

Short to mid-term results with a pyrocarbon implant in the TMC joint concerning pain, Quick-DASH and patient satisfaction are favorable. Change of other outcome data were non-significant. Longer follow-up and a larger series of patients operated on with this implant is needed.

Vascularized Thumb Metacarpal Periosteal Flap for Scaphoid Nonunion in Adolescents: An Anatomical Study and Prospective Cohort Study of 16 Patients

List of authors:
Sergi Barrera-Ochoa*, Gerardo Mendez-Sanchez, Alfonso Rodriguez-Baeza, Xavier Mir-Bullo, Jorge Knörr, Jayme Augusto Bertelli, Francisco Soldado
1 ICATME; Hospital Quirón-Dexeus, Hospital Sant Joan de Deu (Barcelona)
2 ICATME; Hospital Quirón-Dexeus (Barcelona)
3 Universitat Autònoma Barcelona (UAB) (Barcelona)
4 ICATME; Hospital Quirón-Dexeus, Universitat Autònoma Barcelona (UAB) (Barcelona)
5 Hospital Sant Joan de Deu (Barcelona)
6 Governador Celso Ramos Hospital, University of the South of Santa Catarina (Florianópolis, Santa Catarina)

Objectives / Interrogation: Through an anatomical review, the primary aim of this study was to delineate the dorsal thumb metacarpal (TM) periosteal branches of the radial artery (RA). In addition, we report here the clinical and radiological outcomes of a vascularized TM periosteal pedicled flap (VTMPF), supplied by the first dorsal metacarpal artery (FDMA), in a cohort of scaphoid nonunion in an adolescent.

Methods: Ten latex-colored upper limbs from fresh human cadavers were used. Branches of the RA were dissected, noting the periosteal, muscular, and cutaneous branches arising from the FDMA and the radial branch (RB) of the first dorsal intermetacarpal artery (FDIA).

Sixteen patients under age 18 years with scaphoid nonunion, who underwent a VTMPF procedure without bone grafting, were included for this prospective cohort study at a mean follow-up of 10.9 months. Patients were operated on by three different hand surgeons at three hand surgery institutions. All patients received a VTMVF, but with different scaphoid internal fixation modalities, in 14 cases using one or two retrograde 2mm headless compression screws and in 2 cases were not required stabilization.

Results and Conclusions: The FDMA provided a mean 12 periosteal branches (range 9 to 15), and the RB of the FDIA provided a mean five periosteal branches to the dorsal aspect of the TM (range 4-7).

In 13 boys and 3 girls, the mean age was 16.2 years. There were two type D1 nonunions (Herbert classification), six type D2, five type D3, and three type D4. Seven patients previously had undergone an unsuccessful surgical attempt to treat their nonunion. The mean anterior bone defect was 3 mm in length. The patients experienced no postoperative complications. Successful consolidation was achieved in all cases, with 82% cross sectional trabecular bridging at 12 weeks. Pain subsided after surgery and patients experienced improvements in both their QuickDASH and MMWS scores. Overall 34% and 40% gains in strength and wrist motion, relative to the contralateral normal side, were observed. At final follow-up, there were differences between the preoperative versus postoperative hand in wrist range of motion, or either grip or pinch strength.

Conclusions: In this study, the use of VTMPF for scaphoid nonunion in children and adolescents is associated with general good outcomes.

Clinical studying on the reconstruction of extremity skin defect by free ilio groin skin flap

List of authors:
Weiwen Zhang*, Jianwu Qi1, Xin Wang1
1 Ningbo sixth Hospital (Ningbo)

Objectives / Interrogation: To investigate the clinical effect of free iliogroin flap in repairing soft tissue of extremities and combining bone defect.

Methods: From January 2010 to June 2017 75 cases performed with free iliogroin flap to repair skin and soft tissue defect of extremities, including 42 cases of superficial circumflex iliac artery flap (13 with ilium superficial circumflex iliac artery flap, superficial 18 were epi gastric artery flap, 15 cases of superficial circumflex iliac artery and the superficial epigastric artery combined the flap (lobulated flap in 7 cases). 49 cases of hand and skin soft tissue defects were repaired, 26 cases of skin and soft tissue defects were repaired, 18 cases were toe reconstruction, and the smallest area was 5.0 cm *7.0 cm, the largest was 11.0 cm * 23.0 cm. All repair superficial circumflex iliac vein or superficial circumflex iliac vein (21 cases of repair and a concomitant vein). The donor site is directly sutured through flexion and hip flexion. The occurrence of arteriovenous crisis and the principle of treatment were observed within 1 weeks after the operation. After 3 weeks, 1.5 months, 3 months, 6 months, 1 years and 2 years follow-up, we observed the healing of the donor site and the appearance and sensory recovery of the skin flap, and summarized the clinical application characteristics and experience of the flap.

Results and Conclusions: In 75 cases of skin flap, 72 cases survived smoothly, 1 cases had arterial crisis, 2 case had venous crisis, and skin necrosis occurred after conservative treatment. After two stage eschar, subcutaneous soft tissue survived and skin graft survived. A flap cut was removed after a week straight walk for area after two incision dehiscence and suture after healing, healed more than. After 0.5 - 1.5 years of follow-up, the skin was soft, mild and bloated, and the sensation recovered S2-S3, and the line scars in the abdominal donor area were small. The use of free iliac inguinal flap transplantation to repair skin and soft tissue defects of extremities is an axial skin flap. It has a constant blood vessel and easy cutting. It does not damage main vessels. The operation time is short, the flap is large, the donor area can be directly sutured, and the scar is small and hidden. It is one of the better methods to repair the soft tissue defects of the extremities.

The clinical application of type I venous flap of volar forearm in complicated replantation of fingers

To evaluate the clinical curative effect of the type I venous flap transplantation of volar forearm for complicated digital replantation.

List of authors:
Bin Zhu*, Jian Zhang¹, Xin Wang¹, Hong Chen¹, Jiadong Pan¹, Miaozhong Li¹
¹ Ningbo Sixth Hospital (Ningbo)

Objectives / Interrogation: To evaluate the clinical curative effect of the type I venous flap transplantation of volar forearm for complicated digital replantation.

Methods: From May 2009 to June 2016, 8 cases with 12 fingers who underwent digital replantation using type I venous flap of volar forearm for flow-through dorsal veins of finger and covering soft tissue defects, 5 cases were male, 3 female; age 22 to 58 years (mean age 34.3 years) of follow-up observation, observing the postoperative changes of blood supply of the venous flaps and digital replantation. The process of flap survival and contracture of survived flaps.

Results and Conclusions: 8 cases with 12 fingers of replantation were survived without venous crisis, but 2 cases with 3 fingers had arterial crisis. The color of the all venous flaps were reddish with capillary reflux slowly in 1 day after operation. Then superficial skin exfoliating and formatting blisters. Eventually the wound of flaps healing and the flaps survived completely with an average of 28.5 days after surgery (18-36 d). No venous reflux disorder, swelling and congestion of the flaps during the healing procedure. Flap survived without obvious contracture and did not affect the joint flexion.

The type I venous flap of volar forearm can simultaneously flow-through the dorsal veins of fingers and repair the wound. It is suitable for finger replantation with soft tissue defect of the dorsum of fingers and hand.

Salvaging the Congestion or Stasis Compromised Free Perforator Flaps based on a new classification

List of authors:
Jiadong Pan*, Xin Wang
1 Ningbo 6th hospital (Ningbo)

Objectives / Interrogation: To investigate the causes and classification of the congestion or stasis free perforator flap.

Methods: 187 compromised flaps were found in 1236 patients receiving the free perforator flap transfer, and divided into four types based on the size, the characteristics and the progress of ecchymosis which showing on the surface: Type 1 had no ecchymosis. Type 2 had slowly enlarged ecchymosis in a small area. Low perfusion was type 3. Type 4 had a high flap tension with larger ecchymosis size and deeper color in a short time. According to this classification, there were 37 cases in type 1, 68 in type 2, 39 in type 3, 43 in type 4. The conservative treatments such as dressing change, removal of stitches, bleeding with small incisions, local flap massage and thrombolysis were applied to 109 cases including 37 in type 1, 68 in type 2, 4 in type 3. The other 78 cases underwent surgical revision including 35 in type 3 and 43 in type 4. After exploration, 35 in type 4 (44.9%, 35/78) were venous obstruction, 29 (37.2%, 29/78) in type 3 due to artery occlusion, and 14 (17.9%, 14/78) consisting of 8 in type 4 and 6 in type 3 were both of arterial and venous obstruction.

Results and Conclusions: After conservative treatment, 94 (86.2%, 94/109) flaps survived, 13 (12%, 13/109) were partial necrosis, and 2 (1.8%, 2/109) complete necrosis. After surgical revision, 29 cases (82.9%, 29/35) were venous obstruction, 17 (58.6%, 17/29) were arterial cause and 8 (57.1%, 8/14) because of both vessel problem survived finally. Partial necrosis were 4 (11.4%, 4/35), 3 (10.4%, 3/29) and 4 (28.6%, 4/14) respectively. Complete necrosis were 2 (5.7% 2/35), 9 (31%, 9/29) and 2 (14.3%, 2/14). 132 patients (70.6%, 132/187) were followed up from 3 to 21 months. The texture and color of the fully salvaged flap is similar to the non-crisis flap, but it looks like tougher and darker in the partial salvaged flap. Conclusion The stasis and congestion of venous blood in the flap always led to flap necrosis, which may result from either low artery perfusion or poor venous backflow. The clinical classification is objective and easy to observe, which contribute to an early accurate diagnosis and treatment for the compromised flap. The conservative methods are mainly used to save the crisis flap in type 1 or 2, and for the cases in type 3 or 4, the surgical revision is a preferred choice.

Transplanting the posterior interosseous artery perforator lobulated flap to repair soft tissue defect on fingers

List of authors:
Xin Wang¹, Hong Chen¹, Xiaoming Cai¹, Weiwen Zhang¹, Jiadong Pan¹
¹Ningbo sixth Hospital (Ningbo)

Objectives / Interrogation: To explore the surgical method of applying the lobulated flap designed on the polyfoliate posterior interosseous artery perforator (PIAP) to repair the soft tissue defect on fingers and report the clinical outcome.

Methods: From Aug 2011 to Feb 2015, there were 12 patients suffered with soft tissue defect on fingers, repaired with PIAP flaps through anastomosing one group vessel with perforator. All wounds of donor site were closed primarily.

Results and Conclusions: All flaps of 12 cases survived. The clinical results were satisfactory after 3-15 months of following-up. The TAM was 150°-265° (contralateral, 255°-270°).

The use of applying the PIAP lobulated flap to repair the soft tissue defect on fingers is a functional, feasible and effective treatment method.

posterior interosseous artery, lobulated, perforator flap, soft tissue defect
The application of Freestyle concept in anterolateral thigh flap with oblique branch

List of authors:
Hong Chen*, Haoliang Hu³, Xueyuan Li³, Xin Wang³, Jiadong Pan³, Weiwen Zhang³
³ Ningbo Sixth Hospital (Ningbo)

Objectives / Interrogation: To explore the feasibility and clinical effect of freestyle concept in the anterolateral thigh flap with oblique branch repairing the soft tissue defect of extremities.

Methods: Twelve patients with soft tissue defects in extremities were repaired using anterolateral thigh flaps with oblique branch from January 2015 to December 2017. The distance of perforator through the muscle was greater than 8.0 cm. The flaps were harvested based on freestyle concept. End-to-side anastomosis or end-to-end anastomosis was performed, posterior tibial artery end-to-side anastomosis in 3 cases, posterior tibial artery branch end-to-end anastomosis in 2 cases, anterior tibial artery end-to-side anastomosis in one case, anterior tibial artery branch end-to-end anastomosis in one case, radial artery end-to-side anastomosis in 3 cases, and radial artery branch end-to-end anastomosis in 2 cases. The flap size ranged from 10 cm × 6 cm to 18 cm × 9 cm. The donor sites were closed directly for 9 cases and skin grafting for 3 cases.

Results and Conclusions: 11 cases survived uneventfully, one case suffered from arterial congestion, which was solved by reoperation. All of the patients were followed-up 1 to 12 months, average of 5 months. All flaps showed good texture matches and contour. When patients are repaired using anterolateral thigh flaps with oblique branch, the distance of perforator through the muscle is longer, the flaps can be harvested based on freestyle concept and end-to-side anastomosis or end-to-end anastomosis can be performed, good clinical effect can also be achieved.

Early internal fixation combined with free flaps for the treatment of Gustilo type IIIB forearm open fractures with soft tissue defects

List of authors:
Yongjun Rui*, Ming Zhou
1 Wuxi Ninth People’s Hospital (Wuxi City)

Objectives / Interrogation: To investigate the clinical therapy of early internal fixation combined with free flaps for Gustilo type IIIB forearm open fractures.

Methods: A retrospective study was conducted of the 15 patients with Gustilo type IIIB forearm open fracture who had been treated from July 2014 to July 2017 at our department. They were 10 men and 5 women, aged from 22 to 68 years (average, 45.5 years). AO classification: type A 4 cases, type B 9 cases, type C 2 cases. Primary internal fixation and second-stage perforator flaps transfer 11 cases, second-stage internal fixation and flaps transfer 4 cases; all the 15 patients received free flap transplantation, site of the defect: 4 cm×8 cm~8 cm×33 cm. The period between injury to second-stage flap transplantation was 4~28 days (average, 10.2 days). There were all anterolateral thigh perforator flaps.

Results and Conclusions: All the 15 cases of free flaps were survived with no deep infection and osteomyelitis. 4 cases had superficial infection at wound. Partial necrosis happened at the distal end of 2 cases and healed with skin grafts. 1 anterolateral thigh perforator flap encountered vascular complication which survived with 3 cm-in-width skin necrosis at the distal end of the flap after successful surgical exploration. All the patients were follow-up for 12~36 months (average, 18.5 months). All the flap texture was soft, with varying degrees of pigmentation. The sensory recovery of flap was S2 in 2 cases, S3 in 10 cases, S4 in 3 cases. Bone union time ranged from 4 to 14 months (average, 8.6 months), 2 cases of nonunion were treated with autologous iliac bone grafting 8 months after operation. The curative effect was evaluated by Anderson standard: 10 cases were excellent, 3 cases good, 1 cases better and 1 cases poor. Conclusion It is an effective strategy to treat the Gustilo type IIIB forearm open fractures with soft tissue defects by early internal fixation combined with free flaps transfer, which has advantages of shorten the treatment period, recovering exercise early, decrease complications, and satisfactory function.

1 Ningbo sixth Hospital (Ningbo)

Objectives / Interrogation: Objective To introduce indications of palm replantation with degloved or avulsed skin and recovery of hand function

Methods: from June 2011 to January 2015, 10 patients with severed palm with degloved or avulsed skin were treated by replantation. All patients were followed up 8 to 36 months with an average of 14.5 months. In all patients with rigid internal fixation and exquisite soft tissue repair, the functional exercise were performed in early stage after operation.

Results and Conclusions: 10 patients with severed palm were all survived without any postoperative infection. All fractures healed after follow-up of 6–10 weeks with an average of 8 weeks. 8 patients took plate removal and Myotenolysis. According to evaluation standard of upper limb replantation function posposed by Chinese Medical Association, 5 cases got excellent results, 4 good and 1 poor and good rate is 90 percent.

Improving Functional and Aesthetical Result of Radial Forearm Flap

List of authors:
Giovanna Petrella\(^1\), Roberto Adani\(^2\)
\(^1\) Hand and Microsurgery Unit Policlinico di Modena (Modena)
\(^2\) Chief of Hand and Microsurgery Unit Policlinico di Modena (Modena)

Objectives / Interrogation: The radial forearm flap is one of the most reliable conventional type of flaps. This is due to its thinness, pliability, good vascularization, relative hairlessness and good sensation. The disadvantages lies in radial artery sacrifice and donor-site morbidity. The increasing understanding of the local anatomy has allowed for the identification of perforating branches of the radial artery that allow for the subdivision of the radial flap into two or three components.

![Anatomical drawing](image)

Rotation of each small component can reach up 180 degree. This modification allows contouring of the flap to a wide range of recipient sites, while permitting the primary donor side closure [1].

Methods: From 2014 to 2016, 5 patients (4 males and 1 female) were treated by "a modified radial artery perforator flap". Free flaps from the contralateral limb were used in 2 cases and pedicled flaps were used in 3 cases. The age of the patients ranged from 7 to 52 years. The reconstructed areas involved the hand in 4 cases and the elbow in one case, all of which were traumatic in nature. Outcomes included flap survival, complications and donor site morbidity.

Results and Conclusions: All flaps survived without signs of necrosis. The donor site was closed primarily in three cases. In the remaining cases, the donor site was initially covered with a dermal regeneration template followed by skin grafting three weeks later. There were no cases of impaired blood circulation of the hand or cold intolerance after sacrifice of the radial artery. The flap may be considered an alternative method to other reconstructive techniques especially when reconstruction has to match the concept of "like to like".

4 Department of Orthopaedic Surgery, Academic Medical Center Amsterdam (Amsterdam)
5 Orthopaedic Hand and Upper Extremity Service, Massachusetts General Hospital, Boston, MA (Boston)

Objectives / Interrogation: To introduce a technique for the diagnosis of interosseous ligament (IOL) disruption based on lateral displacement of the radius after radial head resection and to determine the cutoff value of the lateral displacement for the diagnosis of disruption, the best elbow position for testing, and the diagnostic performance of the technique in different positions.

Methods: We used 10 fresh-frozen cadavers. After resection of the radial head, a Steinman pin was placed into the radius medullary canal and used to mark the pin location on the capitellum. We applied 1 kg force to pull the proximal radius laterally and measured the displacement in full supination, neutral, and full pronation of the forearm with the elbow in extension and then in 90 flexion. All measurements were performed once with the IOL intact and again with it cut. To assess diagnostic efficacy, receiver operating characteristics curves were constructed. To determine the quality of the technique, we measured the area under the receiver operating characteristics curve for each position. We also determined the cutoff value to obtain the highest sensitivity and specificity.

Results and Conclusions: Results: The area under the curve of the test in extension-supination and flexion-supination showed that these positions were excellent for the diagnosis of IOL disruption. The cutoff value of 5.5 mm lateral displacement in extension-supination had 100% sensitivity and 90% specificity. In flexion-supination, the cutoff value of 9 mm had 100% sensitivity and 90% specificity for the diagnosis of IOL disruption.

Conclusions: This maneuver was reliable and accurate in cadavers with complete IOL disruption. It is likely that in an intraoperative setting, these results will be reproducible.

NUMBER OF WEAVES IS AN IMPORTANT FACTOR IN THE TENSILE STRENGTH OF THE PROXIMAL WEAVE IN TENDON GRAFTING

List of authors:
Abby Choke*, Hamid Rahmatullah bin Abdul Razak¹, Duncan Angus McGrouther¹, Yoke Rung Wong², Wei Lun Cheong¹
¹ Singapore General Hospital (Singapore)
² Singapore General Hospital, Biomechanics Lab (Singapore)

Objectives / Interrogation: Current literature supports the idea of joining tendons or tendon grafts by multiple interdigitating weaves, known as the 'Pulvertaft weaves' in proximal reconstruction of tendon grafts to increase the tensile strength. While a greater number of weaves contribute to greater strength of the reconstruction, additional weaves would add to the bulk which inhibits optimal tendon gliding and postoperative rehabilitation. The aim of this study is to investigate the optimal number of weaves on the tensile strength of tendon reconstruction.

Methods: 36 fresh frozen flexor tendons were harvested and divided into 3 groups with 6 specimens each (G1 - 1 weave; G2 - 2 weaves; G3 - 3 weaves). Longitudinal slits were made on the receiving tendon at 90 degrees perpendicular to the previous slit. The tendon graft was delivered through the slits to form the interdigitating weaves. The tendons were reconstructed using 8 anchoring sutures (Ethilon 3/0) placed at regular intervals.

The tensile load of the repaired tendon was measured by a mechanical tester (Instron Model 3343). Firstly, the repairs clamped at each ends and pre-loaded with 5 consecutive cycles of 2.0 N. The specimen was then pulled to failure at a constant strain rate of 20 mm/min. Variables measured were: maximum load, tensile extension at maximum load, ultimate load and time to failure. One-way ANOVA was used to determine the statistical difference between the groups. A high-speed camera was used to record the mechanism of failure.

Results and Conclusions: The mean maximum load for G1 was 75.18N; G2 90.60N, and G3 89.41N; G2 and G3 showed very similar results but these were not statistically significant. The mean tensile extension at maximum load (G2 14.59mm vs G3 15.80mm, p 0.010); ultimate load (G2 50.46mm vs G3 57.72mm, p 0.049); and time to failure (G2 149.9sec vs G3 173.52 sec, p 0.042) were found to be statistically significant. The modes of failure for all the 18 specimens were suture pull out resulting in gradual failure. One specimen from G2 and G3 demonstrated suture breakage, these were found to have precipitated earlier time to failure.

This study demonstrated that 2-weave tendon grafts were comparable in tensile strength with the 3-weave construct. This suggested that a 2-weave construct could afford sufficient stability for finger and hand rehabilitation following tendon reconstruction. The 2-weave construct is less bulky, which reduces the tendency for tendon adhesion and resistance in gliding.

The diagnosis and treatment for 7 carpal tunnel syndrome cases caused by NTM infection

List of authors:
Xueyuan Li*1, Xiaoling Zhou1, Xin Wang1, Hong Chen1, Miaozhong Li1
1 Ningbo Sixth Hospital (Ningbo)

Objectives / Interrogation: Retrospectively analyze 7 patients diagnosed with CTS caused by NTM infection and explore the clinical character, differential diagnosis and corresponding treatment.

Methods: From June 2015 to June 2017, we collected 7 cases diagnosed with CTS, which during operation, we found granulomas inflammation and send for culture with NTM positive. We then retrospectively analyzed their etiology, clinical character, differential diagnosis, culture results, treatment and prognosis.

Results and Conclusions: 3 of 7 cases had a history of sea creature injury, while 4 cases had not. Clinical presented with numbness and pain, 5 cases had experience acute pain. 4 patients manifested with infectious redness and edema in the fingers while the other 3 patients had no infection signs. The culture showed mycobacterial marinum in 6 cases, in 1 case. EMG showed median nerve moderately compressed for 5 cases, severe for 2 cases. 4 patients took antimycobacterial medication before operation, we did CTR and thorough debridement for 4 patients, and CTR and limit debridement. All the patients get pain relief and numbness improved. All the patients were prescribed with antimycobacterial medication for an average of 2.5 months. 6 of them recovered uneventfully with satisfied function, 1 patient who underwent limited debridement reoccurred in 2 months after surgery who need another thorough debridement and recovered with mild dysfunction.

NTM infection can present with CTS which is difficult to differentiate. Acute and continued pain indicate the present of infection. The main treatment is antimycobacterial medication. Debridement and CTR surgery is for those with obvious nerve compression syndrome while can not relief after conservative treatment.

reparing skin defect of the finger with the free flap which with tendon pedicled on the palmar branch of the suracarpal palmar perforator of ulnar artery

List of authors:
Jianwu Qi⁎, Xiaoming Cai†, Hong Chen†, Weiwen Zhang†
1 Ningbo sixth Hospital (Ningbo)

Objectives / Interrogation: To study the clinical effect of free graft of the compound flap of wrist perforator branch of ulnar artery with partial flexor carpi ulnaris tendon and / or medial forearm cutaneous nerve for the repair of flexor tendon and / or finger nerve defect in dorsalis digitalis skin and soft tissue.

Methods: From June 2010 to June 2017, 35 patients with 36 fingers dorsal skin and soft tissue with extensor tendon defect and 21 patients with metacarpal skin soft tissue with flexor and / or deep flexor tendon were treated clinically. A patient with a defect of the inherent nerve of the finger. The tendons and (or) nerve defects were transplanted with the ulnar flexor wrist tendon and / or the ulnar artery superior palmar perforating branch flap of the medial forearm cutaneous nerve. The length of ulnar flexor tendon was about 2.0 – 5.5 cm with superficial thickness of 0.5 cm. 35 cases (36 fingers with extensor tendon defect) were transplanted to repair the extensor tendon to cover the skin defect. 21 patients with deep flexor tendon and / or finger nerve defect were transplanted to repair. The occurrence of arteriovenous crisis and the principles of management were followed up after operation.

Results and Conclusions: In 56 cases of 57 fingers, 54 fingers flaps survived successfully, and 1 finger appeared arterial crisis, which was relieved after conservative treatment, and later appeared partial necrosis of the distal skin, and scar healed after dressing change. Blisters and purples appeared in 2 fingers, in which 1 finger was partially necrosed, and 1 finger was completely necrosed after dressing change. Skin grafting was performed in the second stage. The flap was followed up for 6 to 24 months; and was similar in color, had no obvious bloated appearance. In the patients with tendon repair, the flexion of the fingers returned to normal or near normal, and the sensory recovery of the nerve repair was s3 / s3 +. The wrist joint movement and flexor muscle strength were not changed.

The ulnar artery has constant cutaneous perforating branches on the palmar side of the wrist, which meets the design requirements, and the skin of this part is similar to the skin texture of the dorsal palm of the finger. It is a good choice to repair the compound tissue defect of the dorsal metacarpal tissue with the free tendon and nerve flap of the ulnar artery.

Repairing donor site of foot after improved Toe-to-thumb reconstruction utilizing superficial circumflex iliac artery perforator chimeric flap

List of authors:
Yaopeng Huang*, Jiadong Pan†, Xin Wang†, Weiwen Zhang†
† Ningbo sixth Hospital (Ningbo)

Objectives / Interrogation: To evaluate the clinical outcome of the method of repairing donor site of foot after improved Toe-to-thumb reconstruction utilizing superficial circumflex iliac artery perforator (SCIAP) chimeric flap.

Methods: Fourteen cases of thumb defect were recruited in our hospital from April 2012 to January 2016. According to Gu Yudong's classification 5 cases met the criterion of type I, 4 cases met the criterion of type II, and 5 cases met the criterion of type III. For type I, the thumb was reconstructed with the great toe wrap-around flap. For type II and III, the thumb was reconstructed by the combined tissue with mutual artery (great toe wrap-around flap, and the bone-tendon tissue of the second toe). All the donor sites of foot were repaired utilizing SCIAP chimeric flap.

Results and Conclusions: All the reconstructed thumbs survived. Among 14 free flaps of donor site, 1 case suffered venous crisis and survived after exploration and rescue surgery. Dorsal skin necrosis of the second toe was found in 1 case, which was healed by local skin flap transposition. All patients were followed-up ranged from 3 months to 30 months (average time was 16 months). In spite of slightly bloated, all the flaps' color and texture was satisfied, and the average healing time of the bone in the donor sites was 2.5 months. All the patients did not feel painful and had no adverse effect when walking and running. Three months after the operation, 5 slightly bloated flaps in the donor sites under went flap plastic and achieved better appearance. On the part of iliaca, there was only one inconspicuous linear scar without any discomfort.

Repairing donor site of foot after improved Toe-to-thumb reconstruction utilizing SCIAP chimeric flap was an ideal method. Using this method, the reconstructed thumb can achieve good appearance and function, all the toes of donor site were reserved, and the disability of the donor site was minimized.

Long-term results after total wrist fusion using the AO-plate

List of authors:
Careen Knie-Heinemann*, Jörg van Schoonhoven
1 Klinik für Handchirurgie Bad Neustadt a.d. S. (Bad Neustadt a.d. Saale)

Objectives / Interrogation: Arthrodesis of the wrist is a salvage procedure for advanced arthritis with painful destruction of the radiocarpal and midcarpal joint after failure of all conservative treatment and motion-preserving procedures. Fusion is performed to eliminate pain and therefore increase function of the hand. The main purpose of this study was to determine long term functional result despite the loss of motion and define possible reasons for remaining pain.

Methods: Inclusion criteria for our retrospectiv study were total wrist fusion with an AO-plate and follow up of more than 10 years. Exclusion criteria were rheumatoid arthritis, congenital malformations and brachial plexus palsy. Between 2002 and 2007 214 patients underwent a total wrist fusion in our clinic, of which 71 patients were available for clinical follow-up examination, x-ray and functional self assesment using the DASH-questionnaire, the patient-rated wrist evaluation score (PRWE-G) and the short form 36 (SF 36) questionnaire. The modified Mayo wrist score was used to assess the clinical outcome. The mean follow-up of the 60 men and 11 women with an average age of 60.8 years was 11.2 years.

Results and Conclusions: Results
The various scores averaged: DASH-score = 30 points, PRWE-G = 31 points modified Mayo wrist score (Krimmer score) 59 points. 70 of the 71 wrists fused primarily. In 23 cases the plate was removed. 18 x-ray demonstrated broken screws. Only 15 patients were complete pain free and the majority complained about pain during stress with a mean of 4/10. In most patients the pain wasn't reproducible during the examination.
The grip strength averaged 92% compared to the other wrist. Despite the remaining pain 98% of the patients were satisfied and 93% would undergo the operation again. Influence of various radiological and clinical factors on the functional result will further be statistically investigated.

Conclusions
Despite loss of wrist motion patients are highly satisfied with the long term result although most patients complain about remaining pain during strong activity that could not further been defined on clinical or radiological examinations. The long term functional result with a mean of 30 points measured with the DASH score appears to be more favorable than the reported midterm results in other studies and is similar to the long term results of partial wrist fusion.

Active Wrist Mobilization after operatively treated distal radius fractures by volar locking plate - a prospective randomized trial

List of authors:
Stefan Quadlbauer*, Christoph Pezzei, Josef Jurkowitsch, Tina Keuchel, Brigitta Kolmayr, Eva Spielvogel, Thomas Beer, Thomas Hausner, Martin Leixnering
1 AUVA Trauma Hospital Lorenz Böhler (Wien)
2 AUVA Trauma Hospital Lorenz Böhler (Wien)

Objectives / Interrogation: Distal radius fractures (DRFs) are very common and surgical treatment by volar locking plates became standard therapy in the last decade. In addition, incidence of DRF will increase until 2030 because of an increased life expectancy. Due to this, surgical treatment and rehabilitation are of great interest. Main aim of this study was to compare an early postoperative mobilization after DRF with a cast immobilization of 5 weeks. Null hypothesis was that an early mobilization results in an equal outcome in range of motion (ROM) and functional outcome scores than an immobilization of 5 weeks.

Methods: One hundred patients with an isolated distal radius fracture treated by open reduction and internal fixation with volar locking plate were prospectively randomized in two groups. One group ("Mobilization group"; Mo) received a removable thermoplastic splint for 1 week and was allowed to move the wrist from the first day after surgery. The other group ("immobilization group"; IM) received a nonremovable forearm cast for 5 weeks. Both groups underwent physiotherapy 2 times a week. At 6 weeks, 9 weeks, 3 months, 6 months, and 1-year postsurgery, ROM, grip strength, and radiographs had been evaluated. Additionally, Quick Disability of the Arm, Shoulder and Hand (QuickDASH) questionnaire, Patient-rated Wrist Evaluation (PRWE), modified Green O'Brien (Mayo) score, and pain according to the visual analog scale (VAS) score was analyzed.

Results and Conclusions: Patients in the EM group showed a significantly better QuickDASH score, ROM in extension/flexion and grip strength at the one year checkup. Radial/ulnar deviation and pain according to the VAS differed significantly up to 9 weeks while supination/pronation and PRWE score was significantly better at 6 months evaluation. Additionally, sick leave and physiotherapy were also significantly shorter in the EM group. There were no significant differences in respect of radiological loss of reduction and complications between the groups.

Conclusions: Early mobilization of the wrist after operatively treated DRFs using volar angular stable locking plates is safe, and results in a significantly better functional outcome up to one year, with shorter duration of sick leave and physiotherapy compared to an immobilization for 5 weeks.

Patient and Carer Satisfaction Post Wrist Arthrodesis in Cerebral Palsy

List of authors: Caitlin Bodian*, Terry Bidwell1, Andrew Irving1
1 Starship Children’s Hospital (Auckland)

Objectives / Interrogation: Cerebral palsy is characterised by static brain injury with progressive musculoskeletal manifestations. This includes spasticity with wrist deformity in a hyperflexed and ulna deviated position. Treatment of severe deformity requires bony correction to restore neutral position, which is usually achieved by a wrist fusion. Our aim was to assess patient and carers post-operative satisfaction following wrist arthrodesis to determine what benefits were being gained from this procedure.

Methods: This is a retrospective case series assessing patients with cerebral palsy who underwent wrist arthrodesis at our institution by a single surgeon with a minimum of 1-year follow-up. We developed a visual analogue scale questionnaire of eight questions in which patients and carers rated the satisfaction of their wrist fusion with regards to pain, function, hygiene, appearance, daily care and overall satisfaction. For each question, a scale from -10 to +10 was given: +10 being the best outcome, 0 being no change, and -10 being the worst outcome. Surveys were anonymous and sent to patients via post. Results of the surveys were our our primary outcomes. Secondary outcomes were complications documented in patient records and radiographic outcome measures from routine post-operative follow-up.

Results and Conclusions: We identified 13 patients who underwent wrist arthrodesis. Four patients had bilateral procedures, giving a total of 17 wrists. Of these 13 patients, eight were quadriplegic and five hemiplegic. Age at arthrodesis ranged from 15-22 years. Pre-operative joint contracture ranged from 60-90 degrees. There were two deaths not related to the procedure. A total of 11 surveys were sent and eight returned (73% response rate). Results from the survey showed the greatest improvements were made in appearance with a mean rating of +6.6, ease of daily cares (+4.9), hygiene (+3.2), and hand function (+2.7). There was a slightly negative change in pain levels (-0.7). Overall, there was a positive satisfaction rating (+5.0).

Complications from the procedure included one non-union, one superficial wound breakdown, one removal of metalware for prominence and one pain syndrome.

Wrist fusion appears to be a beneficial procedure for cerebral palsy patients with severe wrist deformity. Greatest improvements are in daily cares, hygiene and cosmetic appearance. However, it does not significantly improve patient function or pain levels. Patients and carers should be counselled about the limitations of this operation.

Complications after distal radius fractures stabilized by volar locking plate in 392 patients

List of authors:
Stefan Quadlbauer*, Christoph Pezzei, Josef Jurkowitsch, Alexander Pichler, Stefan Schättin, Rudolf Rosenauer, Thomas Beer, Thomas Hausner, Martin Leixnering

1 AUVA Trauma Hospital Lorenz Böhler (Wien)

Objectives / Interrogation: Distal radius fractures (DRF) are the most common occurring fractures in the upper extremities and the incidence is worldwide on the increase due to a growing population in the industrial countries. In the last decade there was significant change in stabilisation away from k-wires and external fixation to open reduction and locking plate fixation. Due to the increased number of DRFs, stabilization methods and complications are of interest in the literature. Many studies reported up to 39% complication rates in volar stabilized DRF. Typical complications included: changes in sensibility, tendon irritation and rupture, hardware malfunction, infection, complex regional pain syndrome (CRPS), and post-traumatical osteoarthritis.

Methods: All patients with DRF that were stabilized between 2013 to 2016, using volar angular stable locking plate and minimum follow-up of 3 months were included. 392 patients medical records (259 female/133 male) with a mean follow-up interval of 11 months (range 3 to 52 months) were analyzed. All recorded complications were documented. Range of motion (ROM) in extension, flexion, supination, pronation, radial- and ulnar deviation of the last follow-up was noted. Age was divided into younger than 65 years and equal or older than 65 years. The primary, postoperative and final checkup radiographs were analyzed for alignment and intra-articular step-off.

Results and Conclusions: A total of 51 (13%) early and 17 late (4%) complications were recorded patients. The most common complications included carpal tunnel syndrome (3%), complex regional pain syndrome (3%) and loss of reduction (2%). Of the 68 complications, only 23 (6%) were directly related to the plate and 73% of all complications occurred in AO type C fractures. Patients without complications showed a significantly better ROM in extension, flexion, pronation and supination than patients with complications. No significant differences in incidence of complications, ROM or loss of reduction could be found between patients over and under 65 years of age.

Conclusion:
Treatment of DRF by volar angular stable locking plate is a safe and results in the majority of the cases a good clinical and radiological outcome with no complications. Age over 65 years is not associated with an increased risk for complications or restricted ROM.

Prevalence of Flexor Carpi Radialis Brevis in Chinese Patients with Volar Wrist Plating Performed for Distal Radius Fracture

List of authors:
Bernadette Lok Yiu Cheng¹, Edmund Leung Kai Yau¹, Norman Wai Chuen Yip¹
¹Queen Elizabeth Hospital (Hong Kong)

Objectives / Interrogation: To evaluate the prevalence of flexor carpi radialis brevis (FCRB) in patients with volar wrist plating done for fracture distal radius in Chinese population

Methods: This is a retrospective single-centre study. In a 3.5-year period from March 2015 to August 2018, 133 patients who suffered from distal radius fracture requiring volar locking plate fixation were recruited. Patients younger than 18 years old were excluded. Non-Chinese patients were excluded.

All data were retrieved from electronic clinical data analysis and reporting system in our hospital. Descriptions in operation records were collected.

All operations were carried out by or supervised by hand specialists. A direct flexor carpi radialis (FCR) approach was used. FCR tendon sheath was incised. FCR and flexor pollicis longus were retracted ulnarly. Pronator quadratus was subperiosteally elevated with an L-shaped incision to expose the underlying distal radius.

All subjects were followed-up in out-patient clinic for at least 3 months. Any complications were recorded.

Results and Conclusions: 133 patients with volar wrist plating performed were identified. 9 patients with FCRB variant were identified (6.8%). 7 were female patients and 2 were male patients. All cases were asymptomatic before the occurrence of the fracture. During surgical dissection, the FCRB were noted to be originated from the volar aspect of the distal third of the radius, occupying part of the radial border of pronator quadratus. The pronator quadratus were hypoplastic. The insertion of FCRB were beyond the surgical exposure of distal radius fracture fixation. No complications were noted during follow up at 3 months.

Literatures on the prevalence of FCRB were scarce. Studies from Japan, Singapore and Brazil reported the prevalence to be 1.6-8.7%. Our series was the first study showing 6.8% prevalence of FCRB in Chinese population with volar locking plate surgery performed.

Although most patients with FCRB variant were asymptomatic, symptomatic cases such as tendinopathy, partial tear, painful forearm mass and intersection syndrome were reported.

In conclusion, in Chinese population with volar locking plate done for distal radius fracture, the prevalence of FCRB was 6.8%.

As volar locked plating is a common way of treating distal radius fracture, knowledge of distal forearm anatomy and the possible variant is important. Surgeons should be aware of such possibility to avoid neurovascular injury in these patients.

High reoperation rate in 13 total wrist arthroplasties after 4 years

List of authors:
Ole Reigstad*, Trygve Holm-Glad, Bjørg Bolstad, Siri Roness, Johanne Korslund, Rasmus Thorkildsen, Magne Røkkum

1 Oslo University Hospital, University of Oslo (Oslo)
2 Oslo University Hospital (Oslo)

Objectives / Interrogation: Wrist arthroplasty surgery is increasingly performed as an alternative to wrist arthrodesis. In our institution all patients with destroyed radiocarpal joints are offered wrist arthroplasty. The patients are included in a prospective follow-up study. The results in non-inflammatory wrist patients are presented.

Methods: 13 (8 women, 9 dominant wrists) patients 68 (44-85) years of age with destroyed radiocarpal joints due to SLAC (8), SNAC (3) and lunate malaci (2) had a ReMotion (Stryker, Michigan, USA) wrist arthroplasty implanted. 5 patients had 6 prior wrist surgeries. 7/8 SLAC wrists had bilateral wrist degeneration. Radiographs were taken and active range of motion, grip- and key pinch strength was measured. The patients completed QDASH, PRWHE and VAS pain score preoperatively and at yearly follow-ups.

Results and Conclusions: During the follow-up period 3 arthroplasties were revised to a new arthroplasty due to distal loosening and osteolysis (2) or massive osteolysis (1). Additional bone removal on the radial side were done in one patient due to impingement. Removal of the two distal screws due to pain in the cmc joints were done in another. Arthrolysis, removal of ectopic bone in the joint, and a Darrachs procedure were done in one patient, and finally one had a CRPS resolving after 2 years. At final follow-up 4 (2-6) years after surgery the clinical results were satisfactory in the non-revised patients, demonstrating significant reduced PRWHE (63 to 31) and VAS pain at activity (69 to 39). QDASH was reduced (49 to 34) and grip strength increased (11 to 15 kgs) but the two latter did not reach statistical significance. The radiographic analysis demonstrated loosening in 2/10 arthroplasties (not revised) and major osteolysis in 2/10. None of the patients regretted choosing arthroplasty as compared to arthrodesis.

Conclusion: Published results on the Remotion wrist arthroplasty has mainly been in inflammatory wrist patients rendering satisfactory results. In our series of non-inflammatory wrist patients we found satisfactory clinical results but a relatively high complication and revision rate after 4 years. Patients prefer arthroplasty to arthrodesis, but they must expect complications, and should be informed about the expected outcomes including additional surgeries, osteolysis and fixation problems.

Treatment of scaphoid nonunion by one, two headless compression screws or plate with or without Extracorporeal Shock Wave Therapy

List of authors:
Stefan Quadlbauer*1, Christoph Pezzei1, Tina Keuchel1, Josef Jurkowitsch1, Thomas Beer1, Thomas Hausner1, Martin Leixnering1
1 AUVA Trauma Hospital Lorenz Böhler (Wien)

Objectives / Interrogation: Non-union of the scaphoid is even today a challenge for the treating hand surgeon and does if occurs, present notable consequences in hand function. Several methods for treating scaphoid nonunions are available, like sole bone graft in the technique according to Matti - Russe, with or without additional stabilization by a headless compression screw (HCS) or plate.

In the last decades, Extracorporeal Shockwave Therapy (ESWT) has become an established procedure for nonunion treatment. However, the mechanism of shockwave therapy is poorly understood, but it’s considered verified, that it leads to an angio- and vasculogenesis in the treated tissue, which causes a persisting increase of blood supply.

Main aim of this study was to investigate union rate and clinical outcome of a combined treatment of scaphoid nonunion by surgery and ESWT and to compare union rates after stabilization by one HCS, two HCS or plate.

Methods: 42 patients with a scaphoid nonunion treated by non-vascularized bone graft from the iliac crest and a interval between injury and surgery of at least 6 months were investigated. 26 patients were treated with an additional ESWT within two weeks after surgery and 16 without. A scaphoid plate was used in 20 patients, a double HCS in 12 patients, and one HCS in 10 patients. Age, gender, range of motion (ROM), date of surgery, the last follow-up examination were included in the statistical analysis. DASH scores, PRWE, the Green 0&Brien Score, and the Michigan Hand Questionnaire score were determined for all patients. A CT was performed in each patient to analyze union and signs of osteoarthritis.

Results and Conclusions: In total 74% (31/42) of the scaphoid nonunions showed bone healing at the follow-up investigation. Patients in the ESWT group showed in 21/26 (81%) and in the group without ESWT 12/16 (75%) bony healing. No significant differences could be found between the groups in ROM, grip strength, DASH score, PRWE score or MHQ. Patients stabilized by one HCS showed in 6/10 (60 %), by two HCS 10/12 (83 %) and by scaphoid plate 17/20 (85 %) union. No significant differences could be found between the groups in respect of VAS, ROM, grip strength, PRWE Score, DASH Score and MHQ.

Conclusion:
The results of this study suggest that a combination of ESWT and surgery is reasonable in treating scaphoid nonunions and a stabilization by two HCS or scaphoid plate provide higher union rates than a stabilization by one HCS.

Factors associated with operative treatment of enthesopathy of the extensor carpi radialis brevis origin

List of authors:
Amir Reza Kachooei*, Mojtaba Talaei-Khoei, David Ring
1 Orthopedic Research Center, Ghaem Hospital (Mashhad)
2 Orthopedic Hand and Upper Extremity Department, Massachusetts General Hospital, Harvard Medical School (Boston)
3 Orthopedic Hand and Upper Extremity Department, Massachusetts General Hospital, Medical School University of Texas, Austin (Texas)

Objectives / Interrogation: This study investigated the factors associated with variation in the rate of surgery for enthesopathy of the extensor carpi radialis brevis (eECRB).

Methods: We used a large database from 3 academic hospitals including 5964 patients with the diagnosis of eECRB from 2001 to 2007. Of those, 244 patients (4%) had surgery for eECRB. We used the date of the first encounter as the date of diagnosis. We also recorded the date of the first cortisone injection and surgery for eECRB. We used Cox multivariable regression analysis to find factors associated with surgery. We considered the following explanatory factors: age, sex, race, diabetes, a diagnosis of major depression, a diagnosis of an anxiety disorder, hospital, provider (surgeon vs. nonsurgeon), corticosteroid injection, and the time from diagnosis to the first cortisone injection.

Results and Conclusions: Results: The hazard ratio of having surgery was 12-times greater if the initial provider was an orthopedic surgeon rather a nonsurgeon and 1.7-times greater at 1 of the 2 hospitals. The rate of surgery varied substantially, ranging from 0% to 22%. Corticosteroid injection delayed the time to surgery but was ultimately associated with a higher rate of surgery. The majority (86%) of surgeries were done within 1 year of the first documented office visit.

Conclusions: It seems likely that an emphasis on the preferences and values of the patient rather than the surgeon would decrease the variation in surgery rates for eECRB observed in this study. Methods for optimizing the influence of patient preferences and values on decision making (eg, decision aids) merit additional study.

Functional outcome following headless compression screw fixation for hamate fractures

List of authors:
Veronique A.J.I.M. van Rijckevorsel*, Caroline A. Selles, Cornelis H. van der Vlies, Niels W.L. Schep
1 Maasstad Ziekenhuis (Rotterdam)

Objectives / Interrogation: Most hamate fractures are treated non-operatively, with percutaneous K-wire fixation, or with excision of a fractured hook of the hamate. Screw fixation is less popular due to the risk of iatrogenic ulnar nerve injury. The aim of this study was to present the functional results of patients with hamate fractures treated with headless compression screws (HCS).

Methods: In this retrospective cohort series, all consecutive adult patients with a hamate fracture, treated with HCS by the same hand-surgeon between August 2012 and November 2017 were screened for inclusion. The primary outcome was the Michigan Hand Outcome Questionnaire (MHOQ) after at least four months follow-up. Secondary outcomes were complications and whether or not patients were able to continue their profession following surgical treatment.

Results and Conclusions: Nine patients were included in this retrospective cohort study. A median MHOQ total score of 67% was reported (IQR 44-76). No ulnar nerve injuries were found. Also, no other complications were found during follow-up. All patients returned to their previous profession or a different profession in the same field. HCS fixation is a safe alternative to treat hamate fractures with good functional outcome.

hamate fracture, osteosynthesis, headless compression screws, functional outcome
Midterm results of scaphoid reconstruction using a free vascularised osteochondral medial femoral condyle flap

List of authors:
Karlheinz Kalb*, Annelie Wiebel
1 Rhön Klinikum AG - Klinik für Handchirurgie (Bad Neustadt)

Objectives / Interrogation: Reconstruction of a destructed proximal pole in scaphoid non-union using a free vascularised medial femoral condyle flap is a sophisticated operation with promising early results published. As there is a lack of midterm results in the literature we analysed our midterm results of this procedure.

Methods: Between 2011 and 2016 76 patients were operated in our hospital using a free vascularised medial femoral condyle flap to replace a proximal scaphoid pole in non-unions. In a retrospective study 44 of these patients (41 men/ 3 women) with a mean age of 31 (20 - 53) years were reexamined with a mean follow-up time of 44 (13-77) months. The examination included the patients history, a clinical examination, establishment of DASH-score and Krimmer-score and standard x-rays of the wrist. 31 out of 44 patients had a history of at least one scaphoid reconstruction before.

Results and Conclusions: Bony consolidation was found in 35 out of 44 patients (80%), partial consolidation in 2 (5%) and persisting non-union in 7 (15%). 5 (11%) patients had had a salvage procedure in the meantime: 4 four corner fusions and 1 proximal row carpectomy. In 12 out of 44 cases the shape of the reconstructed scaphoid was not sufficient especially in complex situations with large bony defects and fixed scaphoid deformity. Osteoarthritic changes of varying degrees were found in 17 patients.
Clinically the patients without salvage procedures had good results with a mean Krimmer-score of 80(38-100), a mean range of motion of 90°, a mean grip strength of 81% of the contralateral side and a mean DASH-score of 15 (0-56), whereas the 5 patients with salvage procedures had worse results with a mean Krimmer-score of 52 (25-70), a mean range of motion of 47°, a mean grip strength of 58% and a mean DASH-score of 19 (8-27). 39 out of 44 patients would choose the same operation once again.
Scaphoid reconstruction using a free vascularised medial femoral condyle flap yields good clinical and radiological midterm results in the majority of these complex cases, but usually not a complete functional recovery. Furthermore our results demonstrate a considerable number of complications which in some cases require salvage procedures with not satisfying results. These aspects have to be discussed with future patients to enable them to have realistic and not enthusiastic expectations.

free vascularised osteochondral medial femoral condyle flap - scaphoid non-union
Articular complications after modern wrist arthroplasty surgery

List of authors:
Ole Reigstad*, Trygve Holm-Glad1, Rasmus Thorkildsen1, Magne Røkkum1
1 Oslo University Hospital, University of Oslo (Oslo)

Objectives / Interrogation: We present 3 complications attributed to wear in a ball-and-socket metal-on-metal (MOM) or metal-on-polyetheretherketone (MOPEEK) wrist arthroplasty (Motec).

Methods: 3 patients/2 men age 51, 52 and 74 years had a Motec wrist implanted for radiocarpal degeneration due to radius fracture (2) or SLAC (1). Two had MOM articulation, one had a MOPEEK articulation. All three had 1, 2 and 5 prior wrist surgeries.

Results and Conclusions: Patient 1 had initial good pain relief and very good range of motion after Darrahcs and arthroplasty insertion. After 9 months she had increasing radial sided pain and an unstable distal ulna. During ulna shortening and additional bone removal the radiocarpal joint exhibited black particles and the PEEK cup was eroded about 20% of the circumference due to impingement dorsally between the cup and the ball neck. It was revised a MOM articulation. Patient 2 had initial good result but developed a dorsal lump after 4-5 months. Infection was excluded (punctured). MR and ultrasound suggested a pseudotumour. No metallosis was seen and the articulation occurred without any macroscopic changes on exploration. Histology revealed granulomatous tissue and chronic inflammation. The articulation was changed to MOPEEK. Patient 3 had multiple procedures prior to wrist arthroplasty surgery. He developed a fixed extension position of the wrist and reduced finger function. He had 2 extensor tenolysis procedures. He developed an extension position of the wrist again, increased pain, reduced finger function and symptoms CTS. Ultrasound exhibited massive flexor tendon synovitis from the distal forearm to the CMC joints. The extended position gave fretting dorsally between the distal screw and the cup (short head articulation). A complete tenolysis and arthrolysis was performed as well as shortening of the radius (removing the integrated radius implant and inserting a new implant more proximally) and changing the articulation to MOPEEK. Histology revealed foreign body giant cells and chronic inflammation. The patients had normal blood chrome and cobalt levels.

Conclusion: modern wrist arthroplasties has performed well in many patients. We found unexpected side effects in three patients. On the articulation side the technology is still immature. Concepts which has proven its endurance in hip arthroplasties (highly crosslinked polyethylene and ceramics) has not been implemented in small joint arthroplasties, reducing the performance and survival of modern small joint arthroplasties.

In Vivo Changes of Subchondral Bone and Cartilage in First Carpometacarpal Joint Osteoarthritis Across Severity Stages

List of authors:
Michael Chu-kay Mak*, Wayne Yuk-wai Lee, Ka-yee Cheuk, Ryan Ka-lok Lee, Pak-cheong Ho
1 Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Prince of Wales Hospital (Hong Kong)
2 Department of Imaging and Interventional Radiology, The Chinese University of Hong Kong, Prince of Wales Hospital (Hong Kong)

Objectives / Interrogation: In osteoarthritis (OA), the site of disease initiation and sequence of degenerative process in subchondral bone and cartilage is not known. Changes of the subchondral bone as degeneration progresses have not been characterized. We hypothesized that in the first carpometacarpal joint (CMCJ), subchondral trabecular bone change could be an early structural feature leading to cartilage loss. Our aim was to determine the in vivo changes of subchondral microarchitecture compared with cartilage volume from early to advanced OA.

Methods: A cross-sectional study on bone and cartilage morphology in patients with different severities of CMCJ OA was performed. 33 patients consecutively seen by a hand surgeon in our orthopaedic unit from August 2017 to June 2018 were recruited. Normal asymptomatic contralateral CMCJs of the patients were used as controls. A total of 57 CMCJs were included of which there were 8 in stage 1, 10 in stage 2, 28 in stage 3, 4 in stage 4, and 7 were normal controls. Severity was staged according to the Eaton and Glickel 1987 radiographic staging.

Subchondral trabecular microarchitecture and cartilage volume were measured by high resolution peripheral quantitative computed tomography (HR-pqCT, voxel size 82µm³) and 3T MRI with hand coil array respectively. A 4mm³ cube of subchondral trabecular bone was extracted at the center of the trapezium articular surface for Individual Trabecula Segmentation. Plate-like and rod-like trabeculae were analyzed. Parameters including volume, thickness, number and density of total, plate-like, and rod-like trabeculae were calculated. Plate-to-rod ratio was obtained.

Cartilage volume was obtained from segmentation with an in-house program.

Results and Conclusions: Osteoarthritic trapezia had decreased subchondral bone density vs controls (590.7 versus 631.3mgHA/mm³, p=0.036) and decreased cartilage volume (8.76 vs 26.78 p<0.001) that correlated with disease staging. There was a significant decrease in rod thickness across the stages starting from stage 1 (p=0.01), and a significant increase in plate-to-rod ratio from stage 2 (p=0.049).

This is the first in vivo study of subchondral bone microarchitecture in osteoarthritis using high-resolution CT, and demonstrated trabecular changes early osteoarthritis. Increase in P-R ratio starting at stage 2 is in agreement with other studies that transformation of rod-like to plate-like trabeculae occurs in advanced OA, which causes change in load-bearing properties, and ultimately cartilage damage.

Displaced scaphoid type B2 waist fractures stabilized by one or two headless compression screws

List of authors:
Stefan Quadlbauer*, Thomas Beer¹, Christoph Pezzi¹, Josef Jurkowitsch¹, Tina Keuchel¹, Thomas Hausner¹, Martin Leixnering¹
¹ AUVA Trauma Hospital Lorenz Böhler (Wien)

Objectives / Interrogation: Scaphoid fractures are rare and account only 2 - 3 % of all fractures and 10 % of all hand fractures. Displaced scaphoid fractures are treated typically with headless bone screws, but a treatment with one screw will not lead to absolute stability. Due to the complex and multidirectional movements of the scaphoid one screw is, specially against rotational forces, insufficient. Therefore, some authors started to use temporary anti-rotational K-wires. The aim of this study was to compare radiological and clinical outcome of unstable scaphoid fractures, stabilized using one or two headless compression screws (HCS).

Methods: A total of 52 patients were included in this study with a mean follow up interval of 43 months. 22 patients were treated using one HCS and 30 with two HCS. Clinical assessment included range of motion (ROM), pain according to the visual analogue scale (VAS), grip strength, the Disability of the Arm, Shoulder and Hand Score (DASH), the Patient Rated Wrist Evaluation (PRWE) Score, the Michigan Hand Outcomes Questionnaire (MHQ) and the modified Green O'Brien (Mayo) Wrist Score. All complications were documented. The follow-up study on each patient included a CT-Scan of the wrist which was analysed for union, osteoarthritis, Dorsiflexed Intercalated Segment Instability and humpback deformity.

Results and Conclusions: Totally 49/52 (94%) of the scaphoid B2 type fractures showed union, 30/30 (100%) in the two HCS group and 19/22 (86%) in the one HCS group. Mean ROM in extension/flexion was 170° (range 80°-179°), in pronation/supination 178° (range 170°-180°) and radial/ulnar deviation 57° (range 30-60). Grip strength of 43 kg (92% of the uninjured hand). No significant differences could be found in respect to ROM, grip strength, VAS and Scores between the groups. Conclusions: The unstable B2 type fractures of the scaphoid, when treated with two HCS and no bone grafting is a safe method, shows a higher union rate and equal clinical outcome compared to stabilization using only one HCS.

Treatment of fingertip injuries with the semi-occlusive dressing

List of authors:
Stefan Quadolbauer*¹, Christoph Pezzei¹, Josef Jurkowitsch¹, Tina Keuchel¹, Rudolf Rosenauer¹, Thomas Beer¹, Thomas Hausner¹, Martin Leixnering¹
¹ AUVA Trauma Hospital Lorenz Böhler (Wien)

Objectives / Interrogation: Injuries to the fingertips are very commonly encountered in the emergency department. V-Y plasty according to Tranquilli-Leali is a widely accepted approach for coverage of these defects in patients with an exposed distal phalanx. The occlusive dressing was first reported on by De Boer and Collinson in 1981; finger stalls consisting of silver sulfadiazine and ointment were used at this time. The occlusive dressing has been developed further in the last 20 years. Mennen and Wiese were the first to use Opsite® foils in 1993. Briefer periods of incapacity for work and nearly complete restoration of sensitivity have been reported in studies. 1997 Vogt et al. observed markedly increased levels of growth factors and immunological factors in the wound exudate.

Methods: 114 fingertip injuries were treated with occlusive dressings between 2008 and 2011. All fingertip injuries (purely soft tissue injuries and amputations with bone involvement) of the distal phalanx were debrided, cleaned with antiseptic, and an occlusive dressing made of Opsite® foil was placed. Bone shortening was not required in any patient. The foils were placed fully on the flexor and the extensor side. After placement of the dressing the patients received a finger wrap-over dressing. The primary occlusive dressing was left in place as long as possible. It was sealed if necessary, and removed only after the wound had healed. Photographs were taken in two planes at weekly intervals until complete healing had been achieved. After the treatment had been concluded. The size of the defect was classified according to Allen. In each patient a Semmes-Weinstein test was performed.

Results and Conclusions: 114 patients were treated with an occlusive dressing. The patients' mean age was 39 years, the mean duration of treatment with an occlusive dressing 20 days. 33 women (29%) and 81 men (71%) were included in the study. Sufficient soft tissue coverage was achieved in all patients and nearly complete regeneration of the fingertip and excellent cosmetic results were achieved in all patients. Complete restoration of sensitivity was observed on the Semmes-Weinstein test in all patients. No patient developed a soft tissue infection, neuroma, or osteitis, and no patient required a secondary flap plasty.

Conclusion: The semi-occlusive dressing is a good treatment option for all kind of fingertip injuries, regardless of the amputation level. Even if the bone is exposed up to the wound level, satisfactory soft tissue cover can be achieved.

Establishing National Diagnostic Reference Levels for Mini C-arm Use, St John’s Hospital Livingston

List of authors:
Philippa Rust*, 1 Mark McCann2
1 St John’s Hospital Livingston (Livingstong)
2 Royal Infirmary Edinburgh (Edinburgh)

Objectives / Interrogation: There is a lack of data regarding the relative amount of patient radiation exposure during mini C-arm procedures. It is critical that diagnostic reference levels (DRL's) are put in place to ensure patient safety. This study aims to be the first to audit large quantities of mini C-arm data, and use the results to generate national DRL’s for mini C-arm use. Furthermore the difference between open and closed surgical procedures and anatomical location of procedure will be analysed.

Methods: Data from procedures using mini C-arms over 5 years has been collected and analysed. Screening times and Dose Area Product (DAP) were recorded for 2033 procedures. 3rd Quartile values for screening time and DAP were calculated for the different groups being analysed. The impact that anatomical location of procedure (digits and hand compared to wrist and forearm) was statistically analysed using ANOVA analysis.

Results and Conclusions: The majority of procedures fall within the 3rd quartile screening time for their given population. The 3rd quartile screening time for all procedures was 23s and 1.6126 cGycm2 for DAP. The 3rd quartile DAP and screening is significantly shorter for closed surgical procedures compared to open procedures. Furthermore, there is significant variation in the screening time and DAP of procedures based on anatomical location. Not only can these results be used to generate new DRL’s for mini C-arm use in the upper limb, but they provide a platform for further training and identification of areas where there were significant outliers during procedures.

Zaidenberg's pedicled vascularized bone-grafting for reconstruction of scaphoid-nonunions - effects and functional outcome in a series of 49 cases

List of authors:
Ben Schacher*, Richarda Böttcher, Arnulf Vogel, Ariane Asmus, Simon Kim, Andreas Eisenschenk, Frank Eichenauer

1 MVZ curadocs (Berlin)
2 Unfallkrankenhaus Berlin (Berlin)
3 Universitätsmedizin Greifswald (Greifswald)
4 Dieter Buck-Gramko Stiftungsprofessur, Hand- und funktionelle Mikrochirurgie, Universitätsmedizin Greifswald (Greifswald)

Objectives / Interrogation: Nonunions of the Scaphoid can result after proximal fractures, failed surgical reconstruction and avascular fragment necrosis. Vascularized bone grafts in various techniques have been proven to be an effective treatment. They can be harvested as pedicled grafts from the direct vicinity of the wrist or as free transplants from other regions. A well-known pedicled vascularized bone graft for reconstruction of the scaphoid was described by C. Zaidenberg in 1991.

Methods: Between 2008 and 2016 a cohort of 49 consecutive patients underwent vascularized bone-grafting, pedicled on the 1,2 intercompartimental, supraretinacular artery in a modified technique based on Zaidenbergs description.

The indication for pedicled grafting, the operative procedure, aftercare and diagnostics to validate consolidation after treatment were prospectively standardized.

We present radiologic outcome / consolidation rates, characteristics of the group and follow-up data over 2 years including functional scores and quality-of-life data until the year 2018.

Results and Conclusions: Impaired perfusion of scaphoid fragments in preoperative contrast-enhanced MRIs indicated for the use of pedicled grafting in this study on the above described cohort. Consolidation could be shown in 37 of 49 cases in CT scans performed after 6 month. Treatment failure correlated with the severity of changes in preoperative MRI. Functional outcomes showed a frequent loss in range of motion of the affected wrist even after successful treatment / consolidation.

Triple nerve transfers for the C5/6 Brachial Plexus injury

**List of authors:**
Ajmal Ikram*
1 Tygerberg Hospital, University of Stellenbosch (Cape Town)

**Objectives / Interrogation:** Assess the functional results of triple nerve transfers for the C5/6 Brachial Plexus injury as a single stage procedure from the dorsal approach to decrease the recovery time post nerve transfers.

**Methods:** All adult patients who presented to our institution in four two years with loss of C5 and C6 after the Brachial plexus Avulsion injury and where primary repair was not possible underwent the Nerve transfers to reconstruct the shoulder abduction, external rotation and elbow flexion as a single stage procedure. Dorsal approach to the spinal accessory nerve was used for neurotization to the SSN, Radial nerve branch to the long head of triceps was used to restore the axillary nerve function and single fascicle of ulnar nerve to the wrist flexor was utilized to target the MCN nerve to the biceps muscle. The patients were follow-up at 6 weeks, 3 months, 6 months, 1 year and 2 years. The muscle charting was done with MRC grading.

**Results and Conclusions:** We currently have done 21 patients with C5/6 Brachial plexus injury which received triple nerve transfers and early results shows the return of biceps function an average of 5 months, the shoulder abduction and external rotation functional recovery is incomplete but functional at 6 months and improved up to 18 months post-operatively.

**Conclusions**
Loss of shoulder abduction, external rotation can be reconstructed as a single stage procedure from the dorsal approach to the spinal accessory & radial nerve, and Oberlin transfer for elbow flexion from volar approach, this has decreased the recovery time as nerve transfers are possible near the target muscles.

Nerve transfers for C5./6 nerve root injury
CMC thumb replacement with Touch implant, a comparative case series with CMC excision arthroplasty

List of authors:
Ajmal Ikram*1
1 Tygerberg Hospital, University of Stellenbosch (Cape Town)

Objectives / Interrogation: Assess the functional and radiological results of thumb CMC joint replacement done at Tygerberg Hospital

Methods: Patients who had one side of CMC joint surgery done at our institution 1-2 years back and now presented with CMC arthritis (Eaton Stage III disease) to the other hand and booked for thumb CMC joint excision arthroplasty were enrolled in this case series.
CMC thumb replacement was done with the same approach as the tightrope procedure, dorsolateral approach between APL and EPB, capsular release was also kept the same way for later repair. Joint replacement was done with un-cemented stem to the metacarpal after preparation of the trapezium the cup was inserted and bipolar head was used for articulation. Capsular repair was performed and thumb spica back slab was applied for two weeks. At follow-up short splint was given for two weeks and mobilization was started.

The patients were follow up at 6 weeks, 3 months, 6 months and one year. The radiological parameters like implant position and height was checked and compared cmc tightrope group as well as the functional outcomes by means of DASH score.

Results and Conclusions: We currently have done 10 patients with CMC implant arthroplasty and at six months post-surgery radiological results shows good position of components with no dislocations.
Functional results of CMC arthroplasty group at six months are the same as in CMC tightrope group with better pinch grip strength.

Conclusion:
CMC implant arthroplasty is less painful as compared to the resection arthroplasty, has earlier return to function, better range of movements and pinch strength almost double the CMC excision arthroplasty site at six months.

Arthroscopic Lunocapitate Fusion with Scaphoid Excision for Treatment of SLAC or SNAC wrists

List of authors:
Won-Taek Oh*, Yun-Rak Choi¹, Ho-Jung Kang¹, Il-Hyun Koh¹, Sang-Yun Lee², Jung-Jun Hong¹, Jin-Chul Oh¹
¹ Yonsei University College of Medicine, Severance Hospital (Seoul)
² National Health Insurance Service, Ilsan Hospital (Goyang)

Objectives / Interrogation: Lunocapitate fusion (LCF) with scaphoid excision is an alternative method of four-corner fusion to treat advanced osteoarthritis of scapholunate advanced collapse (SLAC) or scaphoid nonunion advanced collapse (SNAC) wrists with an advantage of less dissection of carpal ligaments and joint capsule. As a minimally invasive procedure, arthroscopic LCF is expected to have same benefits of open LCF as well as additional merits of fast recovery and cosmetic satisfaction to the patients. We retrospectively reviewed 8 cases of arthroscopic LCF for evaluating clinical and radiological outcomes of this procedure.

Methods: From Jan 2013 to Dec 2016, all patients with SLAC (stage II or III) or SNAC (stage II or III) wrist, who underwent arthroscopic LCF with scaphoidectomy were enrolled in this retrospective study. Union was determined by CT taken 8 to 10 weeks after operation with bridging trabecular at arthrodesis site. These clinical outcomes were assessed preoperatively and last follow-up: visual analogue scale (VAS) pain score, grip strength, active range of motion (ROM), Mayo wrist score (MWS), and Disabilities of Arm, Shoulder and Hand (DASH) score. For radiologic outcomes, carpal height ratio (CHR), lunate coverage index (LCI), and radiocarpal joint narrowing were measured. Any operation-related complications were also evaluated.

Results and Conclusions: The mean follow-up period was 24.9 (12 to 36) months. The union rate was 75% (6 of 8), but it was increased to 100% (4 of 4) when considering cases using 2 screws for fixation. The 2 cases of nonunion had undergone revisional arthroscopic LCF for increasing rate of union.

Volar locking plate fixation for distal radius fractures assisted by intraoperative computed tomographic navigation

List of authors:
Akira Kawabata*, Yukiko Morimoto¹, Yusuke Sogabe¹, Kiyohito Takamatsu¹
¹Yodogawa Christian Hospital, Department of Orthopaedic Surgery (Osaka)

Objectives / Interrogation: Unstable distal radius intra-articular fractures require restoration of alignment, and exact fixation of intra-articular fragments is essential. Here, we employed intraoperative computed tomographic (CT) navigation to accurately insert screws in the intra-articular dorsal fragments during treatment with a volar locking plate for distal radius intra-articular fractures. We evaluated the accuracy of this procedure through preoperative, intraoperative, and post-bone union CT findings as well as the clinical outcomes.

Methods: This study included 18 patients with distal radius fractures, who were treated with a volar locking plate (HYBRIX, Mizuho, Tokyo, Japan) using intraoperative CT (SOMATOM Definition AS, Siemens, Erlangen, Germany) navigation (Kolibri, Brainlab, Feldkirchen, Germany) with a minimum follow-up duration of 12 months. The mean patient age was 60.8 years and the mean follow-up duration was 16.2 months. Based on the AO comprehensive classification of distal radius fractures, 3 cases were classified as C1, 7 as C2, and 8 as C3. We examined the articular displacement and position of the inserted distal screws on CT images. The gap and step off were calculated as the indices of articular displacement. The mean minimum distance between the screw and articular surface and between the tip of the screw and the dorsal cortex were calculated. The three distal ulnar screw positions that influence the stability of the ulnodorsal articular fragment were evaluated. The Mayo wrist score and DASH score were also clinically evaluated.

Results and Conclusions: The mean gap and step off were 3.1 and 1.6 mm preoperatively, 0.9 and 0.3 mm intraoperatively, and 0.3 and 0.3 mm post-bone union, respectively. The mean distances between the screw and articular surface were 1.2, 1.7, and 1.7 mm from the ulnar side intraoperatively and 0.9, 1.3, and 1.4 mm from the ulnar side post-bone union. The mean distances between the tip of the screw and the dorsal cortex were 1.1, 0.5, and 0.9 mm from the ulnar side intraoperatively and 0.9, 0.2, and 0.6 mm from the ulnar side post-bone union. At the final follow-up, the mean Mayo wrist score was 91.7 and the mean DASH score was 6.5.

CT evaluation revealed that the screws were precisely inserted for articular fragments and bone union was achieved, thereby maintaining good intra-articular alignment. The findings demonstrate the accuracy of volar locking plate fixation assisted by intraoperative CT navigation and the good clinical outcomes of this procedure.

The Neurophysiology of Peripheral Nerve Transfers

List of authors:
Konstantin Bergmeister*, Christine Radtke
1 Klinische Abteilung für Plastische und Rekonstruktive Chirurgie, Medizinische Universität Wien (Vienna)

Objectives / Interrogation: Surgical nerve transfers provide the nerve surgeon with the ability to convert proximal into distal nerve lesions and thereby bypass slow nerve regeneration. Many nerve transfer procedures have been described and are successfully used in the reconstruction of brachial plexus and peripheral nerve injury. Despite their success, little is known about the neurophysiological effects of peripheral nerve transfers, especially regarding the motor unit rewiring that results thereby. In this work, we review the neurophysiological effects of nerve transfers in regard to refining surgical procedures and external aspects such as age on outcomes.

Methods: We review the literature investigating peripheral nerve transfers and their effects on the motor unit. Additional information is drawn from classic cross-innervation studies that present a similar surgical nerve transfer procedure and have been well-investigated. Specifically highlighted are the effects of donor nerve quality (agonist or antagonist) and axon quantity (donor-to-recipient ratio) on functional outcomes. Additionally, the poor results of nerve transfers in the lower extremity compared to their success in the upper extremity are discussed.

Results and Conclusions: Few publications, yet with growing tendency, specifically investigate the neurophysiological effects of nerve transfers, as applied in modern nerve surgery. Many conclusions can be drawn from cross-innervation studies. In general, agonist donor nerves provide a higher success rate and less-complicated motor re-education. Donor nerves with similar motor axon numbers as their recipient nerve provide better functional outcomes, likely the result of more functional motor units. This has been specifically shown for brachial plexus reconstruction. Experimentally, hyper-reinnervation, e.g. providing a surplus of axons, provides the best functional outcomes regarding muscle force. High patient age, the need for nerve grafts between donor and recipient, or the use of antagonist donor nerves have been reported to result in inferior results but are no contradiction for the use of nerve transfers in the upper extremity. Understanding the neurophysiological effects of nerve transfers has helped to refine surgical techniques. Future studies will provide additional information on motor unit effects and functional outcomes (muscle force).

Arthroscopic Scaphoid Excision and 4-corner Fusion of Scaphoid Nonunion Advanced Collapse or Scapho-lunate Advanced Collapse Wrist

List of authors:
Jae Woo Shim*, Min Jong Park¹, Hyeon Lee¹, Joo Hwan Kim¹, Young Taek Chae¹, Hee Seol Park¹
¹ Samsung Medical Center (Seoul)

Objectives / Interrogation: Arthroscopic scaphoid excision and 4-corner fusion is a minimally invasive procedure that can be expected to achieve rapid bone union and recovery. The purpose of this study is to report the results of arthroscopic scaphoid excision and 4-corner fusion.

Methods: A total of 14 patients with arthroscopic scaphoid excision and 4-corner fusion from 2011 to 2016 were reviewed retrospectively. The patients with scaphoid nonunion advanced collapse (SNAC) or scapho-lunate advanced collapse (SLAC) stage 2 or higher were included. Scaphoid excision and decortication for 4-corner fusion were performed with arthroscopic assistance. After arthroscopic procedure, dorsal intercalated segment instability (DISI) deformity was corrected and headless auto-compressive screws were inserted through capitate-lunate and triquetrum-hamate-capitate by percutaneous method. Bone union and DISI deformity were evaluated by radiographs. Preoperative and postoperative pain Visual Analogue Scale (pVAS), range of motion (ROM), grip strength, the Modified Mayo Wrist Score (MMWS), and the Disabilities of the Arm, Shoulder and Hand (DASH) score were analyzed.

Results and Conclusions: There were 11 male and 3 female patients, with an average age of 58 years (range, 32-77 years). There were 12 SNAC patients and 2 SLAC patients. The mean follow-up period was 26.0 months (range, 24-34 months). Bone union was observed in 13 patients after mean 8.3 weeks (range, 5-12 weeks). One patient did not show a bony union, but was maintained without symptoms. It was thought to be a stable fibrous union and was observed without additional treatment. There were no other major complications related to surgery. The capitate-lunate angle was significantly reduced from 13.7° preoperatively to 4.1° postoperatively (p<0.001). The flexion-extension arc showed no significant change from 83° preoperatively to 76° postoperatively. The grip strength showed no significant change from 53 lb preoperatively to 56 lb postoperatively. The pVAS, MMWS, and DASH score were significantly improved from 5.1, 56, and 43.3 to 1.3, 69, and 16.1, respectively (p<0.001). Arthroscopic scaphoid excision and 4-corner fusion showed rapid bone union and good clinical outcomes without major complications.

**Anatomic Rationale and Clinical Results for Relative Motion Flexion Management of Acute and Chronic Boutonniere Deformity, Permitting Immediate Active Motion and Functional Use**

**List of authors:**
Wyndell Merritt
1 VCU/MCV, UVA (Henrico)

**Objectives / Interrogation:** We introduced the relative motion splint concept at the 1995 IFSSH meeting in Finland, permitting active motion and functional use following long extensor tendon repair using relative motion extensor (RME) orthoses. Its use is now well established. We now present rationale and results using relative motion flexion (RMF) orthoses for acute boutonniere deformity, allowing use during healing, and the nonsurgical management of chronic deformity.

**Methods:** Cadaver and anatomic study show that placing the injured digit MP joint in 15-20 degrees' greater flexion than adjacent digits can transition a supple boutonniere deformity to full PIP extension by the quadriga effect, transmitting the increased EDC tension to full IP extension by the EDC lateral slips to the lateral bands, with simultaneous relaxation of the lumbrical volar pull by relaxed tension of the attached flexor profundus tendon. Acute injuries were splinted 6 weeks encouraging hand use and avoiding later therapy. Chronic boutonniere cases had serial casting of fixed PIP deformity to maximum extension (none worse than -20 degrees) maintained by 3 months of RMF orthosis use, with full flexion recovered.

**Results and Conclusions:** Since 2003, 8 acute (3 open) and 15 chronic cases are reviewed. Acute cases had supple PIP deformity and maintained full range of motion (minus 15 to 20 degrees MP extension) throughout 6 weeks of splinting without additional therapy. Chronic boutonniere patients treated an average of 40 months after injury had serial PIP casting to extension of 0 to -20 degrees, averaging -3 degrees. This required an average 2.5 weeks of casting. Thereafter therapy recovered full flexion, maintaining PIP extension in the splint for 3 months. Therapy visits averaged 7.5, with the most frequent complication broken orthoses from functional use. Initial joint contracture averaged -29 degrees, and the average improved PIP range of motion was 35.9 degrees, because several chronic boutonniere patients improved PIP flexion as well as extension. RMF splinting safely permits early active motion and hand use after boutonniere injury during 6 weeks of healing, obviating need for additional therapy. Serial PIP casting and use of RMForthoses for 3 months obviated need for surgery in chronic boutonniere deformity, allowing functional use and minimal hand therapy once full flexion was recovered, other than to replace broken orthoses. These patients achieved an "excellent" Strickland classification for boutonniere deformity.

Modified dorsal rotational advancement flap for reconstruction of congenital spade hand combined with one-stage opponensplasty

List of authors:
xiaofang shen*
1 Wuxi NO.9 People Hospital (wuxi)

Objectives / Interrogation: To introduce surgical treatment techniques of congenital spade hand, and focus on the modified dorsal rotational advancement flap to reconstruct the thum web space and one-stage osteotomy transposition of radial finger so as to reconstruct thumb opponensplast.

Methods: Between Jan 2015 to April 2017, using modified dorsal rotational advancement flap, totally six children undergoing congenital spade hand reconstructed thum web space. With 90° rotation, one-stage radial finger osteotomy was used to reconstruct the opponensplast and the alignment was maintained by Kirschner wires. Besides, skin graft repair was used to dorsal thumb and radial side of index finger. Four weeks later, the K-wires were removed and rehabilitation was started. Postoperatively, clinical results were evaluated.

Results and Conclusions: Results: The male-to-female ratio in the 6 patients was 1:1, and the median age was 15.5 months (range, 13-20). 4 of them had spade hand deformity in the left, while 2 in the right, and the patients were followed up for at least 12 months after surgery (range, 12-20). No distinct difference in the skin color between thumb web space and the healthy side was observed in all patients at the final follow-up, the thumb web distance in the affected hands ranged from 3.5cm to 5cm (average, 4.2cm), the depth and dilation extent of thumb web were close to those in the healthy side, and favorable functional recovery was achieved in the thumb opponensplast. 2 affected children had mild scar hyperplasia in the lateral incision, which was mitigated 6 months after wearing the pressure gloves, and no other complication was observed.

Conclusions: Modified dorsal rotational advancement flap combined with one-stage metacarpal osteotomy is an alternative surgical method for treating congenital spade hand deformity. One-stage thumb opponensplast reconstruction is conducive to the early use of the thumb to learning and exercising. In the meanwhile, one-stage surgery dissects neurovascular bundle, which can avoid the separation within scars and reduce surgical risk compared with the two-stage transposition thumb.

Fragment-Specific Fixation versus Volar Locking Plates in non-reducible or redisplaced distal radius fractures. A long-term follow-up of a prospective and randomized study in 50 patients

List of authors:
Marcus Landgren*, Karl Borgstrand¹, Melker Larsson¹, Mats Geijer², Antonio Abramo³, Magnus Tägil¹
¹ Department of Orthopedics (Lund)
² Institute of Clinical Sciences, Department of Radiology (Göteborg)
³ Department of Hand Surgery Malmö (Malmö)

Objectives / Interrogation: To compare the long-term outcome of two types of internal fixation for distal radius fractures, the Volar Locking Plate (VLP) and the Fragment-Specific Fixation (FSF) were compared regarding objective, subjective, radiographic outcome, complications and secondary surgery at 6 to 8 years after surgery.

Methods: 50 patients with distal radius fractures were included in the previously reported original study between December 2010 and December 2012¹. All patients in the previously reported 12-month follow-up were invited. Six patients declined to participate. 44 patients (mean age 64 (27-75) years, 35 women) participated in the present study. Grip strength was determined as primary outcome. Range of motion, patient reported outcome using the short version of Disabilities of the Arm, Shoulder, and Hand (QuickDASH), radiographic outcome, complications, and secondary surgery were considered as secondary outcomes.

Results and Conclusions: Results
We found no difference between the VLP and FSF groups regarding grip strength (92% and 98% of contralateral), median QuickDASH (5 and 3) or range of motion, nor radiographic parameters. The complication rates were similar in both groups, as was the rate of secondary surgery 20% (5/25) in the VLP group and 25% (4/25) in the FSF group.

Conclusions
Surgical treatment of distal radius fractures with VLP and FSF both achieve good and similar results 6-8 years after primary surgery. We found no differences in outcome. We speculate that the differences in subjective and objective outcome between two modern methods of internal fixation are too small to be captured in smaller randomized series using present outcome measures.

Treatment of artificial dermal template to release congenital syndactyly without skin graft

List of authors:
Jianghai Chen*, Fangxing Ai1, Kun Wang1, Yan Zhang1
1 Wuhan Union Hospital, Tongji Medical College, Huazhong University of Science and Technology (Wuhan)

Objectives / Interrogation: Congenital syndactyly is one of the most common upper extremity deformities treated by hand surgeons. The aim of this study was to release congenital syndactyly without skin grafts through treatment of artificial dermis.

Methods: From June 2015 to Jan 2017, the skin defects after syndactyly release were covered with artificial dermis in 22 webs of 14 patients. The wounds were healed in one-stage without skin grafts. Average follow-up was 28 months (range, 18 to 38 months). The post-operative results were assessed with the Vancouver Scar Scale (VSS), the Patient and Observer Scar Assessment Scales (PSAS, OSAS), and visual analog scale (VAS).

Results and Conclusions: All wounds were healed within 6 weeks in average. The Vancouver Scar Scale scores averaged 0.8 (range, 0-2), grade of web creep averaged 1.2 (range, 0-3) for the affected digits. All patients gained satisfactory results in aesthetics and functionality. Thereby, we may conclude that the new procedure is simple and effective for syndactyly reconstruction with less invasion.

Comparisons of MRI and Arthroscopic Findings of Elbow Synovial Plica

List of authors:
Jae Woo Shim*, Min Jong Park¹, Hyeon Lee¹, Joo Hwan Kim¹, Young Taek Chae¹, Hee Seol Park¹
¹ Samsung Medical Center (Seoul)

Objectives / Interrogation: MRI findings with clinical symptoms and physical examinations are important to diagnose elbow plica syndrome, but there are no criteria in MRI diagnosis. We compared MRI findings with arthroscopic findings and analyzed the correlation between MRI and arthroscopic findings.

Methods: We studied the patients undergoing arthroscopic surgery of elbow and performed MRI (3.0T, Philips medical systems) at our department from 2010 to 2016. 38 cases were reviewed consisting of 11 men and 27 women in their median age of 49 (16 to 63 years). Among the surgeries conducted for 38 cases, 30 cases were for lateral epicondylitis, 7 cases were for plica syndrome, and 1 case was for loose body.

MRI was observed in the proton density with fat suppression sequences and the length was measured from the joint capsule to the most extruded area. The anterior plica was measured in the sagittal plane and the posterior plica was measured in the sagittal and coronal plane.

The length of the anterior and posterior plica observed on arthroscopy was measured and compared with MRI. The paired t-test was performed with an equivalence test of ± 1 mm for the equivalence limit. The Pearson correlation analysis was used to analyze the correlation between the MRI and the arthroscopic plica findings.

Results and Conclusions: The median value of the anterior plica measured on MRI was 1.5 mm (0-6.8 mm) and the median value of the anterior plica measured on arthroscopy was 1.8 mm (0-7.1 mm). The two measures were statistically equivalent and the correlation coefficient was 0.718, indicating a statistically significant correlation. (p< 0.001)

The median value of the posterior plica measured on MRI was 3.6 mm (0-6.8 mm) in coronal plane and 5.7 mm (1.9-11.1 mm) in sagittal plane. The median value of the posterior plica measured on arthroscopy was 5.6 mm (1.6-9.7 mm).

The two measures in sagittal MRI and arthroscopy were statistically equivalent, but correlation coefficient was 0.22, indicating no statistically significant correlation (p >0.05). There was a statistically significant difference between the measures in coronal MRI and arthroscopy and the correlation coefficient was -0.05, indicating no statistically significant correlation (p>0.05).

The anterior plica measured by MRI has diagnostic value because it reflect the size observed in the arthroscopy. Relatively, the case of posterior plica is considered to have low diagnostic value due to its low correlation with the arthroscopy.

Volar locking fixation for distal radius fracture in patients with concurrent hip fractures: A matched pair analysis of elderly patients

List of authors:
Hyoung Seok Jung*1, Jae Sung Lee1
1 Hospital of Chung-Ang University of Medicine, (Seoul)

Objectives / Interrogation: To describe the outcomes of operative treatment with volar locking plates in patients with distal radius fractures with concurrent hip fractures and to identify differences in these patients in comparison to a matched control group of patients with isolated distal radius fractures.

Methods: From January 2010 to December 2016, twenty-eight patients who met the criteria of both hip and distal radius fractures were retrospectively reviewed for analysis. Twenty-eight matched patients during the same period were recruited from a cohort of patients who underwent volar locking plate fixation for isolated distal radius fractures. To perform the matched-paired analysis, patients were matched for age, sex, body mass index, fracture type, and bone mineral density (BMD). Radiological assessment including radial inclination, radial length, and volar tilt was performed to evaluate loss of reduction. We also examined range of motion, grip strength, visual analog scale (VAS) and quick Disabilities of the Arm, Shoulder and Hand (DASH) score.

Results and Conclusions: In all patients, the distal radius fractures were ipsilateral to the hip fractures. According to radiological assessment, there were no significant differences between the groups at an immediate post-operative time. At the time of final follow-up, however, there were significant differences in radial length and radial inclination, and all radiological parameters were better in the control group in comparison to the study group. Wrist range of motion was not significantly different between the groups. Furthermore, no difference in pain scores and functional status were detected between the groups based on the VAS and quick DASH scores, respectively. However, grip strength was better in the control group compared with study group. In conclusion, while volar locking plating provides greater stabilization for distal radius fractures, loss of reduction can occur in patients who have sustained simultaneous hip and distal radius fractures although it was not associated with functional outcomes.

**List of authors:**

julio sandoval*, camilo Romero, Viviana Vela

1 fundacion cardioinfantil (bogota)
2 fundacion cardioinfantil (Bogota)
3 Fundacion cardioinfantil (Bogota)

**Objectives / Interrogation:** Introduction: The dorsal ganglions cysts are the most common benign tumors in the wrist. The length of the surgical incision can cause inconformity for the patient, for that reason it is proposed a controlled emptying technique to achieve resection of the mass with a decrease in the size of the injury during the surgery, without modification of the risk of recurrence. We studied the demographic data and the clinical and intraoperative characteristics of these lesions in our population, and determined the recurrence rate with this technique in a population that underwent surgical resection of the ganglion during the period of January 2016 to January 2018.

**Methods:** Methodology: A retrospective descriptive study, case series, was performed in patients diagnosed with a dorsal ganglion cyst from 2016 to 2018, who underwent total resection with a minimally invasive technique with assisted drainage.

**Results and Conclusions:** Surgical technique: The patient is under anesthesia, according to its location, is performed. A 0.6 - 1 cm transverse incision is made on the mass in accordance with the skin folds at that level, then it is dissected by planes. The mass is partially drained with a scalpel, by small dotted incision, maintaining minimal content to avoid losing its visualization and delimitation. The small incision is closed with a mosquito clamp leaving a fusiform sac and keeping some tension. The procedure continues by dissecting and exposing the mass and its pedicle; with the drained content it will be easier to visualize the capsule and perform the resection of the ganglion cyst, from the original pedicle.

Results: 6 patients were found to have met the inclusion criteria for management with assisted voiding technique, the average age was 43 years, the female to male ratio was 1:1, the size of the ganglions cysts was 4 - 2 cm and histological confirmation and resection of the pedicule, capsule and ganglion were performed. There were no recurrences in the patients at the 6-month follow-up. There were no complications. The patients were satisfied with the size of the surgical wound and with the result obtained.

Conclusions: The technique of controlled intraoperative emptying of the dorsal ganglion cyst by minimum incision to improve visualization and complete resection of the lesion does not show an increase in the recurrence rate and is a safe and easy technique to perform. Patients have a small aesthetic wound that meets the patient's expectations without modifying the rate of recurrence.

Surgical management of complex hand's contractures with blended use of mini-invasive procedures and wide awake surgery: case series

List of authors:
antonia russomando*¹
¹ Villa Verde (Reggio Emilia)

Objectives / Interrogation: Complex contractures of the hand following traumatic injuries may involve several joints in the same segment, adhesions of both extensor and flexors tendons. Several surgical procedures may be required in different times: dorsal teno-arthrolysis, flexors tenolysis, treatment of associated complications (fracture's malunions or cartilage loss). The ideal surgical procedure should allows to treat all issues in one surgical step, with surgical approaches more mini-invasive as possible and allows to evaluate the effectiveness of procedure during surgery.

Methods: We report our experience on nine patients affected of complex contracture of fingers who underwent, in one surgical step to dorsal teno-arthrolysis through mini-invasive approaches with small incisions; tenolysis of flexor tendons through minimal exposure using Allis forceps; release of collateral ligament at MP joint to correct rotation instead of osteotomy. Surgery was performed in wide awake. Contracture was following proximal phalanx 's fractures (4 cases), PIP joint fractures(2), sub-amputations( 2) and burns (1). Two patients showed fracture's malunion with rotation and 2 patients cartilage loss of PIP joint. They underwent interposition arthroplasty. All patients started rehabilitation after 48 hours.

Results and Conclusions: Average follow up was 14 months. The mean value of TAM increased from 141,5° before surgery, to 195,23° after surgery; PIP joint active flexion increased from a mean pre-operative value of 38° to 78°, DIP joint active flexion from 10° to 43°; lag of extension was shown after DIP joint arthrolysis (mean 25°). Mean PRWHE score improved from 20.8 to 4.7; grip strength from 18.9 kg to 29.7 kg. Even if lateral ligament release didn't allow the complete correction of rotation, function was improved, patients were very satisfied.

The use of wide awake surgery allows to improve effectiveness of mini-invasive incision performing subcutaneous dissection, without wide exposures; reduces post operative bleeding and swelling, avoids excess of release and following instability. Showing to the patient the immediate result improves his motivation. The flexor tenolysis with Allis forceps could seem a very aggressive procedure, but it is very useful to treat tendons adhesions following fractures or immobilization without adding trauma and scar to the tendon canal. It's not indicated for release of flexor's tendons adhesions following tendons suture because the risk of tendons rupture is higher.

On-Top-Plasty combined Modified Bilhaut-Cloquet Procedure for Complicated Radial Polydactyly

List of authors:
xiaofang shen*1
1 Wuxi NO.9 People Hospital (wuxi)

Objectives / Interrogation: Some radial polydactyly are difficult to classify into Wassel classification. Some features are important in decision of management but are not considered in the Wassel classification. We report our management of complicated Wassel VI or VII Radial Polydactyly with significant hypoplastic metacarpal and both of digits were hypoplastic. Usually the radial digit was functional, while the ulnar digit was motionless. We reviewed the results of our procedures of On-Top-Plasty combined Modified Bilhaut-Cloquet Procedure for the treatment complicated radial of polydactyly of the thumb.

Methods: We reviewed five patients with six radial polydactyly, who underwent this On-Top-Plasty combined Modified Bilhaut-Cloquet Procedure from 2015-2017. The average follow up was eight months. The range of motion and the size of the thumb were measured. Parent's satisfaction was measure by a visual analog scale of 0-10.

Results and Conclusions: All parents were satisfied with the cosmetic and functional results. Compared with the preoperative thumb size and appearance and motion, the average girth of the reconstructed thumb relative to the contralateral thumb was 105%. The width of the thumb nail was similar to the contralateral thumb and was significantly increased as compared to pre-operation.

Conclusions: Our On-Top-Plasty combined Modified Bilhaut-Cloquet Procedure for treatment Complicated Radial Polydactyly is effective in preserving metacarpophalangeal joint motion, minimizing nail deformity.

Application of vascular grafting in syndactyly release of Poland syndrome

List of authors:
xiaofang shen*1
1 Wuxi NO.9 People Hospital (wuxi)

Objectives / Interrogation: Poland syndrome includes the deformity of brachysyndactyly. The etiology of Poland syndrome may be related to the development of the subclavian artery of the fetus at the sixth week of pregnancy. Some patients with Poland syndrome have higher position of palmar digital arteries bifurcation points. In the separation of fingers, the side finger artery is often ligated to obtain the deep web shape and hand function. The purpose of this study was to investigate the effect of superficial dorsal palmar vein grafting on lengthening the unilateral digital artery and deepening the finger web.

Methods: 1. age <3 years old. 2. Poland syndrome hand deformity manifested as 2-5 fingers brachysyndactyly. 3. higher position of palmar digital arteries bifurcation points were found during the separation. From June 2014 to December 2017, a total of 5 patients were treated with palmaro-dorsal superficial vein transplantation to extend the lateral digital artery and deepen the digital webbed. Postoperative follow-up was conducted to observe the depth and morphology of the fingers web.

Results and Conclusions: The operation was successfully completed, all the flap and skin grafting were completely alive, and there were no early complications such as infection and skin necrosis. All patients were followed up for 7-27 months, with an average of 14.3 months. All patients had a reconstruction depth of digital webbed at nearly 1/3 of the proximal phalanx, 5-7 mm deeper than the position of palmar digital arteries bifurcation points, with an average of 6.12 mm. Both the appearance and function were satisfactory without conspicuous scar. The depth, width and slope of the webbed are normal without conspicuous scar.

Conclusion: Using palmaro-dorsal superficial vein transplantation to extend the lateral digital artery and deepen the digital web can not only retain the two digital arteries but also have no additional incisions. The operation of vascular transplantation is simple and the clinical learning cycle is short, so it is suitable for clinical promotion.

Preliminary report for capitolunate arthrodesis for SNAC wrists: radial approach and robot-assist screw insertion

List of authors:
Yang GUO*1
1 Beijing Jishuitan hospital (beijing)

Objectives / Interrogation: The aim of the study was to evaluate short-term results of capitolunate arthrodesis by radial approach and robot-assist screw fixation for the treatment of scaphoid non-union (SNAC) wrists.

Methods: A capitolunate arthrodesis was performed on 6 patients, one woman and 5 men, of 33 years old on average (18-45). All patients were in the 3rd stage of scaphoid non-union degenerative change at time of surgery. The styloidectomy, scaphoidectomy and capitate-lunate arthrodesis was performed by radial approach instead of dorsal approach. Fixations of the arthrodesis with double Acumed cannulated screws were assisted by navigation robot system during insertion stage.

Results and Conclusions: The average follow-up time was 8.7 months (6-12 months). Follow-up evaluation included radiographs, wrist range of motion (flexion-extension, radial-ulnar deviation, and pronation-supination); grip strength; visual analog scale (VAS); and Disabilities of the Arm, Shoulder, and Hand (DASH) questionnaire. The average pain on visual analog scale (VAS) was 1.5. The flexion/extension arc was increased of 15° and strength of 8kg compared to preoperative values on average. All patients returned to their previous working activities. No secondary procedure or complication was observed in all patients.
These results were comparable to or better than the results of previously published techniques in terms of alleviation of pain, grip strength, range of motion and DASH score. The technique has the theoretical advantages of strong compression between capitate and lunate articular cartilage and preserving the dorsal capsular ligament of the wrist joint.

"The role of Magnetic Resonance Imaging (MRI) and Ultrasound (US) in the diagnosis of the thumb Stener lesion"

List of authors: Juan Manuel Breyer*, Diego Junqueras, Nicolas Zilleruelo, Alejandro Bifani, Felipe Saxton, Sebastian Undurraga, Rodolfo Ide, Robinson Gonzalez

1 Clínica Alemana, Hospital del Trabajador (Santiago)
2 Clínica Alemana (Santiago)
3 Clínica Alemana, Mutual de Seguridad (Santiago)

Objectives / Interrogation: The interposition of the fascia of the adductor pollicis muscle in the ulnar metacarpophalangeal (MCP) ligament injury of the thumb (Stener lesion), is a pathology that requires surgical treatment. The ability to accurately diagnose Stener lesion has proven to be difficult and unreliable; the most common imaging methods used to diagnose this injury are US and MRI, however, their utility is not clearly established.

The purpose of this study is to evaluate the diagnostic accuracy of US and MRI for the Stener lesion.

Methods: A descriptive study was carried out in 14 adult patients, operated on suspicion of a Stener lesion of the thumb, with joint instability (more than 30°) after an acute trauma (less than 10 days). Patients with open injuries and fractures were excluded.

After the surgery was indicated, an ultrasound study (evaluated by one observer) and an MRI (evaluated by four observers) were performed, with emphasis on the presence of a Stener lesion. Both exams were blind to the surgeon, patient and observers.

Results and Conclusions: All patients presented complete rupture of the ulnar collateral ligament in the surgery, but only eight of them (57.1%) had the Stener lesion.

For the identification of Stener, the MRI presented a sensitivity of 87.5%, specificity of 66.6%, PPV 77.7% and NPV of 80%. The US had a sensitivity of 100%, specificity of 50%, PPV 72% and NPV of 100%. Moderate to considerable values were obtained in interobserver and intraobserver concordance for MRI.

CONCLUSIONS: In the suspicion of a Stener lesion, US and MRI are complementary studies that would help improve the diagnosis. However, the values of specificity and negative predictive value are insufficient to confirm the Stener lesion and reduce the false positive diagnosis, so their use would not yet fully resolve this situation.

Keywords: Stener Lesion
The flexion-pronation provocation test. A new test for distal biceps tendon pathology

List of authors:
Pieter Caekebeke¹, Roger Van Riet²
¹ ZOL (Genk)
² AZ Monica (Deurne)

Objectives / Interrogation: Background: Partial biceps tendon ruptures are often missed; therefore a reliable clinical test is needed. Hypothesis: Partial distal biceps tendon ruptures and bursitis can be reliably diagnosed with the pronation-flexion provocation test.

Methods: Methods: The pronation-flexion provocation test was performed by a single surgeon in a cohort of 30 patients with a confirmed partial distal biceps tendon rupture and a cohort of 30 patients with other elbow pathology. To perform the flexion pronation provocation test the patient is asked to actively flex the elbow from a pronated position of the forearm with the elbow tucked in to the patient's side and with the elbow in ninety degrees of flexion. The examiner's hands are placed on the patient's forearm and the patient's flexion is resisted. Care is taken not to place the hands on the hand or wrist as resisted wrist flexion might elicit pain in other elbow pathologies. The test is positive when the patient indicates pain when active flexion is resisted.

Results and Conclusions: Results: The flexion-pronation provocation test was positive in all patients with distal biceps tendon pathology. The VAS score averaged at seven out of ten (range 4-9). The VAS score for the supination-flexion resistance test averaged at one out of ten (range 0-5). In the control group the VAS score for the flexion-pronation provocation test averaged at zero out of ten (range 0-1) while the VAS score for the supination-flexion resistance test averaged at 1 (range 0-2). Conclusions: The pronation-flexion provocation test is highly reliable and accurate in the clinical diagnosis of partial biceps tendon ruptures.

Minimally invasive corrective osteotomy of the proximal phalanx: A biomechanical study

List of authors:
Sten Deschuyffeleer\textsuperscript{1}, Joris Duerinckx\textsuperscript{1}, Pieter Caeyebeke\textsuperscript{1}
\textsuperscript{1} ZOL (Genk)

Objectives / Interrogation: Background:
Malunions of phalangeal fractures of the hand form a real challenge to the treating surgeon. Corrective osteotomies of the proximal phalanx need stable fixation to allow immediate active finger motion to prevent postoperative tendon adhesions. Typically this is achieved with plate/screw osteosynthesis. Despite rigorous postoperative mobilization, results are often disappointing due to stiffness. Intramedullary fixation of phalangeal fractures has been popularized recently. These offer a strong and reliable fixation allowing early mobilization. This technique can be performed with minimal disturbance of the soft tissue envelope of the finger. The stability of this type of fixation after open wedge osteotomy has not been tested.

Methods: Methods:
24 paired fresh frozen proximal phalanges were divided into two groups. In twelve phalanges, an apex volar osteotomy was created. In the other half, an apex medial osteotomy was created. In each group, 6 phalanges were stabilized with a dorsal 1.3 mm angular stable plate. The contralateral, paired phalanx was stabilized with a 2.4 mm intramedullary screw. The phalanges were tested in a custom mount in a 3 point bending, load-to-failure protocol. The load was transmitted onto the volar side of the phalanx as this mimics the physiological load of the tendons on the phalanx. A paired t test was used for statistical comparison of the 2 groups.

Results and Conclusions: Results and Conclusions:
Results: The load to failure in the apex medial osteotomy group was 178.5N and 143.8N for the plate and screw and intramedullary screw group, respectively (p=0.3). Stiffness was 63.33N/mm and 55.83N/mm (p=0.22). For the apex volar osteotomy group, these numbers were 263.7N and 160N (p=0.0072) and 220N/mm versus 60N/mm (p=0.0012).

Conclusions: For fixation of an apex medial osteotomy, there is no statistically significant difference in load to failure between an intramedullary screw and an angular stable plate/screw construct. However, after apex volar osteotomy, plate/screw fixation is stronger.

Based on the available evidence, the rigidity provided by an intramedullary screw is probably sufficient to allow immediate active motion after both types of osteotomies. Combined with the advantage of minimal soft tissue disturbance, it seems to be a valid alternative for fixation of these osteotomies. Further clinical investigation in regards to feasibility is needed however.

A Novel Procedure for Chronic Sagittal Band Rupture, Permitting Immediate Active Motion and Hand Use During Recovery

List of authors: Wyndell Merritt*1, Lauren Nigro2
1 VCU/MCV, UVA (Henrico)
2 VCU/MCV (Richmond)

Objectives / Interrogation: Chronic sagittal band ruptures have characteristically been treated by surgical techniques that repair or reinforce the ruptured side to ipsilateral structures, then immobilize in extension 6-10 weeks, followed by an intense course of therapy. Cause of deformity can be traumatic or due to connective tissue weakness, as in Ehlers-Danlos syndrome (EDS) or connective tissue disease. This report supports use of a strong tendon graft centralization and relative motion extension (RME) splinting to preserve motion and function during healing, obviating the need for additional therapy.

Methods: 23 years ago we encountered a rheumatoid arthritis patient who after repeated steroid injections subluxed on both sides of her MP joint. The EDC tendon was centralized by a tendon graft passed through the metacarpal head, then RME utilized for 6 weeks to protect the repair and permit active motion. The result encouraged us to similarly manage the following 22 patients reported, most of whom had traumatic rupture, one with EDS and 3 with rheumatoid arthritis. Tendon grafts have been used from juncturae tendinum, extensor retinaculum, half of the EIP, have of the EFR and most recently the palmaris longus tendon.

Results and Conclusions: These patients were encouraged to resume normal hand function in the splint, and recovered full range of motion without need for additional therapy. The only failure was in a rheumatoid patient with ulnar deviation of her 4th and 5th digits that remained uncorrected by centralization. This surgical technique obviates the need for careful tension adjustment to centralize the tendon, and provides a strong pulley to support patients whose connective tissue strength may be questionable. The use of safe, active motion in an RME orthosis preserves function and avoids need for a prolonged therapy program.

A Modern Adaptation to the Ten Test for the assessment of Digital Nerves

List of authors:
Sunil Parthiban*, Mark Foster¹, Dalia Ghalli¹
¹ Queen Elizabeth Hospital (Birmingham)

Objectives / Interrogation: Digital nerve injuries are common injuries of the hand with variable sensory recovery. These injuries have a significant burden of care and to the wider economy due to delayed return to work. Early, accurate diagnosis of nerve injury allows appropriate planning for surgery and informs the patient early of likely prognosis. There are several methods to assess a digital nerve injury. However, there is yet to be a method that can correctly predict nerve division and is easy to use. The aim of this study was to review the assessment of nerve injury and in particular the use of the Ten Test, and evaluate these in our own patient cohort.

Methods: Our study included patients who had a sensory deficit along the distribution of the digital nerves. We assessed 744 nerves in 370 patients during screening in an investigator led trial for nerve repair (Conduit Nerve approximation versus Neurorrhaphy Evaluation of Clinical outcome Trial). Data was collected prospectively and included the mode of injury, sensory score from 0-10, and operative findings. Patients were excluded if they did not have the Ten Test Score on assessment or if they did not have an operation which confirmed the diagnosis of nerve injury. Statistical modelling was applied to our data.

Results and Conclusions: Results: 159 patients had a complete nerve injury, 484 patients did not have any nerve injury, 46 patients had a bruised or contused nerve and 55 patients had a partial nerve injury. The mean Ten Test score of a patient with a complete nerve injury was 3.13 with a standard deviation (SD) of 0.181. Statistical analysis showed a significant difference in the Ten Test scores between complete digital nerve injury and partial, intact or bruised nerves. Scores of 5 or more showed a negative predictive value of 81.1%. An interesting relationship was noted between the mode of injury and the reliability of the Ten Test score in predicting the severity of the injury which has led to our adaptation of the Ten Test.

Conclusion: The Ten Test can be considered a reliable examination tool in the assessment of digital nerve injuries. Accuracy in nerve injury assessment can be improved when combined with the mode of injury. Further data is required to ascertain whether the Ten Test can be used to rule out nerve injuries in a pre-operative setting.

diagnosis, ten-test, nerve, digital nerve, prospective study, nerve repair
The diagnosis and treatment for extra-pulmonary tuberculosis in the wrist and hand

List of authors:
Rui Zhao*
1 Xijing hospital affiliated Airforce Medical University (Xi’an Shaanxi Province)

Objectives / Interrogation: Analysis the status and regional distribution of tuberculosis in China. Introduce our experiences on the diagnosis and treatment of extra-pulmonary tuberculosis in wrist and hand.

Methods: Tuberculosis is an old and infectious disease. According to the 2018 global tuberculosis report of WHO, the number of new cases was 889,000 and the incidence rate of TB was 63/100,000 in China in 2017. Though the global incidence rate in China has decreased, but a lot of cases of extra-pulmonary tuberculosis in the wrist and hand still could be seen in the northwest China. From 2012 to 2018, 25 patients were diagnosed extra-pulmonary tuberculosis in the wrist and hand in our department and debridement of focal lesion and/or proximal row carpectomy and external fixation were conducted for the treatments according to the degree of lesion. Chemotherapy was recommended for patients including rifampicin, isoniazid, pyrazinamide and ethambutol for three months and rifampicin together with isoniazid for another nine months. First of all, we focused on the relapse of TB in wrist and hand. Then we evaluated the motion of the wrist and joints of hand. And we also measured the VAS score of wrist and hand for assessment the degree of pain.

Results and Conclusions: 25 patients were all followed up. All of patients finished the chemotherapy. The incisions of all cases were primary healing. 3 cases relapsed after 3 months for the first operation. Then they were cured after second debridement for distal row carpectomy. The histopathological examination of tissue showed chronic inflammatory cells with evidence of granuloma with giant cells and central caseation. The range of motion of wrist was obviously limited owing to joint fusion or scar adhesion in the patients with severe erosion in their wrists. The average VAS score of wrist pain decreased from 8.3 to 1.7. Completely debridement of the lesion synovial tissues and bones eroded by mycobacterium tuberculosis combined with early, united, regular, moderate and whole course chemotherapy could be an option for the treatment for the severe extra-pulmonary tuberculosis in wrist and hand.

A Mendelian randomisation analysis suggests that skeletal growth is causal in the aetiology of Carpal Tunnel Syndrome

List of authors:
Akira Wiberg*1, Michael Ng1, Annina Schmid2, Robert Smillie3, Georgios Baskozos2, Michael Holmes3, David Bennett2, Dominic Furniss1
1 University of Oxford, Botnar Research Centre, NDOMRS, Nuffield Orthopaedic Centre (Oxford)
2 University of Oxford, Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital (Oxford)
3 University of Oxford, Nuffield Department of Population Health, Old Road Campus (Oxford)

Objectives / Interrogation: We recently performed the first ever genome-wide association study (GWAS) of Carpal Tunnel Syndrome (CTS), and discovered that several of the putative genes that predispose to CTS are important in skeletal growth. We also found that individuals with CTS are on average >2cm shorter than controls. The aim of this study was to establish whether there is a causal relationship between shorter stature and increased risk of developing CTS.

Methods: Mendelian randomisation (MR) is an analytical method that provides evidence about causal relationships between a risk factor and a disease. It is less susceptible to reverse causation and confounding than conventional observational studies, because inherited genetic variation is randomly allocated at conception.

We performed a two-sample MR analysis using height as the exposure and CTS status as the outcome. We selected 601 single nucleotide polymorphisms (SNPs) for use as instrumental variables for height, taken from a large meta-analysis of adult height GWAS[1]. The genetic effect estimates for these SNPs with CTS risk were obtained from our own GWAS of CTS using data from UK Biobank. The analyses were performed using the MendelianRandomization package for R.

Results and Conclusions: Using the inverse variance-weighted (IVW) MR method on the 601 SNPs identified that a 1 standard deviation (equivalent to 9.24cm) increase in height was associated with an odds ratio (OR) of 0.76 (95% CI: 0.70-0.82, p=2.24x10^{-15}) for development of CTS. The MR-Egger analysis gave an OR of 0.68 (95% CI: 0.52-0.83, p=2.87x10^{-5}) and no evidence to support the presence of confounding arising from the same genetic variants affecting both height and CTS status through different biological pathways (horizontal pleiotropy): intercept=0.0029; 95%CI: -0.0016, 0.0073, p=0.21. These associations persisted in various sensitivity analyses.

This study strongly supports the hypothesis that height is inversely causal in the aetiology of CTS, and, by extension, that altered anthropometric measures (of which height is a proxy) contributes to CTS predisposition. We therefore provide compelling genetic epidemiological evidence that is consistent with previously reported observations that altered hand anthropometric measurements and wrist dimensions correlate with CTS risk. We suggest that a significant proportion of the genetic contribution to CTS risk arises as a result of variants affecting genes that control skeletal growth.

**Prevalence of neuropathic pain in patients who underwent Carpal Tunnel Release (CTR) and outcomes of surgery on neuropathic pain**

**List of authors:**
Mark Tan*1
1 National Healthcare Group (Not a Host City Resident)

**Objectives / Interrogation:** Carpal tunnel syndrome (CTS) is the most common compressive neuropathy and has been reported to affect up to 10% of the general population. Few papers have reported the prevalence of neuropathic pain in CTS as well as the outcomes of surgery on NP. The aim of this study is to determine the prevalence and risk factors of neuropathic pain (NP) in patients who underwent carpal tunnel release as well as the outcomes of surgery on NP.

**Methods:** Patients who underwent Carpal tunnel release from January to December 2017 at Singapore Hospital were enrolled in this study. Neuropathic Pain (NP) was determined by the Douleur Neuropathique en 4 Questions (DN4) with pre and post surgery scores recorded. Data including diabetes, use of gabapentin and pre-operative corticosteroids will be collected. Functional outcome was measured using the (Disabilities of the Arm, Shoulder and Hand) DASH score as well as patient reported satisfaction.

**Results and Conclusions:** A total of 53 patients were identified. There were 37 females and 15 males with an average age of 52 years. 58% of patients were Chinese, 30% Malay and 8% Indian. Results on the prevalence and risk factors for neuropathic pain in patients undergoing carpal tunnel release will be presented. Outcomes of surgery on neuropathic pain will also be discussed.

Outcomes of De Quervain's release from a patient's perspective

List of authors:
Mark Tan*1
1 National Healthcare Group (Not a Host City Resident)

Objectives / Interrogation: De Quervain disease is the second commonest entrapment tendinitis of the hand and wrist following trigger finger. Patients are often treated conservatively with analgesia, splints and steroid injections. De Quervain’s release has been the treatment of choice for many patients who have failed conservative management. The aim of this study is to evaluate the surgical outcomes of Dequervain Release including patient reported experience.

Methods: This is a retrospective study. Patients who underwent DQ release from 2014 to 2017 at a Singapore Hospital were identified and interviewed over the phone in this study. A 28 part questionnaire including demographic data, patient's occupational history, subjective symptoms and patient reported satisfaction will be used.

Results and Conclusions: 99 involved wrists from 95 patients who had surgery were identified. The average age of patient was 46 and 61% of the surgeries were performed on the right wrist. The average follow up period was 28 months. Outcomes of surgery and patient's reported satisfaction will be presented and discussed subsequently.

An ultrasonic diagnostic method by multiple plane scanning and side-to-side comparing for unilateral peripheral nerve entrapment disease.

List of authors:
Xueyuan Li*, Miao Yu1
1 Ningbo No.6 Hospital (Ningbo)

Objectives / Interrogation: To discuss ultrasonic inspection methods and diagnostic indicators by multiple plane scanning and side-to-side comparing for unilateral peripheral nerve entrapment disease.

Methods: Unilateral carpal tunnel syndrome (CTS), cubital tunnel syndrome (CuTS) and radial nerve compression (RNC) patients have been selected as object in this study. The numbers of patients were separately 15, 34 and 13. First, CSASR (cross section area swelling rate) in multiple level was calculated by comparing cross section area of affected side and normal side. Second, the diagnose cut-off value of CSASR was used to diagnose CTS, CuTS, and RNC meanwhile therapy cut-off value to select therapy method. When the maximum value of CSASR was greater than therapy cut-off value, surgical treatment was selected for patients. When the maximum value of CSASR was between the two cut-off values, conservative treatment was selected for patients. At last, the most serious position was determined based on the location where the maximum CSASR value was calculated. The extent of disease was defined by the segment where the CSASR value was greater than diagnose cut-off value.

Results and Conclusions: Diagnose cut-off values of CTS, CuTS and RNC were separately 1.22, 1.51 and 1.50. Therapy cut-off values were separately 1.48, 1.67 and 3.04. The ultrasonic diagnostic method realized localization diagnosis and defined the extent of disease by multiple plane scanning simultaneously, further decreased individual difference, intraneural difference, and interneural difference by side-to-side comparing. The accuracy and objectivity of ultrasonic diagnosis was greatly improved.

**Development of a Mobile App Based on the Oberg Manske Tonkin (OMT) classification to increase its utilization in clinical practice**

**List of authors:**
Lewis Dingle*, Huai Ling Tan¹, Boon Han Charayaphan³, Wayne Lam⁴, Megan Davey⁵, Darryl Chew⁶, Wee Lam¹

¹ Royal Hospital for Sick Children, Edinburgh, St Johns hospital, Livingston, University of Edinburgh (Edinburgh)
² Edinburgh Medical School, University of Edinburgh (Edinburgh)
³ University of Edinburgh (Edinburgh)
⁴ Department of Clinical Genetics, David Brock Building, Western General Hospital, (Edinburgh)
⁵ Division of Developmental Biology, The Roslin Institute (Edinburgh)
⁶ Department of Hand Surgery, Singapore General Hospital (Singapore)

**Objectives / Interrogation:** The Oberg Manske Tonkin (OMT) classification for congenital hand differences (CHD) was introduced in 2013 and subsequently recommended by the IFSSH to replace the pre-existing Swanson's classification. Based on evidence from developmental biology, genetics and clinical features, the OMT eliminated the ambiguities of the Swanson's classification, allowing a robust categorisation of each condition. However, uptake of the OMT remains slow, with surgeons citing difficulties in understanding embryology and other practicalities within a busy clinical practice. Using the OMT to improve communication between different sub-specialties remains difficult. This study examined if a mobile OMT App for smartphone devices would increase its utilisation in clinical practice.

**Methods:** App development was done using the React Native Framework, and distributed for testing using the Apple TestFlight Platform. The App allows search of a condition using traditional CHD nomenclature, as well as keywords such as 'short' or 'fused' fingers to help users unfamiliar with CHD nomenclature. The OMT classification is displayed for each condition, as well as an image/radiograph where possible, plus a short description. Genetic information for syndromes were also included, if known. The Beta version of the App was trialled among 10 participants of various disciplines including congenital hand surgeons, trainees, developmental biologists, geneticists and neonatologists. Each was surveyed on the usefulness of the App as compared to a paper version in the following areas: accessibility, ease of classifying a condition, improved knowledge about the condition and improved communication with other specialties.

**Results and Conclusions:** 83.33% of participants agreed that the OMT itself is useful for clinical use, to improve embryological knowledge (66.67%) and to improve genetic knowledge (33.33%). 100% found it easier to access the OMT using the App as compared to the paper version (40%). 83.3% strongly agreed that ease of access would increase their likelihood of using the OMT. All participants found it easier and quicker when using the App as compared to paper version; 66.7% felt that they could learn more about a condition using the App. Crucially, 66.7% felt that using the App would allow them to communicate better with other specialties.

The OMT App presents a potentially useful platform for the classification of CHD, improved knowledge of embryology among clinicians and communication between different sub-specialties.

Thumb strength and manual ability in radial polydactyly at the interphalangeal and metacarpophalangeal joint level

List of authors:
Robert Dijkman*, Robert Leicher, Ruud Selles, Max Mann, Wiebke Hüsemann, Steven Hovius, Christianne van Nieuwenhoven
1 Erasmus MC (Rotterdam)
2 Catholic Children's Hospital Wilhelmstift (Hamburg)

Objectives / Interrogation: The aims of this study were to quantify strength impairment in radial polydactyly at the interphalangeal and metacarpophalangeal joint level (i.e., Wassel types II and IV), to assess which factors affect thumbs strength in radial polydactyly, and to evaluate the impact of thumb strength impairment on manual ability in radial polydactyly patients.

Methods: Postoperative thumb strength was measured in patients with unilateral radial polydactyly type II and IV using a pinch gauge dynamometer and the Rotterdam Intrinsic Hand Myometer (‘RIHM’). Strength of the unaffected contralateral side was used as the reference. Radial polydactyly type, hand dominance, thenar hypoplasia, number of surgeries, sex, age at follow-up, duration of follow-up, instability, and thumb size were evaluated as potential determinants of thumb strength. Self-reported manual ability was measured using the ABILHAND-kids questionnaire.

Results and Conclusions: Eighty patients were included in this study, with a mean follow-up of 9.4 years. Thumb strength was 86% - 94% of the unaffected contralateral thumb in all measurements. Strength impairment was influenced by hand dominance, thumb size, and number of surgeries. Thumbs of radial polydactyly patients with an affected dominant hand were 10% - 29% stronger on average, compared to patients with an affected non-dominant hand, with exception of metacarpophalangeal flexion strength. Increased thumb size was positively correlated with pinch strengths, whereas increased number of surgeries showed a negative correlation. Forty-three (54%) patients attained the maximum score in the ABILHAND-kids questionnaire. While there was no correlation between relative thumb strength and manual ability, age at follow-up and duration of follow-up were positively correlated to manual ability.

The relatively small but statistically significant strength impairment of radial polydactyly patients does not impair their perceived manual ability. Strength is better in radial polydactyly cases with an affected dominant hand and in cases with relatively larger thumbs. An increase in number of revision surgeries is associated with greater strength impairment.

Treatement of dorsal synovial ganglion of the wrist with percutaneous sclerotheraphy using hypertonic glucose

**List of authors:**
Fernando Silva Pires*, João Baptista Gomes dos santos, Carlos Henrique Fernandes, Flavio Faloppa, Luis Renato Nakachima

1 Dr Diogo de Faria (São Paulo)
2 UNIFESP (São Paulo)

**Objectives / Interrogation:** Synovial ganglion is a benign soft tissue tumor most commonly found in the dorsal region of the wrist. There are numerous forms of treatment described in the literature, among them, observational, aspiration of ganglion fluid and infiltration of corticosteroids or sclerosing agents and surgical resection. Conservative treatment with aspiration with or without infiltration has a low resolution rate (20-30%) compared to surgical treatment (up to 100%), however the surgery is more invasive and has a higher rate of complications. Few sclerosing agents have been studied for this purpose. There are reports of polidocanol and hypertonic serum, however no work using 75% hypertonic glucose.

Hypertonic glucose is considered one of the safest sclerosing agents. Our study was performed with dorsal synovial ganglion aspiration and hypertonic glucose infiltration 75%

**Methods:** Case series, prospective interventional with 45 patients, totaling 47 dorsal synovial ganglion of the wrist, confirmed by ultrasound examination, without previous treatment.

Local anesthesia was performed with 1% lidocaine subcutaneous injection; puncture of the cyst with needle and aspiration of synovial fluid; infiltration of solution containing 3 ml of 75% hypertonic glucose and associated with 0.5 ml of 1% Lidocaine; band Aid. If there was no complete cure or permanence of the cyst within 4 weeks, another puncture and infiltration was performed.

The cure index, the pain intensity by the visual analog pain scale (VAS), the scores of the Quick DASH and Brief Michigan functional questionnaires, the presence of the side effects, range of motion of the wrist and grip strength were evaluated.

**Results and Conclusions:** Of the 45 patients, 30 were female and 15 were male. The mean age was 36.4 years. Of the 47 evaluated ganglion, 24 were on the left side and 23 on the right side, 57.4% evolved to cure, 12.8% presented ganglion without elevation but present palpation and 29.8% were present.

The functional questionnaires and the applied EVA show significant improvement. Side effects were edema and hyperemia for 2 days and skin necrosis in 1 patient treated with dressings. There were no differences in grip strength and range of motion.

It is concluded that the treatment of dorsal synovial ganglion of the wrist with aspiration and infiltration of Hypertonic Glucose 75%, is another new tool for conservative treatment of the ganglion, with a cure rate of 57.4% at 6 months after the procedure.

Anatomical study of dorsal hand vascular network and clinical application of a new multiple intermetacarpal perforators flap.

List of authors:
Regina Sonda*, Andrea Monticelli², Diego Faccio³, Franco Bassetto¹, Cesare Tiengo¹
¹ University of Padua (Padova)
² University of Padua (Cherasco)
³ University of Padua (Sovizzo)

Objectives / Interrogation: The reconstruction of deep defects of dorsal long fingers continue to remain a challenge for the hand surgeon. We investigated the anatomical basis of dorsal hand vascular network to perform a new wide turnover flap.

Methods: In ten fresh frozen upper limbs, injected with acrylic resin, the dorsal surface of hand was dissected. The intermetacarpal spaces and long fingers were evaluated for the characteristic (number, site, interval of origin and course) of dorso-palmar perforators. Wide perforator flap, based on multiple intermetacarpal distal perforators, was used in five patients for the soft tissue reconstruction of multiple dorsal long fingers.

Results and Conclusions: The mean number of perforator vessels of intermetacarpal space was 3.5, mainly septal-type. Proximally to juncturae tendinorum, the vessels were less numerous. The average distance between the more distal intermetacarpal perforator called Quaba perforator and the metacarpophalangeal joint was 1.15 cm (DS 0.58), between Quaba’s and the commissural artery was 1.61 cm (DS 0.66). Proximally to Quaba, constant perforators have been encountered at a mean distance of 28 mm, 37.84 mm, 46.42 mm, 45.5 mm. In long fingers, the mean number of branches for the dorsal cutaneous network was 9 (range 5-15) arising from the proper digital artery. There were not symmetry between radial-ulnar sides, or opposite side of an interdigital-space. In 5 patients a multi-perforator flap, based on distal perforator vessels, has been used to cover the dorsal surface of multiple long fingers. A good aesthetic and clinical result has been achieved at 6 months of follow-up. The perforator arteries network arising from intermetacarpal arteries, allow us to perform a distally based 4 multi-perforator flaps of entire subcutaneous surface of the dorsum to obviate to a microsurgical flap reconstruction. This new flap was then mobilized as a turn-over flap to cover the long fingers and then skin grafted. This autologous-functional reconstruction of all involved fingers allows an early and intense rehabilitation to achieve a better recovery. Subcutaneous surface guarantees tendons and joints gliding, with minimal donor site morbidity. Anatomical knowledge achieved, showed a reliable vascular network, able to support this wide adipofascial flap.

The reconstruction of lateral nail fold in radial polydactyly with a common nail

List of authors:
Weiyang Gao*, Long Wang1, Jian Ding1, Anyuan Wang1, Zongwei Zhou1
1The Second Affiliated Hospital of Wenzhou Medical University, Yuying Childrens Hospital of Wenzhou Medical University (Wenzhou)

Objectives / Interrogation: In this study, we developed a new surgical technique to reconstruct the lateral nail fold of radial polydactyly.

Methods: From December 2012 to October 2015, sixteen cases had a common nail and were treated with a flap from finger pulp. Unilateral inverting suture was performed between the flap and nail bed to reconstruct the lateral nail fold and nail groove.

Results and Conclusions: The follow-up period ranged from 10-45 months. The reconstructed nails had even curvature with a natural-looking of the lunula, and the nail width was about 80%-100% of their normal sides. Four cases had a right angle between the nail epithelium and lateral nail fold, and two had acute angle. The reconstructed nails were asymmetrical in these thumbs. One patients showed a hypertrophy in the lateral nail fold. The reconstructed nails were evaluated by Wang-Gao scoring system (total 12): 10 in two cases, 11 in four and 12 in ten. All the nails had excellent results.

The nail width usually is more than 80% of the normal sides in the radial polydactyly with a common nail. Thus, there is no indication of Bilhaut-Cloquet procedure. Our surgical technique can reconstruct the lateral nail fold and nail groove, and avoid the nail deformity caused by the Bilhaut-Cloquet procedure.

Outcomes after Long Nerve Gap Reconstructions in the Upper Extremity with Processed Nerve Allograft

List of authors:
Bauback Safa*, Timothy Niacaris2, Leon Nesti3, Jozef Zoldos4, Jaimie Shores5, Gregory Buncke1
1 The Buncke Clinic (San Francisco)
2 JPS Health Network (Fort Worth)
3 Walter Reed National Military Medical Center (Bethesda)
4 Arizona Center for Hand Surgery (Phoenix)
5 Johns Hopkins Bayview Medical Center (Baltimore)

Objectives / Interrogation: Long segmental nerve defects after traumatic injuries pose a significant surgical challenge. Current treatment modalities include nerve autograft, nerve transfers, and most recently processed nerve allograft. Recovery outcomes in these repairs however are often limited due to the challenges of this study population. Data was queried from an on-going nerve repair registry for subjects reporting long term follow-up after reconstruction in the upper extremity with processed nerve allograft. Here we report on the recovery outcomes of long gap nerve injuries reconstructed with processed nerve allografts in the upper extremity.

Methods: The RANGER® Study is a multi-center IRB/Ethics approved registry designed to collect data on the use and outcomes of processed nerve allografts (Avance® Nerve Graft, AxoGen). The registry database was queried for upper extremity nerve repairs 30mm or greater with a minimum of 12 months of follow-up data. The cohort was further stratified into sensory and mixed/motor nerve subgroups. Outcomes data were incorporated into the MRC scale for sensory and motor function. Meaningful recovery was defined as = S3/M3 on the MRC scale with higher thresholds defined at S3+/M4 or greater.

Results and Conclusions: The long gap cohort consisted of 91 injuries (58 sensory and 33 mixed/motor nerves). The mean age was 41±18 (18-76) years. The median time to repair was 6 days after injury. Mean gap length was 39±11 (30-70)mm. The mean follow up time was 21 months. Overall meaningful recovery was reported in 81% of repairs with 43% reaching higher thresholds. Meaningful recovery was reported in 81% of sensory nerve repairs. Return of sensory or motor function was reported in 73% and 63% respectively in the mixed/motor subgroup. These outcomes were comparable to historical literature of long gap reconstructions with nerve autograft. No related adverse events were reported.

Processed nerve allograft can successfully be used in long gap nerve reconstructions. Meaningful recovery was reported in 81% of repairs with outcomes as expected across subgroups. No adverse events were reported. These outcomes compare favorably to historical data in the literature for nerve autograft. Limitations of this study include the challenges of obtaining long term follow-up, observational study design, and lack of an active control. The registry continues to collect outcomes data on the use of processed nerve allografts.

The classification and treatment of the polysyndactyly of middle finger

List of authors:
Xiaofei Tian*
1
1 Children’s Hospital of Chongqing Medical University (Chongqing)

Objectives / Interrogation: The polysyndactyly of the middle finger usually manifests as the polydactyly of middle finger and at least one of the duplicated middle fingers fused to adjacent fingers. Most cases are distinctly different from the polysyndactyly of the ring finger and haven't appropriate classification to guide surgery. Here we proposed a classification system and discuss the treatment.

Methods: Classified the osseous syndactyly as complex type, cutaneous syndactyly as simple type and classified the polydactyly of middle finger from type I to VIII based on the level of bifid or duplicated skeleton. 19 cases was classified into: Type I 1 cases, Type III 2 cases, Type V 5 cases, Type VI 7 cases, Type VII 4 cases and 3 cases belonged to complex syndactyly. The surgical procedures were performed based on the characteristics of different types. Usually the hypoplastic finger was removed, and the preserved finger was separated from fused adjacent finger by zigzag incisions and using consecutive gull wing flap to construct the two webs at the same time. The final shape and function of affected fingers were followed-up.

Results and Conclusions: All cases were operated successfully. The adjacent fingers in simple type cases were nearly normal. However, all the preserved middle fingers were still suffering from different degree of hypoplasia and abnormality of joints. 4 cases accepted a latter surgery to correct the shape and to improve the function.
We proposed the classification of the central polydactyly, which is similar to the Wassel classification of thumb polydactyly. It will be easily acceptable by most clinicians and be more convenient for academic exchange. There are different characteristic in different types and Type V and VI were more common. Type V usually manifested as bifid proximal phalanxes with both hypoplasia middle fingers but usually minimal lateral deviation. Type VI usually manifested as duplication of proximal phalanxes, usually associates convergence of both middle fingers, similar to the Wassel IV-D type polydactyly of thumb. To select which finger to remove, one should consider to the characteristics of the above different types. The deformity of the preserved finger should be corrected as possible. But in most cases, the residual deformity of the middle finger may still need a second-stage surgery. Skin graft may not be needed in some cases by using consecutive gull wing flap to construct the two webs and transferring the remaining flap from the excised duplication.

Ulnar shortening osteotomy as treatment for ulnar impaction syndrome. An 8-year follow-up.

List of authors: Pedro Jesús Jiménez Hidalgo*1, José A. Oteo1, Patricia Merino1, Cristina Llarena Barroso1
1 Hospital Universitario de Fuenlabrada (Fuenlabrada, Madrid)

Objectives / Interrogation: The ulnar impaction syndrome is a source of ulnar wrist pain. The diagnosis includes physical examination and radiological signs of ulnar impaction, although not all cases of radiographic impactions are symptomatic.

The objective of the study is to evaluate the results of ulnar shortening osteotomy fixed with a compression plate on the volar face of ulna for primary ulnar impaction syndrome, 8 years of follow up.

Methods: Retrospective review of 10 patients with primary ulnar impaction syndrome intervened in 2009 and 2010, mean follow up of 8,7 years.

The following data observed genre, age, range of motion (pronation, supination and Kapandji scale), grip strength, pinch strength, VAS and DASH.

A P-A and lateral x-ray of forearm were made for assessment changes on distal radio-ulnar joint ant carpal-ulnar joint.

Results and Conclusions: 10 patients (6 women, 4 men), mean age 44.4 years (26-62 years). 3 were intervened on the left hand. All patients had right dominance. Intervention was made with Acumed Osteotomy System (Acumed®) with mean shortening of 2,3 cm.

The osteotomy consolidation was achieved between 2-10 months (mean 6.3). 4 patients were intervened for extraction of the material due to discomfort. The extraction was made between 1 and 7 years (mean 3 years). Just one x-ray showed a distal radius osteophyte.

Results were analyse using Wilcoxon test. Mean values of grip strength was 26,8 kg and pinch mean strength was 7,4 kg, we did not found statistical difference compared to contralateral (grip strength p = 0,345, pinch strength p = 0,35).

Mean values of pronation was 90º, supination was 83,5º, Kapandji 9,6. There was no difference on the range of motion between both extremities (pronation p = 0, supination p = 0,109, Kapandji p = 0,317).

There was no difference on the VAS scale, mean value of 0.9 points (p = 0,317). The DASH score mean results were 12,72 points.

A correlation was found using Spearman test between the DASH scale and both the grip strength (p < 0,05) and the pinch strength (p < 0,05). There was no difference between VAS scale results and grip (p = 0,059) or punch strengths (p = 0,127).

We concluded that ulnar shortening provides excellent long-time results, with no difference on either motion values (pronation, supination, Kapandji scale, grip strength and punch strength), VAS or DASH between the intervened extremity and the collateral at 8 years after the procedure.

It also suggest that DASH may have better correlation with surgical results in terms of strength than VAS.

Keywords: Ulnar shortening, Ulnar impaction syndrome
Surgical Management of Thoracic Outlet Syndrome: A Single-Centre Review

List of authors:
Karen Slater¹, Andrew Hart², David Leonard²

¹ Canniesburn Plastic Surgery Unit, Glasgow Royal Infirmary, University of Glasgow, University of British Columbia, Vancouver, Canada (Glasgow)
² Canniesburn Plastic Surgery Unit, Glasgow Royal Infirmary, University of Glasgow (Glasgow)

Objectives / Interrogation: Thoracic outlet syndrome (TOS) results from compression of one or more of the brachial plexus, subclavian vein, or subclavian artery as they pass from the neck into the axilla. Presenting signs and symptoms, location of compression, and responsible structures can vary. We sought to review the indications, operative findings, treatment, and outcomes for all patients treated at our centre.

Methods: A retrospective review of all thoracic outlet syndrome patients treated surgically by a single operator was performed. Patients were identified by theatre logbooks. Data was extracted via review of medical records, theatre records, and investigations.

Results and Conclusions: 32 primary procedures (7 bilateral, 7 right-sided, 11 left-sided) were performed in 25 patients (18 female) from October 2010 to September 2018. Surgical indications included one or more of sensory change (24/32), weakness (23/32), or neurogenic pain (20/32) in 31 out of 32 cases.

One case was abandoned intra-operatively due to respiratory compromise. All other patients were treated with surgical exploration, release/excision of compressive soft tissues, neurolysis, and rib resection if indicated. Compressive structures included scalene musculature, fibrotic tissues, first rib, and anomalous structures including cervical rib, with multiple involved structures documented in 29 of 31 cases.

Complications were common (19/31), with cervical plexus pain/paraesthesia occurring most frequently (12 cases, 1 refractory). Major complications (1 haemothorax, 1 pneumothorax) occurred in 2 cases. Satisfactory symptom resolution was reported by 84% of patients (26/31). 1 patient underwent surgical re-exploration for recurrent symptoms.

The operative findings demonstrate varied and multiple structures contributing to thoracic outlet syndrome. Surgical decompression is individualized according to the pathology encountered. Despite a high rate of minor complications, surgical exploration and decompression effectively treats TOS symptoms in the majority of patients.

**Oral presentation or poster presentation: Tendon**

**Injection into both compartments is more effective than an extensor pollicis brevis compartment alone in de Quervain disease?**

**List of authors:**
Hyoung Seok Jung¹, Jae Sung Lee¹
¹Hospital of Chung-Ang University of Medicine, (Seoul)

**Objectives / Interrogation:** In de Quervain’s disease (dQD), it has been described in many previous studies that failure to inject of steroid into the first compartment could result in persistent symptom. Therefore, recent studies have been focused on ultrasound (US) guided accurate intra-synovial injection into the abductor pollicis longus (APL) and extensor pollicis brevis (EPB) tendons for enabling the steroid to reach both tendon sheath in patients with complete septation. We hypothesize that accurate injection of steroid into an EPB compartment alone is as effective as injection into both compartments in dQD.

**Methods:** A prospective, randomized controlled study was performed at a single center between 2017 and 2018 using patient who presented with dQD. The patients were divided into two groups: Group 1, in which we injected into the compartments of APL and EPB tendon, respectively and Group 2, in which we injected only into the EPB compartments. All injections were performed by single orthopedic surgeon under US-guided. Pain and functional outcome was assessed by visual analogue score (VAS), quick Disabilities of the Arm, Shoulder, and Hand (DASH) scores and subjective response of patients.

**Results and Conclusions:** A total of 27 US-guided injections have been performed in 27 patients after clinical and ultrasound examination. 14 patients were classified into group 1 and 13 patients were into group 2. Pain on the 100 mm VAS for the group 1 was 82.8 and group 2 was 72.7 at baseline. At 2 weeks after steroid injection, pain and clinical scores improved in both groups. However, there was no significant differences in pain and clinical scores at 2, 6 weeks and final follow-up. Furthermore, no significant differences were seen in subjective response and the ratio of surgeries/total in each group. In conclusion, Our findings suggest US-guided injection targeting the EPB alone is as effective as targeting both compartments in dQD patients with complete septation.

Radioscapholunate (RSL) fusion for posttraumatic osteoarthritis (PTRO) or type II scapholunate advanced collapse (SLAC). Functional results for both etiologies.

List of authors:
Guillaume Bacle*, Christofer Powell2, David McCombe2, Anthony Berger2, Stephen Tham2
1 CHRU de Tours, Hôpital Trousseau, Inserm U1253 (Tours)
2 Bernard O’Brien Institute Of Microsurgery, VHSA (Melbourne)

Objectives / Interrogation: Background
Despite a high complication rate when looking at long term follow-up, RSL fusion is a therapeutic option for arthritis affecting the radioscaphoid and radiolunate joints. However, its role in management of SLAC wrist remains poorly defined and RSL fusion for the SLAC type II wrists is not an option commonly discussed. Indeed, the mainstays of treatment for this condition remain proximal row carpectomy (PRC) or four corner fusion.

Objectives and interrogation
The objective of this study was to determine if there were differences in outcome for RSL fusion when performed for SLAC II wrist as compared to that performed for post traumatic radiocarpal OA (PTRO).

Methods: Patients who had undergone RSL fusion for either SLAC II wrist or PTRO joint were identified from surgeons' records. Data collected included patient demographics, co morbidities, operative data and postoperative complications. Participants were asked to complete DASH and PRWE questionnaires. They were also asked to rate level of pain on a VAS as well as satisfaction score. Objective functional outcomes were measured in terms of range of motion at the wrist and grip strength. Follow-up x-rays were also performed.

Results and Conclusions: Flexion-extension arc was better in the SLAC group and radio-ulnar deviation better in the PTRO group though none reached statistical significance (p>0.05). Grip strength (both as an absolute value and as percentage of uninjured side) was better in the SLAC group and came to statistical significance. Functional measures of DASH and PRWE were also better in the SLAC group.
There was no significant difference in Pain VAS score or satisfaction in either group. Both groups scored low for pain and high for patient satisfaction. Analysis of the follow up x-rays indicated that all those which had not gone onto complete wrist fusion demonstrated successful bony union.

Conclusions
RSL fusion when performed for PTRO can be a very effective procedure in terms of range of motion, functional outcome assessment and patient satisfaction. When SLAC is the indication for surgery the results would suggest that FCF is superior. Indeed, when we compare our results to published series and that performing RSL fusion in a SLAC wrist is more technically demanding, FCF would seem to remain the better option for SLAC wrist.

6 Keimyung University, Dongsan Medical Center, Daegu, Korea (Daegu)
7 Asan Medical Center, University of Ulsan, Seoul, Korea (Seoul)

Objectives / Interrogation: The human hand is an organ specialized for fine motion and sensation, hence the relatively large representation of it on brain homunculus. The pathway of sensation starts from information sent by mechanoreceptors in the hand. This study reports the topography of Pacinian corpuscle in the fingertips of human, as the critical apparatus.

Methods: Ten fingers from both hands of one fresh frozen cadaver were examined. Glabrous skin distal to the distal interphalangeal joint was harvested deep to the periosteum, including its fat and subcutaneous tissue. The fingertips were divided into 10 specimens, consisting of 5 distal parts and 5 proximal parts. Modified gold chloride stain was performed. Sectioned specimens were observed under light microscopy and the volume was measured. The density of the corpuscle in the radial and the ulnar sides of the fingers, in the proximal and the distal sides, and in the right and the left hand were compared.

Results and Conclusions: Results: The Pacinian corpuscles were only observed in the subcutaneous tissue. There was no significant difference in terms of density between distal to proximal sides and right to left hand. Ulnar and radial sides showed statistically significant difference in the fingers except for the thumb.

Conclusion: The Pacinian corpuscle is present with different density depending on its locations on the human finger tips' pulp.

Costochondral interposition arthroplasty in treatment of basal thumb arthritis

List of authors:
Agnieszka Mandziuk*, Miho Nicoloff, Simon Cleenewerck
1 Bonifatius Hospital Lingen (Lingen)

Objectives / Interrogation: Trapeziectomy remains gold standard in treatment of basal thumb arthritis. This presentation handles the technique of costal cartilage interposition arthroplasty with special attention to the additional arthritis of the scaphotrapezoidal joint.

Methods: The main agenda of the presentation is to primarily focus on 26 patients afflicted by the disease who, according to Eaton-Littler classification, were categorized as stage IV, and who from 2015 on were treated with trapeziectomy, costochondral autograft and ligament reconstruction. Surgery was performed with additional interposition arthroplasty of the scaphotrapezoidal joint with a cartilage chip. Thumb and wrist were immobilized postoperatively for 4 weeks in a spika type cast/orthosis. The results were assessed by Buck-Gramco scale after 14-36 months.

Results and Conclusions: In total we could assess well or very well 20 patients. Radiologically there was no migration of thumb metacarpal in any of the patients. The vitality of costal cartilage was evidenced in MRI performed on random patients, which further more demonstrated the correct position of the cartilage chip.

Since 1995 interposition arthroplasty with costal cartilage in basal thumb arthritis has been performed with generally very good results.

The special attention to the scaphotrapezoidal joint seems to be reasonable and the interposition of a cartilage chip appears to be a suitable solution.

AN UNUSUAL LUMP IN THE HAND: DESMOPLASTIC FIBROBLASTOMA

List of authors:
rudo Madada-Nyakauru*, Ian Grant
1 Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust (Cambridge)

Objectives / Interrogation: Soft tissue tumours of the hand are common and usually benign. Enlargement of tumours within the confined spaces of the hand can cause pain and stiffness. We report the case of a desmoplastic fibroblastoma (collagenous fibroma): a rare histological finding in the hand. Only a small number of sporadic cases and series have previously been documented.

Methods: A 41 year old right hand dominant male presented with worsening wrist pain and decreased range of movement. Eight years earlier he had sustained a scaphoid fracture which was successfully managed with six weeks of immobilization. He had plain film X-rays of his wrist requested in primary care, which were unremarkable. He subsequently developed a visible dorsal wrist soft tissue swelling and was referred to the hand clinic of a University Teaching hospital

Results and Conclusions: Magnetic Resonance Imaging (MRI), showed an abnormal mass arising dorsal to the capitate and extending through the gap between the second and fourth extensor compartment to lie immediately beneath the skin, measuring 15 mm thick by 27 mm wide and over 40 mm longitudinally. His management was discussed in a sarcoma-multi-disciplinary clinic: he was offered an excision biopsy.
Surgery was performed under general anaesthetic with tourniquet control. A marginal excision was performed: histology of the excised specimen showed well demarcated lobules comprising dense fibrous stroma and scattered spindle cells.
Immunohistochemistry showed minimal expression of Actin, Desmin and other diagnostic surgical pathology protein markers such as S100, CD34 or Epithelial membrane antigen (EMA). These histopathological and immunohistochemistry findings supported the diagnosis of a desmoplastic fibroblastoma.
After 4 weeks he returned to work as a security guard, his pain was reduced, his wrist mobility and hand strength returned to within 90% of his contralateral limb within 8 weeks.

Prior to surgery the most likely diagnosis seemed to be a Giant Cell Tumour: definitive diagnosis required histological assessment.

Reporting the behaviour and appearance of rare soft tissue tumours should help future hand surgeons to consider a more comprehensive list of possible causes for a lump, and allow more confident decision making

Reconstruction of fingertip amputations in children with composite autograft and semi-occlusive dressing: CASOD, new technique

List of authors:
Manuel Mendez\textsuperscript{1}, Daniela Aguirre\textsuperscript{2}, Magdalena Mendez\textsuperscript{3}
\textsuperscript{1} Teleton Santiago, Clinica Las Condes (Santiago)
\textsuperscript{2} Clinica Las Condes (Santiago)
\textsuperscript{3} Universidad Católica de Chile (Santiago)

Objectives / Interrogation: The reconstruction of fingertip amputations in children is challenging. There are many procedures described to treat this injury, none of which present optimal results. Repositioning of the amputated segment as an autograft or with microsurgical techniques seems to offer the best outcome. It allows to preserve otherwise irreplaceable structures, such as the nail bed and the hyponychium, enabling children to maintain an anatomically and functionally normal fingertip. We present a series of three pediatric patients treated with this proposed method, which combines composite autograft and semi-occlusive dressing (CASOD technique).

Methods: Patients were admitted to the operating room. Under anesthesia, surgical irrigation and debridement, with excision of part of the adipose tissue of the fingertip was performed, followed by suture of the amputated segment. In cases of bone involvement, a hypodermic needle was placed as fixation method. A semi-occlusive wound dressing (Tegaderm \textsuperscript{®}) was placed for 6 weeks. Patients were evaluated weekly to ensure the dressing maintained its sealing properties.

Results and Conclusions: Results: 3 patients were included in this study, with ages between 18 months-10 years. The amputation level, according to the modified Ishikawa classification was 1a (1 patient) and 1b (2 patients). Patients were followed-up for 13 months. In all three cases, the fingertip was preserved without necrosis or any other complication. The anatomy and aesthetic aspect of the fingertip was maintained.

Conclusions: this technique -"CASOD"- provides a new, simple and reproducible approach that offers good results. For this technique, preserving the wound's inflammatory exudate is fundamental, since it supplies the environmental conditions for regeneration without scar tissue formation. A wider number of patients needs to be recruited to this study in order to validate the technique.

Neurovascular Island Flap for Thumb Duplication Reconstruction- a Novel Treatment with Long Term Outcomes

List of authors:
Michael Chu-kay Mak*, Esther Ching-san Chow², Bo Liu³, Wing-lim Tse¹, Pak-cheong Ho¹
¹ Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Prince of Wales Hospital (Hong Kong)
² Department of Orthopaedics and Traumatology, United Christian Hospital (Hong Kong)
³ Dept. of Hand Surgery, Beijing Ji Shui Tan Hospital, Peking University (Beijing)

Objectives / Interrogation: Pulp and nail asymmetry is commonly seen in thumb duplication. In hypoplasia of both digits, conventional reconstruction or Bilhaut-Cloquet procedure and its modifications may not be possible or may lead to poor cosmetic outcome. To improve aesthetic and functional results, a novel reconstruction technique with neurovascular island flap with long-term outcome was developed.

Methods: 14 patients with thumb duplication aged 8 to 18 months were operated between 2002 and 2013 in our center. All patients had significant hypoplasia and asymmetry of the pulp and nail of the planned retained digit. A dorsal-based neurovascular island flap including part of the pulp tissue, nail bed, with or without the associated phalangeal bone was raised from the planned ablated digit basing on its single neurovascular bundle. On combining the flap to the proper digit, meticulous repair of the nail bed, nail fold and pulp tissue using fine sutures under magnification. All patients were followed up to monitor the aesthetic, functional and radiological outcome, using the Tada and JSSH scores. A novel aesthetic scoring system was proposed which assessed size, shape, scar, smoothness of nail, and symmetricity. Parents, an occupational therapist and a hand surgeon participated in assessment.

Results and Conclusions: The mean follow up period was 7 years 11 months. 13 patients underwent the flap procedure and all flaps survived. In 1 patient, flap procedure was not proceeded as the pedicle was not well developed. Nail width and pulp circumference were restored compared with the normal thumb.

Pre-op (left) and post-op (right) after neurovascular pulp island flap procedure

The mean Tada and JSSH scores were 4 (3-5) and 17.5 (16-19) respectively. Suture size, the use of microscope, or combination of bone did not affect outcome. The proposed aesthetic scoring system was able to assess and highlight the cosmetic aspect of
the outcome, and correlated well with the parents' satisfaction (p=0.049).

In selected cases of thumb duplication with significant pulp hypoplasia and nail asymmetry, the neurovascular pulp and nail island flap is a safe and effective means to restore symmetry for improvement of aesthetics.

Role of the interosseous membrane and TFCC in distal radioulnar joint instability in Galeazzi fracture: Anatomical and biomechanical study

List of authors:
Claudia Lamas-Gómez*, Ariadna Da Ponte-Prieto¹, David Gutierrez-Medina², Rosa Morro-Martí², Ignasi Gich-Saladich¹, Manuel Llusà-Pérez²
¹Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona (Barcelona)
²Hospital Clinic. Universitat de Barcelona (Barcelona)

Objectives / Interrogation: Most Galeazzi fractures can be treated adequately with ORIF of the radius alone, but some will remain unstable at the DRUJ and require repair of the TFCC. The purpose of this study was to define and measure DRUJ dislocation and instability associated with the sequential sectioning of the different bands in the interosseous membrane (IOM) and TFCC in a simulation of a Galeazzi fracture.

Methods: Methods: Twelve fresh-frozen cadaver forearms were dissected and the different parts of the IOM were measured. Their were 6 men and 6 women with a mean age 74 years-old. We examine the anatomy and function of the forearm IOM and define the importance of anatomic divisions within IOM. Each forearm was them mounted into a wrist and forearm biomechanical device (Mecmesin AFG/AFTI Multitest-d ®, Virginia, USA). We simulated a radius fracture in all the specimens. A force of 25 N, 50 N and 75 N was applied. The load data (N) were correlated with the displacement data (cm). We sequential sectioning: 1) Central Band (CB); 2) CB plus Distal Oblique Bundle (DOB); and 3) CB plus DOB plus TFCC. The degree of displacement (cm) in DRUJ were measured in the three groups with the different loads. We evaluated differences in variables using Student’s t-test and ANOVA for groups. We considered 2-tailed p values less than 0.05 to be statistically significant.

Results and Conclusions: Results. In the specimens the average radial length was 23.38 cm and the average ulnar length was 25.5 cm. The average length of the radial origin was 13 cm and the ulnar origin was 5.7 cm. The CB has an average width of 2.5 cm. The CB of the IOM contributes 70% to the mechanical stiffness of the forearm, while the TFCC contributes 20% and the DOB contributes 10%. In-group 1 applying progressive loads (25/50/75 N) the average DRUJ displacement (cm) was 4.3, 5.9, and 7.9 cm respectively. In-group 2 was 5.2, 5.7, and 6.9 cm respectively. In-group 3 was 6.2, 8.1, and 9.9 cm respectively. Our study showed a correlation between the increase in applied load to the same injury and the degree of displacement (P=0.001). In-group 3 the degree of DRUJ displacement was statistically significant (p= 0.04).

Conclusions: CB is the crucial region within the IOM in restraining proximal migration. The TFCC also acts to resist proximal radial migration. Migration of the radius under loads implies disruption of both the CB and the TFCC. The DOB does not seem to have a relevant role in the displacement and in the transverse instability in forearm.

TFCC; DRUJ dislocation; Galeazzi fracture; Radial shaft fracture
Treatment for PIP joint flexion contracture in stenosing tendovaginitis using resection of the flexor digitorum superficialis.

List of authors:
Jiro Namba*, Michio Okamoto²
¹ Hoshigaoka Medical Center (Hirakata)
² Yao Municipal Hospital (Yao)

Objectives / Interrogation: Generally, PIP flexion contracture associated with finger stenosing tendovaginitis is resolved by incision of A1 pulley which is a major obstruction site. In spite of the favorable result of A1 pulley release, sometimes certain degree of contracture did not go away due to remaining sliding disorder at other sites except A1. We reviewed whether excision of total or half slip of the flexor digitorum superficialis (FDS) tendon was practicable for primary or revision cases with refractory flexion contracture.

Methods: We identified 12 fingers in 12 patients who underwent FDS resection. The average age was 76 years old (62-91). 2 fingers had one prior A1 pulley release and 1 had 2 previous surgeries. Diabetes were involved in 4. The long finger was affected in 11 and index finger in one. The intraoperative findings on tendons were recorded. Clinical outcome was reviewed including ROM, grip strength, Visual analogue score (VAS).

Results and Conclusions: The mean preoperative PIP contracture was 28 degrees. The ulnar half slip of the FDS was excised in 4, both slips in 8 fingers. Intraoperative full extension was achieved in 11 cases, and no other soft tissue release like capsule and volar plate was conducted. All FDS tendons had longitudinal internal lesions and enlargement. The postoperative PIP contracture was 7 degrees, full extension was achieved in 7 fingers at a mean of 18 months postoperative. No case of swanneck deformity was recognized. VAS was 14 points, and grip strength was 86% against contralateral side. Total active arc motion was 241 degrees. Between half slip and total resection, total arc was significantly different with 219 / 252 degrees, as opposed to insignificance among the other variables.

Resection of hemi or total slip of FDS is an effective method for treatment of residual PIP contracture. In consideration of total arc motion in our cases at final follow up, total resection might provide wider space for flexor digitorum profundus to glide than half slip.

Open wedge phalanx osteotomy for correction of Wassel type IV-D thumb duplication with zigzag deformity

List of authors:
Jianghai Chen*, Fangxing Ai, Kun Wang, Yan Zhang
1 Wuhan Union Hospital, Tongji Medical College, Huazhong University of Science and Technology (Wuhan)

Objectives / Interrogation: Wassel type IV duplications angulated inversely is the most complicated and common subtype associated with Wassel type IV polydactyly. The objective of this study is to align the IP joint by use of open wedge proximal phalanx osteotomy to obtain better outcome for reconstruction of zigzag deformity.

Methods: Between 2015 and 2017, 14 patients were treated for thumb duplication with zigzag deformity by use of open wedge osteotomy at the proximal phalanx to correct deviation at the interphalangeal joint from the central axis. The mean age of patients at the time of surgery was 11 months (range, 6-15 months). Preoperative and postoperative X-ray were obtained in all cases to provide information about the zigzag pattern of bone involvement and monitor growth changes over time. Patients were followed for a mean of 26 months (range, 16-36 months).

Results and Conclusions: The results were evaluated according to form for thumb polydactyly of the Japanese Society for Surgery of the Hand. By the end of follow-up, 12 cases were rated good, 2 cases fair. Therefore, this approach may be considered as a good alternative for reconstructing Wassel type IV polydactyly with zigzag deformity.

Keywords: thumb duplication, Wassel type IV, zigzag deformity, open wedge osteotomy
Computer navigated reduction of scaphoid non-unions and displaced scaphoid fractures- a cadaveric study

List of authors:
Pak-cheong Ho¹, Elvis Chun-sing Chui³
¹ Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Prince of Wales Hospital (Hong Kong)

Objectives / Interrogation: Scaphoid non-union results in humpback deformity, pronation of the distal fragment, and a bone defect in the non-union site with shortening. To improve accuracy of scaphoid fracture fixation or non-union reconstruction with bone grafting, we hypothesize that pre-operative planning and computer navigated reduction is feasible and results in good correction of alignment. We propose a method of anatomical reconstruction in scaphoid non-union by computer-assisted preoperative planning combined with intraoperative computer navigation, which can be performed in conjunction with arthroscopic bone grafting technique.

Methods: The first model consisted of a scaphoid bone with a simulated fracture, a forearm model, and an attached patient tracker was used. 'Pre-operative' CT scan was done. The proximal scaphoid fragment was attached to the model. 2 titanium K-wires were inserted into the distal scaphoid fragment. 3D images were acquired (3D Iso-C, Siemens) and matched to those from the computed tomography (CT) scan. In an image processing software, the non-union was reduced and pin tracts were projected into the proximal fragment. The K-wires were driven into the proximal fragment under computer navigation. Reduction was assessed by direct measurement.

These steps were repeated in 2 cadaveric upper limbs. A scaphoid fracture was created and a patient tracker was inserted into the radial shaft. Simulated reduction and planning of pin tracts into the proximal fragment was done as in the first model. Using these planned tracts, the K-wires were driven into the proximal fragment under computer navigation. Direct visual assessment of reduction was done and post-fixation CT was obtained to assess reduction.

Results and Conclusions: In both models, articular stepping was less than 1mm, and scaphoid length was restored with less than 1mm discrepancy. Part analysis of the CT showed good matching with mean root mean square analysis of 0.5mm.
This is the first report on the use of computer navigation on reduction of malalignment in the wrist. Further study in real patients is warranted to demonstrate clinical benefit.

Polyaxial locking plate fixation for volar-displaced distal radius fractures including marginal fractures

List of authors:
Keikichi Kawasaki*, 1, Katsunori Inagaki2, Takeshi Sakai1, Tetsuya Nemoto2, Sadaaki Tsutsui2, Hiroki Nishikawa2, Kayo Tsuzawa2, Wakako Sakamoto2
1 Showa University, Yokohama Northern hospital (Yokohama) 
2 Showa University (Tokyo)

Objectives / Interrogation: The volar-displaced distal radius fractures was considered to be easy to treat before. Harness reported that there were 7 cases of palmar subluxation after volar plating for distal radius fractures. He described all cases were B3 type of AO-classification and it was important to fix the fragment of volar lunate facet fragment (VLF fragment). We also reported 20 cases of palmar subluxation, and 17 cases of them were Smith's or volar Barton's fractures. From our data, the average of longitudinal distance of VLF fragment was under 10 mm, and only 34% of VLF fragment was supported with the plate. As our strategy for volar-displaced distal radius fractures, we place Polyaxial Locking Plate (PLP) as distally and ulnar as possible. This time, we report the treatment result of volar-displaced distal radius fractures including marginal fractures.

Methods: The number of cases that had been operated for distal radius fractures in Showa University after 2015 were 131 hands of dorsal-displaced type and 35 hands of volar-displaced type. Among the latter, 33 hands, which are followed up more than six months, were subjected to this study. The mean age was 60.3 years old, male: female was 11:22 cases, and the mean follow-up period was 9.5 months. For CT in pre-operation, there were 9 hands (27.3%) of double fracture-line in VLF fragment and 7 hands (21.2%) of palmar subluxation. Monoaxial Locking Plate (MLP) were used for 4 hands and PLP for 29 hands. As the mean followed up period was 9.5 months. As for an additional procedure, spring wire fixation by Moore were used for 5 hands, plate with mini-plate was used for 1 hand, and artificial bone was used for 8 hands. We investigated the clinical evaluation, the radiological evaluation and complications of these cases.

Results and Conclusions: [Results]
For the all cases, fractures were united. The correction loss of various parameters was slight (UV: VT: RI was 0.9 mm: 0.2 degrees: 0.8 degrees). The mean of the modified Mayo score was 86.2 points. As the complications, palmar subluxation were 2 cases, carpal tunnel syndrome was 1 case, ulnar abutment syndrome was 1 case and CRPS was 1 case.

[Conclusion]
The results of our treatment for volar-displaced distal radius fractures were almost good, but there were two cases of palmar subluxation after volar plating. For prevention of palmar subluxation, it is important to support the VLF fragment perfectly. We should select rim plates or some additional procedures for the cases under 10 mm of longitudinal VLF fragment.

volar-displaced distal radius fractures, Polyaxial locking plate, Palmar subluxation after volar plating
Functional Outcome for Arthroscopic Treatment of Septic Arthritis of the Wrist

List of authors:
Esther Man-wai Chow*, Jimmy Kit-yan Lau¹, Lucci Lugee Liyeung¹, Michael Chu-kay Mak¹, Wing-lim Tse¹, Pak-cheong Ho¹
¹ Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Prince of Wales Hospital (Hong Kong)

Objectives / Interrogation: Septic arthritis is a potentially joint destructing condition if not treated properly, and septic arthritis of the wrist accounts for an estimated 5% of septic arthritis of all joints.
Arthroscopic lavage is a well established treatment for septic arthritis of the knee, hip or shoulder. However, previous studies on treatment of wrist arthroscopy were limited to case reports or retrospective studies focusing on open treatment. There is also insufficient data on functional outcome following treatment. Our study aims to establish the effectiveness of arthroscopic treatment and to investigate the functional outcome.

Methods: This is a retrospective study reviewing all cases of septic arthritis of the wrist treated by arthroscopic lavage over a period of 10 years from 2007 to 2016. Clinical data collected included age, gender, history of prior injury, duration of symptoms, culture of joint aspirate, and radiological findings.

An arthroscopic technique and any additional procedures performed are described. Intraoperative findings, duration and type of antibiotics used, number of operations performed, and length of hospital stay were reviewed.
Functional outcomes included range of motion and subjective evaluation with QuickDASH (Disabilities of the Arm, Shoulder, and Hand) score questionnaire.

Results and Conclusions: From 2007-2016, 14 patients (10 males and 4 females) with 15 septic wrists underwent arthroscopic surgery. One patient had both wrists involved. The average age at time of operation was 63.9 years old and the average duration of symptoms before admission was 6.08 days. Average follow up time was 10 months.
The most notable risk factors were diabetes mellitus and immunosuppression conditions which were present in 8 patients. All except 2 patients (83.3%) responded well to single arthroscopic treatment. Two required subsequent operations for concomitant tenosynovitis. There were no complications. The most common isolated organism was staphylococcus aureus. At an average follow up of 10 months, one case (8.3%) had signs of severe joint erosion on subsequent X-Ray. The average QuickDASH score was 19.7 out of 100. Duration of symptoms of 5 days or more prior to presentation was associated with a poorer QuickDASH score.

With a low re-operation rate and good functional outcome which is comparable to open treatment from previous studies, arthroscopic treatment is a safe and effective alternative to open procedure as a first-line treatment for septic arthritis of the wrist.

septic arthritis of wrist, wrist arthroscopy, arthroscopic synovectomy, functional outcome
Evaluation of Nerve Reconstruction in the Hand by Gap Length with Processed Nerve Allograft

List of authors:
Bauback Safa*, Timothy Niacaris2, Sonu Jain3, Mehir Desai4, Fraser Leversedge5, Gregory Buncke1
1 The Buncke Clinic (San Francisco)
2 JPS Health Network (Fort Worth)
3 Ohio State University (Columbus)
4 Vanderbilt Health (Nashville)
5 Duke Health (Durham)

Objectives / Interrogation: Nerve gap injuries associated with hand trauma are very common. Current reconstruction methods for addressing nerve gaps include nerve autograft, processed nerve allograft, and synthetic conduits. Data were queried from the on-going international registry for nerve reconstructions with processed nerve allograft to determine effect of gap to outcomes. We report on the return of meaningful sensation by gap length after nerve repairs in the hand.

Methods: This multicenter IRB/Ethics approved international registry is designed to collect data associated with processed nerve allografts (Avance® Nerve Graft, AxoGen). The registry database was queried for nerve repairs in the hand with a minimum of six months of quantitative follow-up. Demographics, nerve injury/repair, assessments, and safety were evaluated. Data included static/moving 2-point discrimination, Semmes-Weinstein Monofilaments, and tens score. The cohort was stratified into three gap groups: Small (< 15mm), Mid (15-29mm), and Long (≥30mm). Meaningful recovery was defined as S3 or greater on the MRC scale. Higher thresholds of recovery were evaluated in repairs with at least 1-year follow-up.

Results and Conclusions: The cohort consisted of 325 nerve injuries. The mean patient age was 42±16 years; patients were predominantly male. The mean time-to-repair was 1 (0-2579) days. Mean gap length was 20±13mm. The mean follow-up time was 11.6 months. Overall meaningful recovery was reported in 87% of repairs with 70% reaching higher thresholds. Return of sensation was consistent across gap subgroups: Small (91%), n=104; Mid (87%), n=137; and Long (83%); n=83. Outcomes by mechanism of injury were significantly different (p=0.03) with lacerations and complex injuries (gunshots/blast, amputations, avulsions) reporting 91%, n=206 and 80%, n=95 recovery respectively. No related adverse events were reported.

Processed nerve allograft can be used successfully with consistent outcomes in both short and long gap reconstructions. Overall meaningful recovery was reported in 87% of repairs. Limitations of this study include the observational study design and lack of active control. These outcomes compare favorably to historical data in the literature for nerve autograft and exceed those for conduit.

nerve repair, nerve reconstruction, processed nerve allograft
Investigation into the Complex and Co-ordinated Anatomy of Preaxial Polydactyly

List of authors:
Julia Dong Hwa Oh*1, Zoe Sudderick1, Lynn McTeir1, Wee Leon Lam2, Megan Davey1
1 Roslin Institute (Edinburgh)
2 Royal Hospital for Sick Children (Edinburgh)

Objectives / Interrogation: Radial or preaxial polydactyly (PPD) is a common congenital hand difference of varying severity, popularly classified as according to Wassel's classification (1969) depending on the level of skeletal duplication. Much of the focus, therefore, has been on the bony architecture in PPD, rather than the soft tissues. Embryologically, PPD is classified as a malformation in the radial-ulnar axis under the Oberg Manske Tonkin (OMT) classification, with the underlying pathology thought to be due to abnormal Sonic hedgehog (SHH) expression in the limb bud. Other than digit number and identity, the SHH-axis controls musculature, tendon and vascular patterning. The aim of this study is to investigate the relationship between the bony architecture and the associated soft tissues, including anatomical variations in musculature and innervation in an animal model of induced polydactyly.

Methods: We induced PPD in a chicken limb model using beads soaked in either SHH protein or retinoic acid (SHH agonist) implanted into the anterior early limb bud (20HH/3.5 days of development, equivalent to Carnegie stage 130). Manipulated embryos were examined at seven days of development after cartilage pattern of digits has been established. In addition to skeletal anatomy, secondary changes in limb patterning affecting the soft tissues were also studied using wholemount RNA in situ hybridisation in combination with histology. Muscle was labelled with MyoD, nerves with Schwann cells marker, tendons with Scleraxis and cartilage was stained with Alcian Green.

Results and Conclusions: Polydactyly was reliably induced both in models using retinoic acid or SHH protein beads. As predicted, soft tissue anatomy was also altered in polydactylous limbs. The changes were categorised and compared to control limbs (without manipulations). Results will be discussed.

We present an early model which can be utilised in the future to assist prediction of not just skeletal duplications, but also deviations in soft tissue anatomy in polydactylous digits.

WALANT or Bier Block? A Prospective Cohort Study for Patients’ Perspective on Anesthesia Type for Carpal Tunnel Surgery

List of authors:
Egemen Ayhan¹, Filiz Akaslan²
¹ University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology - Hand Surgery (Ankara)
² University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Anesthesiology and Reanimation (Ankara)

Objectives / Interrogation: Regional intravenous anesthesia (Bier block) has been used for carpal tunnel surgery (CTS). Recently, wide awake local anesthesia no tourniquet (WALANT) has been increasing its popularity for many hand surgery procedures. We aimed to compare patients’ CTS experience with two different anesthesia methods.

Methods: Patients’ CTS were performed either with WALANT (epinephrine 1:100.000, lidocaine 1%, bicarbonate %8.4) or with Bier block (lidocaine 1%, bicarbonate %8.4) anesthesia methods. Patients were requested to fill patients’ satisfaction form after the surgery. In the form, patients’ were appealed to quantify their pain levels on visual analog scale (VAS), asked to compare the operation with dental procedures and their expectations, and questioned for their desires about re-operation with the same anesthesia method. The results were compared for two anesthesia methods.

Results and Conclusions: There were 54 cases operated with WALANT and 34 cases operated with Bier block anesthesia methods (72 patients, 16 bilateral). There were no significant differences between mean ages (WALANT 50.9, Bier block 52.4) and median VAS (during local anesthesia injection, during surgery, and during the postoperative first day) of the two groups. Bier block patients reported moderate (median VAS score 5) tourniquet pain. When compared with dental procedures; 90.7% (49/54) of WALANT patients, and 42.4% (14/33, one patient reported to have no dental experience) of Bier block patients reported the CTS to be an easier procedure (p<0.0001). When compared with patients’ expectations; none 94.4% (51/54) of WALANT patients, and 52.9% (18/34) of Bier block patients reported the CTS to be an easier procedure than they expected (p<0.0001). For the re-operation when needed; 96.3% (52/54) of WALANT patients, and 41.2% (14/34) of Bier block patients reported their desire for the same anesthesia method (p<0.0001). Thirteen patients who were operated bilaterally (one side with WALANT, and the contralateral side with Bier block) were asked for their anesthesia choice; 11 preferred WALANT, one preferred RIVA, and one reported no difference. Three patients were operated bilaterally with WALANT for their both hands because they did not accept operation with RIVA.

WALANT anesthesia method offers a better patients’ satisfaction for CTS than Bier block. This is mostly related to tourniquet pain of Bier block patients. Nowadays, many surgeons prefer WALANT anesthesia for a wide variety of hand surgery procedures.

Keywords: carpal tunnel, WALANT, Bier block
Brachial Plexus Birth Injury: An Epidemiological State Level Analysis of Trends and Risk Factors

List of authors:
Sarah Sibbel*, Andy Lalka, Jane Gralla
1 Children’s Hospital Colorado, Orthopedics Institute (Aurora)
2 University of Colorado, Anschutz Medical Campus, Department of Pediatrics (Aurora)

Objectives / Interrogation: Brachial plexus birth injury is a condition in which the brachial plexus is thought to be damaged during the birth process. Studies have cited a varying incidence rate ranging from 0.5 to 4.0/1000 live births. The purpose of this study is to evaluate birth claims data in the state of Colorado over a 15 year period to identify risk and protective factors for brachial plexus birth injury (BPBI).

Methods: A data request was made to the Colorado Hospital Association for birth claims data. We requested all birth claims from the years 2000 to 2014. ICD9 codes for variables of interest included: brachial plexus birth injury, shoulder dystocia, heavy-for-dates, macrosomia, breech delivery, instrumented birth, birth hypoxia, and gestational diabetes. Descriptive statistics and univariate analysis was performed on birth claims. A multivariable logistic regression model quantified both risk and protective factors as odds ratios (OR) with 95% confidence intervals (CI).

Results and Conclusions: There were 966,906 birth records received from state hospital association. The brachial plexus birth injury rate was 0.63/1000 live births averaged over all years. The mean birthweight was 3187 grams for the total population and 3807 grams for the BPBI births. Each year after the year 2000 reduced the chance of BPBI by 4% (OR 0.96, 95%CI: 0.94, 0.97, p<0.001). Asian, black, or Hispanic were more likely to have a BPBI than white births. Births impacted by shoulder dystocia (OR 49.77, 95%CI: 39.23, 62.77, p<0.001), instrumented forceps births (OR 21.29, 95%CI: 11.90, 35.47, p<0.001), breech delivery (OR 17.75, 95%CI: 5.73, 42.33, p<0.001), and gestational diabetes (OR 5.69, 95%CI: 4.16, 7.66, p<0.001) were at higher risk of BPBI. Cesarean Delivery (OR 0.27, 95%CI: 0.20, 0.36, p<0.001) was protective of BPBI but multiple gestation (OR, 4.86 (95%CI: 2.55, 8.43, p<0.001) was not. Colorado births experienced a decreased risk of BPBI from 0.82/1000 live births in 2000 vs. the US rate of 1.6/1000 (p<0.001) to 0.56/1000 in 2012 vs. the US rate of 0.9/1000 (p=0.003). Brachial plexus birth injury rate decreased between 2000 and 2014. Historically Colorado has had a lower BPBI rate than the United States. Shoulder dystocia, instrumented forceps birth, gestational diabetes, and breech delivery are significant predictors for BPBI. Increased awareness of shoulder dystocia and instrumented birth have been hypothesized to have reduced these rates. Non-white patients also appear to be at higher risk for BPBI.

Correlation of Tinel sign and site of ulnar nerve compression in cubital tunnel syndrome

List of authors:
Michelle Spiteri*, Christopher Little¹
¹ Nuffield Orthopaedic Centre (Oxford)

Objectives / Interrogation: Cubital tunnel decompression is usually performed to address symptoms of ulnar nerve compression at the elbow. Nerve conduction studies (NCS) are commonly obtained to confirm compression neuropathy prior to scheduling surgery; in a small percentage of cases, surgery is performed despite normal NCS results based on clinical symptoms and signs. Percussion irritability of the nerve, referred to as Tinel's sign, is a common physical finding taken to confirm nerve irritability at a particular site. The aim of this study was to evaluate the presence and site of this sign for the ulnar nerve preoperatively, and to correlate this with the intraoperative site of compression.

Methods: The notes and NCS results of patients undergoing cubital tunnel decompression with or without anterior subcutaneous nerve transposition were reviewed pre-operatively and compared to the surgical findings recorded by an independent observer, masked to the pre-operative results; the surgical site of compression was then correlated with the site of a Tinel sign, if this was present, and NCS findings. Patients who had nerve decompression as part of a bigger reconstructive procedure were excluded.

Results and Conclusions: Thirty-eight cases were identified between June 2017 and September 2018. 92% of patients had a Tinel sign. This was distal to the medial epicondyle in 17 cases, with intra-operative nerve compression noted beneath the humeroulnar aponeurotic arcade between the tendinous attachment of the two heads of flexor carpi ulnaris. The Tinel sign was posterior/proximal to the medial epicondyle in the remaining 21 cases, with intra-operative nerve compression in the retroepicondylar groove in 12 cases, and evidence of compression at both these sites in the other 9 cases. In cases were no Tinel sign was present, compression was identified in the retroepicondylar groove. Hour glass deformity and change in nerve texture with visible and palpable nerve thickening was not present in the absence of a Tinel sign. There were no cases of more proximal nerve compression.

The Tinel sign is a useful adjunct to NCS that can be used to plan surgical approaches as it correlates with the site of nerve compression when this is caused by a defined structure. In cases where nerve compression occurs over longer segments or at multiple sites, this sign is only present consistently at the more proximal site of compression. Therefore, in patients who have this sign distal to the epicondyle, a more limited approach can be safely considered.

**Vascularized bone graft (VBG) from distal radius in the treatment of scaphoid nonunions associated to proximal pole osteonecrosis**

**List of authors:**
Stefano Galli*, Claudio Bertoli

1 Orthopaedic Clinic - Spedali Civili di Brescia (Brescia)

**Objectives / Interrogation:** The aim of the study was to investigate the effectiveness of the use of a vascularized pedicle bone graft of distal radius for scaphoid nonunions with osteonecrosis and its validity in correcting bone deformity too, even if the quality of the donor bone is not macroscopically so high as that used in free bone graft flaps.

**Methods:** We treated 12 patients, suffering of established scaphoid nonunion, with a VBG of the distal radius. All presented a scaphoid nonunion associated with proximal pole osteonecrosis; 8 of them presented a carpal collapse too.

An interposition palmar-based wedge graft was used in 8 cases and an inlay graft in 4 cases.

Functional outcome was assessed with DASH questionnaire, PWRE score, modified Mayo Wrist Score. Mean outcome measures of pain, range of motion and grip strength were evaluated. Time to return to daily activity was also recorded.

Radiological assessment was performed at the last follow-up visit with conventional X-rays and Computer Tomography scans, evaluating bone union and presence of osteoarthritis, measuring revised carpal height ratio, lateral intrascaphoid and radio-lunate angles.

**Results and Conclusions:** At an average follow-up of 7 years mean DASH score was 5, mean PRWE score was 16,4, mean MWS was 80,5. Mean VAS pain score was 2,7. Flexion-extension arc of the wrist averaged 73,7 % of the uninjured side; radial-ulnar inclination arc averaged 83 % of the uninjured side. Grip strength averaged 89,6 % of the unaffected hand. Return to previous activity averaged 6 months.

At the radiological evaluation bone union was obtained in 100% of cases, with a mean union time of 5 months. Ectopic ossification was present in 2 cases. Mean carpal height ratio was 1,55, mean lateral intrascaphoid angle was 21°, mean radio-lunate angle was 6,09°. There were signs of degenerative changes at the radio-scaphoid joint, confined to the radial styloid region, in only 2 cases; both benefited from a radial stiloidectomy. No sign of arthritic progression was detected at final follow-up.

We consider VBG a good method to increase the proportion of healed fractures in higher risk patients. We demonstrated that this technique is also valid in correcting bone deformity.

The advantages of these procedures are their relative technical ease compared with other methods of vascularised bone transfer (free flaps), the ability to limit dissection to a single surgical incision, the possibility to obtain additional nonvascularized cancellous graft, if needed, from the same harvest site.

**Keywords:**
scaphoid nonunion, avascular necrosis, vascularised bone graft
**Mallet Finger Splinting - No Skin Irritation, No PIP Stiffness**

**List of authors:**
Egemen Ayhan¹, Yakup Kuzucu², Emrah Efe Aslaner³, Zeynep Tuna⁴

¹ University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology - Hand Surgery (Ankara)
² University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Orthopaedics and Traumatology (Ankara)
³ Baskent University (Adana)
⁴ Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation (Ankara)

**Objectives / Interrogation:** Conservative treatment of mallet finger injury was reported to fail in some patients due to discontinuation of splinting especially because of skin complications within the splint. We thought that the complication rates would decrease with an appropriate patient education about splint use. Therefore, the aim of this study was to assess the complication rate and clinical results of conservative treatment of mallet finger with detailed instructions of splint use.

**Methods:** Fifty consecutive patients with mallet finger deformity were enrolled. They were instructed to wear the splint 24/7 for the first six weeks and advised to take it off once a day for 10 minutes for their skin to vent. They were strictly told to support the distal interphalangeal (DIP) joint during wear on and off. Besides, free proximal interphalangeal joint (PIP) movement was emphasized within the splint. Following six weeks 24/7 regime, night splinting continued for two more weeks. Patients were called for last follow-up and assessed for "Outcome Measures for Mallet Finger Injury" including pain, stiffness, range of motion (ROM), functional impairments and satisfaction.

**Results and Conclusions:** Thirty patients admitted for follow-up and the mean age was 37.1. Average follow-up duration was 6.4 (3-14) months. None of the patients gave up wearing the splint during the treatment period as no skin irritation was seen and PIP joints’ ROM were not affected. Nine patients were injured on their 5th finger, 13 were on 4th and 8 were on 3rd finger. Ten of the patients had bony mallet injury. According to the applied criteria, 20 of the patients achieved at least three criteria. Extensor lag was less than 20° in 19 patients and flexion arc was more than 50° in almost all patients (n: 28). Most patients (n: 20) reported noticeable pain or stiffness in their finger and 14 patients had difficulty during heavy activities. Satisfaction level was at least 9/10 in 17 patients.

Detailed education about the splint use to prevent the patients' complaints resulted in satisfactory clinical results. It also improved the compliance with the splinting regime with no skin irritation or excessive stiffness of the finger. Therefore, the clinicians should spare some more time for patient education for its potential benefits like the decrease in the need for surgery after a well-applied splinting treatment.

Bone Grafting for the Correction of Nonunion or Malunion of Long Bones in the Upper Extremity: A Systematic Review

List of authors:
TJ France*, Zachary Diltz¹, Sonu Jain¹
¹ Ohio State College of Medicine (Columbus)

Objectives / Interrogation: Autologous iliac crest has long been considered the best graft option as an adjuvant modality in the fixation of bone nonunions or malunions as a result of its osteoinductive, osteoconductive, and osteogenic properties. However, the clinical benefit from autologous bone graft in general and iliac crest specifically has not consistently demonstrated. Additionally, the use of iliac crest bone increases the risk of complications and leads to longer recovery and/or higher patient morbidity. The aim of this systematic review was to collect and summarize the current literature comparing different forms of bone graft used in the surgical correction of nonunions and malunions of the humerus, radius, and ulna. In this way, we sought to challenge the belief that autologous iliac crest provides superior clinical outcomes to other forms of graft.

Methods: A comprehensive systematic review was performed of PubMed, Embase, Scopus, SPORTDiscus, and the Cochrane Library for all relevant articles. A total of 4,043 publications were reviewed. Inclusion criteria: 1. Studies comparing at least 2 different forms of bone graft or one form of bone graft versus no graft in treatment of malunions or nonunions in upper extremity long bones, 2. Participants 18 years or older, 3. At least 5 participants in each arm. A total of 20 articles met our inclusion criteria and were used in this review.

Results and Conclusions: Iliac crest autograft provided superior results in union rates and time to union compared to synthetic graft, such as bone metalloproteinase-7 and platelet-rich plasma. Calcium phosphate cement was an exception, demonstrating similar union rates. The combination of synthetic bone graft and autograft improved the healing rate. Allograft demonstrated comparable union rates and time to union to autograft, but had significantly shorter surgical time and hospital stay. There was a significantly shorter interval from surgery to union when allograft was combined with autologous bone marrow stem cells. Multiple articles call into question the utility of bone graft after demonstrating that surgical fixation of upper extremity nonunions and malunions without bone graft provides acceptable results. Bone graft, even autologous iliac crest bone, may not be necessary as an adjuvant in the correction of every upper extremity long bone nonunion or malunion. However when graft is used the current literature supports composite grafts over the use of autograft alone.

Tetraplegia Hand Surgery. The Cypriot Perspective

List of authors:
Constantinos Kritiotis\textsuperscript{1}, Christiana Fakonti\textsuperscript{2}, Jan Friden\textsuperscript{3}, Sabrina Koch Borner\textsuperscript{3}
\textsuperscript{1} Manchester Hand Centre (Manchester)
\textsuperscript{2} Paraplegic Department, Nicosia General Hospital (Nicosia)
\textsuperscript{3} Swiss Paraplegic Centre (Nottwil)

Objectives / Interrogation: We present the creation of the Cypriot Tetraplegia Hand Surgery Service, the acceptance in the SCI patients community as well as our results thus far.

Methods: All tetraplegic patients who express an interest for reconstructive procedures are referred and evaluated by authors (1) and (2). Procedures are carried out twice per year, every March and October. More complex cases are referred to the Centre where Author (3) works. The International Classification for Surgery of the Hand In Tetraplegia is used to evaluate patients and identify surgical candidates. Surgical candidates are evaluated preoperatively with the Canadian Occupational Performance Measure (COPM) and also captured on video performing certain tasks (eating with utensils, holding a bottle etc). Patients who receive a triceps reconstruction are evaluated with the Motor Research Council Grade, before and after the procedure.

The two major procedures that we perform is the posterior deltoid to triceps transfer using a tendon graft for triceps reconstruction and the ALPHABET procedure for grip reconstruction. \cite{1}

Patients following surgery start their rehabilitation immediately with protected active motion. The patients are evaluated at six months post op again with the COPM and the difference is calculated to record the patient reported outcome.

Results and Conclusions: So far, seven procedures have been carried out on six patients with another two scheduled for October 2018 and two for March 2018.

Patients who received the procedures

Of the 21 patients who were seen by our service, 12 were candidates for surgical procedures and 7 either received or are scheduled to receive the procedures.

Patients who received a posterior deltoid to triceps transfer had a significant increase in triceps strength resulting in better wheelchair propulsion.

COPM increase in patients who received a grip reconstruction was on average 6.175.

Conclusion: Tetraplegia Hand Surgery can produce life changing results and should be routinely offered to all tetraplegic patients.
International collaborations can enhance patient trust and lead to better outcomes.

FUNCTIONAL RESULT OF WRIST ARTHRODESIS IN SEVERE INJURIES OF BRAQUIAL TRAUMATIC PLEXUS. INITIAL EXPERIENCE

List of authors:
MARIA HORTENCIA CORIA DONCEL*, Gustavo Javier Nizzo Miguens¹, Flavio Cesar Ivalde¹, Nicolás José Marazita³, Nestor Danilo Batalgia¹, María Victoria Gonzalez¹
¹Hospital de Clinicas Jose de San Martin (Buenos Aires)

Objectives / Interrogation: Report the functional result of wrist arthrodesis in 3 patients, treated at our university hospital.

Methods: This is a descriptive, cohort study that reports the result in 3 male patients diagnosed with a complete traumatic right brachial plexus injury. All of them present a postoperative follow-up of 12 months. For the selection of these patients, it was previously confirmed that they presented stability of shoulder and elbow flexion of 110 degrees with adequate function of trapezius, serratus anterior and pectoralis major and minor. The presence of neuropathic pain, the presence of radiographic consolidation of the arthrodesis and functional capacity were evaluated using the modified quick DASH scale before and after the surgical intervention and throughout the follow-up. This allowed us to determine concisely the improvement of the overall function of the upper limb.

All our patients were included in the same rehabilitation protocol, carried out by our kinesiologist, always making decisions in conjunction with the surgical team.

Results and Conclusions: The patient achieves work reinsertion, clinically and visually arthrodesis allows him to perform load work (3 kg) achieving good press with arthroded hand, in this way he is partially incorporated into the external environment, improving their living conditions; both professionally and psycho-socially. We consider that the reconstruction of the function of the member in stages could be a viable option, the wrist arthrodesis would be the last link of this reconstruction, and would represent the clasp of the scapular waist. We believe fundamental the management of these patients by an interdisciplinary team made up of kinesiologists, neurosurgeons and traumatologists for the evaluation of the lost functions to recover. We acknowledge that the sample size is small and that a greater number of cases could grant these conclusions, however we can cautiously say that this would be the first functional recovery report at 12 months after wrist arthrodesis.

Scaphoid Skyline View (SSV): A Useful Method to Detect Intrarticular Screws at the Proximal Pole of the Scaphoid During Retrograde Fixation

List of authors:
Juan Breyer*, Alfonso Perez¹, Pamela Vergara¹, Pedro Ruiz¹
¹Hospital del Trabajador (Santiago)

Objectives / Interrogation: Screws protruding the proximal pole of the scaphoid during retrograde scaphoid fixation with cannulated screws may lead to unfavorable outcomes. Conventional intraoperative radiographic views have limitations to detect this complication.
We propose a modification of the Skyline view of the distal radius (Joseph et al 2011, Riddick et al. 2012) to assess the proximal pole of the scaphoid tangentially.
The aim of this study was to evaluate the ability of a new radiographic view, tangential to the proximal pole of the scaphoid, the Scaphoid Skyline View (SSV), to detect intrarticular screws during retrograde fixation of the scaphoid.

Methods: 9 fresh frozen adult cadaveric wrists without degenerative radiographic signs were used. A retrograde screw was inserted with a volar percutaneous retrograde technique.
Radiographic views studied were: posteroanterior (PA), PA with ulnar deviation (PAUD), lateral (L), oblique pronated (OP), PA with extension and ulnar deviation (PAEUD) and the SSV.
SSV is obtained with aligning the forearm at 30º respect to the Xray beam and maximum wrist flexion.
Baseline X rays were recorded with screw flush to the proximal pole, visualized directly through a limited dorsal capsulotomy. The screw tip was advanced sequentially 0.5 mm measured with a digital caliper through the dorsal approach. After every screw advance all views were repeated until screw prominence a was noticed in all images.
The mean articular protrusion (mm) required to detect intrarticular screws was compared between different radiographic views using oneway ANOVA.
Accuracy of the different radiographic view was studied with ROC curve analysis. Statistically significant differences were considered with p<0.05.

Results and Conclusions: The mean (SD) protruding length (in mm) required to detect articular screws with different radiographic views was:
PA 1.9 (1), PAUD 1.8 (1.1), OP 1.4(0.9), L 1.1(0.7), PAEUD 1.2 (0.7), SSV 0.8 (0.3). Statistically significant differences were found between groups (oneway ANOVA, p=0.014, F=3.756). SSV had the highest accuracy with an area under curve of 0.92 (95% Confidence interval: 0.831-1).

Conclusions
SSV was able to detect intrarticular screws with less than 1mm, being the most accurate view.
Other radiographic views showed similar ability to detect protruding screws as described in literature¹.
This radiographic view could avoid complications when used during retrograde fixation of the scaphoid with cannulated screws.

MICROSURGICAL FLAPS IN GENERAL ORTHOPAEDIC SURGERY: INDICATIONS AND RESULTS

List of authors:
Raquel Bernardelli Iamaguchi1, Gustavo Bersani da Silva3, Alvaro Baik Cho1, Teng Hsiang Wei1, Marcelo Rosa de Rezende1, Renan Lyuji Takemura4, Felipe Burgos1, Rames Mattar jr1
1 University of Sao Paulo (SAO PAULO)

Objectives / Interrogation: The advances of reconstructive microsurgery in orthopaedic surgery provided better functional and aesthetic results and prevented many indications of amputations. The indications of free flaps for the treatment of traumatized extremity is increasing, including, open wounds, long bone defects, muscle impairment after brachial plexus injuries, reconstruction of pinch with toe to hand transfer, among others. The combination of treatment are described as orthoplastic and early transference for centres for combined treatment is recommended in literature. We describe an orthopaedic microsurgery group with residency performing free flaps for orthopaedic injuries with indications and evaluating predictors factors influencing free flaps outcomes in musculoskeletal system.

Methods: From July 2014 to July 2018, patients undergoing microsurgical free flaps were consecutively included in this cross-sectional study. Data regarding personal medical history, intraoperative microsurgical procedure and laboratory tests were collected. Complications and free flap results were observed during follow-up.

Results and Conclusions: A total of 128 flaps in 126 patients were evaluated. The mean age was 34.8 years with 103 male patients. The most frequent cause of the musculoskeletal defect was traumatic in 79 patients (61.7%), followed by brachial plexus injury in 34 patients. Complications of type III Clavien-Dindo Classification were observed in 42 microsurgical flaps. Seven cases (5.5%) had partial loss of the flap. Twelve cases progressed to total loss of the flap (9.4%). The overall success rate of the microsurgical flaps was 90.6%. In the multivariate analysis, the risk factors for complications were: ischemia time greater than or equal to 2 hours (p = 0.037), end-to-side arterial anastomosis (p = 0.021) and obesity (p=0.012). The indication of take-back flap to operative room was associated with a higher incidence of total loss (p <0.001). In the multivariate analysis, the independant risk factor for partial flap loss was the presence of thrombocytosis (p=0.004).The main indication of microsurgical flaps in orthopaedic surgery was trauma with complex wounds, followed by free functional muscle flap for brachial plexus injury and limb reconstruction after tumor resection We observed a statistically significant increase in complications in patients with ischemia time greater than 2 hours, obesity and end-to-side arterial anastomosis.

Development and biomechanical analysis of a new 4-strand suture for transosseous flexor tendon repairs in zone 1

List of authors:
Patrick Harenberg*, Jörg Grünert, Marcus Lehnhardt, Samuel Christen
1 Department of Plastic Surgery, Burn Centre, Hand Surgery Centre, University Hospital Bochum (Bochum)
2 Department of Hand, Plastic and Reconstructive Surgery, Kantonsspital St. Gallen (St. Gallen)

Objectives / Interrogation: Development of a transosseous suture for zone 1 repairs that can withstand immediate controlled active motion rehabilitation.

Methods: 30 deep flexor tendons and distal phalanges were harvested from pigs feet. Tendons were cut perpendicular at the joint line. Tendons were randomly assigned to one of three groups: (1) A hole was drilled through the base of the distal phalanx in a coronar plane. A 18G hypodermic needle was passed through the drill hole. Two additional needles were passed from the tendon insertion to the lateral ends of the drill canal. A 3-0 PDS suture is passed through the needles with successive removal of the needles. An unarmed needle is placed at the free end of the suture. The tendon is sutured to the bone in a Krackow-like technique. (2) like (1) but two additional epitendinous figure-of-eight stitches with 5-0 PDS are placed, (3) Only the needle through the drill hole is used. The end of a 4-0 Supramid loop is passed through the needle and the needle is removed. A second supramid loop is threaded through the already placed loop, linking them. The needles at both ends are passed to the tendon insertion. The tendon is first sutured to the bone in a Zechner-like technique and the knot is pulled tight. Two additional Krackow-like locking loops are performed at each side of the repair. Placement of an epitendinous suture like in (2). Completed repairs were fixed in a biomechanical testing machine, a 1N preload was applied followed by distraction at a rate of 1cm/min. During distraction, photos in two planes were recorded together with distraction and applied force. For statistical analysis force at a 2mm gap in the repair (2GF) and ultimate failure load (UFL) were recorded. Tamhane's T2-test was used for group comparisons during statistical analysis.

Results and Conclusions: Results:
Mean 2GF was 6.4N for group 1, 23.2N for group 2 and 52.8N for group 3. Differences were significant at p<0.001 between all groups. Mean UFL was 55.6N for group 1, 53.2N for group 2 and 63.3N for group 3. No statistically significant differences were detected. No suture pull-outs occurred. No common suture breaking point was noted at UFL.

Conclusion:
Addition of two epitendinous stitches significantly improves 2GF in zone 1 repairs. Furthermore, the presented 4-strand technique can withstand enough force to allow for immediate controlled active motion rehabilitation.

Management of Scaphoid Fractures at a Tertiary Center in the UK: The University Hospital North Midlands Experience

List of authors:
Yasser Al Omran*, Zamira Keeling, Manikandar Srinivas Cheruvu, Karam Ahmad, Ashley Brown, Kevin Smith
1 University Hospital North Midlands NHS Foundation Trust (Stoke-on-Trent)

Objectives / Interrogation: Carpal bone fractures encompass approximately 18% of all hand fractures; with scaphoid fractures being the most common of these fractures. Up to 40% of scaphoid fractures are missed at initial presentation as plain radiographs lack adequate sensitivity to detect a fracture immediately after injury and so many cases are managed non-operatively initially. In the United Kingdom, The National Institute of Clinical Excellence (NICE) issued guidance on non-complex fractures in February 2016 and have recommended that MRI should be considered as first-line imaging for suspected scaphoid fractures. We report on a select group of patients in which operative management of scaphoid fractures was necessary before and after introduction of this guideline.

Methods: A retrospective chart review of patients with scaphoid fractures who required operative fixation was undertaken between January 2015 and August 2018 was undertaken. We evaluated many aspects including implementation of the nice guideline in these cases, time to presentation to the orthopedic team, time to decision to operate and complications.

Results and Conclusions: 31 cases were reviewed and tabulated. Operative cases ranged from percutaneous screw fixation, headless compression screws and open reduction internal fixation +/- bone graft. We report on the outcomes of these patients and identify key trends and lessons that we have learnt over this time period.

FREE FLAPS RECONSTRUCTION IN PEDIATRIC PATIENTS FOR LIMB DEFECTS

List of authors: Raquel Bernardelli Iamaguchi*, Gustavo Bersani da Silva, Alvaro Baik Cho, Teng Hsiang Wei, Marcelo Rosa de Rezende, Rames Mattar Jr
1 University of Sao Paulo (SAO PAULO)

Objectives / Interrogation: Free flaps in the pediatric population are less common and when indicated the expectations to avoid amputation is high. The objective of this study is to describe indications and results of free flaps for limb reconstruction in pediatric patients.

Methods: From July 2014 to January 2018, patients undergoing microsurgical free flaps in an Orthopedic Hospital were consecutively included in this cross-sectional study. Data regarding personal medical history, intraoperative microsurgical procedure and laboratory tests were collected. Complications and free flap results were observed during follow-up.

Results and Conclusions: 19 free flaps in 19 patients were studied. The most common indications were skin or bone defects caused by trauma (7 patients), tumor (5 patients) and congenital pseudarthrosis of the tibia (3 patients). The most indicated flap was vascularized fibular flap in 8 patients, followed by anterolateral thigh flap in 4 patients. Complications were observed in 4 patients and were: one dehiscence, one re-exploration of anastomosis with resolution of thrombosis and two cases of thrombosis of microanastomosis with avascular fibular flap. Of these two cases, one fibula was maintained avascular and the second case was submitted to trans-femoral amputation. 18 patients could preserve their limbs and in one case a toe-to-hand transfer was successfully performed.

Conclusion: Free flaps in children are safe and indications are restricted to precise indications of providing alternative to amputations and improving the function of patients.

**Do we need electrophysiological measurements for the diagnostics of carpal tunnel syndrome**

**List of authors:**
Balazs Lenkei*, Adrienn Lakatos¹, Zsolt Szabo¹
¹ Miskolc Hand Surgery Center (Miskolc)

**Objectives / Interrogation:**
In our practice electroneurography (ENG) was an obligatory examination procedure in cases suspicious for carpal tunnel syndrome. Nowadays it seems to have less importance. The aim of our study was to analyze the necessity of electrophysiological measurements before carpal tunnel release.

**Methods:**
Method: We run a prospective data collection of all operated carpal tunnel patients in our unit. For this study we included the patients operated for carpal tunnel syndrome in the last 4 years. The patient with incomplete datasheets were excluded from the study. Daytime and nighttime numbness, pain levels and subjective satisfaction of the patient were registered by a Visual Analogue Scale preoperatively and 1 week, 6 weeks, and 12 weeks postoperatively. Significance was evaluated using Z-test (p=0.05).

**Results and Conclusions:**
Results: 168 patients were operated without ENG, and 284 patients had positive ENG previous the operation. In the preoperative data, the ratio of patients with symptoms for less than 3 months was 7 % in the group without ENG and 20% in the group with ENG. The patients with ENG had a longer anamnestic period. The average of the VAS points for night pain was 6.99 VAS for those without ENG, compared to the with 6.47 ENG group. No other significant differences were found between the two groups. The subjective satisfaction level after 3 months was 8.31 VAS point without ENG and 8.61 with ENG.

Conclusion: Both groups had a good healing tendency. It seems that in the hand of experts, to diagnose and for treatment of carpal tunnel syndrome does not mandatory to have ENG examination. In our view ENG examination should be reserved to those patients with controversial symptoms.

THERAPEUTIC APPROACH FOR ULNAR NERVE ENTRAPMENT IN PERFORMING MUSICIANS

List of authors:
Adriana Pemoff¹, Candelaria Torre², Hernán Blanchetiere³, Soledad Lett², Ivonne Gomez Avellaneda², Fernanda Coscueta³
¹ Hospital Fernandez, Fundación Las Manos del Músico, Climba (Buenos Aires)
² Hospital Fernandez, Fundación Las Manos del Músico (Buenos Aires)
³ Fundación Las Manos del Músico (Buenos Aires)

Objectives / Interrogation: There are some instrumentalist musicians who present risk factors that increase the incidence of ulnar nerve entrapment, such as valgus and forced elbow flexion, during their performance. The aim of this study is to report incidence and therapeutic approach of ulnar nerve entrapment at the elbow in performing musicians treated in our center. We propose the surgical technique of Osborne ligament reconstruction in patients with risk of dislocation of the ulnar nerve due to a vicious postures during their instrument execution.

Methods: We performed a retrospective, descriptive study between 2001 and 2018. We included 2387 instrumentalist musicians treated at our center. There were 71 patients with related symptoms of ulnar nerve entrapment and confirmed diagnosis with electrophysiological and image studies, always performed by the same professional. Of the total population, 15 were violinists, 27 guitarists, 5 double bass players, 7 bandoneonist, 9 pianists and 8 cellists. All of them presented epitrochlear pain and sensitive symptoms during their performance. Risk factors were identified as posture execution in flexion and forced elbow valgus, with scapular dyskinesia. The initial therapeutic approach was the treatment of these risk factors associated with physiotherapy and music counseling. Most of them responded to conservative treatment by improving their execution posture, but 8 required surgical intervention. The surgical technique consisted of internal elbow approach, with complete liberation of the ulnar nerve according to conventional technique and the additional Osborne ligament reconstruction with triceps fascial flap.

Results and Conclusions: A total of 71 patients with ulnar nerve entrapment were included. 63 had resolution of their symptoms, by improving scapular dyskinesia, vicious postures and forced elbow valgus during their instrument performance. 8 patients continued with symptoms, and were treated by surgical intervention consisting of ulnar nerve release associated with Osborne ligament reconstruction to avoid dislocation of the ulnar nerve due to the forced elbow valgus remnant. In performing musicians population with ulnar nerve entrapment, the initial approach is aimed to correct vicious postures like forced elbow valgus and the improvement of scapular dyskinesia. In cases of failure in conservative treatment, surgical intervention is proposed, and must include, in addition to the nerve release, a mechanism of nerve containment, due to the risk of dislocation.

Injection of a concentrated bone marrow punctate into denervated muscles can improve the results of their reinnervation. Our first clinical experience.

List of authors:
Igor Kurinniy*, Serhii Strafun¹, Andrii Lysak¹
¹ SI “ITO of NAMS of Ukraine” (Kyiv)

Objectives / Interrogation: Determine the effectiveness of concentrated punctate bone marrow injection into muscle after their denervation.

Methods: During 2016-2018, to 56 patients (35 men, 21 women) with peripheral nerves injury (brachial plexus - 43; axillary nerve - 3; radial nerve - 6; median nerve - 3; ulnar nerve - 1) concentrated bone marrow punctate injection into the denervated muscle was performed after nerve surgery. Scheme: 1 week prior to surgery - PRP injection, during surgery - injection of a concentrated bone marrow punctate into the target muscle, and then PRP injection in 2 weeks postop. Subsequently, injection of concentrated bone marrow punctate was repeated 1 time every three months until the moment of effective reinvention. The control of hypotrophy and reinnervation of the muscle was performed using sonography and ENMG.

Results and Conclusions: Control sonographic examinations have shown that the injection of a concentrated bone marrow punctate into the denervated muscle significantly slows the process of hypotrophy. In the ENMG of target muscles - large motor units was detected (which significantly exceeded those that could be recorded in the muscles which did not administer the injection of a concentrated bone marrow punctate). According to the authors, this suggests the stimulation of terminal collateral sprouting.

Injection of concentrated bone marrow punctate into the denervated muscles - significantly improves the process of their reinnervation due to the slowdown of hypotrophy, and stimulation of terminal collateral sprouting.

bone marrow, muscle reinnervation, regenerative medicine, denervated muscle
Does A1 Pulley Release for Trigger Finger Have an Effect on Grip and Pinch Strengths?

List of authors:
Kadir Uzel*, Velat Celik¹, Atilla Arik¹, Can Emre Bas¹, Metin Manouchehr Eskandari¹
¹ University of Mersin, School of Medicine, Department of Orthopaedics and Traumatology, Division of Hand Surgery (Mersin)

Objectives / Interrogation: A frequently performed operation, release of A1 pulley for triggering fingers and thumbs usually results in high patient satisfaction. In this study we aimed to assess its effect on grip and pinch strengths.

Methods: This prospective cohort study was performed in 26 patients who were operated between March 2016 and May 2018. There were 17 women and 9 men. The mean age of the patients was 53 (min=17, max=71). A total of 30 A1 pulley releases were performed (in 9 thumb, 1 index, 12 middle and 8 ring fingers). All of the operations were performed under local anesthesia using transverse skin incisions. Grip and tip-to-tip pinch strengths were recorded both pre-operatively and 3 months after the surgery. To compare pre and postoperative strengths, Wilcoxon and paired samples t-tests were used for grasp and pinch values, respectively.

Results and Conclusions: Both grip and pinch strengths showed statistically significant (p<0.05) increases postoperatively. Regarding details, grip strength increased in 23 hands while in 2 hands decreased and in one hand remained the same. Pinch strength increased in 28 fingers of 24 patients while decreased in one and remained the same in another patient. When we planned the study, we had hypothesized that A1 pulley release might lead to loss of grip and/or pinch forces by an increase in bowstring effect of flexor tendons. Verifying the part of our hypothesis about the increase in bowstring, Park et al in their recently published article state that ultrasonography shows significant bowstring of flexor tendons at 12th week postoperatively. Due to our results, the probable increase in bowstring of flexor tendons have no adverse effect on pinch and grip strengths at 3rd postoperative month. We think that the main reason of significant increase in grip and pinch strengths which we found in our patient group after release of triggering fingers might be due to recovery from the painful condition.

trigger finger, A1 pulley release, grip strength, pinch strength
How does thenar atrophy influence the outcome of carpal tunnel release?

List of authors:
Adrienn Lakatos*, Balazs Lenkei1, Zsolt Szabo1
1 Hand Surgery Center, Miskolc (Miskolc)

Objectives / Interrogation: Visible thenar atrophy is described as the more severe stage of carpal tunnel syndrome. Our hypothesis was that patients operated presenting thenar atrophy have worse outcome.

Methods: Our self-made prospective database was used to evaluate the preoperative and postoperative data. The question form was filled preoperatively then postoperatively at 1 week, at 6 weeks and at 3 months. The patients were distributed into two groups: with and without thenar atrophy. Subjective data as daytime numbness, nighttime numbness, nighttime pain, disturbance in everyday work and satisfaction were recorded and evaluated on Visual Analogue Scale 1-10 (VAS). Grip and pinch strengths were measured using hand dynamometer grip gauge and pinch gauge. Significance was evaluated using Z-test (p=0,05).

Results and Conclusions: 467 patients with carpal tunnel syndrome were operated in our center from 01.01.2014. to 31.08.2018. 10 patients had to be excluded due to lack of data. 182 had visible thenar atrophy prior the operation while 275 patients had no thenar atrophy. In both groups the average age was 61 and 65 years respectively. 75% of the patients were women.

We found no significant difference between the average values of the two groups neither preoperatively, nor postoperatively. 12 weeks after the operation the daytime numbness decreased by 3,41 VAS points in the group with thenar atrophy and by 3,63 VAS points in the group without thenar atrophy. The level of nighttime numbness dropped by 5,98 points if there was thenar atrophy and by 6,18 points if there was not. By this time both groups reached the preoperative strength values and the group with atrophy even increased the grip strength by 0,4 kg and the pinch strength by 0,8 kg. Throughout the postoperative period the level of satisfaction was high in both groups (8,8 VAS points).

Conclusion: Based on our results we can conclude that our hypothesis was wrong thus thenar atrophy does not influence the outcome of carpal tunnel release.

TRIQUETRUM CONTROVERSIES IN LIMITED CARPAL FUSIONS

List of authors:
Essam ElKaref*, Walid Metwaly
1 Alexandria University (Alexandria)

Objectives / Interrogation:
To demonstrate the pros and cons of triquetrum excision in management of limited degenerative wrist arthritis.

Methods: A prospective single-center study of twenty-two patients (21 male and one female) presented with painful wrist arthritis due to stages 2 or 3 scapholunate advanced collapse or scaphoid non-union advanced collapse wrists. All were treated by three corner fusion (fusion of lunate, capitate and hamate with excision of both scaphoid and triquetrum). Subjective and objective outcome measures were evaluated pre and post-operatively using wrist function scoring system. This study raises the question “should we excise the triquetrum or keep it in place?” The final clinical and radiological outcomes were judged against our previous triquetrum sparing procedures, and also were compared with the studies in the literature concerning lunocapitate fusion with or without excision of triquetrum.

Results and Conclusions: The debatable factors affecting the short and long term results were studied and applied to or cases (with excision or with sparing of the triquetrum). Relative data in the literature also analyzed and compared to our findings. The results were in favor of its excision.

Triquetrum preservation or excision in limited carpal fusions did considerably affect rate of union, time to union as well as the other functional parameters.

Keywords:

Long term results of dynamic tenodesis for management of camptodactyly as an intrinsic minus deformity.

List of authors:
Essam ElKaref*1
1 Alexandria University (Alexandria)

Objectives / Interrogation: An imbalance between finger flexors and extensors would seem like the primary cause of camptodactyly. It is probably because of deficient intrinsics’ function. The long term (more than 10 years) results of management of such problem is presented.

Methods: Isolated (non syndromic) symptomatic camptodactyly affecting 56 fingers of 32 children were comprised. An abnormal lumbrical muscle of the affected finger was reported in all cases; being absent, rudimentary or abnormally attached. Surgical treatment using dynamic tenodesis (Lasso procedure), that aims at metacarpophalangeal joint stabilization and a better extensor-flexor forces balance, so enhancing proximal interphalangeal joint extension, was used. All tight soft tissue structures were also released.

Results and Conclusions: After a mean follow-up period of 12.4 years, 49 fingers were rated as good or excellent results according to modified Siegert et al. (1990) grading system. The mean final proximal interphalangeal joint flexion deformity was 12o with a mean gain in motion of 75o. Joint subluxation, lack of full flexion and stiffness occurred in seven fingers. Three were subjected to further surgery and another four had improved with exercises.

The used procedure is rather simple. The outcome of management of camptodactyly, with the use of this method, is encouraging and no longer unpredictable.

Palmar and complex distal flap in macrodactyly surgery

List of authors:
Vladimir Zavarukhin*¹
¹ St Petersburg University Clinic (Saint-Petersburg)

Objectives / Interrogation: Operative treatment of macrodactyly is one of the most complex surgery. Operative technique requires the observance of a narrow "corridor" between the maximum possible resection of excess soft tissues, the shortening of the ray segments and at the same time the preservation of the blood supply of the finger.

Methods: 18 patients with macrodactyly were treated in the St. Petersburg University Clinic last 2 years. The selection criteria for this group were the enlargement of bone and soft tissues; size of affected rays were smaller or equal parent's; angulation deformity or hyperextension in DIP joints were presented. The design of the surgery included performing the palmar flap on the digital artery from one of the side of finger and distal flap on the artery from the other side. Shortening/ angular correction/ arthrodesis was used with combination of debulking. During debulking procedure distal part and free border of the palmar flap were resected.

Results and Conclusions: The presented method allowed simultaneously shortened the finger and perform circular debulking of the affected ray in all patients. Marginal necroses of the palmar flap, not exceeding 6 mm2 in area, were detected only in two patients.

Conclusions: The presented design of the surgery in macrodactyly allows to perform in one step shortening of the affected ray with circular debulking. This design is characterized by a low frequency and severity of complications associated with blood supply (11.1%)

Treatment of dorsal defect finger with modified fibular free flap of great toe

List of authors:
Linglong Zhao*, Xuejun Yu, Shengtao Xiang, Wen Zheng, Xiaoqiang Shi
1 521 Hospital of Norinco Group (Xi’an)

Objectives / Interrogation: To evaluate the outcome of the procedure of using the free flap vascularized by the fibular side of the great toe to treat finger dorsal skin defect

Methods: From June 2013 to August 2016, 18 patients with finger skin defects were repaired by modified fibular side pulp flap of great toe. The portable Doppler was used to detect and identify the artery perforator from the fibular side skin of great toe before the operation. The design area of the modified fibular side pulp flap of great toe is between the traditional dorsal flap of foot and the fibular side pulp of the toe. The area of the flaps ranged from 3.2 cm × 2.4 cm to 7.6 cm × 2.8 cm.

Results and Conclusions: RESULTS: All of the 18 flaps survived at the last office visit, and the wounds in the donor and recipient areas healed well. In 18 patients in this group, 4 cases of skin flaps appeared vesicles within 1 to 2 days after operation. The epidermis of vesicles was dislocated after 1 month. There was no obvious different appearance between graft skin flap and normal skin tissue at last. The follow-up period ranged from 7 to 16 months. There was no pigmentation on the surface of the flap. The texture, shape and function of the finger were satisfactory. Two points of flaps discrimination restored 4 to 6 mm, sensory function of flaps restored S3 to S4. The donor site of the flap was covert, and the function of the foot was unaffected.

Conclusion: The tissue structure of the modified fibular side pulp flap of great toe is similar to the dorsal skin of finger. This free flap is satisfied in the shape, easy to harvested and the blood supply was constant in its location. The appearance and function of finger were recovered well after repairing. It is avoids secondary injury of the injured finger with adopting local pedicled skin flap for repairing. It is an ideal repair method for large area dorsal skin defect of the finger.

Carpal Tunnel Syndrome - Should we treat it mini-open or endoscopic?

List of authors:
Fernando cruz*, silvia silverio, leonor fernandes
1 hospital Lusiadas (Lisboa)
2 hospital Lusiadas, hospital santanna (Lisboa)
3 hospital Lusiadas, centro hospitalar torres vedras (Lisboa)

Objectives / Interrogation: CTS affects an important part of active population, and leads to impairment in hand function, leading to surgical treatment when conservative measures fail.
There is still controversy regarding which technique would be more appropriate to treat this pathology.
In this study we evaluate and compare results of a single-approach endoscopic technique (Agee) and a mini-open procedure, to help the surgeon to decide which technique is more effective.

Methods: In a one year period, a single surgeon treated 43 patients with carpal tunnel syndrome in an out-patient basis with two different methods:
Group A (Mini-open, n=16), were treated with mini-open approach over the retinaculum.
Group B, (endoscopic, n= 27) were treated endoscopically, with Agee single approach technique.
Post-operatively patients were examined at 2 days, 1 and 2 weeks and 1, 3 and 6 months if needed. All the patients were analyzed at the final follow-up using the Modified Mayo Hand score and Visual Analogue Scale.

Results and Conclusions: Average age, male-female ratio, and dominant - non-dominant ratio of both groups were similar.
Three initial endoscopic approaches were converted to mini-open due to incomplete visualization of retinaculum, and were excluded. Two patients of endoscopic group were revised with an open procedure, after maintaining the symptoms post-operatively, and in both cases we found an incomplete distal resection of the retinaculum.
Complication rate was 3/16 (22%) in group A, and 16/27 (53%) in group B. The main complaint of endoscopic group were transient paresthesias of the 2nd and 3rd fingers, lasting between 3 to 6 months post-operatively. No major complications were seen in this series. No significant difference were found in operative time between procedures
Endoscopic group have an early return to work (14 days vs 21 days in open group).
Cost evaluation show a lower cost in mini-open of 200 euros comparatively with endoscopic technique.
Average final Mayo score at 6 months were similar in both groups.
Conclusion:
Endoscopic treatment of CTS provide shorter post-operative period but a longer period of residual paresthesias in about half of the patients.
Open treatment presents longer post-operative period, but better early functional outcome, without residual paresthesias or further surgical treatment.
In overall the mini-open procedure is more cost-effective than the endoscopic procedure, and should be preferred for the treatment of carpal tunnel syndrome.

Keywords:
Physical and Occupational Hand Therapy for Musicians - A Retrospective Study of Patient-Perceived Outcome and Comparison to Symptomatic Treatment

List of authors:
Julia Betzl*, Kai Megerle
1 Muskerambulanz - Klinikum Rechts der Isar (München)

Objectives / Interrogation: There are no standard methods of treatment for musicians with hand and wrist problems interfering with their ability to play. Many are treated conservatively, either symptomatically or with physical/occupational hand therapy. As there is little scientific data on the subject, it was the authors' aim to retrospectively analyze and compare the patient-perceived impact of these therapies.

Methods: 58 patients (31 female, 27 male, mean age 46 years) who visited the music-medical outpatient clinic between 01/15 and 02/18 were surveyed, using a previously developed questionnaire on pain and impairment (on a numeric rating scale (NRS) of 0 to 10), plus epidemiological data. Exclusion criteria were surgery, a history of specific hand trauma and failure to contact by the third try. The primary outcome was defined as an improvement of at least 3 points on the NRS. 35 patients were professional musicians, 9 university music students, 7 retired, 6 amateurs and 1 high-school student preparing for university auditions. 27 played string instruments, 15 piano, 2 woodwinds, 5 plucked, 1 percussion and 8 two or more instruments. Playing time per day averaged at 2.9 hours. 33 received physical/occupational hand therapy, 25 were treated symptomatically (e.g. rest and pain medication), based on individually evaluated, patient-specific criteria such as severity and duration of symptoms, plus expected compliance and time of recovery.

Results and Conclusions: Of 33 patients who followed at least 6 sessions of hand therapy, 24 reported an improvement in pain and 25 in impairment. For the 25 patients treated symptomatically, it were 15 (pain), respectively 13 (impairment). 29 patients changed their playing and practicing habits after hand therapy, 13 after symptomatic treatment. Alterations included longer and more frequent breaks, warming-up and cooling-down periods, use of relaxation techniques, increase of awareness to the physical limitations of practicing, and changes to position, playing technique and literature.

This is one of the largest numbers of musicians ever surveyed after following hand therapy and the only perceived-outcome comparison of hand therapy and symptomatic treatment. The response to hand therapy was good and the self-perceived impact positive. In contrast, patients treated symptomatically reported a less favorable outcome.

This analysis will build a base for future research, such as a specific hand therapy regime for musicians with hand or wrist problems interfering with their ability to play.

Use of reverse end-to-side suture to create a supercharge in spinal accessory nerve transfer to suprascapular nerve

List of authors:
joaquim casanas*,1, MANUEL LLUSA2, ISABEL FERNANDEZ CONEJERO1, M.ROSA MORRO2
1 traumaunit. Centro Medico Teknon (SANT CUGAT DEL VALLES)
2 traumaunit. Centro Medico Teknon, Hospital Clinic de Barcelona, Departamento de Anatomia y Embriologia Humana. UB (SANT CUGAT DEL VALLES)

Objectives / Interrogation: Nerve transfer has clearly shown to be a great technique to restore some nerve palsies. Spinal accessory to suprascapular is probably one of the most popular nerve transfers to restore shoulder function. The use of intraoperative nerve recording to measure the amount of nerve action potential (NAP) transferred has added an important value to expect a successful results. In addition, in cases where some residual nerve conduction in the receptor nerve is detected, the use of reverse end-to-side suture (RETS) can be useful in order to do a supercharge. In those situations when donor nerve is not long enough to connect directly with the receptor nerve, a RETS with allograft is indicated to fill in this gap.

Methods: Three men between 2015 and 2016 has been treated with a partial suprascapular function after brachial plexus lesion. Age ranges from 27 to 48 yo. When under brachial plexus revision, some residual function in suprascapular nerve is present, a RETS with spinal accessory nerve is indicated. In situations without suprascapular nerve transection from the upper trunk, a nerve gap is left, which we fill in with an allograft. Spinal accessory is transected when 150 mv level of NAP is identified. Termino-terminal suture with allograft is performed at that proximal level and end-to-side suture distally, to suprascapular nerve. Evaluation is done with clinical function regarding shoulder abduction and external rotation and improvement in amplitude of suprascapular nerve conduction in postoperative nerve conduction studies.

Results and Conclusions: Spinal accessory nerve is recorded and transected when 150 mv are still present, when in suprascapular nerve at least 60 mV or some activity in CMAP is found, a RETS as a supercharge is indicated. The mean gap left was 3cm and was covered by allograft. The mean range of motion improved from 40 degree FA to 120°, and strength and update amplitude value went from 0.3 mV to 3.5 mV after 3 moths postop explained by reinnervation along allograft. In conclusion, transfer enough NAP from donor nerve is crucial for successful results in nerve transfers, so we believe more proximal neurotomy with a high NAP and allograft interposition is preferable than an end-to-end suture with low NAP conduction in donor nerve.

BIOLOGICAL THERAPY IN DELAYED DISTAL RADIUS FRACTURE HEALING. CASE REPORT.

List of authors:
Adriana Pemoff*, Candelaria Torre, Hernán Blanchetiere, Soledad Lett, Gabriel Clembosky, Maria Eulalia Landro

1 Hospital Fernandez, Fundación Las Manos del Músico, Climba (Buenos Aires)
2 Hospital Fernandez, Fundación Las Manos del Músico (Buenos Aires)
3 Climba (Buenos Aires)
4 Hospital Fernandez (Buenos Aires)

Objectives / Interrogation: Currently, the study of cellular and molecular biology has allowed to restore or improve organs and tissues function injured by certain diseases or traumatisms. Recent studies indicate that bone marrow concentrate with its mesenchymal and hematopoietic stem cells population, along with growth factors, shows anti-inflammatory, immunomodulatory, chondrogenic, osteogenic and osteoinductive qualities. Platelet-rich plasma is a derivative of autologous peripheral blood, a concentration of platelets in a small amount of plasma, which has a very important role in inflammatory modulation and specially in regulation and stimulation of regenerative processes of different tissues. The aim of our study is to demonstrate the effectiveness of this type of biological therapy in delayed fracture healing, presenting a clinical case.

Methods: A 41-year-old patient who works as a legal assistant, suffered a motorcycle accident and presented a distal radius fracture of his right wrist, treated with open reduction and internal fixation with distal radius blocked plate. He arrives to our medical control after 7 months without radiographic or tomographic consolidation signs, mild pain during forced pronation or supination. With diagnosis of delayed fracture healing, we offered the biological therapy contribution: percutaneous application of bone marrow concentrate (from his iliac crest) + peripheral blood PRP.

Results and Conclusions: After the serial radiological and tomographic controls, changes in the consolidation process began to be seen at the 6th week and was completed after 6 months of the biological therapy, without pain in the fracture focus and complete mobility of the wrist.

We conclude that percutaneous application of autologous biological supply: bone marrow concentrate + platelet-rich plasma is a minimally invasive, effective, safe, economical and viable technique for the treatment of delayed fracture healing.

biological therapy, delayed fracture healing, bone marrow concentrate, PRP
**Helical tendon repair: description of a new technique and comparative biomechanical analysis with two standard techniques**

**List of authors:**
Carlos Eduardo Torres Fuentes*, Francisco Sebastian Carvajal Flechas, Julian Andres Hernandez Beltran, Juan Sebastian Abaunza, Brenda Melissa Barragan, Dayanna Carmona, Angelica Maria Ramirez

1 Fundación Universitaria de Ciencias de la salud, Hospital San José (Bogotá)
2 Fundación Universitaria de Ciencias de la Salud, Hospital San José (Bogotá)
3 Universidad Central (Bogotá)

**Objectives / Interrogation:** Describe a new tendon repair technique for the management of hand flexor tendon injuries and compare their biomechanical characteristics with two conventional techniques of 4-strand cruciate repair, in an ex vivo experimental animal model with porcine tendons.

**Methods:** We describe a technique that consists in a 6-strand cruciate repair that crosses the tendon in an helical form.

This is a comparative experimental biomechanical study in ex vivo animal models. We harvested 66 porcine flexor tendons, a transverse cut at the middle of the tendons was made and these was repaired according a random assignment in six groups: Helical tendon repair made by experienced surgeon, Helical tendon repair made by surgeon in training, Adelaide tendon repair made by experienced surgeon, Adelaide tendon repair made by surgeon in training, modified Kessler tendon repair made by experienced surgeon and modified Kessler tendon repair made by surgeon in training. All the repair were made with 4-0 vascular prolene. The repaired tendons were pulled until failure using an universal test machine. The measuring and registering were made in a blinded manner, recording the ultimate tensile strength, load to 2-mm gap force, stiffness, and mechanism of failure.

**Results and Conclusions:** The Helical tendon repair (65 N) had greater ultimate tensile strength than the Adelaide tendon repair (46 N) and modified Kessler tendon repair (36 N). This is an easy and reproducible technique that can be performed by any surgeon. It resists the forces required for an early active hand mobilization. The repair biomechanic has a greater stability due to its configuration that involving the entire tendon cross-sectional area.

Oberlin technique assisted with intraoperative nerve recording

List of authors:
joaquim casanas*¹, MANUEL LLUSA², ISABEL FERNANDEZ CONEJERO¹, M.ROSA MORRO²
¹ traumaunit. Centro Medico Teknon (SANT CUGAT DEL VALLES)
² traumaunit. Centro Medico Teknon, Hospital Clínica de Barcelona, Departamento de Anatomía y Embriología Humana. UB (SANT CUGAT DEL VALLES)

Objectives / Interrogation: Fascicles identification to optimize nerve transfer is usually an issue during surgery. Anatomic fascicular variability is frequent. Potential of each fascicle is of at most importance to decide which one must be transferred. Intraoperative nerve recording (NAP) and CMAP evaluation guide us to choose the best option for nerve transfer surgeries.

Methods: Oberlin procedure has been performed under intraoperative nerve recording to evaluate which is the best fascicle to be harvested and CMAP in intrinsic and extrinsic muscle obtained. From 2007 to 2013, 36 patients (34 male, 2 female), ages ranges from 17 to 55 have been treated using this method.

Adequate stimulator, recorder, intramuscular needles and settings for multiple channel electromiograph is necessary. Careful intraneural dissection to split fascicles of ulnar nerve and low stimulus intensity is crucial to apply this technique properly. CMAP technique on FCU, hypothenar and first dorsal interosseous muscle were done to record proper fascicle donor. At the same time, we identified and measured NAP of the selected fascicle to optimize results of Oberlin nerve transfer. Activity in the biceps branch was also recorded to decide end-to-side (ETS) or reverse end-to-side (RETS) suture.

Results and Conclusions: Although is described motor fascicles for FCU must be elevated from anteroexternal area of ulnar nerve, we have found just 58% motor nerves are coming from this area, 25% from posteroexternal and 16% from anteroexternal. Reinnervation appears between 3 and 8 months, 91% ETS sutures were performed and 9% RETS sutures in cases we detected some nerve conduction in the biceps motor branch.

We consider CMAP above 500mV in FCU and NAP fascicle greater than 100 mV is necessary to obtain good results. NAP lower than 50 mV get poor results.

Final muscular strength range from 3/5 to 4+/5. We have no failure in any case in terms of EMG reinnervation, however, the amount of NAP transferred is related to clinical results.

So, we can conclude that not all proper fascicles are in the anteroexternal axial section of ulnar nerve and intraoperative nerve recording give us relevant information to localize it, such as measurement of the amount of axonal charge transferred which is correlated with clinical results.

Squamous cell Carcinoma - “The most common Hand malignancy”

List of authors:
Christoph Tasch*, Evi Morandi, Robert Zimmermann, Eva-Maria Baur

1 University Hospital for Plastic Surgery Innsbruck, Medical University (Innsbruck)

Objectives / Interrogation: According to literature squamous cell carcinoma is the most frequent malignant tumor of the hand with 58-90%. In particular organ transplant patients have a 65 to 200 times greater risk of developing squamous cell carcinoma with more aggressive progression compared with the general population.

Methods: On the basis of our patients between 2013-2017 we want to work up squamous cell carcinoma in the hand, provide a literature review and give treatment guidelines.

Results and Conclusions: At the University Hospital for Plastic, Reconstructive and Aesthetic Surgery Innsbruck 24 squamous cell carcinoma out of 32 malignant/semimalignant skin tumors (melanoma n=6, basal-cell carcinoma n=2) were presented between 2013 and 2017. The average age at diagnosis was 72, with a 1:1 male to female ratio. In 75% the tumor was localized on the dorsum of the hand. In 3 Patients who underwent immunusuppression after organ transplantation, squamous cell carcinoma was characterized by rapid growth, multiple lesions and a high rate of local recurrence.

As stated in literature squamous cell carcinoma was the most common hand malignancy in our patients. Especially in organ transplant recipients squamous cell carcinoma was more aggressive than in nonimmunocompromised patients and therefore these patients should be routinely screened at regular intervals for skin lesions. As hand surgeons, it is important to know about the risk of squamous cell carcinoma (SCC) in the upper extremity.

NERVE TRANSFER TO RESTORE THENAR MUSCLE IN LOW MEDIAN NERVE PALSY

List of authors:
M. ROSA MORRO*, joaquim casanas, Manuel LLUSA, Isabela Fernández Conejero, Diana Ortega
1 Trauma unit, Centro Medico Teknon, Hospital Clinic de Barcelona, Departamento de Anatomía y Embriología Humana. UB (Sant Cugat del Valles)
2 Trauma unit, Centro Medico Teknon (Sant Cugat del Valles)

Objectives / Interrogation: Nerve transfer has changed peripheral nerve and brachial plexus expectations to restore function of damaged nerves. Several transfers have been described for multiple lack of function and each patient must be studied carefully in order to offer the best plan to recover function.
Anterior Interosseous Nerve (NIA) has been described to restore ulnar motor function in patients with ulnar nerve palsy, severe compression or low brachial plexus injuries. We decided to use NIA as a motor nerve to restore thenar muscle function in a selected group of patients with no motor thenar function and viability of NIA after partial brachial plexus injury. Accurate nerve conduction studies (NCS) are crucial to indicate this nerve transfer.

Methods: According to this principles, 3 patients have been treated during 2014-2015, age ranges from 28 to 57 yo, 2 females and one male. Preoperative diagnosis supported by precise NCS is crucial to be sure pronator quadratus function is normal, as well it was uninjured or successful reinnervated.
Surgical technique was assisted by intraoperative nerve recording (INR) to identify any residual nerve action potential (NAP) in the motor branch of the median nerve or compound motor action potential in the thenar muscles (CMAP). This way, intraneural dissection is avoided in cases with some or no activity, nerve dissection was performed from distal to proximal to identify fascicular group track to thenar muscle. Reverse end-to-side suture was performed in cases with some NAP recorded and end-to-end when NAP was absent.
Reinnervation was measured by NCS.

Results and Conclusions: Improve in CMAP at thenar muscle was achieved in all three cases. Initial reinnervation was detected at 4 months and improvement of thenar CMAP was measured with a mean rate of 2.4 mV. Clinically, patients recover some abduction function and atrophy of thenar muscles.
So, we can conclude that although indications for this nerve transfer are restricted, clinical results are successful to restore thenar abduction with no morbidity of tendon transfer. Nerve conduction studies also demonstrated improvement. Reverse end-to-side suture also reveals effectiveness of this method.

USE OF BIOLOGICAL THERAPY IN POST-SURGICAL SCAR ADHERENCES IN PERFORMING MUSICIANS

List of authors:
Adriana Pemoff*, Candelaria Torre, Hernán Blanchetiere, Soledad Lett, Maria Eulalia Landro
1 Hospital Fernandez, Fundación Las Manos del Músico, Climba (Buenos Aires)
2 Hospital Fernandez, Fundación Las Manos del Músico (Buenos Aires)
3 Hospital Fernandez (Buenos Aires)

Objectives / Interrogation: We propose, through a retrospective study, the possibility of improving functionality linked to the performance of instrumentalist musicians who had adhesions of their post-surgical scars that affected the correct execution of their instrument.

Methods: We describe 4 musician patients: one with a history of olecranon osteosynthesis, with elbow scar adhesion that limited flexion-extension, another with a history of TFC plastic reconstruction, with scar adherence on the ulnar side of the wrist with pain and limitation of pronosupination and ulnar deviation. Another patient with a history of multiple interventions for scapholunate lesion with extensive incisions and scar adherence on the dorsolateral border of the wrist with regional pain due to neuritis of the radial nerve sensory branches and finally a patient with a history of EPL tenorrhaphy with scar adherence and limitation of the mobility of the thumb.

Three of the cases were treated by percutaneous rigotomy and injection of platelet-rich plasma (PRP) + stem cells derived from autologous adipose tissue and the fourth, only rigotomy with autologous PRP.

Results and Conclusions: In all cases, the range of regional joint mobility, pain according to VAS and improvement in instrument performance were evaluated objectively, as well as, subjectively with the DASH method, finding in all cases, symptomatic and functional improvement.

We believe that biological therapy is an alternative for hypertrophic or adherent scars in performing musicians who are limited in the proper execution of their instrument.

A new minimally invasive technique of the bone marrow concentrate injections improves hand function and reduces pain in the selected scaphoid nonunions

List of authors:
Kaja Gizewska-Kacprzak*¹, Ireneusz Walaszek², Andrzej Bohatyrewicz²
¹ Department of Pediatric and Oncological Surgery, Urology and Hand Surgery, Pomeranian Medical University in Szczecin (Szczecin)
² Department of Orthopaedics, Traumatology and Oncology, Pomeranian Medical University in Szczecin (Szczecin)

Objectives / Interrogation: The scaphoid fractures are the most common carpal bone fractures. Often misdiagnosed can lead to a nonunion. The scaphoid nonunion changes carpal biomechanics and leads to wrist arthrosis. The aim of the study was to evaluate the administration of the autologous bone marrow stem cells in the selected scaphoid nonunions as a new minimally invasive alternative treatment.

Methods: A consecutive series of 28 patients (25 men and 3 women, 17-58 years old, average 30.7 years) with scaphoid nonunions was analysed. The criterion for inclusion were fibrous nonunions with minimal sclerosis changes (up to 1 mm) - grades 2 and 3 in the Slade classification confirmed in a computed tomography scan (Slade 2 - 64.3% (18), Slade 3 - 35.71% (10).

The patients were examined prior and after the treatment using the Visual Analog Pain Scale (VAS) and the Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire supplemented with an assessment of the active range of motion (AROM) and the grip strength. An X-ray evaluation was compared with the preoperative findings.

Scaphoid nonunion was identified under a fluoroscopy. Later 2-3 needles were inserted to the scaphoid and nonunion with arthroscopic guidance.

In the second stage of the procedure, 60 ml of bone marrow were aspirated from the anterior iliac crests, later injected into a Harvest BMAC system, centrifuged and concentrated in a cell separator. Two to three ml were injected into the scaphoid bone through previously inserted needles. A splint was applied for 5 weeks.

Results and Conclusions: After the treatment there was an improvement in all measured features: decrease in DASH: \( p < 0.0001 \), decrease in VAS: \( p < 0.0001 \), increase in grip strength: \( p = 0.001 \) and increase in AROM: \( p = 0.2099 \).

The highest percentage of patients with positive changes was observed in the reduction of pain (96.4%) and in the DASH score (85.7%). Both in grip strength and in AROM most of the patients presented positive changes. The results were not correlated with patients' age, therefore the outcome was better the older the patients were. There were 2 cases without a bone union, nevertheless with an improvement in DASH and VAS.

There was no significant impact of the initial status on the level of the improvement.

In conclusion, our new minimally invasive technique can be an attractive treatment option for scaphoid nonunions with minimal sclerosis with a significant impact on patients' hand function and pain reduction, improving the quality of life.

Keywords: scaphoid non-union, bone marrow stem cells, arthroscopy, minimally invasive surgery
A new combined treatment for Kienböck's disease: bone leveling procedure with bone marrow mesenchymal stem cell administration

List of authors:
Ireneusz Walaszek*1, Agnieszka Dabek-Szwajlik1, Elzbieta Gawrych2, Justyna Rajewska-Majchrzak2, Milosz Parczewski3, Kaja Gizewska-Kacprzak2
1 Department of Orthopedics, Traumatology and Oncology, Pomeranian Medical University in Szczecin (Szczecin)
2 Department of Pediatric and Oncological Surgery, Urology and Hand Surgery, Pomeranian Medical University in Szczecin (Szczecin)
3 Department of Infectious, Tropical Diseases, and Immune Deficiency, Pomeranian Medical University in Szczecin (Szczecin)

Objectives / Interrogation: Avascular necrosis of the lunate bone (Kienböck's disease) is a rare entity that leads to a significant hand dysfunction. Treatment algorithms are variable up to radical salvage procedures. The aim of this study was to analyse the results of a treatment combining surgical bone leveling intervention with autologous stem cell administration.

Methods: Nine consecutive patients with advanced Kienbock disease underwent treatment with surgical osteotomies and direct injections of bone marrow concentrate to the lunate bone. Individually regarding anatomical prerequisites certain surgical techniques were applied, as radial shortening in the ulnar positive variance and capitate shortening in the ulnar neutral variance. The patients were examined prior and after surgery using the Visual Analog Pain Scale (VAS) and the Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire supplemented with an assessment of the active range of motion (AROM) and the grip strength. An X-ray evaluation was compared with the preoperative findings.

Results and Conclusions: Preoperative hand function was impaired in all of the patients (median DASH: 27, with 56% of grip strength and 60% of AROM compared to the unaffected side). The preoperative pain was extensive (median VAS: 7). Following the presented combined interventions, a significant decrease in DASH score (median: 12, p = 0.0077), a reduction of pain (median VAS: 2, p = 0.0076) and an increase in grip strength (median: 61%, p = 0.007) were observed.

The study provides a protocol for combining bone leveling procedures with a direct administration of bone marrow cells in the treatment of avascular necrosis of the lunate bone that could be easily implemented in surgical practice. The combined treatment method has promising results as the improvement of hand function and the decrease in pain. The suggested technique can protect patients with Kienbock disease from salvage procedures with a restricted range of motion of the wrist.

bone avascular necrosis, Kienbock disease, mesenchymal stem cells, bone marrow cells,
5 to 7 years results using a mini-TightRope (Arthrex) alone to suspend the thumb metacarpal after a trapeziectomy in the treatment of thumb carpometacarpal osteoarthritis: proving the 5-year successful outcomes of this method.

List of authors:
Martin Wells¹, Cameron Anley², Sean Pretorius¹, Ajmal Ikram²
¹ Mediclinic Panorama (Cape Town)
² Tygerberg Hospital (Cape Town)

Objectives / Interrogation: On review of the current literature, the most common procedure for painful carpometacarpal joint of the thumb (CMC-I) osteoarthritis remains trapeziectomy with or without tendon suspension and interposition. We were encouraged by excellent 2-year results using the mini-TightRope (mTR) to suspend the thumb metacarpal, replacing the need for tendon suspension and interposition. The aim of this prospective study is to report minimum 5 years (to 7 years) results of 67 patients operated from 2010 to 2013 using the mTR alone for suspension following trapeziectomy in advanced CMC-I osteoarthritis.

Methods: 67 Patients (72 thumbs) (F: 64 M: 3), mean age 60 (44-76) years, with painful CMC-I osteoarthritis, treated conservatively longer than 1 year, were studied. The surgical technique included open trapeziectomy with suspension of the thumb metacarpal to the 2nd metacarpal using a mini-TightRope. Patients were immobilised for 10 to 14 days and range of motion exercises started. Pain was recorded on a visual analogue scale (VAS) before surgery and after 6, 12 and 60+ months. Thumb function was also recorded, measuring quick DASH, key pinch grip strength, first webspace angulation and range of motion (Kapandji method). Radiographic measurements included the trapezial space ratio. Any complications were documented.

Results and Conclusions: 67 patients (F: 64 M: 3) (72 thumbs) were reviewed after 5 years, mean follow-up of 6 years. Their mean age was 60 (44-76) years. There was no intraoperative complication nor need for device removal. The average VAS pain improved from 7.66 preop to 0.07 postoperatively. The average quickDASH improved from 60 to 5.5. The first webspace angulation improved from 33.6° to 38.1°. The range of motion improved from average 7.8 (Kapandji score) preop to 9.3 postop. The average key pinch grip of the operated thumb was 3.36 kg preop and improved to 3.74 kg postoperatively, 94% of the nonsurgical side. The trapezial space ratio averaged 0.2 with minimal metacarpal subsidence. Use of the mTR to suspend the thumb metacarpal following trapeziectomy is a simple procedure allowing for early mobilisation of the thumb postoperatively. It provides significant improvement in pain (VAS) and function (qDASH), improves range of motion, webspace, and pinch strength. There have been no complications related to the mTR. We conclude, based on 5-year results, that using a mini-TightRope is a safe and effective method to suspend the thumb metacarpal after trapeziectomy, without need for immobilisation nor tendon harvest.

TRANSFER OF THE EXTENSOR INDICIS TO EXTENSOR POLLICIS LONGUS IN CASES OF INJURY OF THE EXTENSOR TENDON, SEQUEL OF FRICTION WITH SCREW OF VOLAR PLATE OF DISTAL RADIO.

List of authors:
Santiago Moreno*, Daniel Moreano, Marco Yanez
1 Pontificia Universidad Catolica del Ecuador (Quito)

Objectives / Interrogation: INTRODUCTION.
The first finger is fundamental for the correct operation of the hand, allows one of the main functions that is the realization of clamp. Extensor Pollicis Longus tendon rupture can be spontaneous, traumatic, secondary to rheumatoid arthritis, secondary to the use of corticosteroids or as a sequel of friction with a screw of a volar plate used for the treatment of fractures of distal radius. The direct sutures of the injured ends of the Extensor Pollicis Longus under the extensor retinaculum have a high failure rate. Transposition of the Extensor Indicis is a surgical technique to be considered for the repair of this type of injuries. The objective of this work is to demonstrate the surgical technique that we use after a rupture of the EPL tendon by friction of screws placed in a DVR plate with favorable functional results.

Methods: A 42-year-old female patient who, after falling from her own height with a left wrist in extension, presented a fracture of the distal radius Fernandez III, AO 2R3A2.2. Surgical treatment, open reduction plus internal fixation with a volar plate for distal radius (DVR) is performed. Two years after the surgery the patient presented an inability to extend the distal phalanx of the thumb, with apparent loss of strength, which is why an ultrasound study was performed that reported empty space in the third extensor compartment, absence of Extensor Pollicis Longus tendon, in addition to surgical material (screw), that crosses the dorsal cortex and is evidenced in the third compartment. The tendon ends are located at 2.3 cm. Tendinous transfer of the Extensor Indicis tendon to the Extensor Pollicis Longus tendon is performed, with adequate functional recovery.

SURGICAL TECHNIQUE
Identification of the Extensor Indicis tendon at the level of the wrist and distal tenotomy at the metacarpophalangeal level. The extraction of the Extensor Indicis tendon and the distal end of the Extensor Pollicis Longus is performed, both ends are faced, and a terminal term repair is carried out using the pulvertaft technique.

Results and Conclusions: The rupture of the Extensor Pollicis Longus secondary to friction by a volar plate screw of distal radius is a rare complication, however, it causes serious functional limitations. Direct repairs of injured extremities, under the extensor retinaculum, are associated with a high failure rate, so the transfer of the Extensor Indicis to the Extensor Pollicis Longus is a relatively simple technique to perform, with good functional results.

Total wrist arthroplasty in rheumatoid and post traumatic wrist: long term follow-up.

List of authors:
Sandra Pfanner*, Andrea Poggetti2, Giovanni Munz1, Guidi Giulia3, Massimo Ceruso1
1 Hand and Reconstructive Microsurgery Unit, AOU Careggi (Florence)
2 Hand and Reconstructive Microsurgery Unit, AOU-Careggi (Florence)
3 Florence (Florence)

Objectives / Interrogation: To report the long-term follow-up outcomes of 43 total wrist arthroplasty (TWA) in rheumatoid and post traumatic wrists.

Methods: From 2003 to 2018 8 men and 35 women, aged 32 to 74 (mean 62) years underwent 43 total wrist arthroplasties for rheumatoid arthritis (n=29) and post-traumatic arthritis (n=14) using the Universal 2 wrist prosthesis in 24 Patients, Integra Freedom Wrist System in 6 Patients, ReMotion in 11 Patients and Emi-Prosthesis in 2 cases. The mean follow-up was 82.3 months (range: 2-12 years). Pre and post-operative Visual Analogue Scale (VAS), Quick Disabilities of the Arm, Shoulder and Hand (DASH) score and the Patient-Rated Wrist Evaluation (PRWE) score were performed. The Authors also evaluated: Range of motion, neurovascular and tendon status, stability, dislocation rate. The X-Ray views was performed to evaluated implant and screws alignment and fit and loosening.

Results and Conclusions: All patients had good or complete pain relief, the mean visual analogue scale pain score was 1.0 (pre-op 9.0). The mean grip strength improved and postoperatively was 11kg (Jamar). The mean total active motion (AROM) of flexion-extension was 73.4°; radial-ulnar deviation 25.7°. The mean QuickDASH score was 32 and PRWE was 40.3. Revision surgical procedures were performed in 7 cases (18,6%): 6 carpal components were revised (polyethylene inserts wear and/or carpal ulnar screw loosening secondary to intra-operative malalignment) and 1 radial component, in 4 cases total implant failed, Swanson's silicone spacer was applied (n=3) or wrist joint fusion (n=1).

Long term results in TWA suggest a pain relief and improves function both in rheumatoid and post traumatic arthritis. Nowadays the wrist arthroplasty can be considered as a predictable functional option to managing wrist joint arthritis in selected cases and patients.

Combined Total Wrist Arthroplasty with Ulna Head Prosthesis in a Rheumatoid Patient with gross Distal Radio-Ulnar Joint instability using Interosseous Membrane Reconstruction with Brachioradialis tendon graft

**List of authors:**
Marcio Aita*, Ricardo Kaempf de Oliveira², Raimundo Araujo Filho³, Bruno Biondi⁴, Pedro J Delgado⁵, Gustavo Mantovani Ruggiero⁶

1. Parsante (São Bernardo do Campo)
2. Hospital Mãe de Deus (Porto Alegre)
3. Santa Casa de Misericórdia (Maceió)
4. Faculdade de Medicina do ABC (São Bernardo do Campo)
5. Hospital Universitário HM Monteprincipe (Madrid)
6. SP hand center (São Paulo)

**Objectives / Interrogation:** Background
We report a patient with Rheumatoid Arthritis, submitted to Total Wrist Arthroplasty (TWA) and Ulna Head Prosthesis (UHP), addressing a previous gross instability of Distal Radio-ulnar Joint (DRUJ) by ligament reconstruction of the distal part of interosseous membrane using brachioradialis (BR) tendon graft. The surgical technique is described as well the follow-up after 6 years from the surgery showing a good outcome.

Potential benefit of combining TWA with UHP is a more balanced load distribution on the wrist, compared to Darrach. The technique of BR tendon reconstruction of IOM for DRUJ instability was largely used by the authors with reliable results, on post traumatic injuries.

**Methods:** Case Description
The patient was a 38-year-old woman presented with wrist degenerative deformity by RA in his right, dominant wrist. Wrist radiographs and CT scan demonstrates signs of advanced arthritis, affecting radio-carpal, midcarpal and DRUJ, with dorsal dislocation of the ulnar Head. The patient was directed by other hand surgeons to undergo total wrist arthrodesis associated with the Darrach procedure, an indication not accepted by her. Twenty-four months later, the patient complained of persistent wrist pain and radiographs signs worsened.

On pre operative physical examination, there was a painful limited mobility on the wrist. Wrist flexion was limited to 30°; extension was limited to 10°. Pronation was 70° and supination 45°. The patient's Disabilities of the Arm, Shoulder and Hand (DASH) score of was 54, and the visual analog scale (VAS) pain score was 7. Grip strength was 38% of that achieved by the wrist on the unaffected side.

Since the patient expectation was a functional motion on her dominant wrist, we decided for entire Wrist Replacement using a TWA technique with Radio-carpal prosthesis and ulna head replacement addressing the DRUJ instability by reconstruction of the distal part of interosseous membrane using BR tendon.

**Results and Conclusions:** On follow-up 6 years after surgery, the patient exhibited good wrist, forearm, and elbow range of motion, with 70° flexion, 60° extension, 20° radial deviation, 30° ulnar deviation, 85° pronation, and 90° supination. The patient had normal movement of all digits, a DASH score of 5, VAS of 0, and grip strength of 92% the unaffected wrist. Wrist radiographs shown articular congruency of DRUJ and radio carpal joint and good bone attachment to the implants.

Differential Effectiveness for Trigger Thumb and Finger Injections

List of authors:
Lauren Wessel1, Evan O'Donnell1, Aaron Chen2, Jeffrey Stepan1, Daniel Osei1
1 Hospital for Special Surgery (New York)
2 Weill Cornell Medical College (New York)

Objectives / Interrogation: Literature examining the effectiveness of corticosteroid injection as a treatment method for trigger finger has typically grouped all of the digits together, with no distinction made between the thumb and lesser fingers. In this study, we use the novel ICD-10 coding to determine if the effectiveness of corticosteroid injections in the thumb and lesser fingers differs according to affected digit.

Methods: We queried a national insurance database from 2007 to 2017 to identify all patients who were treated for a trigger digit with 6-month follow-up. We categorized trigger digits by laterality and by digit (thumb, index, long, ring and small fingers). We reviewed all tendon-sheath injections and trigger digit releases (TDR) during the observation period. The time in days from trigger digit diagnosis to TDR was recorded and compared between thumb and all other fingers. Kaplan-Meier survival curves were calculated to analyze the effectiveness of tendon sheath injection and conversion to TDR.

Results and Conclusions: The study population included 38,268 patients with the diagnosis of a trigger digit (TD) and 6-month follow-up. Long and ring fingers were treated most commonly, accounting for 32.2% and 27.2% of all digits, respectively. Trigger thumbs accounted for 22.3% of the study population. While the lesser fingers converted to release in an average of 170 days (SD 114.5 days) after injection, thumbs converted to release on an average of 130 days (SD 94.2 days)
Among digits that went on to surgical release, trigger thumbs on average progressed to surgical release 40 days more quickly than lesser fingers. Notably, our analysis revealed that the overall survival wasn’t affected in the same way, as the number of days from trigger digit diagnosis to release in the thumb and fingers were very similar. Taken together, these data suggest that corticosteroid injection is less effective in alleviating symptoms in thumbs than in fingers and that trigger thumb may be more recalcitrant to non-operative treatment than trigger finger.

Incidence of peripheral nerve trauma in England between 2006-2016 - time to increase resources for peripheral nerve trauma of the hands and upper limb?

List of authors:
Jacky Chen*, Ralph Murphy1, Adam Reid1
1 Wythenshawe Hospital (Manchester)

Objectives / Interrogation: To establish the common patterns of peripheral nerve injury in England between 2006-2016

Methods: This is a retrospective observational study using cross-sectional data collected by Hospital Episode Statistics (HES) between 2006-2016 in England. Data included all primary diagnoses coded using ICD-10 codes within the study period for all hospital attendance episodes. All peripheral nerve injury codes were included and subclassified by anatomical region, age and gender.

Results and Conclusions: A total of 65,163 peripheral nerve injuries were coded over the study period. The commonest site of injury was consistently the upper limb with a median of 94.8% over 10 years (range 93.8%-95.2%, Interquartile range 0.5%), followed by lower limb at 3.0% (2.8-2.4%, 0.3%), head and neck at 2.0% (1.5%-2.7%, 0.2%) and trunk at 0.3% (0.2-0.5%, 0.2%).

Within the upper limb peripheral nerves group the majority of injuries occurred to nerves distal to the wrist (median 84.4%, range 81.5%-86.7%, Interquartile range 1.5%) followed by nerve injuries between the wrist and elbow (8.5%, 6.9-11.3%, 1.3%) and then injuries proximal to the elbow (7.2%, 6.0-8.1%, 0.6%). Of note, finger and thumb nerve injuries represented 55.4% (52.0-61.5%, 4.2%) of all injuries of the upper limb.

Nerve injuries distal to the wrist were commoner in males (70.6%, 68.8%-71.5%, 1.3%). The commonest age range to sustain injuries were patients in their third decade (27.2%, 26.0-27.9%, 0.9%), followed by the fourth (18.9%, 18.3-19.7%, 0.8%), the fifth (17.5%, 16.9-18.2%, 0.8%), the sixth and second decade (12.2%, 11.8-13.0%, 0.3% and 12.1%, 11.8-13.1%, 0.72%). The first decade and beyond the seventh decade complete the rest of the age profiles with diminishing numbers towards the extremes of life.

Conclusion
The upper limb and hands are consistently the most common regions that sustain peripheral nerve injury. The patient group most likely to present with peripheral nerve injuries are males in their third decade with finger nerve injuries. Future research into nerve surgery and allocation of resources should take these data into account. In addition, research identifying other risk factors for injury is needed.

Reconstruction of Blauth type IIIb hypoplastic thumb with half 2nd metacarpal and tendon transfer

List of authors:
Yousheng Fang*1
1 Department of hand surgery, Huashan hospital, Furan university (Shanghai)

Objectives / Interrogation: Parents usually want a five-digit-hand for the child with Type IIIb hypoplastic thumb, though pollicization has excellent function results but 4-digit hand. Most parents concern more about the number of digit than the function of the hand. We reported our technique with half 2nd metacarpal transfer to reconstruct the 1st CMC joint and followed by tendon transfer to reconstruct the main function of the thumb.

Methods: We reported 14 thumbs of 12 children with IIIb hypoplastic thumb. The average age of surgery was 1.5 years (one year two months to two years one month). The surgery was performed in two stages. The first stage was to reconstruct the proximal part of the 1st metacarpal with half of the proximal 2nd metacarpal. Half year later, the second stage was performed with tendon transfer. Thumb extension was reconstructed with EDI tendon and thumb opposition with FDS from ring finger, MP joint was stabilized by tendon transfer in the meantime. All the children were followed up. The growth and the function of the reconstructed thumb were recorded and compared with contralateral thumb.

Results and Conclusions: The complete union of the bone transfer was seen in 10 of 12 children, and the other two with non-union was fixed with K-were during the second stage of surgery. The growth to reconstructed thumb still slower than the contralateral thumb, the grip and pinch power was less than the contralateral one, however, the parents were satisfied with five-digit thumb and the function.

In conclusion, the reconstruction of the Blauth type IIIb hypoplastic thumb with half second metacarpal and tendon transfer is an acceptable alternative to those who can not accept the procedure of pollicization.

HOW TO IMPROVE AND DIRECT THE NEURONAL GROWTH PROCESS. THE FUTURE FOR PERIPHERAL NERVE REGENERATION

List of authors:
Andrea Poggetti*, Sandra Pfanner, Massimo Ceruso
1 Hand and Reconstructive Microsurgery Unit, AOU-Careggi (Florence)
2 Hand and Reconstructive Microsurgery Unit, AOU Careggi (Florence)

Objectives / Interrogation: Peripheral nerves injuries are common lesions than cause loss of function and poor outcome. In case of severe nerve gap (>50mm), the gold standard remains the autologous graft. The limits are: functional damage at the donor site, double surgical access and the lack of large amounts of grafts. In response to injury, Schwann cells (SC), take advantage to extracellular matrix (ECM) connection, proliferates in organized structures than guiding axons during regeneration.

Methods: Researchers focused two main areas of investigation: the role of the interaction between cells with the extracellular membrane (ECM) and the forces acting during axonal elongation.

Results and Conclusions: Regarding the contact between cells (nervous and glial) and physical stimuli arising from the ECM, the tissue engineering build artificial surfaces than reproduce the topographical signals of the ECM (Micro and Nano size spur). The influence of micro and nano-topography on cells behaviour is explored both in vitro and in vivo. SC quit on the anisotropic substrate aligning preferably along the axis of the topographical signal, while cells cultured on flat surfaces show a random orientation. In reference to the forces acting during axonal elongation in 1984 Bray demonstrated in vitro that the application of a mechanical tension by micro-needles of glass inserted in the growing cones, helped the axon's elongation, without reducing the diameter. Riggio et all proposed to use, in vitro, nervous Rat PC12 Cells cultured with magnetisable nanoparticles (MNPs) (1-100mgml-1), "assimilated" by cells by endocytosis. Subsequently, an external magnetic field was applied. The association of the nanoparticles and an external magnetic field, generating a tension force in order of pN, virtually able to guiding axonal growing and orienting cells along the direction of the magnetic force(4). The Author investigated the early step of in vivo application of this technique and used an experimental model of the median nerve injury in rats. The data show that did not hinder with the nerve regeneration (one week after injury, it is evident the presence of Schwann cells migrated from the proximal to the distal stump). The MNPs were endocited by Schwann cells, but also within the same nerve fibres. Finally, in case of severe nerve gap the gold standard remain the autologous nerve graft, however the technique could be overcome in the future by different and alternatives solutions.

Wide Awake surgery, team work between surgeon, anesthetist and patient.

List of authors:
Filipa Santos Silva¹, Patricia Wircker², Osvaldo Cardoso¹, João Maia¹
¹ Hospital Cuf Descobertas (Lisboa)
² Hospital Cascais (Alcabideche)

Objectives / Interrogation: One of the most significant advance in knowledge about hand anesthesia is based on the safety of local infiltration of epinephrine. It promotes vasoconstriction and combined with lidocaine or ropivacaine eliminates the need for sedation, brachial plexus blocks and general anesthesia for frequent hand surgeries.

The wide-awake anesthetic-surgical technique traditionally described in the literature consists of local administration of lidocaine and epinephrine by the orthopaedic surgeon. We adapted this technique to our surgical practice, in a teamwork between orthopaedics and anesthesia. Several hand surgical procedures were performed with this protocol. In this paper we describe the procedures and results of 9 patients whose follow up was documented.

Methods: We describe 9 procedures that were evaluated and documented: 5 surgeries of arthrolysis and tenolysis, 3 tendinous section repair and a metacarpal desrotative osteotomy with arthrolysis and tenolysis. In all cases, the anesthetist performed a distal peripheral block at the level of the radial, ulnar and median nerve, according with the required territory (2-3 mL of ropivacaine at 3.75 mg/mL). 20 minutes after, epinephrine is locally infiltrated in doses up to 15 mL in the palmar region, 2 mL on the 1st and 2nd phalanges and 1 mL on the 3rd phalanx. Surgery starts in 30 minutes. No tourniquet was used. Patients were fully aware throughout the procedure, moving the concerned segment when requested, allowing tendon tension and excursion assessment, suture strength, release efficacy and movement correction.

Results and Conclusions: Distal block with ropivacaine, in the referred doses, makes an effective sensory blockage for a 12 hours average period, maintaining the motor capacity that allows active mobilization by the patient during the surgical procedure demonstrating the effectiveness of the surgical procedure. Ropivacaine and epinephrine were effective in pain and hemorrhage control, removing the need for sedation and tourniquet. Positive results were obtained in hand fractures surgeries, repair and tendon transpositions. It enables the patient to collaborate during the surgery by actively performing the movement that needs to be tested. Reduces complications of rupture, incomplete tenolysis or joint stiffness by allowing motion monitoring intra-op and early rehabilitation post-op. Allows a more effective pain control than the traditionally one, since the effect is longer with ropivacaine.

Modified proximal capitate osteotomy in a chronic isolated lunate dislocation - a new perspective in treatment of Kienbock disease?

List of authors:
Ireneusz Walaszek*, Kaja Gizewska-Kacprzak
1 Department of Orthopaedics, Traumatology and Oncology, Pomeranian Medical University in Szczecin (Szczecin)
2 Department of Pediatric and Oncological Surgery, Urology and Hand Surgery, Pomeranian Medical University in Szczecin (Szczecin)

Objectives / Interrogation: Isolated lunate dislocation is one of the most severe carpal instability lesion. Despite devastating changes in wrist anatomy it can be misdiagnosed. We present a case of an isolated lunate dislocation diagnosed 14 weeks after injury with avascular necrosis (AVN) of the lunate.

Methods: A 37-years-old male, a manual worker injured his right (dominant) wrist during a fall. He was initially diagnosed as a wrist sprain. One month later due to a persistent pain, an X-ray was performed with no recognition of wrist pathology. The patient came with a stiff wrist to an outpatient clinic 14 weeks later. His pain was 8 in the Visual Analogue Scale (VAS). The wrist was swollen with no active range of motion (AROM). Grip strength was 12% of the opposite hand, Mayo Wrist Score-5, and Disabilities of the Arm, Shoulder and Hand (DASH)-76.2. The symptoms of the median nerve dysfunction were present. The radiograms were reevaluated with a diagnosis of a lunate dislocation.

The patient was qualified for surgery. Preoperatively, computed tomography confirmed the isolated lunate dislocation with an injury of proximal capitate cartilage.

From volar and dorsal approaches a severe damage to the cartilage of the capitate and a fibrosis of the lunate were identified. The lunate was necrotic with loss of the cartilage and was excised. Due to a chondromalacia of the capitate, a proximal row carpectomy was excluded. We chose a proximal osteotomy of the capitate and a free cortical graft to remodel the shape of the capitate. A graft from the iliac crest was harvested to preserve its convex shape covered with soft tissue to be positioned as the new articular surface facing radiocarpal joint. The graft and remaining capitate were stabilized with a cage plate. The scaphoid and the capitate were fixed with a cannulated screw.

A bone union was achieved after 8 weeks. In a 6 months follow-up the pain was 0-1 in VAS, Mayo Wrist Score (80), DASH (10.9) and AROM and grip strength - 70 % of the opposite hand. The patient has returned to his previous occupation.

Results and Conclusions: This is the first report of a modified proximal capitate osteotomy with a free bone graft in the lunate dislocation with the AVN of the lunate with a coexisting chondromalacia of the capitate. Our method reduces the potential risk of double non-union and capitate head necrosis observed in the Graner's procedure as there is only one bone-union necessary. We assume that our modification could be an attractive option for the advanced Kienbock disease.

ARTROSCOPIC EVALUATION OF LIGAMENT INJURIES ASSOCIATED TO INTRAARTICULAR DISTAL RADIUS FRACTURES

List of authors:
Aldo Villavicencio*, Rene Jorquera¹, Pablo Orellana¹, Francisco Melibosky¹, Peter Cobb¹, Andres Almonacid¹
¹ Clinica Indisa (santiago)

Objectives / Interrogation: Our objective is to describe associated ligament injuries in intraarticular distal radius fractures using arthroscopic assistance. Additionally, to characterize these findings according to stability and need for treatment (either arthroscopic or open).

Methods: Retrospective study including 85 distal radius fractures treated surgically with open reduction and internal fixation and arthroscopic assistance between January 2017 and July 2018. Inclusion criteria were intraarticular fractures with indication of surgical treatment, in high demand patients. Low demand patients, as well as extraarticular and non operated fractures were excluded. All wrist fractures in this study were treated with open reduction and internal fixation using locking volar plate, and wrist arthroscopy to assess articular surface and associated ligament injuries. Findings related to Triangular Fibrocartilage Complex, Scapholunate Ligament and Lunotriquetral Ligament were recorded and classified according to Palmer and EWAS Classification, respectively. Finally, arthroscopic findings were classified as "stable" and "unstable" according to they need to undergo additional procedures for stabilization. No functional results were evaluated.

Results and Conclusions: From a total of 85 fractures, 49 (57.6%) presented at least one ligament injury during arthroscopic evaluation. 31 (36.5%) fractures were associated to Triangular Fibrocartilage Complex lesions. When evaluating intrinsic ligament injuries, 27 (31.8%) cases had Scapholunate Ligament and 12 (14.1%) Lunotriquetral Ligament injuries. Of the total number of ligament injuries, 12 (14.1%) Triangular Fibrocartilage Complex, 15 (17.6%) Scapholunate Ligament and 9 (10.6%) Lunotriquetral Ligament tears needed some additional surgical procedure for stabilization. In conclusion, the total number of ligament injuries found in association to intraarticular distal radius fractures is similar to other publications. Moreover, proper characterization of these lesions allow us to have a more accurate idea of which will need further treatment.

Histologic Analysis of the Nail Apparatus in Regard to Subungual Melanoma: Anatomical Study in 21 Cadavers

List of authors:
Byung Jun Kim¹, Hyunwoo Kim¹, Julong Hu¹, Jin Hyun Kim³, Hyokyung Yoo³, Na Hee Yu¹, Sung Tack Kwon¹
¹Seoul National University Hospital (Seoul)

Objectives / Interrogation: Breslow thickness is the most important factor that determines treatment plans and the prognosis of the melanoma. However, this cannot be directly applied to the subungual melanoma considering the unique anatomy of the nail unit. The aim of the present study is to analyze the anatomy of the nail unit in order to get information for the functional surgery of the subungual melanoma.

Methods: Twenty-one cadavers were enrolled in this study. Bilateral thumbs and big toes were obtained, and midline longitudinal cross-section slides were made with a thickness of 10 micrometers. The distances from the nail bed to the underlying bone were measured at multiple points including the nail matrix and the hyponychium.

Results and Conclusions: The distance between the nail bed and the underlying bone was the shortest at the nail matrix and the longest at the hyponychium. At the nail matrix, the distance showed $1.10 \pm 0.43$ mm in the thumbs and $1.12 \pm 0.39$ mm in the big toes, respectively. At the hyponychium, the distance was $2.86 \pm 0.82$ mm in the thumbs and $2.71 \pm 0.80$ mm in the big toes, respectively.
This is the first study that measured the distance between nail bed and bone at multiple points in Korean. Nail bed showed the shortest distance to the underlying bone at the nail matrix. The results of this study will help to build up a new staging system and surgical methods of subungual melanoma in the future.

FATGRAFTING IN DUPUYTREN DISEASE

List of authors:
Cesare Tiengo*, Diego Faccio², Regina Sonda¹, Erica Dalla Venezia¹, Andrea Monticelli³, Franco Bassetto¹
¹ University of Padua (Padova)
² University of Padua (Sovizzo)
³ University of Padua (Cherasco)

Objectives / Interrogation: Several pathogenetic hypothesis were described for fascia proliferation in Dupuytren's disease. The surgical approach aim to treat the macroscopic manifestation of finger retraction in the most advanced recurrent disease. It became necessary to investigate the cellular Dupuytren develop to find out new therapeutic approach to permit a more sparing surgery and to treat all severe cases. In fact, some clinical studies assess as, in addition to fascia, palmar skin and fat-derived cells may be a potential source of cells causing the Dupuytren disease. Based on this observation, the introduction of the fat graft palmar replacement by lipofilling technique joint to traditional aponeurectomy have shown promising long term good result.

Methods: A retrospective study was performed on patients treated for Dupuytren recurrence by selective aponeurectomy and fat graft. 44 patients, with five years of follow, were treated for recurrent Dupuytren disease (30 patients previously undergoing aponeurectomy and 14 patients undergoing infiltration with collagenase). An aponeurectomy was performed in all cases with complete removal of affected fascia. At the end of procedure all the surgical site and neighboring rays were filled by fat graft from the abdomen (mean 12cc). Primary endpoint was skin texture, quality of scar, tendon gliding, pain and complications. Secondary endpoint was to observe the recurrence of the disease by echography evaluation.

Results and Conclusions: The patients were evaluated after 3 years from surgery to verify effects. Good results emerged from many patients concerning: the degree of flexion and extension of the operated fingers, the degrees of active and passive mobility of the MCF and IF joint, pain, sensitivity, flexion strength and scars. Only three patients presented a relapse. All patients underwent ultrasound evaluations six months and on1 and 3 year after surgery, documenting the persistence of adipose tissue in rays involved. Fat grafting is a common procedure in reconstructive and aesthetic surgery, colled as "lipofilling''. For the presence of adipose derived stem cell (ADSC) and cytokines it is employed in several clinical procedures as severe Dupuytren especially for its possible role in modulating the fibroproliferative diathesis.

The morphological, functional results and limited incidence of recurrences in treated patients would seem to confirm that aponeurectomy and lipofilling may represent a new weapon in cases of aggressive disease.

Dupuytren, lipofilling, aponeurectomy
CLASSIFICATION OF DISTAL FINGER TUMOURS

List of authors:
Ali Cavit*¹, Tufan Kaleli¹, Mehmet Tunc Mocan², Sercan Capkin¹
¹ Uludag University Faculty of Medicine (Bursa)
² Igdir State Hospital (Igdir)

Objectives / Interrogation: This study aims to define a new classification system by dividing the distal finger into zones according to their anatomical formations and natural boundaries, to determine the histopathologic diagnosis of the finger tumours presenting in these regions and examine the tumour distribution according to these zones.

Methods: Between January 1995 and February 2016, 61 patients with distal finger tumours and tumour-like lesions were retrospectively evaluated. Patients' gender, age, clinical features, radiological findings, tumour localisations and histopathologic features were evaluated. The distal finger was divided into two zones (zone 1 and 2) according to their anatomical characteristics; zone 1, the interphalangeal joint of the thumb, distal interphalangeal joint of the other fingers and the surrounding soft tissue; zone 2a, nail and surrounding structures; zone 2b, distal phalanx zone and zone 2c, finger pulp.

Results and Conclusions: Lesions originating from soft tissue and bone comprised 91.8% (n = 56) and 8.2% (n = 5) of the tumour and tumour-like lesion population, respectively. According to our distal finger tumour classification, majority tumours and tumour-like lesions were located in zone 2a (nail complex; 44%), followed by zone 1 (joint and surrounding soft tissue; 30%). The most common tumour lesion according to the identified zones was GCTTS in zone 1 and zone 2c, glomus tumour in zone 2a and enchondroma in zone 2b.

The widespread use of this classification system could provide an idea of the possible pathologies when encountering a patient with a distal finger mass, thereby enabling more accurate surgical planning.

Soft tissue tumours, bone tumours, finger, classification, tumour-like lesions.
A successful use of collagenase injection multiple fingers contractures in a child in the course of a generalized collagenopathy and Arnold Chiari Malformation Type I

List of authors:
Kaja Gizewska-Kacprzak*, Ireneusz Walaszek
1 Department of Pediatric and Oncological Surgery, Urology and Hand Surgery, Pomeranian Medical University in Szczecin (Szczecin)
2 Department of Orthopaedics, Traumatology and Oncology, Pomeranian Medical University in Szczecin (Szczecin)

Objectives / Interrogation: Dupuytren disease is extremely rare among the pediatric population. We present an extremely rare case bilateral multiple finger contractures of a yet unknown collagenopathy in a child treated with collagenase injection.

Methods: A 17-year-old girl presented in a Pediatric Hand Surgery ambulatory with advanced contractures of II-V fingers in both hands. The left hand (4th finger) had been already operated in another centre as a Dupuytren disease with postoperative complications and severe progression of the contracture. History taking and a detailed clinical examination drew hand surgeons attention to contractures of both feet, complains of recurrent headaches, nystagmus and an unusual forced position of the head - intensifying the progeria of the mandibula. A neurosurgical reevaluation of the past head scans confirmed the Arnold Chiari Malformation Type I with a severe inclination of the cerebellum tonsils into the foramen magnum and dens axis compression of the pons. The girl was qualified for an urgent neurosurgical intervention.

The girl underwent craniocervical decompression with a posterior occipital stabilisation with no complication. In an 8-month follow-up, there was a significant clinical improvement with

The patient was qualified to following hand procedures: first collagenase injection into the overgrown aponeurosis in the II-IV fingers of the right hand. Later under the general anaesthesia contractures of the right-hand were stretched reaching the full range of motion. At the same time, an open fasciectomy with a tendon reconstruction was performed to the III and IV fingers of the left hand. The wound healing was uncomplicated and the patient continued rehabilitation improving significantly everyday activities.

A wide genetic testing confirmed multiple mutations linked with the rare disease also including collagenopathies, but no clear diagnosis was stated.

Results and Conclusions: The collagenase injection was a successful treatment option in this rare case. What's more the unknown course of the disease favour the minimally invasive methods.

In conclusion, the treatment option for finger contractures has to be adjusted individually. A team approach in the Pediatric Hand Surgery can be an example of a holistic treatment to a young patient that can benefit from the most up-to-date methods of treatment.

Iatrogenic Injuries of Motor or Mixed Motor/Sensory Nerves

List of authors:
Chye Yew Ng\(^1\), Jagwant Singh\(^1\), Andrew Fowler\(^1\), Feiran Wu\(^2\), Sohail Akhtar\(^1\)
\(^1\)Wrightington Hospital (Wigan)

Objectives / Interrogation: To report patterns of iatrogenic nerve palsies referred to a tertiary peripheral nerve injury service.

Methods: This was a retrospective review of patients who presented with new-onset nerve palsy involving a motor or mixed motor/sensory nerve following an operation. Cutaneous neuromas alone were excluded.

Results and Conclusions: Between 2013 and 2018, 70 patients were referred to our unit with new-onset postoperative nerve palsies. There were 31 males and 39 females, with a mean age of 54 years (range 7-85). Apart from one case who was referred intraoperatively, the median duration from the index surgery to the date of referral was 6 months (range 7 days - 7 years). 24 (34%) referrals were made over 12 months postoperatively. The longest delay was seen in the spinal accessory nerve group with a mean delay of 2 years.

The nerves involved in the order of frequency were 14 radial, 10 axillary, 9 sciatic, 9 spinal accessory, 5 ulnar, 4 musculocutaneous, 3 posterior interosseous, 3 medial cord, 3 tibial, 5 median, 2 long thoracic, 1 C5 root, 1 common peroneal and 1 lateral cord.

The commonest index surgery was 26 (37%) arthroplasty, followed by 14 plating, 10 soft tissue excision, 4 wiring, 3 entrapment release, 3 removal of metalwork, 3 tenodesis, 2 arthroscopy, 2 nailing, 1 fusion, 1 manipulation and 1 thoracotomy.

9 patients (13%) showed signs of spontaneous recovery under review and were managed nonoperatively. 61 patients (87%) proceeded with secondary surgery, including 44 neurolysis, 6 nerve graftings, 5 nerve transfers, 1 direct muscular neurotisation, 2 distal releases and 3 tendon transfers.

The false assumption that most postoperative nerve palsies would recover spontaneously still appears to be prevalent among surgeons, as reflected by the significant delay in referrals. Majority of these cases will warrant secondary reconstructive surgery and delay in treatment may have a negative impact on the ultimate outcome.

MICROSURGERY TRAINING WITH SMARTPHONE

List of authors:
Sercan Capkin1, Ali Cavit1, Tufan Kaleli1
1 Uludag University Faculty of Medicine (Bursa)

Objectives / Interrogation: Microsurgery is widely used in experimental research models and clinical surgery. However, microsurgical applications require precise technical skills and continuous training. Here, we proposed a new, low cost, practical microsurgery training model, which can be easily applied using smartphones at home or at office.

Methods: Test platform was created using latex gloves, and a phone holder was then positioned at one side of a table. A smartphone with 10x magnification was secured on the phone holder. Microsurgical device habit, stitching and knotting exercises by making cuts at different angles on the glove model were performed, which was recorded live under the 10x magnification of the phone camera.

Results and Conclusions: Features that emphasise and distinguish this method from the other microsurgical methods are as follows: Easy implementation, easy accessibility, low cost, can be applied at home or office to allow continuity of practical education, allows taking snapshots or recording live videos of the surgery, the video can be viewed several times to rectify the mistakes made. Moreover, smartphones also have the option of being managed with voice commands for taking photos and videos. The disadvantages of the proposed method are that it does not offer the high magnification rate of a surgical microscope and that it lacks clinical applications.

We recommend that the practical microsurgery model presented in this study should be applied to basic microsurgery education and also used as an alternative training model owing to its easy application, easy accessibility and low cost. We believe that with technological advancements, this model has the potential for incorporation in future microsurgical clinical applications.

**Surgical treatment for patients who fail to conserve the complete rupture of the collateral ligament in the proximal interphalangeal joint.**

**List of authors:**
Young Hwan Kim*1
1 SoonChunHyang University Bucheon Hospital (Bucheon-si)

**Objectives / Interrogation:** The purpose of this study was to compare the preoperative and postoperative outcomes of Surgical treatment for patients who fail to conserve the complete rupture of the collateral ligament in the proximal interphalangeal (PIP) joint.

**Methods:** A complete rupture of the collateral ligament was confirmed by radiologist using ultrasound or MRI for patients who had symptoms after 4 weeks of conservative treatment. Eleven patients underwent operative collateral ligament repair using an anchor. All patient was followed up for at least 6 months postoperatively. We evaluated clinical outcomes preoperatively and at 6 months follow-up: 1) range of motion of the PIP, 2) joint stability, 3) VAS score, and 4) Fusiform index of the PIP joint.

**Results and Conclusions:** There was no instability in the lateral stress test at 6 months follow-up. The ranges of motion of the PIP were not statistically different between preoperative and at 6 months follow-up. Patients had less pain but cosmetic appearance of the PIP joint did not improve.
Surgical treatment for patients who fail to conserve the complete rupture of the collateral ligament in the proximal interphalangeal joint can provide good joint stability, functional recovery.

VERSATILITY OF SURAL FLAP FOR LOWER MEMBER OSTEOCUTANEOUS INJURIES: REVISION OF 40 CASES.

List of authors:
Santiago Moreno*, Daniel Moreano1, Marco Yanez2
1 Pontificia Universidad Catolica del Ecuador“ (Quito)

Objectives / Interrogation: INTRODUCTION. The repair of losses of substances in the leg, ankle and foot, which are produced by high-energy trauma, are a challenge for orthopedic surgeons. For this, the reverse flow sural fascio-cutaneous flap appears as a viable and safe alternative for cutaneous coverage of substance losses or complications of traumas and fractures exposed in these regions.

Methods: MATERIALS AND METHODS.
In the period from January 2014 to May 2018, 40 reverse flow sural flaps were performed. Thirty-eight patients of the 40 operated on were evaluated once one patient lost the follow-up and another did not meet the inclusion-exclusion criteria, therefore, they were not considered in the analysis.
As an inclusion criterion, all patients operated on to make a reverse flow sural fascio-cutaneous flap regardless of age, gender or agent causing the lesion were considered and patients with associated pathologies such as rheumatoid arthritis, peripheral vascular diseases and the abandonment of the disease were excluded treatment.

Results and Conclusions: Of the 40 patients analyzed, the average time of hospitalization was 45.3 days, since all the patients were discharged from the hand surgery team after 24 hours of the procedure.
The series consisted of 32 male patients and 8 female patients with an average age of 38.9 and 31 years, respectively.
Of these patients only three were not victims of direct trauma, being hospitalized for chronic osteomyelitis, cutaneous pressure ulcer in a patient with diabetes mellitus and another derived from spinal cord injury with paraplegia.
Traumatic causes included motorcycling accidents with 17 cases, corresponding to 42%, followed by falls of height with 11 patients, corresponding to 27%, followed by road accidents, direct traumas, crushes, etc.
A total of 11 complications were identified, corresponding to 27% of the total cases, with the partial necrosis identified in 6 patients, of which four were closed by second intention and two required skin graft placements in necrosis. A case of ischemia of the flap, interpreted as a strangulation of the pedicle, had the need to reposition the flap in its normal anatomical position.
There was survival of all the flaps performed, with satisfactory coverage of the lesions despite the complications described.
CONCLUSION.
The reverse flow sural flap, with wide fascia segment, is a useful and versatile flap that can be easily lifted to reconstruct soft tissue defects of the leg in the middle and distal third, ankle, hindfoot and foot.

CAMPER'S CHIASM: ANATOMICAL STUDY AND CLINICAL IMPLICATIONS IN FLEXOR TENDONS SURGERY

List of authors:
Diego Faccio*, sara montanari1, Nicola Maschio2, Franco Bassetto2, Cesare Tiengo2
1 University of Padua (Sovizzo)
2 University of Padua (Padova)

Objectives / Interrogation: The complete lesions of the flexor tendons are complex problems in hand surgery. In cases of concomitant lesions of the flexor tendons in zone 2, the exclusive tenorrhaphy of the flexor digitorum profundus (FDP) or the tenorrhaphy of the FDP associated with one of the two slips of flexor digitorum superficialis (FDS) is the intervention that most limits the development of a flexor-extensor deficit in the post-operative period. Inside digital channel, FDS is divided into two slips, ulnar and radial, before insertion from a fundamental structure for stability and dynamic function: Camper's Chiasma. The purpose was to establish correlation between anatomical structure and flexor tendon function at Camper's chiasm, and describe relationships between chiasma and surrounding structures (phalanges, pulleys, skin folds and vincula). This can guide for the best operative option. Another objective is to provide a rational basis for choice the FDS slip to be sacrificed in palliative procedures.

Methods: 36 fingers in 9 hands were studied from fresh corpse. A broken-line incision was made on the volar skin of the fingers. The skin flaps and subcutaneous tissue were lateralized and pulleys were incised exposing flexor tendons. We have observed the anatomy of Camper's chiasma with its vascularization and we have measured the distances between chiasma, articular structures and pulleys.

Results and Conclusions: In all examined fingers we observed a certain degree of asymmetry in the representation and direction of the two slips of the FDS which constitute the chiasm. In most cases at level of II and III finger the ulnar band is constituted by a greater quantity of fibers and some of these decusses in a unidirectional manner at the level of the Camper's chiasma reaching and reinforcing the radial insertion. Inverse behavior was often observed at the IV and V finger of the hands examined. This asymmetry seems to be correlated with the vascular supply by vincula longa. Contrary to literature, we have observed a constant asymmetry of Camper's chiasm tendon fibers. The direction of the tendon structures and the force vectors that are activated during the flexion could be an explanation for this asymmetry for blood supply at the level of one of the two FDS slips. This could guide the surgeon towards the choice to repair and protect the most vascularized slip in case of post-traumatic reconstruction or elective transposition surgery, with advantages for good healing.

BILATERAL CARPAL TUNNEL SYNDROME: A COMPARATIVE STUDY BETWEEN THE RELEASE OF THE SIMULTANEOUS MEDIAN NERVE AND IN TWO STAGES BY LOCAL ANESTHESIA WITH EPINEPHRINE

List of authors:
Samuel Ribak*, Flavia Magalhaes Nunes¹, Rafael Barcelos de Campos¹, Alexandre Tietzmann¹, Ricardo Kaempf²
¹ Puc Campinas University (Cotia)
² Puc Campinas University, Hospital Santa Casa de Porto Alegre (Cotia)

Objectives / Interrogation: Carpal tunnel syndrome (CTS), is the most common of the peripheral nerve compression syndromes of the upper extremity. Generally, patients have bilateral symptoms. The counterpoint of the need for an earlier return to both daily and professional routine work associated with new outpatient anesthetic techniques has led to studies for the simultaneous decompression of the carpal canal. Such assumptions underscore the importance of decision making in relation to the patient with bilateral symptoms and surgical necessity. In order to perform surgery on an ambulatory level, either in one or both upper limbs, without the need for tourniquet and sedation, the local anesthesia technique with lidocaine and epinephrine combination has been shown to be a good option. Thus, the proposal of this study is to compare the functional and satisfaction results of the median nerve release simultaneously and in two stages in patients with bilateral carpal tunnel syndrome and in these, to verify the feasibility of the local anesthesia technique with the use of lidocaine associated with epinephrine.

Methods: This is a prospective study with data analysis (DASH, functional quality of life, return to activities, ENMG and patient satisfaction) of 106 patients. Divided into two groups, group I underwent bilateral surgery simultaneously and group II underwent two-step surgical procedure using local anesthesia proposed in both groups.

Results and Conclusions: DASH from preoperative to postoperative showed improvement in both groups, with a greater variation in group I from 27.1 to 10.1. The return to daily activities of group I was 7.39 days and the mean of the two values in group II was 5.66 and the sum was 11.31. The return to practical activities was 19.12 days in group I, the mean in group II was 23.95 and the sum of 47.91. Minimal bleeding was observed after the skin incision and dissection in 86.3% without compromising the surgical field. In 2 cases, anesthesia was required. Conclusion: bilateral nerve release performed simultaneously and in two stages presents good results, with significant improvement of the DASH and the time of return to the work activities in cases operated simultaneously. The local anesthesia technique with lidocaine and epinephrine is safe and effective.

Keywords: carpal tunnel syndrome, bilateral, simultaneous surgery, epinephrine, local anesthesia
Epidemiology of postoperative elbow contracture release and associated factors

List of authors:
Lauren Wessel*, Alex Gu¹, Evan O’Donnell¹, Shawn Richardson¹, Duretti Fufa¹, Daniel Osei¹
¹Hospital for Special Surgery (New York)

Objectives / Interrogation: Little is known about the epidemiology of elbow contracture or of elbow contracture release. The purpose of this study was to define the incidence of elbow contracture development and release after surgical treatment for elbow trauma and to identify patient and treatment factors that may predict contracture development.

Methods: We queried a national insurance database from 2007 to 2017 to identify all patients treated for elbow trauma with a minimum of 1-year follow-up. We identified the subset of these patients who had a concomitant diagnosis of contracture on follow-up visit. Procedural codes were used to determine the cohort who underwent contracture release. Mean time to contracture diagnosis and surgical release were calculated. Multivariate regression analysis was performed to calculate the impact of age, Charlson-Dey Comorbidity Index (CCI), head injury, obesity, and anticoagulation use on the progression to elbow contracture release.

Results and Conclusions: The study population included 15,368 patients who were surgically treated for elbow trauma with a minimum of 1 year follow-up after fracture surgery. In total, 1,033 (6.7%) patients were diagnosed with a contracture following fracture and, of those, 79 (0.5%) patients ended up receiving contracture release. On average, time to contracture diagnosis was 3.6 months (SD: 7 months; range: 1 day- 39 months) and time to contracture release was 8.4 months (SD: 10.54 months; range: 1 month-51 months). A CCI of 5, age less than 30, age between 50-69, head injury, obesity and male gender were independently associated with progression to surgical contracture release, whereas use of anticoagulation, CCI less than 5 and age greater than 70 were protective.

The sural flap for "off-label indications". Retrospective comparative study with the sural flap for classic indications.

List of authors:
Alvaro Cho*1, Carlos Ferreira2, Luiz Longuino2, Luiz Sorrenti2, Lendro Kiyohara1
1 Instituto de Ortopedia e Traumatologia da FMUSP, Grupo de Mão e Microcirurgia da FMABC (sao paulo)
2 FMABC (Sto André)

Objectives / Interrogation: The objective of this study is to verify whether or not the sural flap can be employed to treat wounds other than the classical locations or in the presence of local risk factors for the flap's vascularity.

Methods: Between 2006 and 2016, 44 consecutive cases of sural flaps were performed in 44 patients in two universities hospitals. They were retrospectively analysed in terms of flap viability and divided into two groups according to the indication for the sural flap. Group A was comprised of 31 patients with classical indications for the sural flap such as defects located at the distal third of the leg and hindfoot and with an intact posterior leg. The flaps were elevated from the posterior aspect of the leg at the musculotendinous junction of the gastrocnemius muscle. The pivot point was planned approximately 5 cm proximal to the tip of the lateral malleolus, according to the classical description of Masquelet et al.(1992). Group B was formed by 13 patients with local risk factors that could potentially jeopardise the flap's pedicle (scarring or previous incisions located around the pivot point of the flap at the postero-lateral aspect of the leg) or to cover defects in which the sural flap is not usually indicated such as the middle third of the leg or forefoot. In these cases, the flaps were harvested from a more proximal area than usually are and the pivot point was also moved proximally to avoid scarred areas or pre-existing incisions.

Results and Conclusions: In Group A, there were 6 cases of partial flap loss (19,35%) and 2 cases of total flap loss (6,45%). In Group B, we observed only 4 cases of partial flap loss (30,76%), without any complete flap loss. There was no statistically significant difference in the occurrence of partial or total flap loss among the two groups (p= 0.73). Conclusions: The percentage of flap loss was not increased when the sural flap was used to cover more proximally or distally located wounds, even in the presence of previous incisions or scars nearby the flap's pedicle. Although partial flap loss occurred quite frequently with the sural flap, it did not jeopardize the soft tissue coverage because in most instances it occurred at the more distal and superficial part of the flap.

Keywords:
sural flap, soft-tissue defects, leg, risk factors
A New technique for the treatment of the Distal ulnar fractures associated with distal radial fractures in older adults using intramedullary wiring.

List of authors:
Sadaaki Tsutsui*, Keikichi Kawasaki², Katsunori Inagaki¹
¹ Showa university, Department of Orthopedics (Tokyo)
² Showa University, Yokohama Northern hospital (Yokohama)

Objectives / Interrogation: There is no clear consensus about the optimal treatment of distal ulnar fractures associated with distal radial fractures in older people. The aim of this article is to review the impact of intramedullary Kirschner wire fixation of the distal ulna fractures associated with distal radius fracture.

Methods: 17 patients in whom an intramedullary Kirschner wire fixation was used to repair the distal ulna fractures associated with the distal radius fractures were reviewed retrospectively with minimum follow-up of 23.6 months (range, 6-42 months) after surgery. The mean age of the patients were 73.2 years and all of the patients were female.
According to the Biyani Classification of ulnar Fractures, there were 9 simple fractures of the ulnar neck (type 1), 3 T or Y shaped fractures of the ulnar head (type 2), and 4 fractures of the styloid process and neck (type 3), 1 comminuted fracture of the neck and head (type 4).
The surgical procedures were as follows: at first, the distal radius fractures were fixed rigidity with a volar locking plate. Secondly, distal ulna fractures were fixed with antegrade intra-medullary wiring from olecranon to the ulnar head. We investigated the clinical evaluation, the radiological evaluation and complications of these cases.

Results and Conclusions: [Results]
All fracture sites displayed union, and the mean loss of reduction of the ulnar variance was 0.36mm, mean angular deformity of the distal ulna metaphysis was measured 2.5(±3.5) degrees.
The mean motion of the wrist was as follows: flexion 63.6°; extension 71.8°; pronation 85°, supination 87.9°. The Average grip strength was 88.1% of the contralateral uninjured extremity. There were no infections and no wound problems. According to the Mayo wrist score, there were 10 excellent, 5 were good, 2 were poor results at final evaluation. There was no instability of the distal radioulnar joint. 16 patients had a second operation to remove the ulnar wires.

[Conclusion]
For elderly patients, the fixation of distal ulna fracture associated with distal radius fracture using intramedullary wiring can achieve healing with good alignment, satisfactory function.

Treatment of Unstable Scaphoid Nonunion Using Volar Locking plate

List of authors:
Young Woo Kwon¹, Jong Woong Park¹, In Cheul Choi¹, Ji Hun Park²
¹ Korea University Anam Hospital (Seoul)
² Korea University Guro Hospital (Seoul)

Objectives / Interrogation: Purpose: The purpose of this study was to assess union and complication rates associated with the use of volar locking plate and wedge bone grafting for the treatment of unstable scaphoid fracture waist nonunions.

Methods: Methods: A total of 8 patients (7 male and 1 female; mean age, 32.38 years) with unstable scaphoid waist nonunions were treated by reduction of the collapse deformity, insertion of volar wedge bone graft, and internal fixation with the use of volar locking plate and screws with a mean follow up of 9.25 months. The mean duration of nonunion was 19 months. Three of the 8 patients were smokers. Thumb spica splint was recommend for 2 weeks after operation and The wrist is then supported with a removable thumb spica brace until there are radiographic signs of scaphoid healing. Union was determined by radiographs and computed tomography, and range of motion, scapholunate and radiolunate angles were calculated on final radiographs and follow-up computed tomography.

Results and Conclusions: Results: All 8 scaphoids united in a mean time for 8.5 weeks (6 - 12 weeks). Both scapholunate angle and radiolunate angles decreased, returning to normal range. The average extension-flexion arc of the injured wrists was 128 degrees (59° flexion, 69° extension), which was improving 34% of pre-operative range of motion and 16 % less than that of the uninjured wrists. Pro- and supination were normal. All patients had satisfactory correction of scaphoid deformity and the associated dorsal intercalated segment instability. No hardware problems were identified and no revision procedures have been necessary during follow-up period.

Conclusion: The use of volar locking plate with wedge bone graft for the treatment of unstable scaphoid nonunion is safe and effective. It may provide rapid union and permit earlier rehabilitation of the wrist.

Osteoid osteoma of the third metatarsal bone: A case report

List of authors:
Gyeong Min Kim*, Kyu Bum Seo

1 Jeju National University Hospital (Jeju-do)

Objectives / Interrogation: Osteoid osteoma is a benign bone tumor composed of osteoid and atypical bone. The most commonly known sites of following tumor are long tubular bones, especially femur and tibia. Yet, development of osteoid osteoma in the foot is unusual, and there aren't much reported literatures of metatarsal osteoid osteoma.

Methods: A fourteen-year-old boy was presented in our outpatient clinic with five months history of painful swelling over the dorsal aspect of the left forefoot. Radiographic evaluation, including anteroposterior and oblique views of the foot, demonstrated a small radiolucent area in mid-diaphysis area of the third metatarsal bone, surrounded by reactive sclerosis.

Axial computed tomography of the third metatarsal bone showed enlarged metatarsal containing low attenuation nidus with intrinsic calcification and surrounding sclerosis.

As for surgical intervention, longitudinal incision on the lateral side of the third metatarsal was used for exposure. With guidance of K-wire under C-arm image intensifiers, and the lesion and surrounding bone were surgically excised using rongeur to match the contour of the original metatarsal.

Results and Conclusions: Osteoid osteoma developed in metatarsal bone is relatively rare. A detailed clinical history with a high index suspicion is required for accurate diagnosis. For immediate and permanent remission of symptoms without recurrence, adequate surgical excision of the tumor lesion is essential.

TIP FINGER TRAUMATIC INJURY. TREATMENT WITH SEMI-PERMEABLE MEMBRANE

List of authors:
MARCELO SCHIEBER*1, ADRIANA BEATRIZ PEMOFF1, MARIA EMILIA CAPELLA1, PEDRO NICOLAS TAJAN1, ANALIA CLAUDIA BOIANELLI1, ANABEL OVIEDO1, ALDO PAYALAF1, FEDERICO CASTILLO1
1 Centro Médico Integral Fitz Roy (Buenos Aires)

Objectives / Interrogation: Tip finger injury is a prevalent pathology in manual workers. Different surgery techniques have been described for their treatment, with the aim to restore length, functionality and to recover sensitivity in tip finger pulps. Our work shows that, by using the conservation treatment with semi-permeable dressing, good results are obtained without causing injury to adjacent parts of the hand, as in the case of flaps and grafts. Moreover, finger length could also be preserved.

Methods: A retrospective study was carried out in 33 patients, 43 fingers, with one-year follow-up, using Professor Dr. Rodolfo Cosentino's classification (TYPE A Amputation with right angle A1- Distal without bone exposure. A2- through bed nail. A3- next to bed nail matrix. A4- next to interphalageal joint. TYPE B- dorsal angulation amputation. TYPE C- palmar angulation amputation. TYPE D- lateral angulation amputation)
Injuries type A to D were included. All of the injuries were treated with semi-permeable dressing every seven days, till epithelialization was achieved.
In order to evaluate results, skin coverage time and return time to work were registered. Besides, monofilament test (Semmens-Weinstein) was used so as to measure sensitivity recovery.
Out of the 43 fingers studied and according to Cosentino classification, we registered: A1 (out of 4 cases: 2 full touch recovery, 2 slight touch reduction), A2 (out of 5 cases: 1 full touch recovery, 4 slight touch reduction), A3 (out of 12 cases: 5 full touch recovery, 6 protective touch reduction, 1 anesthesia), B (out of 6 cases: 2 full touch recovery, 4 slight touch reduction), C (out of 10 cases: 2 cases of slight touch reduction, 6 protective touch reduction, 1 protective touch loss, 1 anesthesia) and D (out of 6 patients: 1 full touch recovery, 1 slight touch reduction, 4 full touch recovery)

Results and Conclusions: RESULTS
In 100% of the cases skin coverage was achieved, independently of the traumatic injury mechanism.
Differences were seen as regards reepithelization time according to injury type, presence of sequels at nail level (bed nail, matrix and onychogyphosis flaws), touch recovery and return to work.

CONCLUSIONS
As a conclusion, we can state that the method is simple, easily reproducible, extrapolable in a wide range of ages and injuries, with good functional and cosmetics results without compromising surrounding areas as it occurs in cases of free skin grafts or local flaps.

Failure of Percutaneous A1 pulley release in Trigger Digits

List of authors:
Neunghan Jeon*, Min Jong Park1, Jae Woo Shim1, Hyun Jun Kim1
1 Samsung medical center (Seoul)

Objectives / Interrogation: The purpose of this study is to identify the risk factors that contribute to persistent symptoms after the percutaneous release, thus requiring further treatment such as triamcinolone (TA) injection or open surgery.

Methods: 341 digits (256 patients) of percutaneous A1 pulley release were performed from December 2014 to August 2017 by a senior surgeon at a single center. We excluded 19 patients (25 digits) whose record of underlying medical condition was not available at this center. We conducted a retrospective study on the remaining 316 digits.

Results and Conclusions: During the period, no serious complication (e.g. infection, tendon rupture) was reported, and 2 cases of incomplete release were observed.
41 digits (12.9%) needed additional TA injection to relieve remaining symptoms. 8 digits (2.5%) required open surgery due to persisting symptoms even after TA injection. We had to perform A2 pulley partial release in 5 patients. Tenosynovectomy was performed on 7 patients. During open surgery, FDS thickening was observed in 2 patients, fibrotic tissue formation in 3, and adhesion in 1.

Of the failure cases of percutaneous release, the middle finger was the most common (40.2%), and the thumb came up second (24.1%). However, the thumb was the least likely to receive further treatments after percutaneous release (5.3%). The percentage of additional procedures done was higher in male patients (18.2%, 14 out of 77 digits) than in female patients (14.6%, 35 out of 239 digits). Age showed a negative correlation with the likelihood of receiving further treatment (30.8% in age group 30-40, 14.2% in 50-60, 14.1% in 70-80). But these were not statistically significant. (gender, p=0.456; age, P=0.144).

We investigated whether DM and rheumatoid diseases, both known to affect the connective tissue, were relevant risk factors, but the results were not significant. (DM, P=0.107: Rheumatoid disease, P=0.313).

Most cases which needed additional treatment after percutaneous release of trigger digits had refractory inflammation. Although not statistically proven, male and younger age patients tend to have higher possibility of additional treatments.

Trigger finger, percutaneous release
Long-term results of thumb polydactyly we operated.

List of authors:
Sohachi Toriyabe*, Shigeko Ushio
1 Sendai Medical Center, Plastic, Reconstructive and Hand Surgery (Sendai)
2 Sendai Plastic and Hand Surgery Clinic, Tohoku Hand Surgery Center (Sendai)

Objectives / Interrogation: Thumb polydactyly is the most common disorder of congenital deficiencies in the hand, and there are many reports. After initial surgery, it causes cosmetic or functional disorders such as deformation, scar contracture, conflict movement disorder, joint disturbance. Those requiring these revision surgeries We investigated 516 cases of poliomyeliasis experienced in the past 30 years and examined the initial surgery and secondary modification with respect to type classification and surgical procedure.

Methods: From 1985 to 2015, there were 516 cases of thumb polydactyly surgery performed at Tohoku University Department of Plastic Surgery and Sendai Medical Center Surgery surgery. Among 516 cases, 341 cases and 366 fingers were observable for 5 years or more. Among those who underwent secondary revision surgery, 81 cases and 84 fingers were found.

Results and Conclusions: The postoperative results were evaluated according to the function evaluation table of the Japanese Surgical Society and their average scores were 18.1 for Wassel type 1, 16.4 for type 2, 14.9 for type 3, 17.2 for type 4, 16.3 for type 5 and 16.1 for type 6. In addition, the evaluation scores increased in all cases where the second modification was made. Surgery of thumb polydactyly is a good result. On the other hand, many cases require secondary modification. In the distal phalanx type, scar contracture revision and joint plasty are often used, and in the case of the proximal phalanx, in addition to them, there are many requiring osteotomy and replacement of abductor pollicis brevis muscles, MP joint formation. Metacarpal bone type had scar revision, surplus bone resection and so on. There were 81 cases of secondary modification, but the necessary surgical method was found out by type. It is necessary to feed back this by secondary revision surgery and verify initial surgery.

Midterm results of scaphoid excision and bicolumnar carpal fusion using retrograde headless screws

List of authors:
Sebastian Undurraga1, Kendric Au1, Braden Gammon1
1 The Ottawa Hospital (Ottawa)

Objectives / Interrogation: Longstanding un-united scaphoid fractures or scapholunate insufficiency can progress to degenerative wrist osteoarthritis, termed scaphoid non-union advanced collapse (SNAC) or scapholunate advanced collapse (SLAC) respectively. Scaphoid excision and partial wrist fusion is a well-established procedure for the surgical treatment of this condition. In this study we present a novel technique and mid-term results, where fusion is reserved for the lunocapitate and triquetromatate joints, commonly referred to as bicolumnar fusion. The purpose of this study was to report functional and radiological outcomes in a series of patients who underwent this surgical technique.

Methods: This was a prospective study of 23 consecutive patients (25 wrists) who underwent a bicolumnar carpal fusion from January 2014 to January 2017 due to a stage 2 or 3 SNAC/SLAC wrist, with a minimum follow-up of one year. In all cases two retrograde cannulated headless compression screws were used for inter-carpal fixation. The clinical assessment consisted of range of motion, grip and pinch strength that were compared with the unaffected contralateral side. Patient-reported outcome measures, including the DASH and PRWE scores were analysed. The radiographic assessment parameters consisted of bone fusion and appearance of the radiolunate joint space.

Results and Conclusions: The average follow-up was 2.9 years. The mean wrist extension was 41°, flexion 36° and radial-ulnar deviation arc was 43° (70%, 52% and 63% of contralateral side respectively). Grip strength was 40 kg and pinch 8.9 kg, both 93% of contralateral side. Residual pain for activities of daily living was 1.4 (VAS). The mean DASH and PRWE scores were 19±16 and 29±18 respectively. There were three cases of non-union (fusion incidence 88%). Two wrists were converted to total wrist arthroplasty and one partial fusion was revised and healed successfully. The radio-lunate joint space narrowing had progressed in 2 patients but did not affect their functional outcome.

Conclusion: After bicolumnar carpal fusion using retrograde screws, patients of this series maintained a functional flexion-extension arc of motion, with grip-pinch strength that was close to normal. These functional outcomes and fusion rates were comparable with standard 4-corner fusion technique. This technique has the advantage that compression screws are placed in a retrograde fashion which does not violate the proximal articular surface of the lunate, preserving the residual load-bearing articulation.

Hybrid vascularized bone and soft tissue transfer for massive bone and skin defect of the digit. -Surgical Technique and mid-term follow up-

List of authors:
Naohito Hibino*, Yoshitaka Hamada1, Ryosuke Satoh2, Masahiro Yamano1, Tomoya Terai1, Tokio Kasai1
1 Tokushima Prefecture Naruto Hospital (Tokushima)

Objectives / Interrogation: Although living bone can be transplanted as a vascularized bone graft for traumatic injuries with massive bone and dorsal skin defects of the digit, it is difficult to work the bone into various fine shapes, especially if the parts required are small and contain joints. Applying a free bone graft raises concerns regarding bone resorption, fracture of the grafted bone, and non-union of the docking site. We hypothesize that a vascularized periosteal flap (VPF) from the medial condyle of the femur[1] can promote the blood flow for free bone molded in fine shaped and provide the bed for the free skin graft. The purpose of this study is to evaluate the VPF promote remodeling of the free bone graft and provide the bed of skin graft in clinical setting.

Methods: We reconstructed a bone defect with inadequate surrounding soft tissue using a free bone graft wrapped with a vascularized corticoperiosteal flap from the medial condyle of the femur. We expected the vascularized periosteum to augment blood flow for the free grafted bone and to provide the bed for the free skin graft. We utilized this procedure in 2 cases of traumatic bone injury with a dorsal skin defect of the digit that occurred in industrial accidents.
Results and Conclusions: The vascularized corticoperiosteal grafts from the femur prevented atrophy and resorption of the free grafted bone, promoted bone remodeling, and provided a less bulky appearance of the skin. This method could be a useful option for reconstructing wide defects of small bone with a poor-quality surrounding environment.

Clinical characteristics of primary and post-traumatic osteoarthritis of the distal radioulnar joint

List of authors:
Shukuki Koh*, Junko Otsuka\(^1\), Emiko Horii\(^1\)
\(^1\)Japanese Red Cross Nagoya Daiichi Hospital (Nagoya)

Objectives / Interrogation: Distal radio-ulnar joint (DRUJ) is one of the most frequently affected joint with osteoarthritic (OA) change among wrist articulations. Most articles regarding the DRUJ OA is surgical procedure-oriented, and usually includes both OA and rheumatoid arthritis as the subject. There are few reports which are etiology-oriented, and information about detailed clinical characteristics of the primary and post-traumatic DRUJ OA are lacking.

Methods: Twenty-six wrists with in 23 patients (13 male and 10 female) underwent surgical intervention in our hospital between Apr 2009 and Mar 2017. Their medical records were retrospectively reviewed. Fisher's exact test was used to compare the primary (group A) and post-traumatic (group B) DRUJ OA.

Results and Conclusions: Group A consisted of 21 wrists of 8 male and 10 female patients with an average age of 74.7 year-old. Fifteen (83.3%) of them were in their 7th or 8th decades (p=0.089). In 8 patients who had unilateral surgery, contralateral wrist X-ray showed asymptomatic DRUJ OA, thus 11 (61.1%) had bilateral OA (p=0.037). All of these wrists had ulnar variance of 3 mm or more. Wrist pain tended to be less in group A. Only 3 wrists were with severe pain, and 9 wrists were painless. The most frequent chief complaint was dropped finger(s) in 15 patients (p=0.055). In 7 patients, attritional extensor rupture was observed in more than 2 fingers. None had supination restriction.

Group B consisted of 5 wrists of 5 male patients with an average age of 63.8 year-old. The gender ratio was significantly different from group A (p=0.046). Two had malunion of the distal radius fracture, and 2 had malunion of the Galeazzi fracture-dislocation. One wrist sustained growth arrest of the ulna after a physis injury of the distal ulna in his early teenage. The patients in group B tended to have severe pain (4 wrists, p=0.062), and supination was less than 50 degrees in 2 wrists (p=0.004). In 2 patients, attritional rupture of extensor tendon to the little finger was noted, but there was no patient with multiple finger involvement. Primary and post-traumatic DRUJ OA exhibited distinct clinical characteristics. Most patients with primary OA were over 70 year-old, and bilateral involvement suggested inherent wrist morphology as an etiological factor, therefore the primary OA might increase as the population ages. The wrist pain tended to be mild in primary OA, and the patients often sought medical attention only after the extensor tendon rupture occurred.

distal radioulnar joint, osteoarthritis, extensor tendon rupture
KAPLAN DISLOCATION IN CHILDREN: A RARE PATHOLOGY AND A NEW REDUCTION TECHNIQUE

List of authors:
JHON FREDY CASTAÑEDA*, TATIANA MARIA ALVARADO1, MARCO TULIO MAHECHA1, DIEGO FERNANDO RINCON2
1 UNIVERSIDAD NACIONAL DE COLOMBIA (BOGOTA)
2 UNIVERSIDAD INDUSTRIAL DE SANTANDER (FLORIDABLANCA)

Objectives / Interrogation: INTRODUCTION: Kaplan dislocation is described as the blocked palmar displacement of the second metacarpal head in the ligamentous and tendinous structures, which generates an eyelet mechanism that limits the reduction with conventional techniques. This presentation is very rare in children and the lack of knowledge makes treatment difficult that can lead to complications derived from inadequate management.

OBJECTIVES: To evaluate clinically the pediatric patients with diagnosis of Kaplan dislocation and propose a new reduction technique in the pediatric population.

Methods: METHODS: Retrospective Case Series study. Six male patients were evaluated, with an average age of 9.3 years. All of them underwent the proposed reduction maneuver (rotation and ulnar deviation). Clinical and radiological follow-up was performed at 6 months.

Results and Conclusions: RESULTS: In five of six (83%) patients, the proposed closed-reduction maneuver was performed successfully: hyperextension of the index MF while performing rotation and concomitant ulnar deviation of the joint. One of the patients required an open reduction by palmar approach. Post-reduction mobility evidenced almost complete arcs in all patients. There were no complications associated, presence of joint stiffness or instability.

CONCLUSIONS: Kaplan dislocation in children is not frequent. The classical maneuver of reduction is just successful in around 10 - 20 % of the cases. Closed-reduction should be attempted with the proposed maneuver that seeks to reject the volar plate of the MF joint to facilitate its reduction. Its success rate is high, as 83% if it is done early (less than 72 hours). This maneuver is a very good management option with very good clinical and functional results.

SAILOR FINGER

List of authors:
MARCELO SCHIEBER*¹, ADRIANA BEATRIZ PEMOFF¹, MARIA EMILIA CAPELLA¹, PEDRO NICOLAS TAJAN¹, ANALIA CLAUDIA BOIANELLI¹, ANABEL OVIDIO¹, ALDO PAYALF¹, FEDERICO CASTILLO¹
¹Centro Médico Integral Fitz Roy (Buenos Aires)

Objectives / Interrogation: A series of fractures in finger phalanges in sailors' hands, occurring during their work at sea, with completely different retellings as to how the injuries were caused, raises suspicion on whether they could have been self-inflicted. The aim of this report is to reproduce in cadaverous upper limbs the mechanisms related by patients and compare their fracture pattern. The results confirmed the hypothesis of self-inflicted injuries

Methods: Between 2014-2017, 76 patients were assisted in our center. They were sailors in fishing ships, presenting phalange fracture and finger traumatism. All of the cases were reported to have happened in the high seas and all of the fishermen work for three fishing companies with the same labor risk insurance company. Classifying the fractures according to AO classification, we found that 41% belonged to type 78.2.2.3.A1, 30% were type 78.2.2.2A1 and 18% type 78.3.3.2.C, 11% showed variable patterns.
42% had injuries in multiple fingers, 13% combined injuries in one finger. 45% had a single injury in only one of their fingers. The mechanisms described were: 9 cases for winding, 28 for squid pills, 16 caused by doors, 5 for de-glazing, 9 for tray handling and 9 due to falls from height. In order to confirm our hypothesis related to self-inflicted injuries, we carried out cadaverous test using 34 three-phalange fingers reproducing the mechanisms described by patients.

Results and Conclusions: The cadaverous test showed a lack of relationship between the descriptions made by patients and the results obtained when reproducing the mechanism on cadaver upper limbs.
1-In the case of simulated winding using a steel tube, showed only interphalangeal dislocation.
2-As regards simulation of squid pills and de-glazing by using ice blocks, the results showed two type F3 fractures.
3-In relation to injuries caused by slammed doors, two fractures were reproduced with different patterns, depending on the number of fingers involved.
Our hypothesis has been confirmed by using a hammer as injuring tool, which in 100% of the cases reproduced supracondylar fracture (78.2.2.3.A1) and diaphyseal fracture (78.2.2.2A1), which were the most frequent injuries in the patients assisted. The results obtained through cadaverous tests confirmed that the mechanism using a hammer by applying dorsal force.
It is worth mentioning that in 71% of the cases, the patients who were assisted related injuring mechanisms that did not coincide with the mechanism reproduced in cadaverous model.

Evolution of skin lesion healing in rats submitted to treatment with sterile plastic as a dermal substitute.

List of authors:
Rafael Saleme alves¹, Edson Kenji Nakano¹, Barbara do vale¹, Bernardo Barreto Correa¹, Nuha Ahmed Dsouki², Juliana Mora Veridiano¹, Monica Akemi Sato¹
¹ FMABC (São Paulo)

Objectives / Interrogation: Polytrauma patients usually have severe wounds, which require prolonged and costly treatment. Deep skin lesions are characterized by destruction of epithelial tissue and exposure of structures such as fascia, muscles, tendons, and nerves. The healing process occurs through contraction of the wound edges and has three phases: inflammation, epithelization and remodeling, until tissue integrity is achieved. At the closure of these lesions, the simplest form should be used, seeking the best method to achieve the normal function of the limb affected by the lesion. Dermal substitutes are widely used in the areas of reconstructive and plastic surgery. No previous study has investigated if sterile plastic covering a skin lesion would be useful on healing process.

The aim of this study was to evaluate the healing process on induced wounds covered with sterile plastic or rayon bandage in rats.

Methods: We used adult male Wistar rats (~ 420 g, N=9). All procedures were approved by the Animal Ethics Committee. Each rat was anesthetized with 2% isoflurane in 100% O2 and two lesions with 2 X 2 cm separated by 1 cm of distance were carried out in the skin of the rat's back. The lesions were covered with sterile plastic (obtained from the sterile urine collector) or rayon bandage (control) and the edges of both coverings were sutured in the rat skin with 3.0 mm nylon suture. Veterinary Pentabiotic (2000 U/mL, i.m., single dose) was used as prophylactic measure and tramadol (10 mg/kg i.m., every 12 h) was injected for 3 days after surgery for analgesia. At 7, 14 or 21 days after performing the surgery, rats (N=3/group) were euthanized with sodium thiopental (100 mg/kg, i.p.) and the lesion sites were sampled and stored in 10% formalin solution for histological preparation. The tissues were embedded in paraffin and sliced in microtome (20 thickness/slice). Histological sections of the wound were stained using Hematoxylin-Eosin or PicroSirius red and analysed in microscope (Nikon®).

Results and Conclusions: The plastic group shows a slower healing compared to rayon bandage in a period of 14 days and presented a considerable increase of eosinophils at this time point. At the end of 21 days, collagen fibers type 1 and 3 and fibroblasts were found in the healing tissue in samples covered either with sterile plastic or rayon bandage. Conclusion: The sterile plastic could be used as a possible low-cost dermal substitute.

Objectives / Interrogation: Perfect reconstruction of impaired limb is the ultimate goal of plastic and reconstructive surgery. Comparing to axolotls who can completely regenerate the whole limb, the regeneration ability in mammals are greatly limited. Fingertip is the only compound tissue which can regenerate in human and mice. Regeneration of mouse digit tip requires nail stem cells and their differentiation, suggesting that the nail organ can provide key factors that stimulate digit regeneration. However, the identity and differentiation of human nail stem cells is largely unknown.

Methods: Discarded human fingertip specimens in plastic surgery of congenital polydactyly were used to obtain the nail organ. Immunohistochemistry was applied to detect specific markers and locate different cell types in the nail organ. Immunofluorescence of single-cell preparations of the nail organ was performed to determine the percentage of specific cell populations.

Results and Conclusions: Epithelial cell markers, KRT14 and KRT17, expressed in human nail fold and along the nail bed. At the nail fold, a small cell population positive for KRT17 expressed Ki67 as well. Immunofluorescence of single cell preparation of the nail fold tissue indicated 5% Ki67/KRT17 double positive cells, suggesting a potential stem cell population. Ki67 positive cells were not present in distal nail bed as indicated by both immunohistochemistry and immunofluorescence of the cell suspensions. In conclusion, we identified a potential human nail stem cell population that located at the nail fold and co-expressed KRT17 and Ki67. Single-cell sequencing of the nail fold tissue could be a ideal method to further delineate the identity and the differentiation process of human nail stem cells.

Objectives / Interrogation: Polytrauma patients usually have severe wounds, which require prolonged and costly treatment. Deep skin lesions are characterized by destruction of epithelial tissue and exposure of structures such as fascia, muscles, tendons, and nerves. The healing process occurs through contraction of the wound edges and has three phases: inflammation, epithelization and remodeling, until tissue integrity is achieved. At the closure of these lesions, the simplest form should be used, seeking the best method to achieve the normal function of the limb affected by the lesion.

Dermal substitutes are widely used in the areas of reconstructive and plastic surgery, and one of the most widely used is the Single Layer Integra®. Nevertheless, no previous study has evaluated the evolution of skin healing through histological analysis in induced wounds.

Objective: This study aimed to investigate the healing process in induced wounds covered with Integra® and rayon bandage in rats.
